# Frequency Estimators

# Randomization

- Randomization opens up new routes for tradeoffs in data structures:
  - Trade worst-case guarantees for average-case guarantees.
  - Trade exact answers for approximate answers.
- These data structures are used *extensively* in practice. Each of the next four lectures is on something you're likely to encounter IRL.
- Each of the next four lectures explores powerful techniques that are useful in navigating the rivers of Theoryland.

# Where We're Going

- ***Frequency Estimation (Today)***
  - Can we count quantities without actually counting them?
- ***Hash Tables (Tuesday / Thursday)***
  - Everyone agrees these are good ideas. How do you design fast hash tables, and why are they fast?
- ***Approximate Membership (Next Tuesday)***
  - Squeezing as much value from our bits as possible.

# Outline for Today

- ***Hash Functions***
  - Understanding our basic building blocks.
- ***Count-Min Sketches***
  - Estimating how many times we've seen something.
- ***Concentration Inequalities***
  - "Correct on expectation" versus "correct with high probability."
- ***Probability Amplification***
  - Increasing our confidence in our answers.
- ***Count Sketches***
  - These ideas transfer well. Here's another example.

# Preliminaries: ***2-Independent Hashing***

# Hashing in Theoryland

- In Theoryland, a hash function is a function from some domain called the ***universe*** (typically denoted $\mathscr{U}$) to some codomain.
- The codomain is usually a set of the form

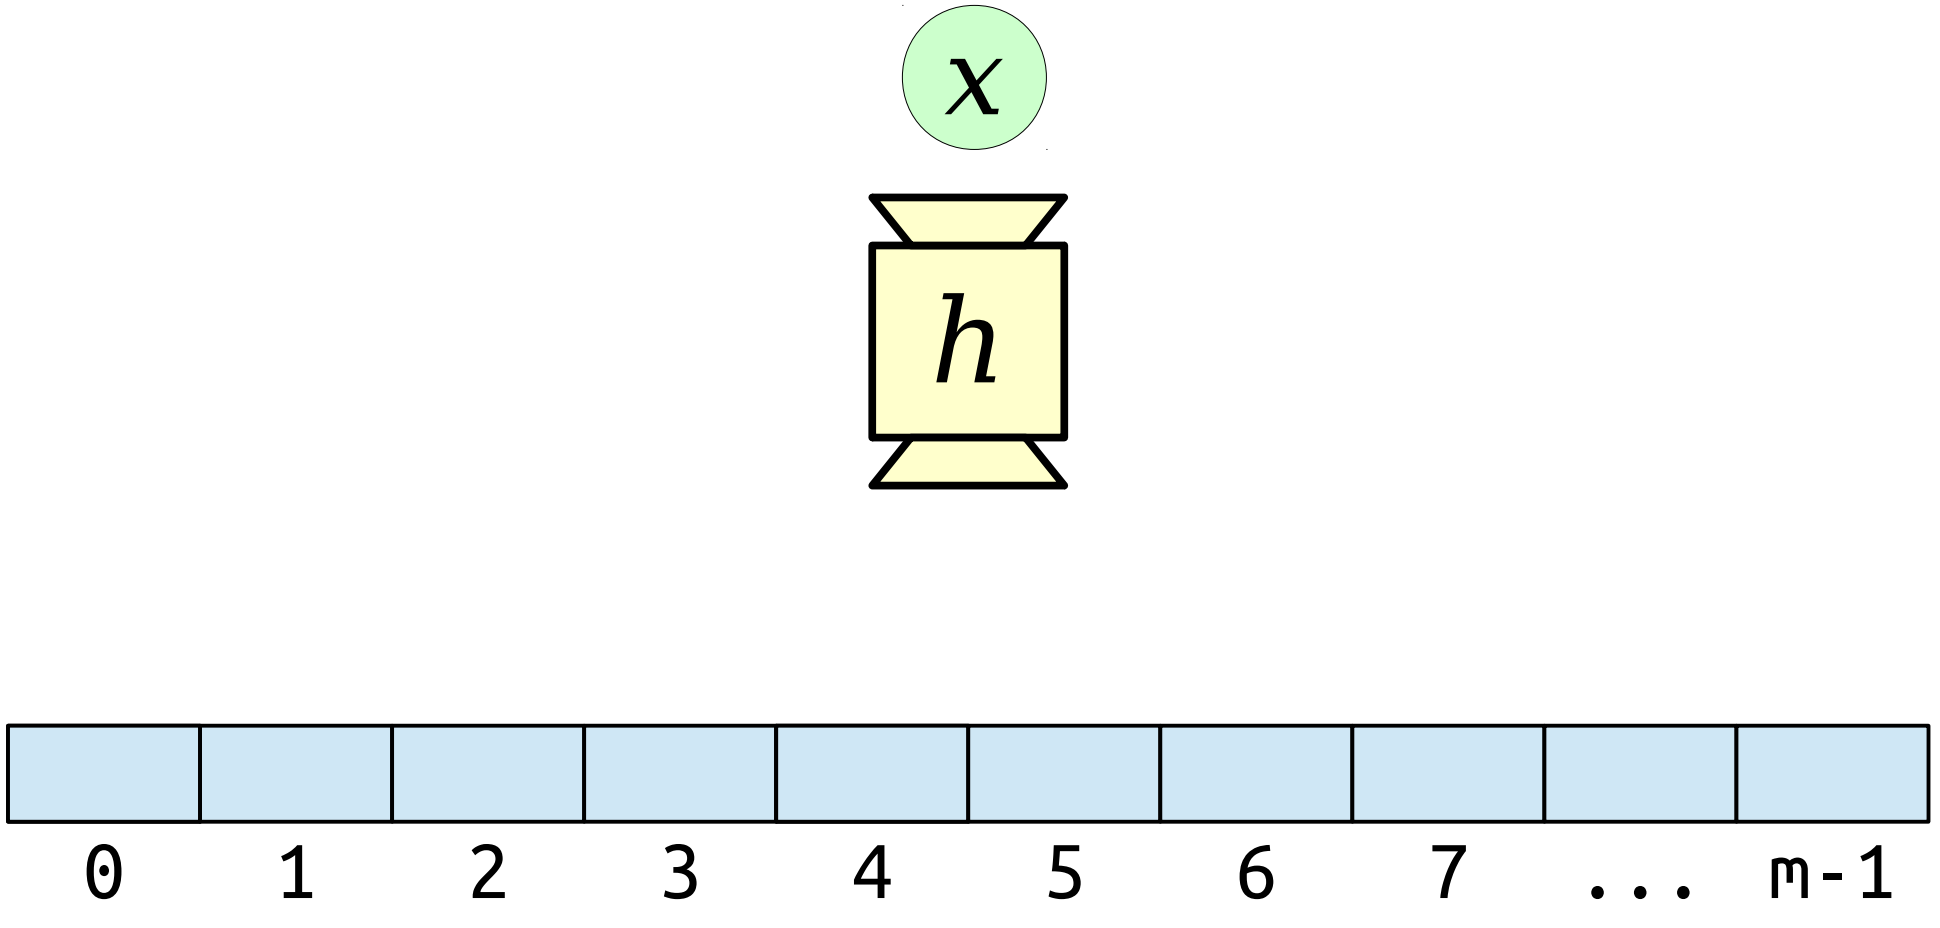
$$\mathbf{[}m\mathbf{]} = \{0, 1, 2, 3, \ldots, m - 1\}$$

