CS106A Handout #29 Winter 2013-2014 February 28, 2014

# **Assignment 6: NameSurfer**

Assignment by Nick Parlante, with revisions by Patrick Young and Eric Roberts

At this point, you now possess all the tools necessary to build an impressive piece of software to explore interesting data sets. You've seen file I/O. You've seen arrays, ArrayLists, and HashMaps. You've seen interactors. It's now time to pull your talents together to build a program to visualize important trends in American society: The *NameSurfer*, a program that displays the popularity of baby names over the course of the past century. In doing so, you'll hone your programming skills, learn more about object-oriented design, and will end up with software that can take data and make it come to life.

## Due Wednesday, March 12 at 3:15PM

Assignment Review Hours: Thursday, March 6 from 5:30PM – 6:30PM in Hewlett 200

### Overview of the NameSurfer project

Against all bureaucratic stereotypes, the Social Security Administration provides a neat web site showing the distribution of names chosen for children over the last 100 years in the United States (http://www.ssa.gov/OACT/babynames/). The Social Security Administration provides data that shows the 1000 most popular boy and girl names for children at 10 year intervals. The data can be boiled down to a single text file that looks something like this:

```
NamesData.txt

Sam 58 69 99 131 168 236 278 380 467 408 466 997

Samantha 0 0 0 0 0 272 107 26 5 7 63

Samara 0 0 0 0 0 0 0 0 0 886 0

Samir 0 0 0 0 0 0 0 920 0 798 0

Sammie 537 545 351 325 333 396 565 772 930 0 0 0

Sammy 0 887 544 299 202 262 321 395 575 639 755 0

Samson 0 0 0 0 0 0 0 0 0 915 0

Samuel 31 41 46 60 61 71 83 61 52 35 28 32

Sandi 0 0 0 0 704 864 621 695 0 0 0 0

Sandra 0 942 606 50 6 12 11 39 94 168 257 962
```

Each line of the file begins with the name, followed by the rank of that name in each of the 12 decades since 1900, counting the current one: 1900, 1910, 1920, and so on up to 2010. A rank of 1 indicates the most popular name that year, while a rank of 997 indicates a name that is not very popular. A 0 entry means the name did not appear in the top 1000 names for that year and therefore indicates a name that is even less popular. The elements on each line are separated from each other by a single space. The lines happen to be in alphabetical order, but nothing in the assignment depends on that fact.

As you can see from the small excerpt from the file, the name Sam was #58 in the first decade of the 1900s and has since dropped to the bottom of the Top 1000 list. Samantha popped on the scene in the 1960s (possibly because the show *Bewitched*, which had a main character named Samantha, ran on television during those years) and was *extremely* popular ten years ago, but is now just *very* popular. Samir didn't even appear on the Top 1000 list until the 1980's. The database counts children born in the United States, so trends in particular names tend to reflect the evolution of ethnic communities over the years.

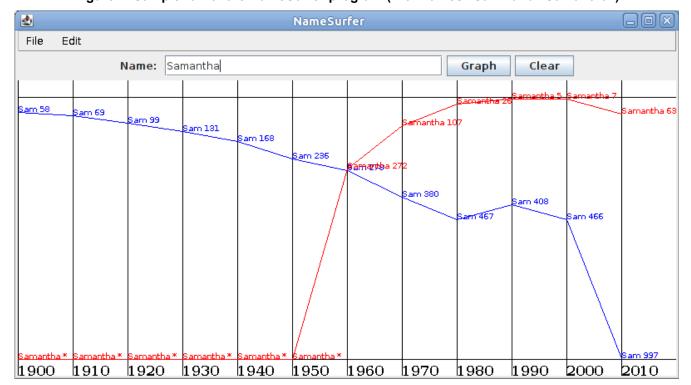

Figure 1. Sample run of the NameSurfer program (with names "Sam" and "Samantha")