$$h : \mathscr{U} \to [m]$$

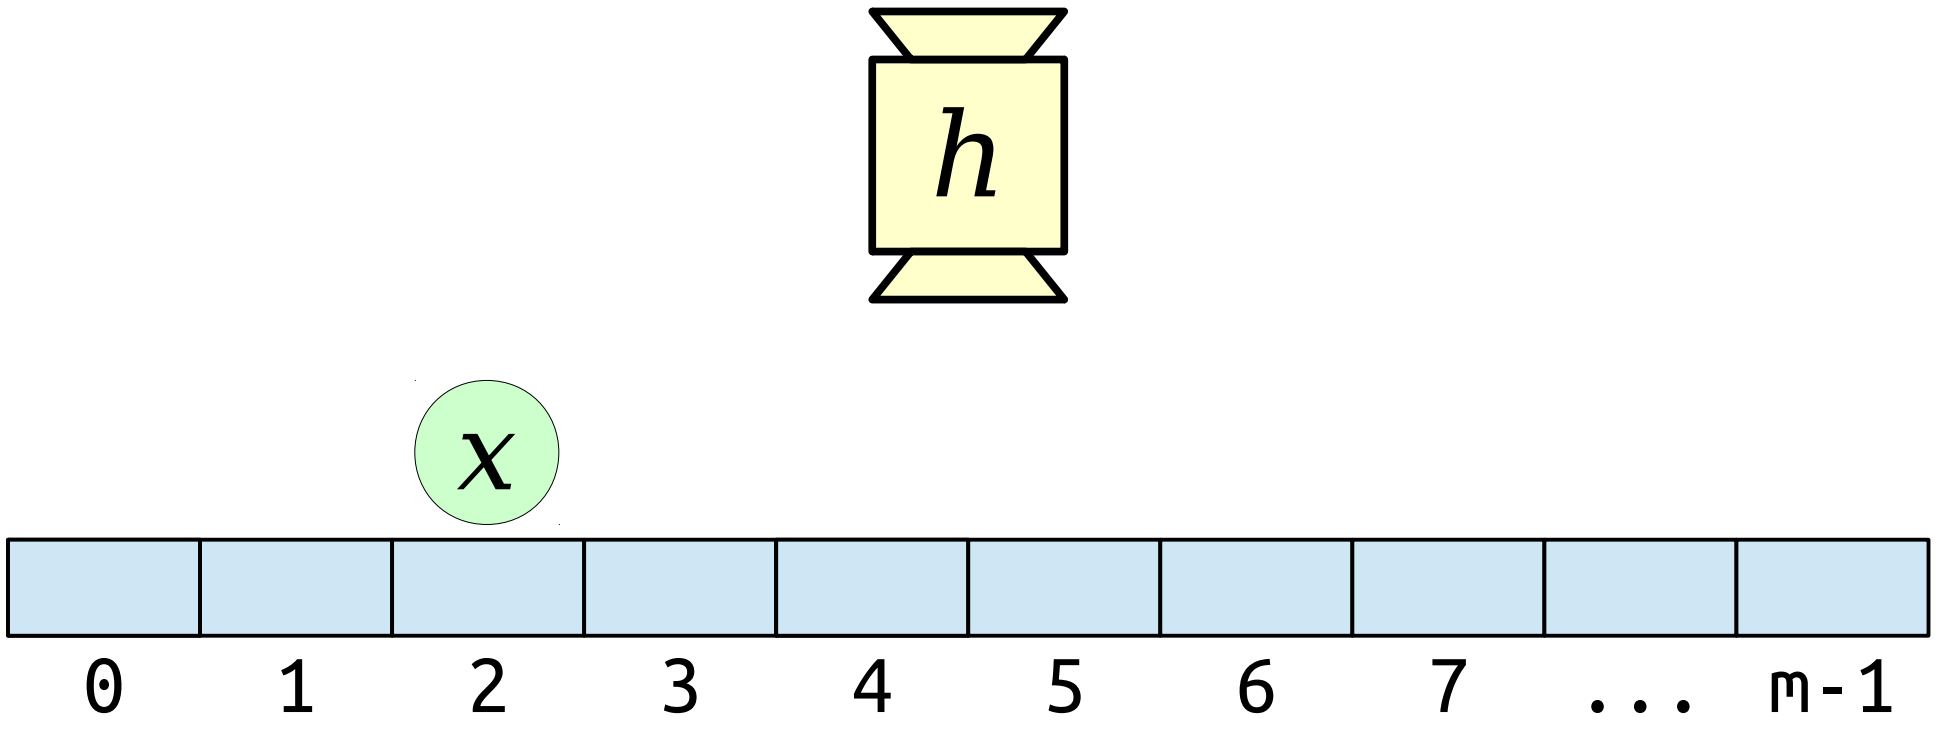
# Families of Hash Functions

- A ***family*** of hash functions is a set $\mathscr{H}$ of hash functions with the same domain and codomain.
- We'll usually sample hash functions uniformly and independently from a family as needed.
- ***Key point:*** The randomness in our data structures almost always derives from the random choice of hash functions, not from the data.
- ***Question:*** What makes a family of hash functions $\mathscr{H}$ a "good" family of hash functions?

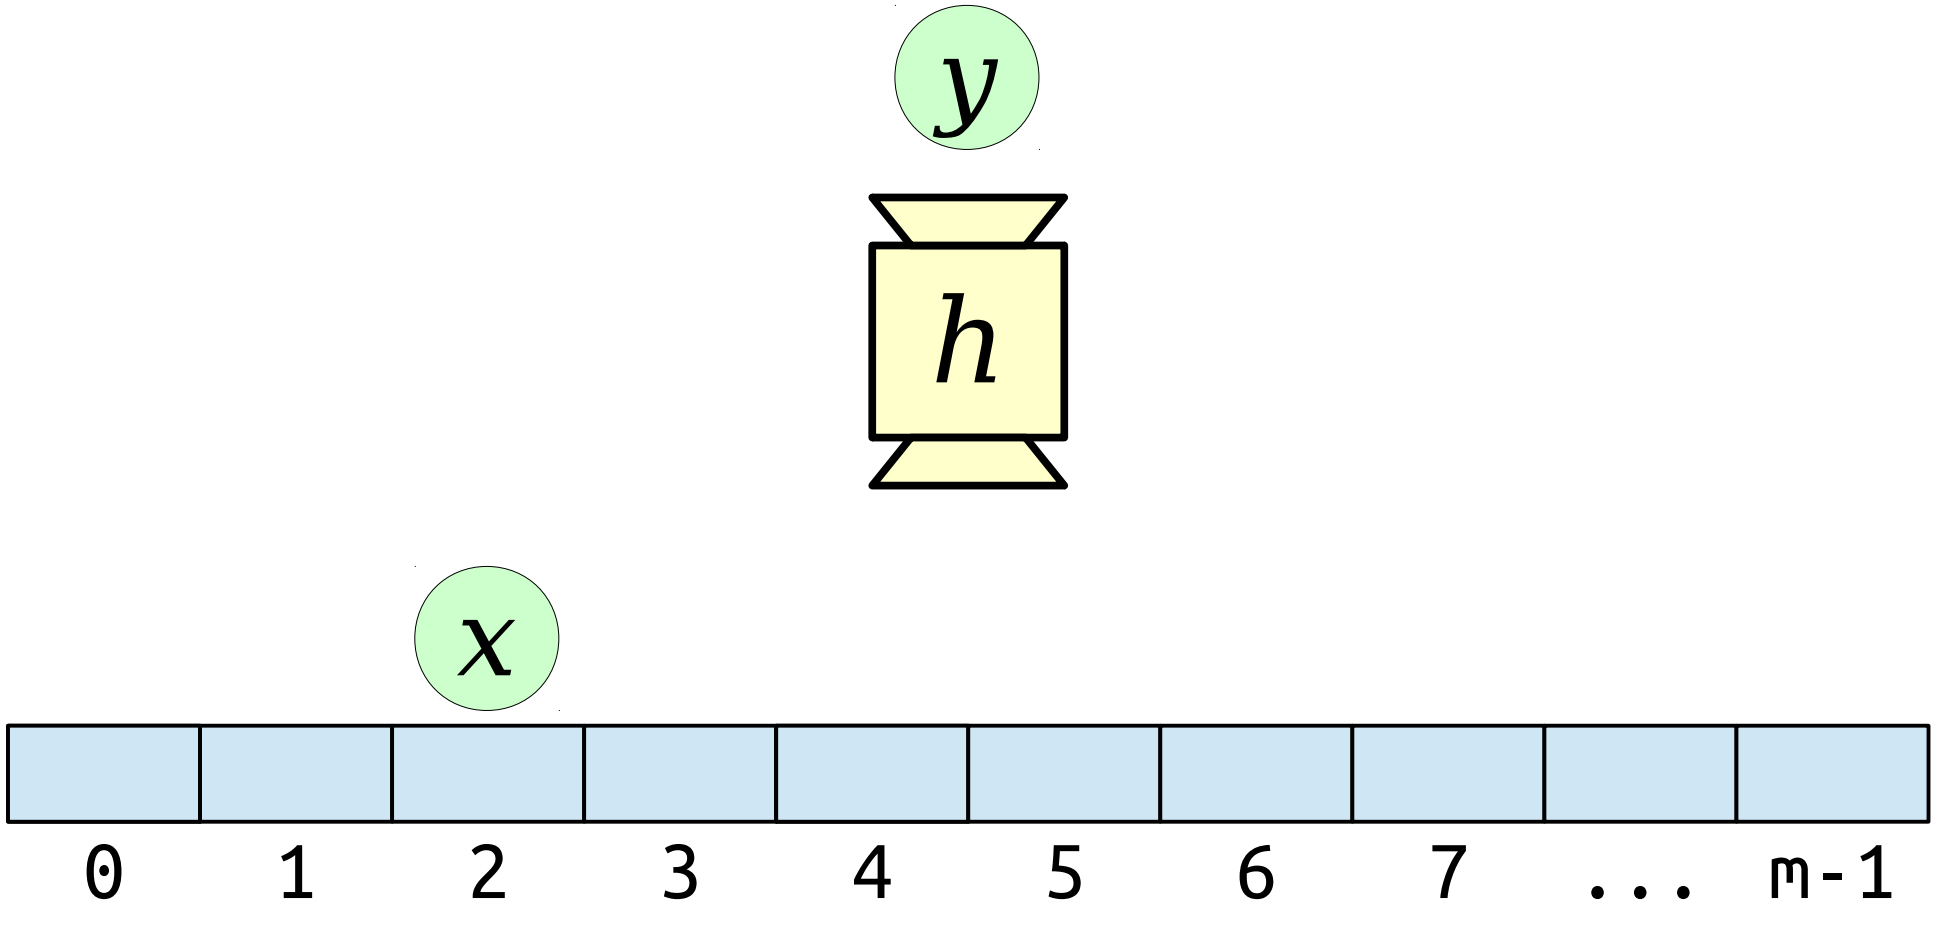
***Goal:*** If we pick $h \in \mathscr{H}$ uniformly at random, then $h$ should distribute elements uniformly randomly.



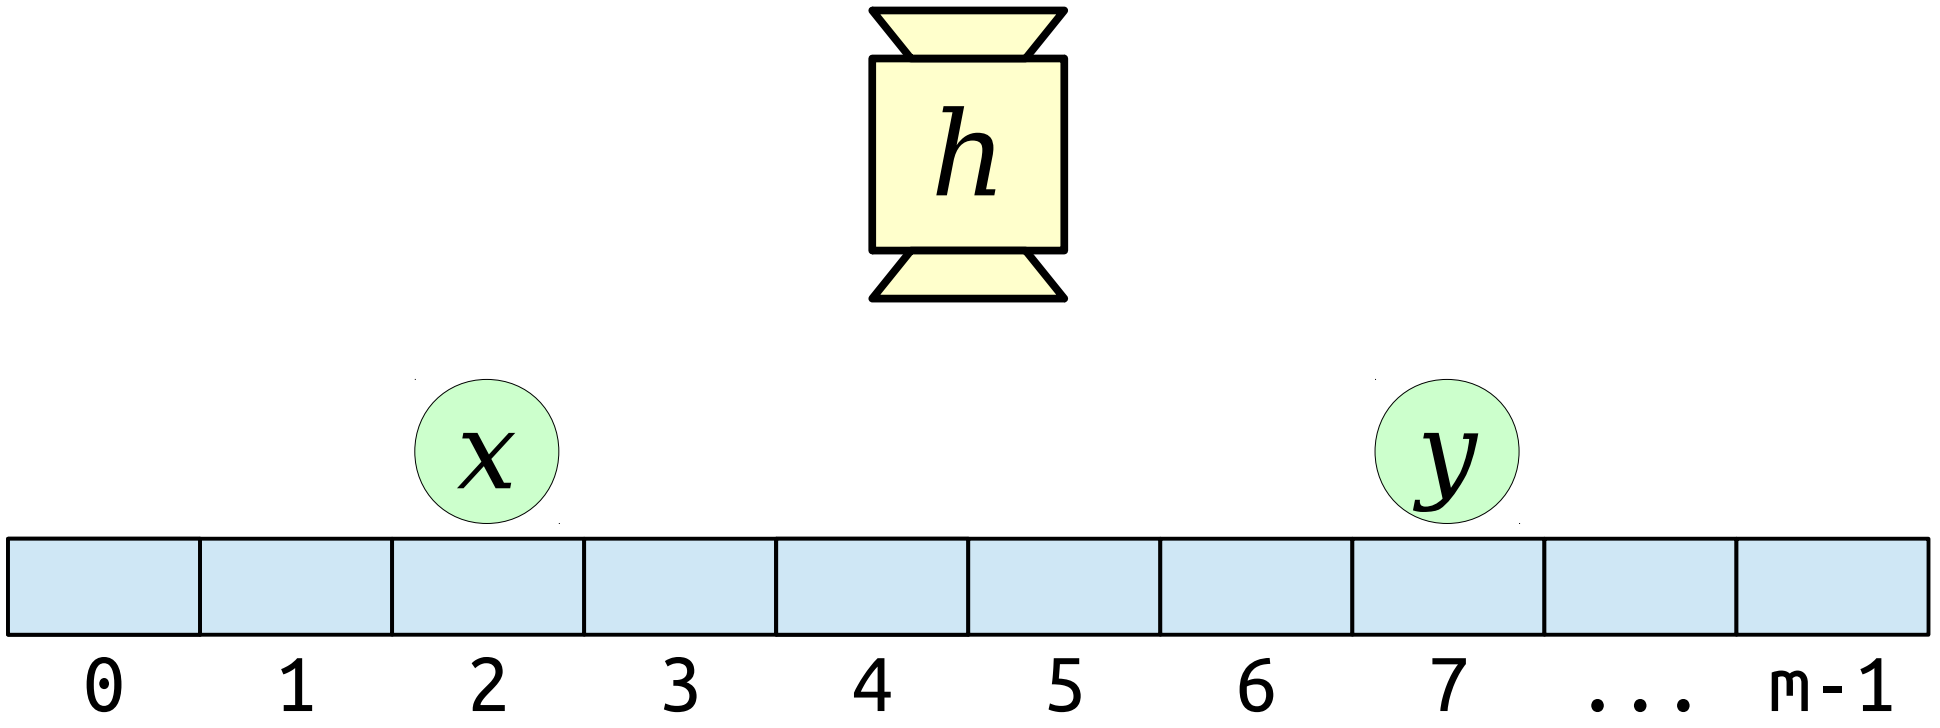
***Goal:*** If we pick $h \in \mathscr{H}$ uniformly at random, then $h$ should distribute elements uniformly randomly.



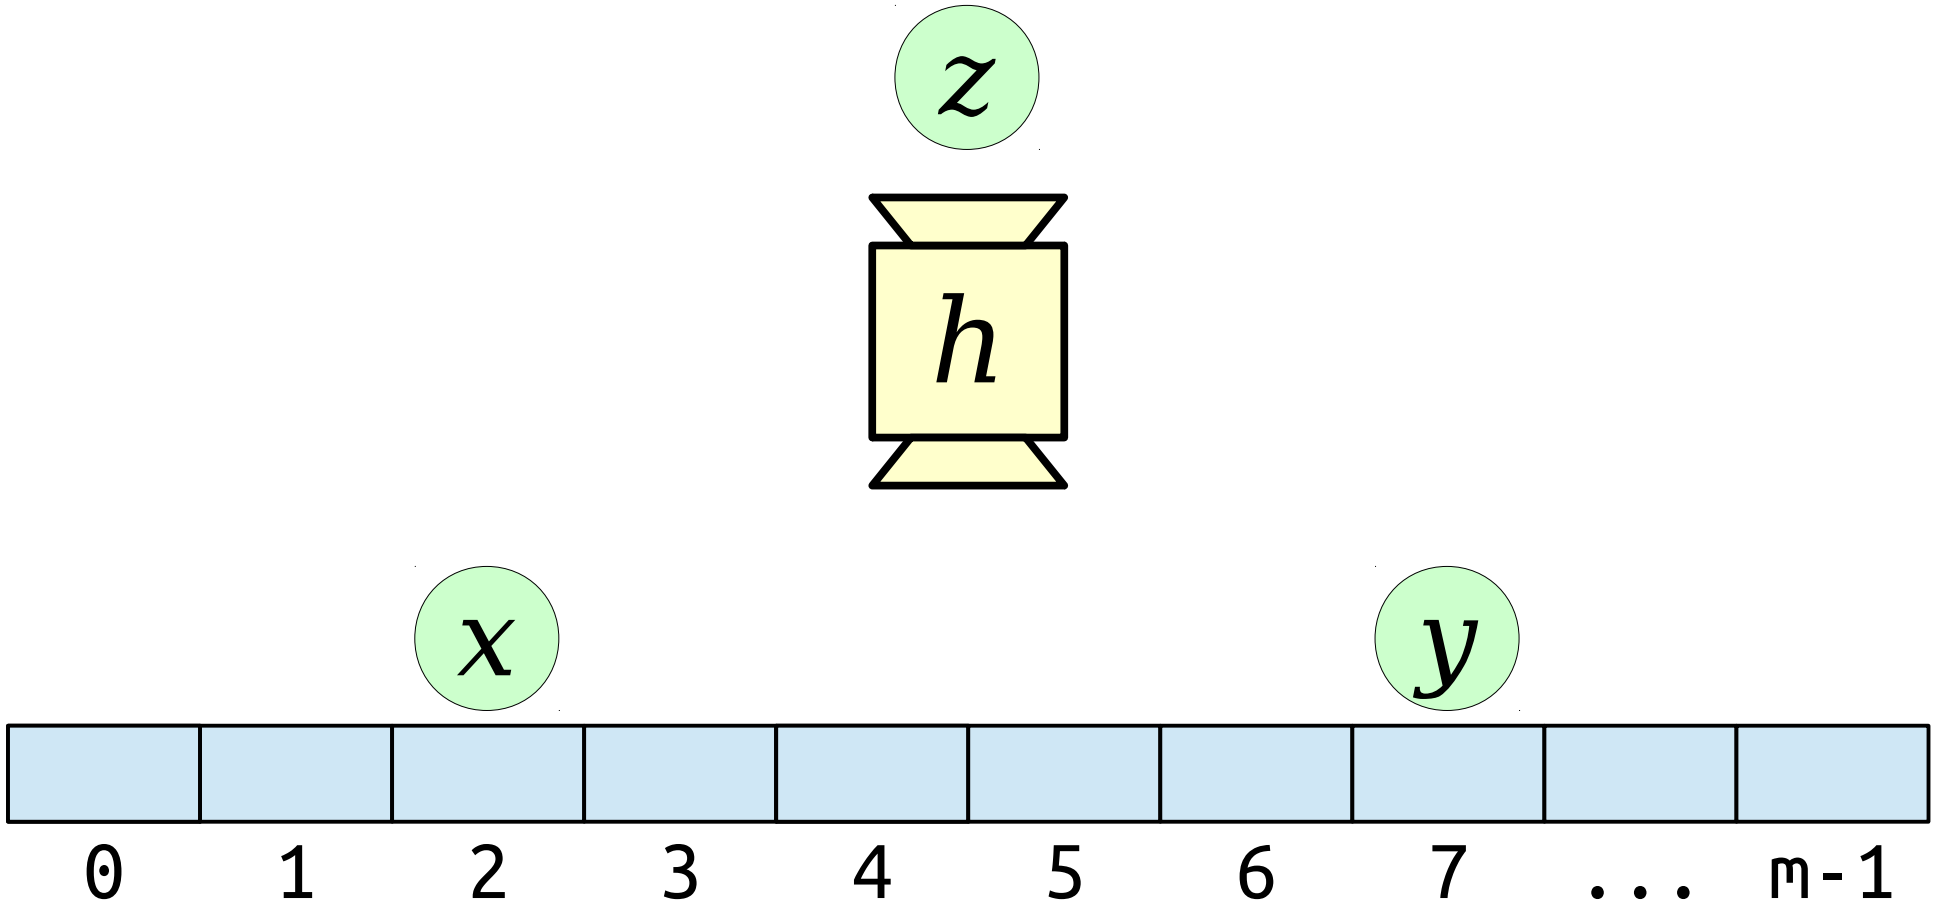
***Goal:*** If we pick $h \in \mathscr{H}$ uniformly at random, then $h$ should distribute elements uniformly randomly.



***Goal:*** If we pick $h \in \mathscr{H}$ uniformly at random, then $h$ should distribute elements uniformly randomly.



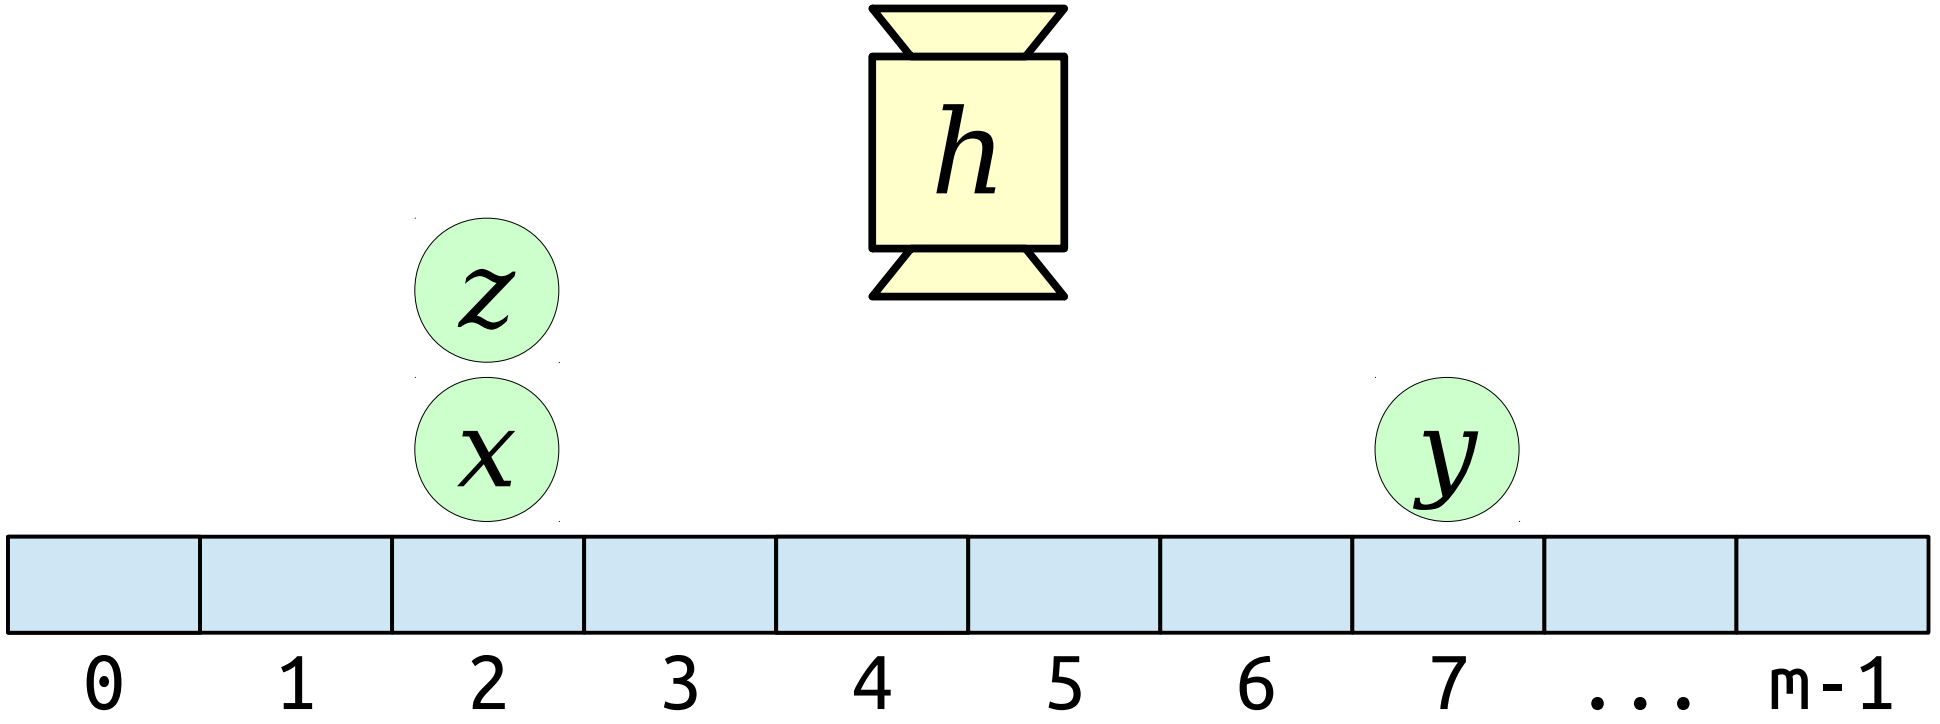
***Goal:*** If we pick $h \in \mathscr{H}$ uniformly at random, then $h$ should distribute elements uniformly randomly.