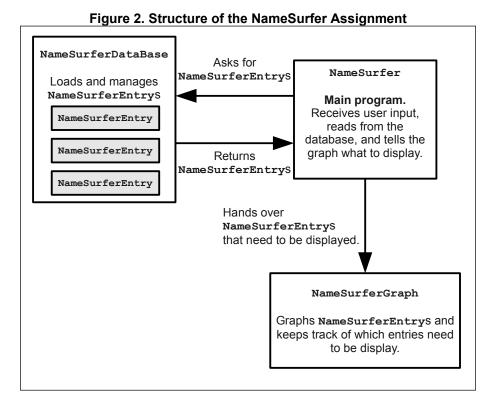

The goal of this assignment is to create a program that graphs these names over time, as shown in the sample run in Figure 1. In this diagram, the user has just typed samantha into the box marked "Name" and then clicked on the "Graph" button, having earlier done exactly the same thing for the name sam. Whenever the user enters a name, the NameSurfer program creates a new plot line showing how that name has fared over the decades. Clicking on the "Clear" button removes all the plot lines from the graph so that the user can enter more names without all the old names cluttering up the display. Note that the program is not case sensitive to the names that the user types into the "Name" textbox. So, the user could enter "Samantha", "SAMANTHA", "samantha" or "sAmAnThA" and the program would display the graph for the name "Samantha".

To give you more experience working with classes that interact with one another, the **NameSurfer** application as a whole is broken down into several class files, as follows:

- NameSurfer—This is the main program class that ties together the application. It is responsible for creating the other objects and for responding to the buttons at the bottom of the window, but only to the point of redirecting those events to the objects represented by the other classes.
- NameSurferConstants—This interface is provided for you and defines a set of constants that you can use in the rest of the program. Any class that implements the NameSurferConstants interface will automatically have access to these constants, as you can see from the provided starter files.
- NameSurferEntry—This class ties together all the information for a particular name. Given a NameSurferEntry object, you can find out what name it corresponds to and what its popularity rank was in each decade
- NameSurferDataBase—This class keeps track of all the information stored in the data files, but is completely separate from the user interface. It is responsible for reading in the data and for locating the data associated with a particular name.

• NameSurferGraph—This class is a subclass of GCanvas that displays the graph of the various names by arranging the appropriate GLine and GLabel objects on the screen, just as with the various graphical programs you've written this quarter.

Even though the class structure sounds complicated, the NameSurfer application code is about the same size as the Readability Indices code. We recommend that you make slow and steady progress on this assignment rather than waiting until the last minute, since this will be your first time writing your own classes.

#### Milestone 1: Assemble the GUI interactors

If you look at the bottom of Figure 1, you will see that the region along the NORTH edge of the window contains several interactors: a Jlabel, a JTextField, and two JButtons. Since putting up interactors is something you haven't done in previous assginments, you probably want to work on this step before it becomes complicated with all the other parts of the assignment. Thus, your first milestone is simply to add the interactors to the window and create an implementation for the actionPerformed method that allows you to check whether you can detect button clicks and read what's in the text field.

The simplest strategy to check whether your program is working is to change the definition of the NameSurfer class so that it extends ConsoleProgram instead of Program, at least for the moment. You can always change it back later. Once you have made that change, you can then use the console to record what's happening in terms of the interactors to make sure that you've got them right. For example, Figure 3 shows a possible transcript of the commands used to generate the output from Figure 1, in which the user has just completed the following actions:

- 1. Entered the name sam in the text field and clicked the Graph button.
- 2. Entered the name samantha in the text field and then typed the Enter key.
- 3. Clicked the Clear button.

The hard part about reaching this milestone is understanding how interactors work. Once you do, writing the code is quite straightforward – it's only 10 to 15 lines of code.

Figure 3. Illustration of Milestone 1

#### Milestone 2: Implement the NameSurferEntry class

The starter file for the NameSurferEntry class appears in full as Figure 4 on the following page. As with the other files supplied with this assignment, the starter file includes definitions for all of the public methods we expect you to define. The method definitions in the starter files, however, do nothing useful, although they occasionally include a return statement that gives back a default value of the required type. In Figure 4, for example, the getrank method always returns 0 to satisfy the requirement that the method returns an int as defined in its header line.

Methods that will eventually become part of the program structure but that are temporarily unimplemented are called **stubs**. Stubs play a very important role in program development because they allow you to set out the structure of a program even before you write most of the code. As you implement the program, you can go through the code and replace stubs with real code as you need it.

The NameSurferEntry class encapsulates the information pertaining to one name in the database. That information consists of two parts:

- 1. The name itself, such as "sam" or "samantha"
- 2. A list of 12 values indicating the rank of that name in each of the decades from 1900 to 2010, inclusive.