***Goal:*** If we pick $h \in \mathscr{H}$ uniformly at random, then $h$ should distribute elements uniformly randomly.

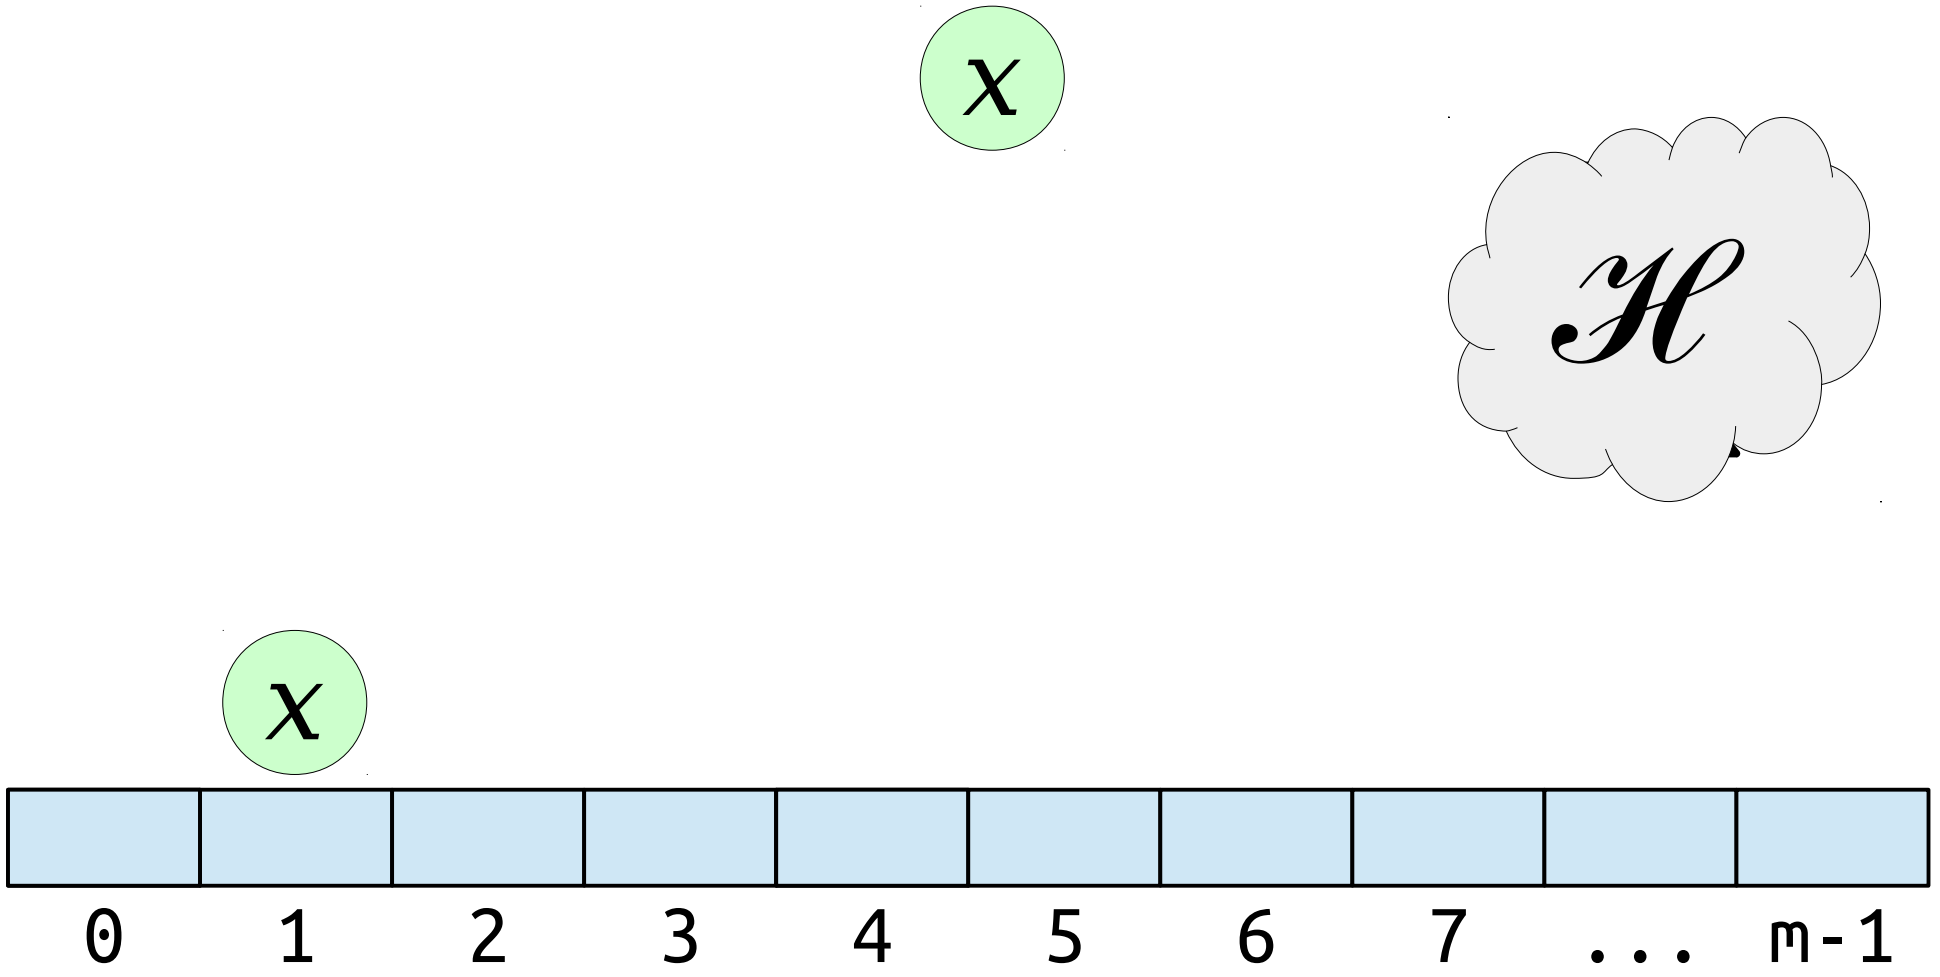
***Problem:*** Representing a hash function for a sample of $n$ elements from $\mathscr{U}$ requires $\Omega(n \log m)$ bits.

***Question:*** Do we actually need true randomness? Or can we get away with something weaker?



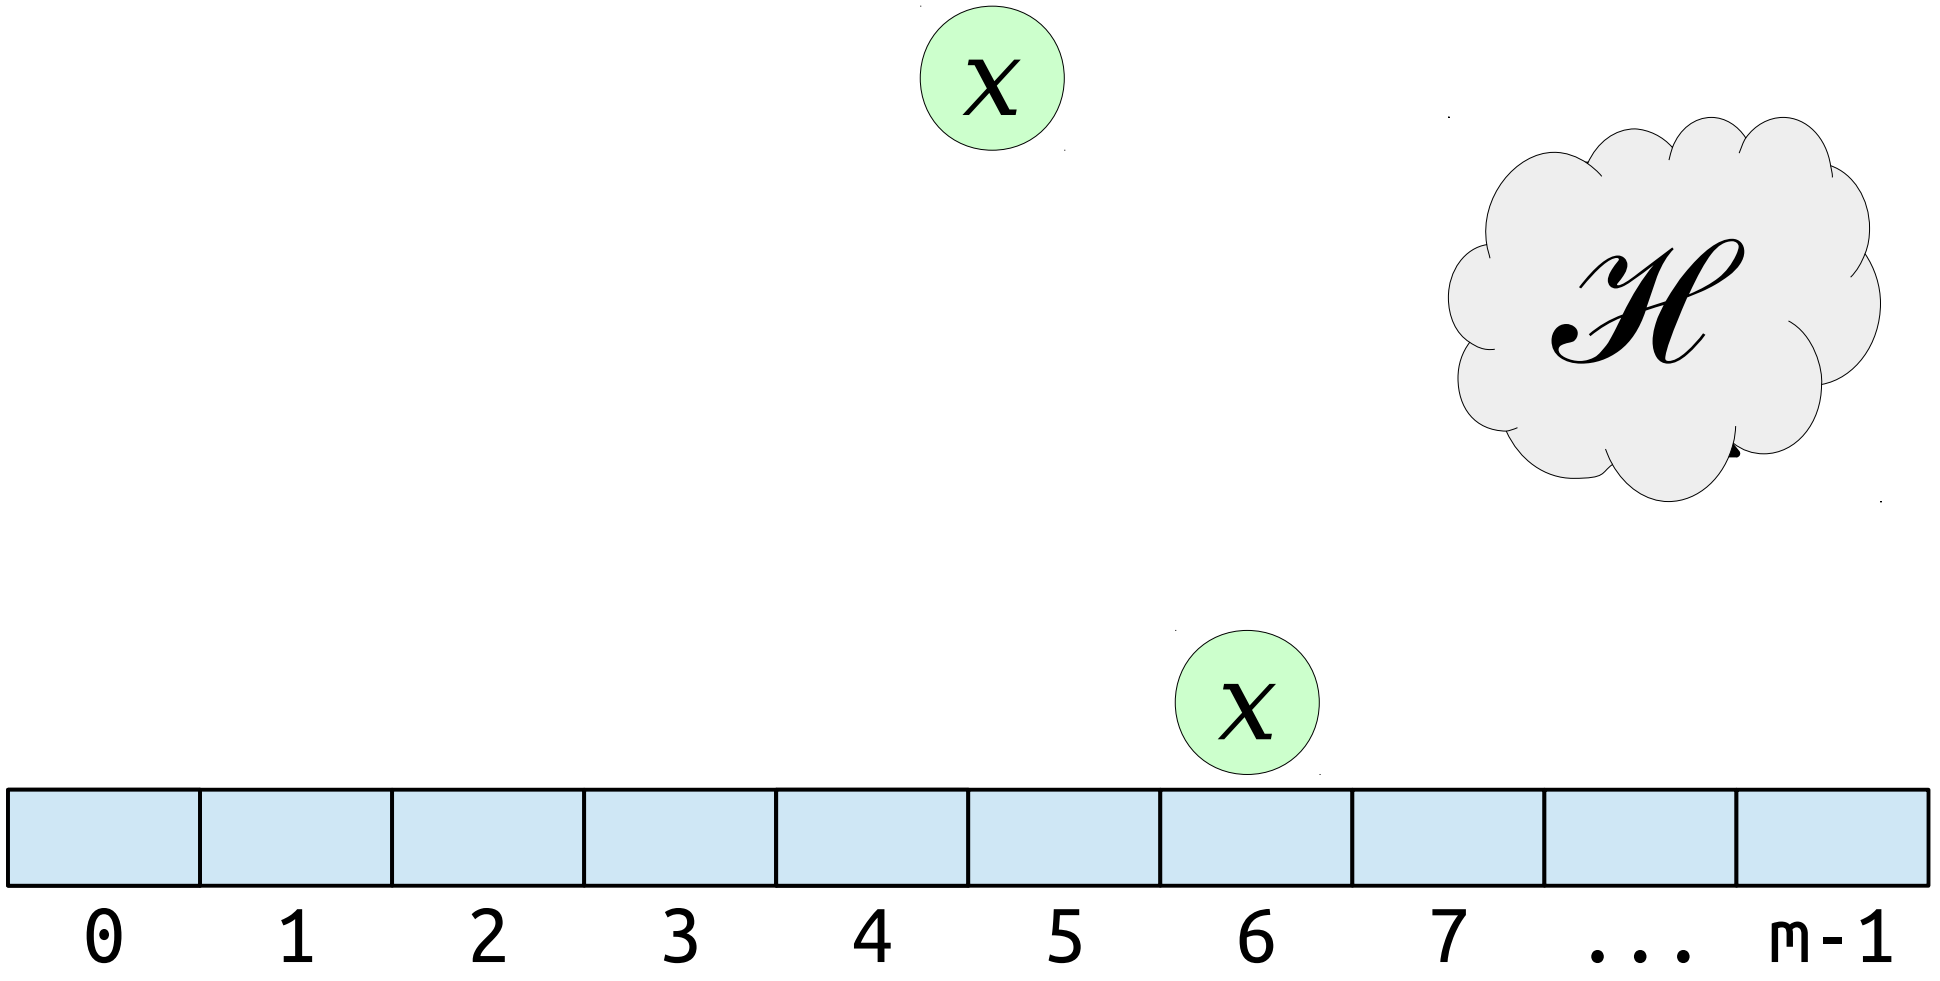
***Distribution Property:***
Each element should have an equal probability of being placed in each slot.

**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**



***Distribution Property:***
Each element should have an equal probability of being placed in each slot.

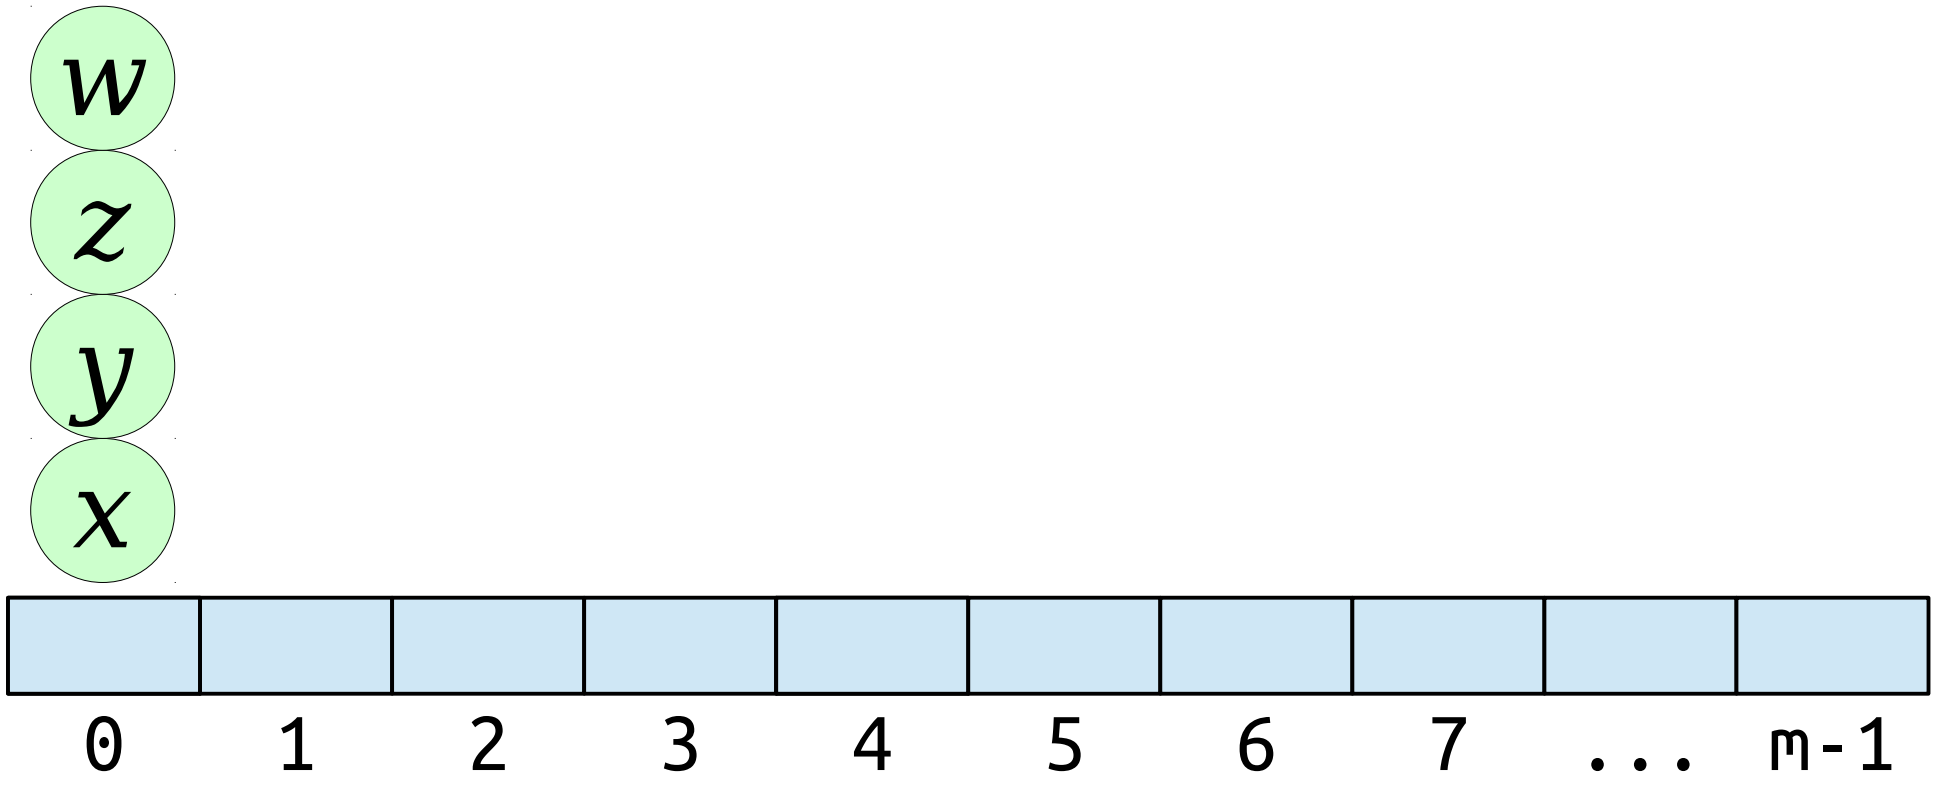
**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**