The class definition begins with a constructor that creates an entry from the line of data that appears in the NamesData.txt file. For example, the entry for sam looks like this:

```
Sam 58 69 99 131 168 236 278 380 467 408 466 997
```

The idea behind the design of this constructor is that it should be possible to read a line of data from the file and then create a new entry for it using code that looks like this:

```
String line = rd.readLine();
NameSurferEntry entry = new NameSurferEntry(line);
```

The implementation of the constructor has to divide up the line at the spaces, convert the digit strings to integers (using Integer.parseInt), and then store all of this information as the private state of the object in such a way that it is easy for the getName and getRank methods to return the appropriate values. To split the line apart at the spaces, you may want to look into the string.split method, which can be used to split the initial string into a string[] of smaller pieces. You may also want to look at the stringTokenizer class, which can also be used to split the string apart.

Figure 4. Starter file for the NameSurferEntry class

```
* File: NameSurferEntry.java
* This class represents a single entry in the database.
* NameSurferEntry contains a name and a list giving the popularity
* of that name for each decade stretching back to 1900.
import acm.util.*;
import java.util.*;
public class NameSurferEntry implements NameSurferConstants {
      /* Constructor: NameSurferEntry(line) */
     /**
      * Creates a new NameSurferEntry from a data line as it appears
      * in the data file. Each line begins with the name, which is
      * followed by integers giving the rank of that name for each
      * decade.
      */
     public NameSurferEntry(String line) {
           // You fill this in //
     }
      /* Method: getName() */
      * Returns the name associated with this entry.
     public String getName() {
           // You need to turn this stub into a real implementation //
           return null;
     }
     /* Method: getRank(decade) */
      * Returns the rank associated with an entry for a particular
      * decade. The decade value is an integer indicating how many
      * decades have passed since the first year in the database,
      * which is given by the constant START DECADE. If a name does
      * not appear in a decade, the rank value is 0.
     public int getRank(int decade) {
           // You need to turn this stub into a real implementation //
           return 0;
     }
     /* Method: toString() */
      * Returns a string that makes it easy to see the value of a
      * NameSurferEntry.
     public String toString() {
           // You need to turn this stub into a real implementation //
           return "":
     }
}
```

The last method in the starter implementation of NamesurferEntry is a tostring method whose role is to return a human-readable representation of the data stored in the entry. For example, if the variable entry contains the NamesurferEntry data for sam, you might want entry.tostring() to return a string like this:

```
"Sam [58 69 99 131 168 236 278 380 467 408 466 997]"
```

Defining tostring for a class has the wonderful advantage that it makes it possible to print out objects of that class using println, just as you do for primitive values. Whenever Java needs to convert an object to a string, it always calls its tostring method to do the job. The default definition of tostring in the object class doesn't supply much useful information, and you will find that your debugging sessions get much easier if you can look easily at the values of your objects.

To show that you've got NameSurferEntry implemented correctly, you might want to write a very simple test program that creates an entry from a specific string and then verifies that the other methods work as they are supposed to.

#### Milestone 3: Implement the NameSurferDataBase class

The next step in the process is to implement the NameSurferDataBase class, which contains two public entries:

- A constructor that takes the name of a data file and uses that to read in the entire set of data from the file into internal data structures that allow the class to keep track of all the records as a database.
- A findEntry method that takes a name, looks it up in the stored database (note that your program should <u>not</u> be case sensitive regarding the name), and returns the NameSurferEntry for that name, or null if that name does not appear.

The code for this part of the assignment is not particularly difficult. The challenging part lies in figuring out how you want to represent the data so that you can implement the **findEntry** method as simply and as efficiently as possible.

To test this part of the program, you can add a line of code or two to the NameSurfer program so that it creates the NameSurferDataBase and then change the code for the button handlers so that clicking the "Graph" button looks up the current name in the data base and then displays the corresponding entry (using its toString method), as shown in Figure 5 below.

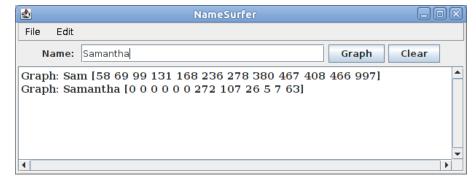

Figure 5. Illustration of Milestone 3

## Milestone 4: Create the Background Grid for the NameSurferGraph class

The next step in the process is to begin the implementation of the NameSurferGraph class, which is responsible for displaying the graph in the window by building the underlying model. The starter code for the NameSurferGraph class appears in Figure 6 on the next page.