***Distribution Property:*** Each element should have an equal probability of being placed in each slot.

**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

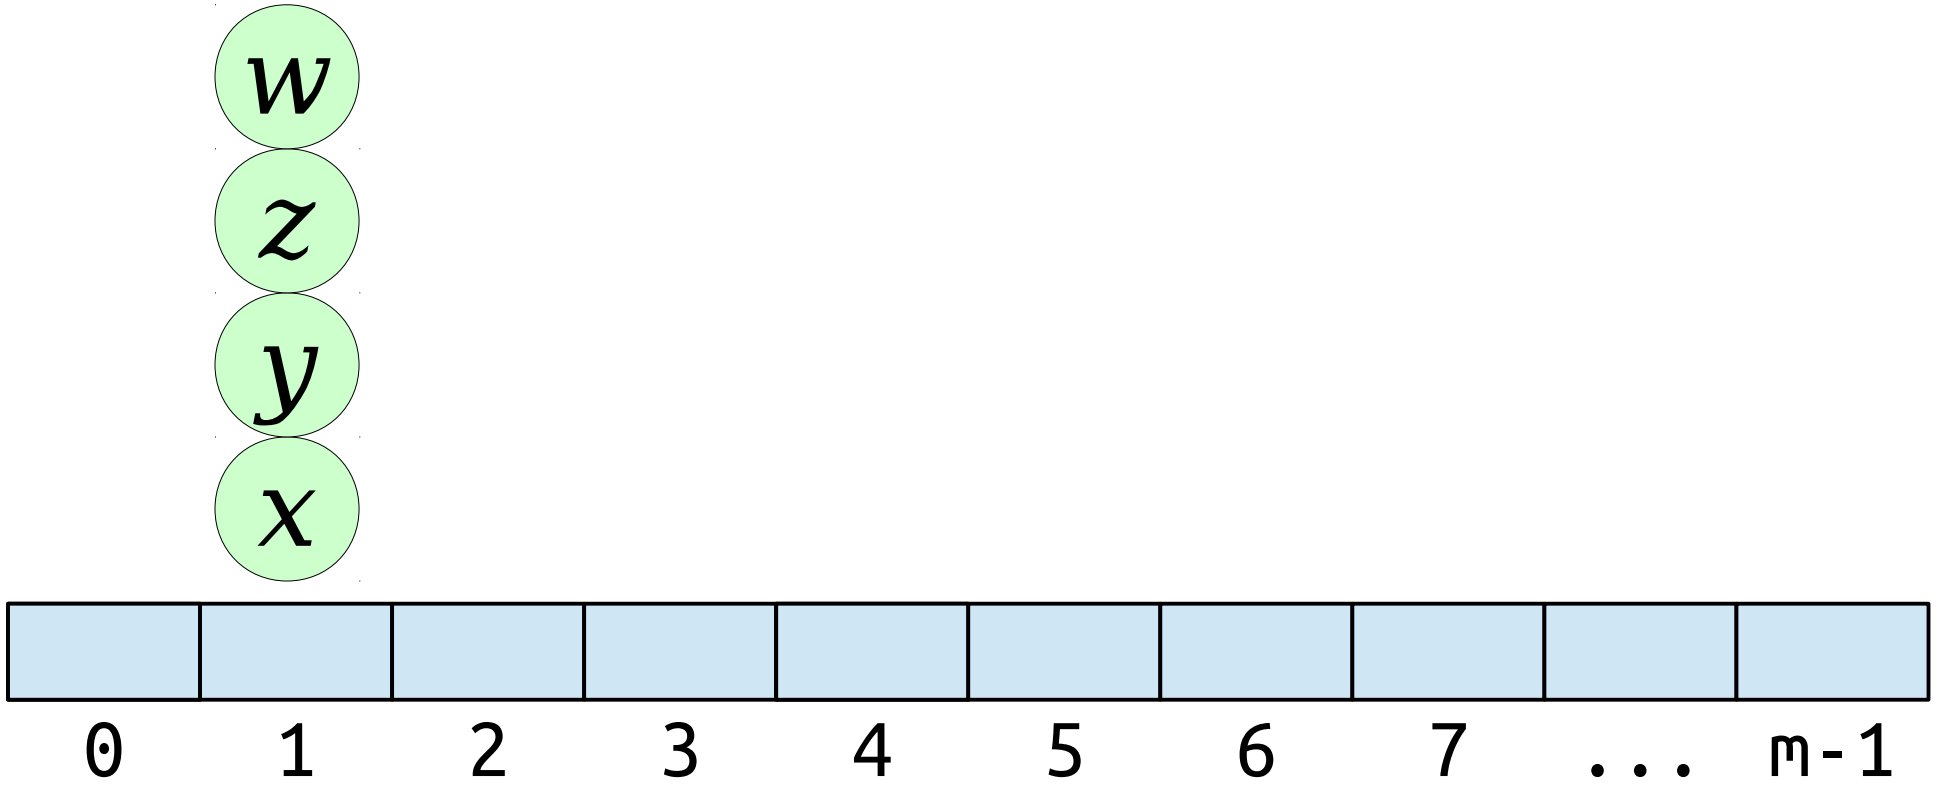
***Problem:*** This rule doesn't guarantee that elements are spread out.



***Distribution Property:*** Each element should have an equal probability of being placed in each slot.

**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

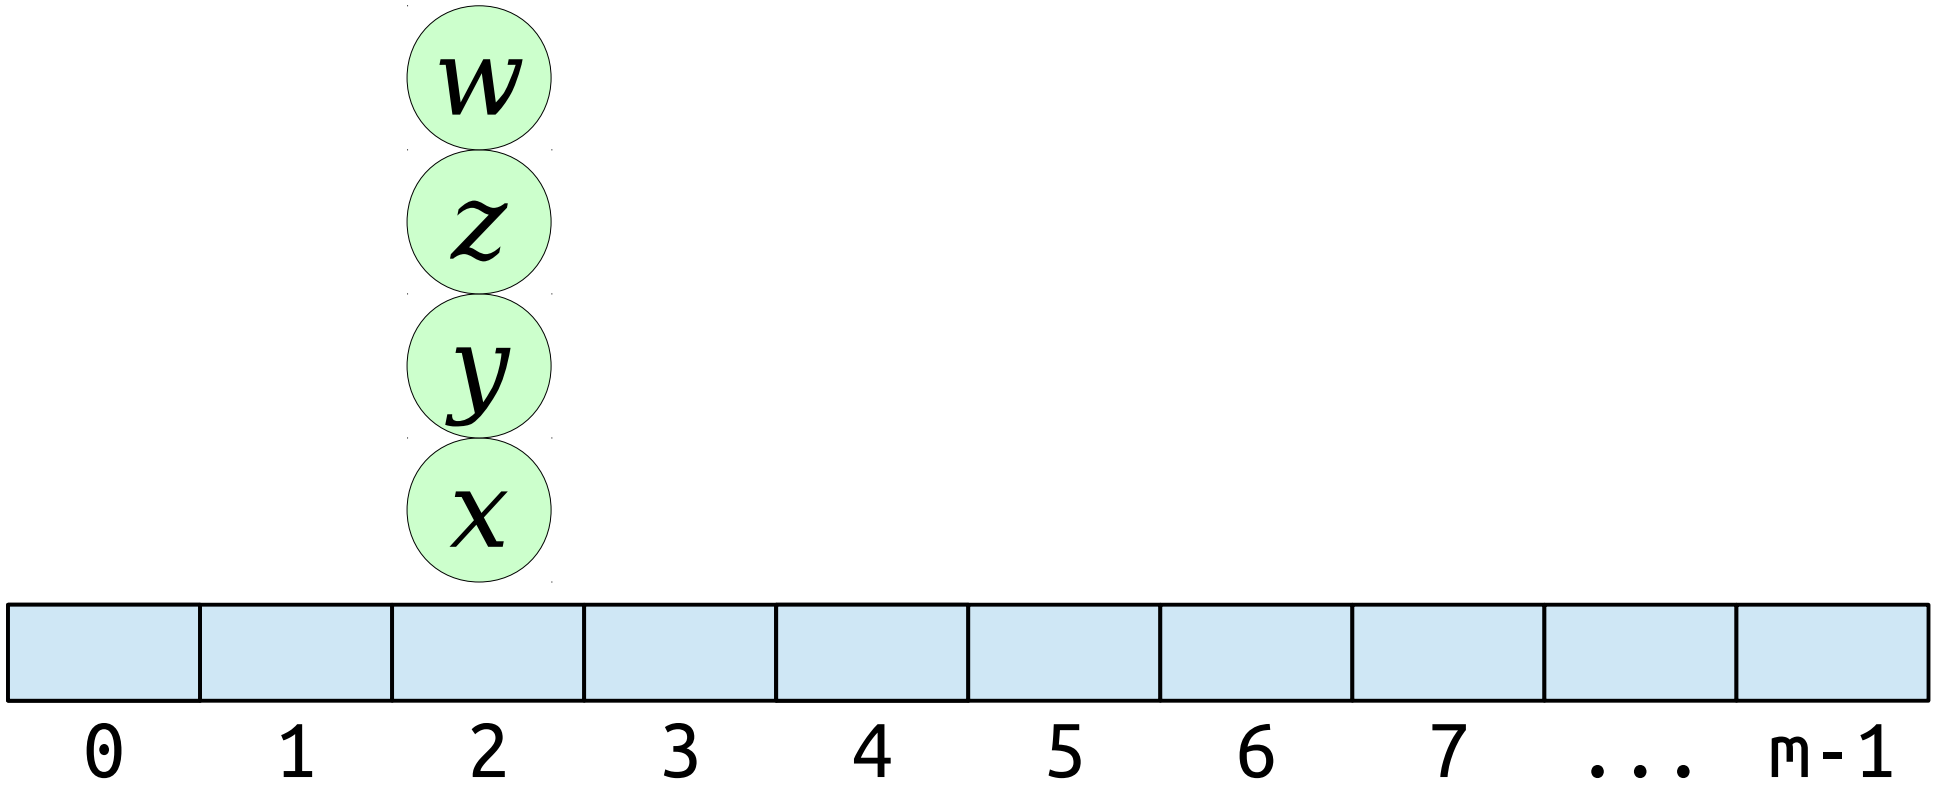
***Problem:*** This rule doesn't guarantee that elements are spread out.



***Distribution Property:*** Each element should have an equal probability of being placed in each slot.

**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

***Problem:*** This rule doesn't guarantee that elements are spread out.

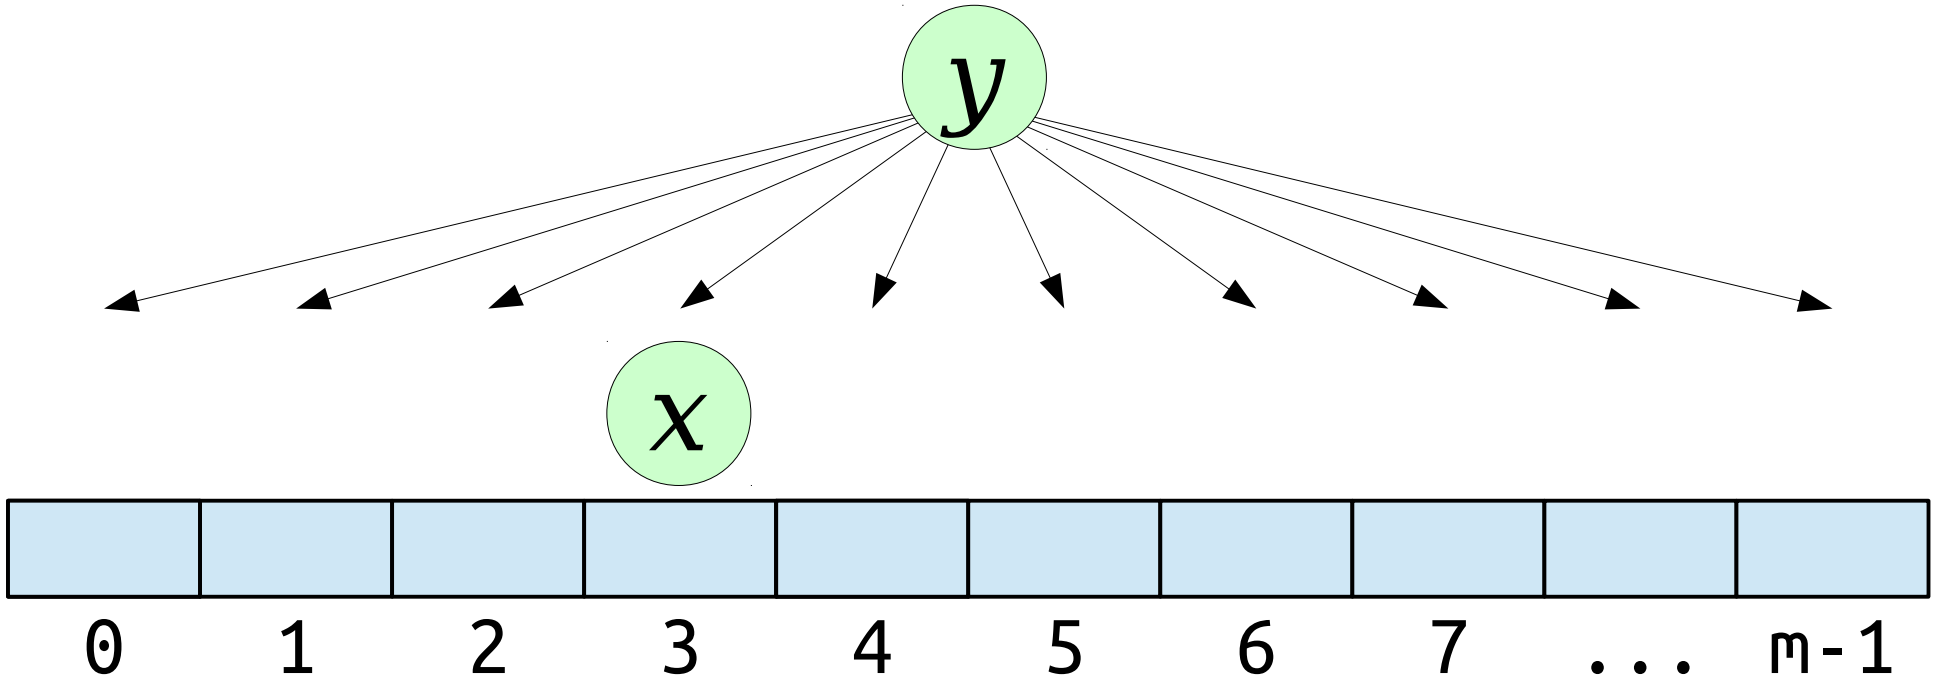


***Distribution Property:***
Each element should have an equal probability of being placed in each slot.

**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

***Independence Property:***
Where one element is placed shouldn't impact where a second goes.

**For any distinct $x, y \in \mathscr{U}$ and random $h \in \mathcal{H}$, $h(x)$ and $h(y)$ are independent random variables.**



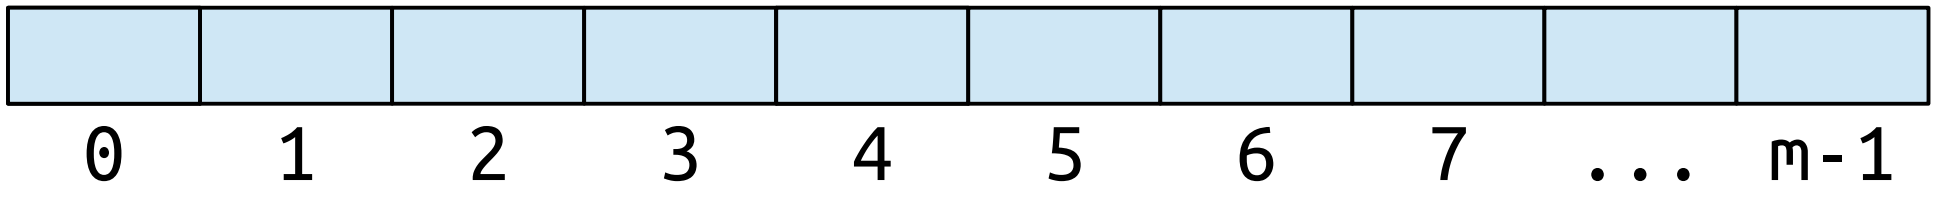
***Distribution Property:***
Each element should have an equal probability of being placed in each slot.

**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

***Independence Property:***
Where one element is placed shouldn't impact where a second goes.

**For any distinct $x, y \in \mathscr{U}$ and random $h \in \mathcal{H}$, $h(x)$ and $h(y)$ are independent random variables.**

A family of hash functions $\mathscr{H}$ is called ***2-independent*** (or ***pairwise independent***) if it satisfies the distribution and independence properties.

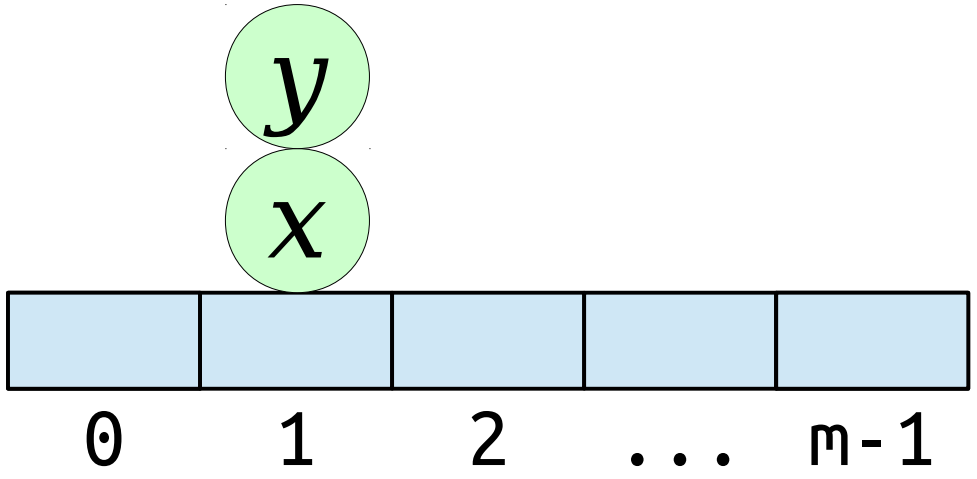


**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

**For any distinct $x, y \in \mathscr{U}$ and random $h \in \mathcal{H}$, $h(x)$ and $h(y)$ are independent random variables.**

***Intuition:***

2-independence means any pair of elements is unlikely to collide.



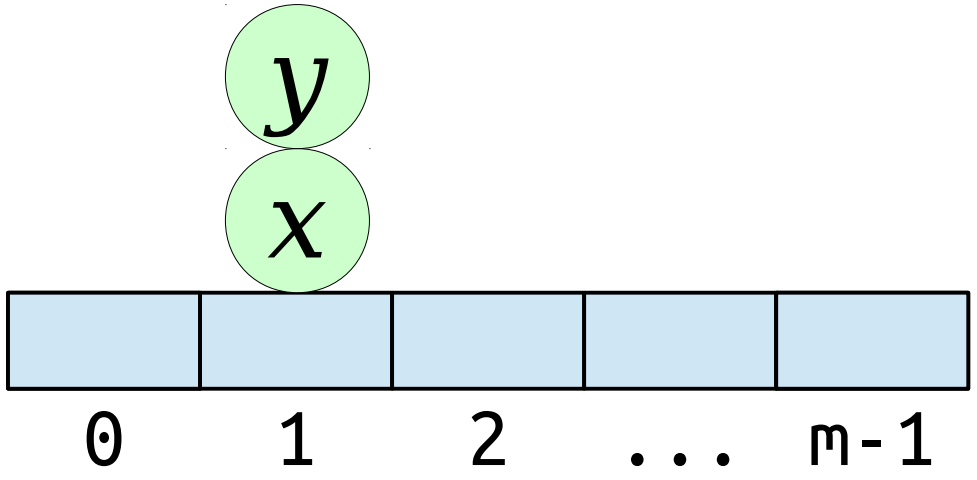
**For any $x \in \mathcal{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

**For any distinct $x, y \in \mathcal{U}$ and random $h \in \mathcal{H}$, $h(x)$ and $h(y)$ are independent random variables.**

***Intuition:***
2-independence means any pair of elements is unlikely to collide.

$$\Pr[h(x) = h(y)]$$

***Question:*** Where did these elements collide with one another?

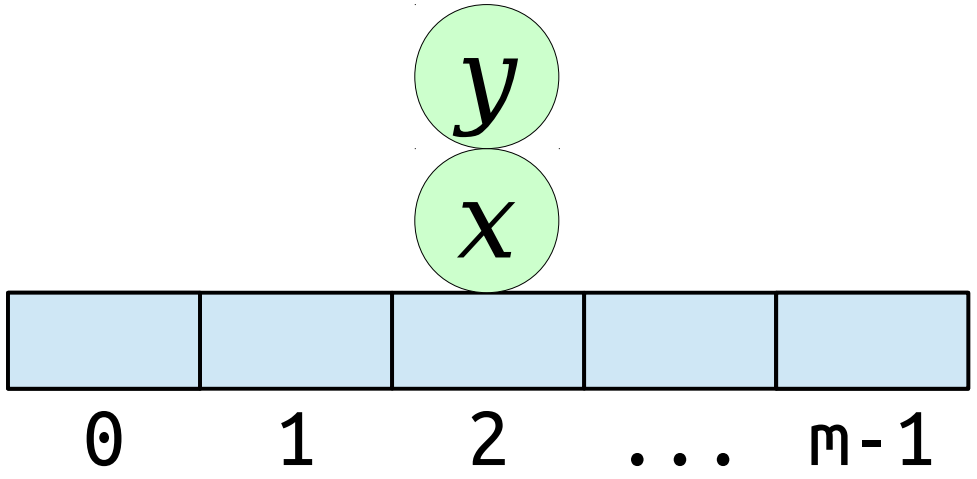


**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

**For any distinct $x, y \in \mathscr{U}$ and random $h \in \mathcal{H}$, $h(x)$ and $h(y)$ are independent random variables.**