Figure 6. Starter file for the NameSurferGraph class

```
/*
* File: NameSurferGraph.iava
* This class represents the canvas on which the graph of
* names is drawn. This class is responsible for updating
* (redrawing) the graphs whenever the list of entries changes
* or the window is resized.
import acm.graphics.*;
import java.awt.event.*;
import java.util.*;
import java.awt.*;
public class NameSurferGraph extends GCanvas
      implements NameSurferConstants, ComponentListener {
      * Creates a new NameSurferGraph object that displays the data.
     public NameSurferGraph() {
           addComponentListener(this);
            // You fill in the rest //
     }
     /**
       * Clears the list of name surfer entries stored inside this class.
     public void clear() {
           // You fill this in //
      /* Method: addEntry(entry) */
      * Adds a new NameSurferEntry to the list of entries on the display.
      * Note that this method does not actually draw the graph, but
       * simply stores the entry; the graph is drawn by calling update.
     public void addEntry(NameSurferEntry entry) {
            // You fill this in //
      }
      * Updates the display image by deleting all the graphical objects
      * from the canvas and then reassembling the display according to
      * the list of entries. Your application must call update after
      * calling either clear or addEntry; update is also called whenever
      * the size of the canvas changes.
      */
     public void update() {
            // You fill this in //
     /* Implementation of the ComponentListener interface */
     public void componentHidden(ComponentEvent e) { }
     public void componentMoved(ComponentEvent e) { }
     public void componentResized(ComponentEvent e) { update(); }
     public void componentShown(ComponentEvent e) { }
}
```

There are a couple of important items in the NameSurferGraph starter file that are worth noting:

- 1. This class extends GCanvas, which means that every NameSurferGraph object is not only a GCanvas but also an instance of all the superclasses of the GCanvas class. GCanvas is a subclass of Component in the standard java.awt package and therefore is part of the hierarchy of classes that can be added to the display area of a program. Moreover, it means you can call any GCanvas methods, like add or remove, from within NameSurferGraph.
- 2. The starter file includes a tiny bit of code that monitors the size of the window and calls update whenever the size changes. This code requires only a couple of lines to implement, but would be hard to explain well enough for you to implement on your own. Writing a page of description so that you could add a couple of lines seemed like overkill, particularly given that the strategy is easiest to learn by example.

To start the process of adding the graphing code, go back to the **NameSurfer** class and change its definition so that it extends **Program** (as it usually did) rather than the temporary expedient of extending **ConsoleProgram** (if you were using that for debugging). At the same time, you should remove the various **println** calls that allowed you to trace the operation of the interactors in the earlier milestones.

Now, you'll need to declare a **NameSurferGraph** private instance variable in your main **NameSurfer** class:

```
private NameSurferGraph graph;
```

You should then change the **NameSurfer** class so that it creates a new **NameSurferGraph** object and adds that object to the display, as follows:

```
graph = new NameSurferGraph();
add(graph);
```

If you run the program with only these changes, it won't actually display anything on the screen. To create the graph, you need to implement the update method, which will almost certainly involve defining private helper methods as well. As a first step, write the code to create the background grid for the graph, which consists of the vertical line separating each decade, the horizontal lines that provide space for the top and bottom borders (which are there to ensure that the text labels stay within the window bounds), and the labels for the decades. As with all the graphical applications you've written, the lines and labels are represented using GLine and GLabel objects, which you add to the graph in the appropriate positions.

#### Milestone 5: Complete the Implementation of NameSurferGraph

In addition to creating the background grid, the update method in NameSurferGraph also has to plot the actual data values. As you can see from Figure 6, the NameSurferGraph class includes two methods for specifying what entries are displayed on the screen. The addEntry method adds a new NameSurferEntry to a list of values that are currently on the display. The clear method deletes all of the entries in that list so as to clear the graph.

It is important to note that neither addEntry or clear actually changes the display. To make changes in the display, you need to call update, which deletes any existing GObjects from the canvas and then assembles everything back up again. At first glance, this strategy might seem unnecessary. It would, of course, be possible to have addEntry just add all of the GLines and GLabels necessary to draw the graph.

The problem with that approach is that it would no longer be possible to reconstruct the entire graph. In this example, you need to do just that to create a new graph whenever you change the size of the display. By storing all of the entries in an internal list, the NameSurferGraph class can redraw everything when update is invoked from the componentResized method.

There are a couple of points that you should keep in mind while implementing this part of the program:

- To make the data easier to read, the lines on the graph are shown in different colors. In the sample applet on the web site, the first data entry is plotted in blue, the second in red, the third in purple, and the fourth in black. After that, the colors cycle around again through the same sequence. You can choose the colors as you see fit.
- The fact that rank 1 is at the top of the window and rank 1000 is at the bottom means that it can sometimes seem confusing that rank 0—which means that the name does not appear in the top 1000 values for that year—appears at the bottom. To reduce the apparent discontinuity between rank 1 and rank 0, the entries for names that are absent from the data for a decade are <u>listed</u> with an asterisk instead of a numeric rank. You can see several examples of this convention in the data for samantha in Figure 1.

#### **Milestone 6: Writeup**

Once you've finished all the coding for this assignment, we'd like you to do a quick writeup answering some questions. Edit the writeup.txt file with your answers to the following questions.

Suppose that you want to plot two different types of data in the NameSurfer program: baby name popularities (as you're already doing), and surname popularities. Suppose you also have a second data file containing the popularities of surnames in the United States over time, structured in the same way as the baby names file. These questions ask you about the changes you would need to make to your program in order to support this.

- 1. What changes would you make to the interactors in your program to support the two different data sets? Why? Where in the program would you make these changes? You don't need to give any actual code here just describe the changes at a high level.
- 2. What changes would you make to your program in order to store and retrieve information about two different types of data? Where in the program would you make these changes? As before, you don't need to give us actual code here; high-level descriptions suffice.
- 3. What changes, if any, would you make to the NameSurferGraph to differentiate between baby names and surnames? As before, you don't need to give us actual code here; high-level descriptions suffice.

#### **Possible Extensions**

There are a lot of things that you could do to make this program more interesting. Here are just a few possibilities:

- Add features to the display. The current display contains only lines and labels, but could easily be extended to make it more readable. You could, for example, put a dot at each of the data points on the graph. Even better, however, would be to choose different symbols for each line so that the data would be easily distinguishable even in a black-and-white copy. For example, you could use little circles for the first entry, squares for the second, triangles for the third, diamonds for the fourth, and so on. You might also figure out what the top rank for a name is over the years and set the label for that data point in boldface.
- Plot the data differently. Right now, your program visualizes the data by just showing its popularity over time. What other information about the names could you display? Consider plotting the rate of change over time, or (if you're statistically-minded) the correlation of various names. Can you find any interesting trends in baby names that aren't apparent purely through their popularity?
- Allow deletion as well as addition. Because the screen quickly becomes cluttered as you graph lots of names, it would be convenient if there were some way to delete entries individually, as opposed to clearing the entire display and then adding back the ones you wanted. The obvious strategy would be to add a "Delete" button that eliminated the entry corresponding to the value in the "Name" box. That approach, however, has a minor drawback given the design so far. If you added a bunch of entries to the graph and then deleted the early ones, the colors of the later entries would shift, which might prove disconcerting. Can you redesign the color-selection strategy so that displayed entries retain their color even if other entries are removed?
- Try to minimize the overprinting problem. If the popularity of a name is improving slowly, the graph for that name will cross the label for that point making it harder to read. You could reduce this problem by positioning the label more intelligently. If a name were increasing in popularity, you could display the label below the point; conversely, for names that are falling in popularity, you could place the label above the point. An even more challenging task is to try to reduce the problem of having labels for different names collide, as they do for sam and samantha in Figure 1.
- Adjust the font size as the application size changes. One of the wonderful features of this program is that it redraws itself to fill the available space if you change the size of the window. If you make it too small, however, the labels run together and become unreadable. You could eliminate this problem by choosing a font size that allows each label to fit in the space available.
- Change out the data set. The type of data you're exploring in this assignment is called *time-se-ries data* because it encodes values over time. There are many other time-series data sets out there, though: you could look at stock prices, population totals, literacy rates, etc. See if you can find any other data sets that you could add into the program!
- Rewrite the application to use the model/view/controller pattern. The NameSurfer prorgam turns out to be an ideal application for the model/view/controller pattern described in Chapter 14. If you finish the standard assignment, you might try to reimplement it so that it maintains a separate model that can support multiple viewers. If you made this change, you could, for example, add a "Table" button to the application that would add a second viewer to the application, which would display the results in tabular rather than graphical form.