***Intuition:***
2-independence means any pair of elements is unlikely to collide.

$$\Pr[h(x) = h(y)]$$



***Question:*** Where did these elements collide with one another?

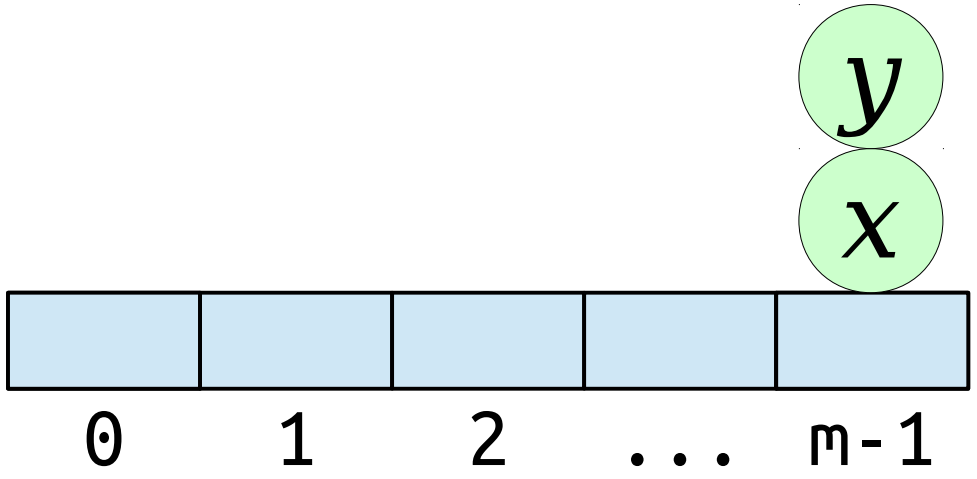
**For any $x \in \mathcal{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

**For any distinct $x, y \in \mathcal{U}$ and random $h \in \mathcal{H}$, $h(x)$ and $h(y)$ are independent random variables.**

***Intuition:***
2-independence means any pair of elements is unlikely to collide.

$$\Pr[h(x) = h(y)]$$

***Question:*** Where did these elements collide with one another?



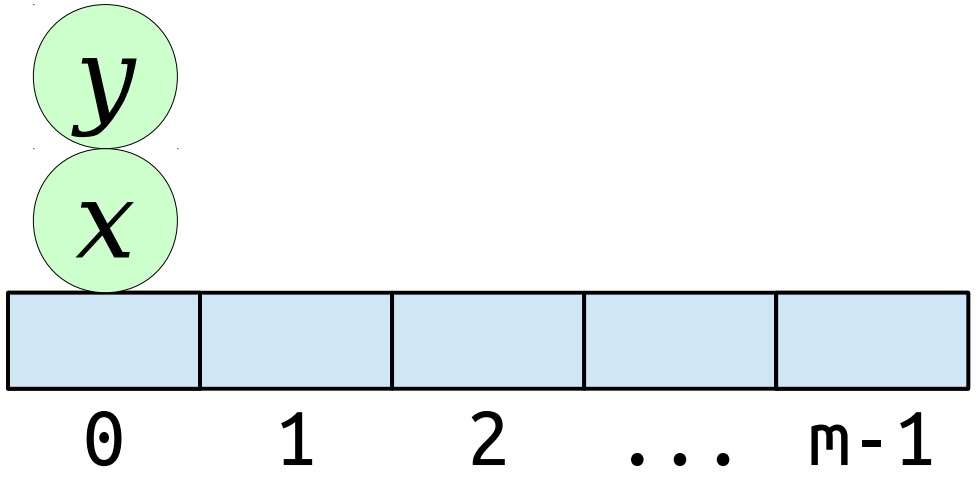
**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

**For any distinct $x, y \in \mathscr{U}$ and random $h \in \mathcal{H}$, $h(x)$ and $h(y)$ are independent random variables.**

***Intuition:***
2-independence means any pair of elements is unlikely to collide.

$$\Pr[h(x) = h(y)]$$

***Question:*** Where did these elements collide with one another?



**For any $x \in \mathcal{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

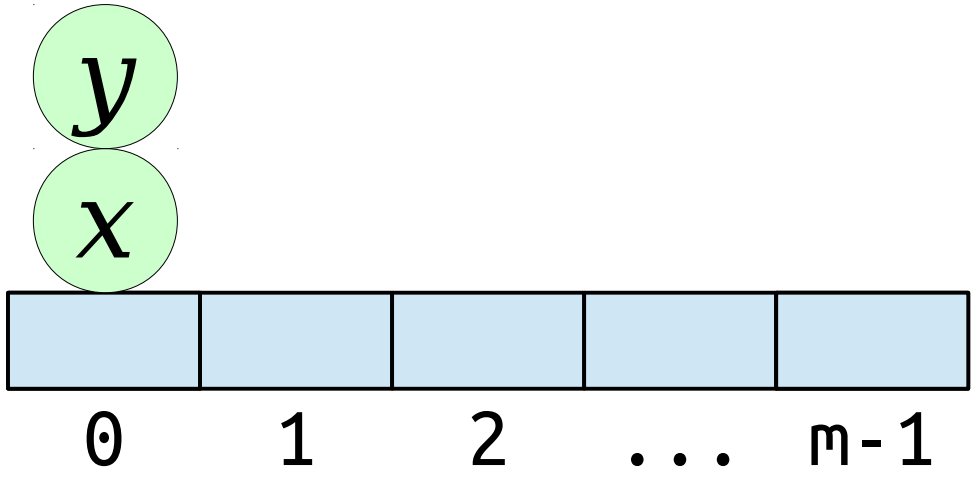
**For any distinct $x, y \in \mathcal{U}$ and random $h \in \mathcal{H}$, $h(x)$ and $h(y)$ are independent random variables.**

***Intuition:***
2-independence means any pair of elements is unlikely to collide.

$$\Pr[h(x) = h(y)]$$

$$= \sum_{i=0}^{m-1} \Pr[h(x) = i \wedge h(y) = i]$$

***Question:*** Where did these elements collide with one another?



**For any $x \in \mathcal{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

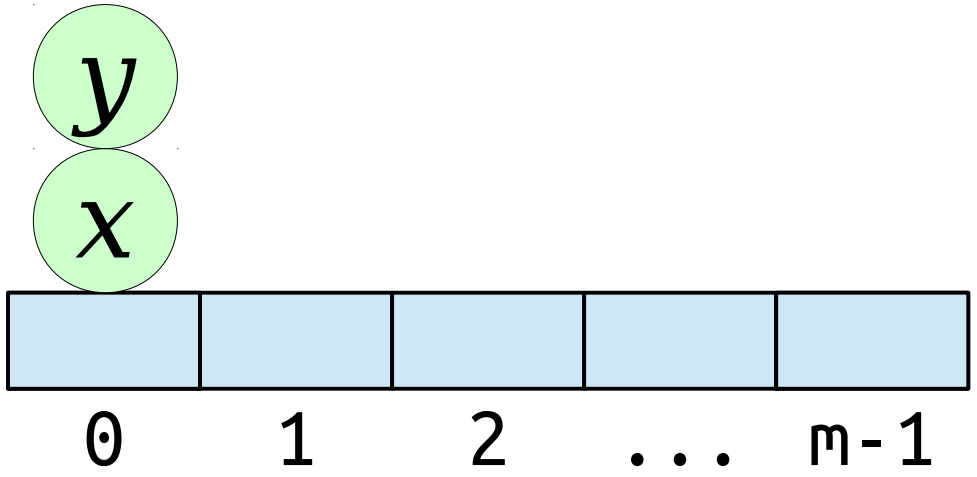
**For any distinct $x, y \in \mathcal{U}$ and random $h \in \mathcal{H}$, $h(x)$ and $h(y)$ are independent random variables.**

***Intuition:***

2-independence means any pair of elements is unlikely to collide.

$$\Pr[h(x) = h(y)]$$

$$= \sum_{i=0}^{m-1} \Pr[h(x) = i \wedge h(y) = i]$$



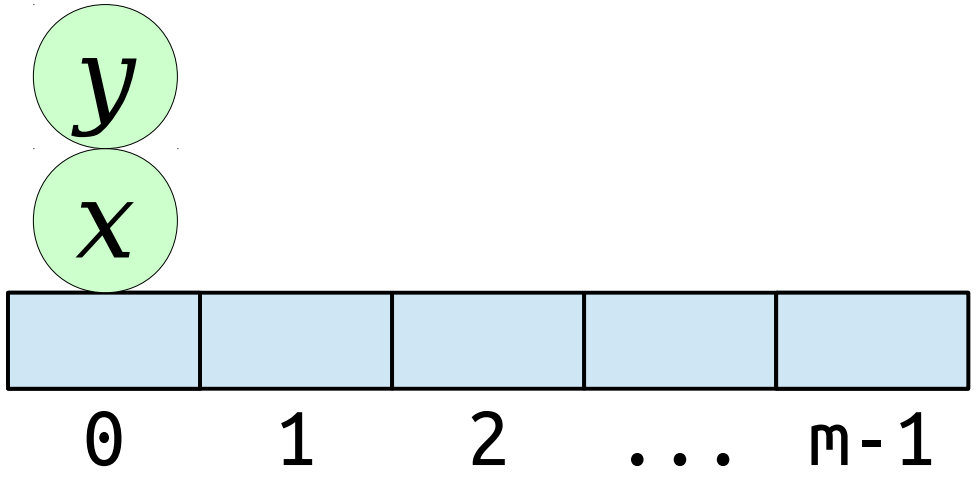
**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

**For any distinct $x, y \in \mathscr{U}$ and random $h \in \mathcal{H}$, $h(x)$ and $h(y)$ are independent random variables.**

***Intuition:***
2-independence means any pair of elements is unlikely to collide.

$$\Pr[h(x) = h(y)]$$

$$= \sum_{i=0}^{m-1} \Pr[h(x) = i \wedge h(y) = i]$$



**For any $x \in \mathscr{U}$ and random $h \in \mathcal{H}$, the value of $h(x)$ is uniform over $[m]$.**

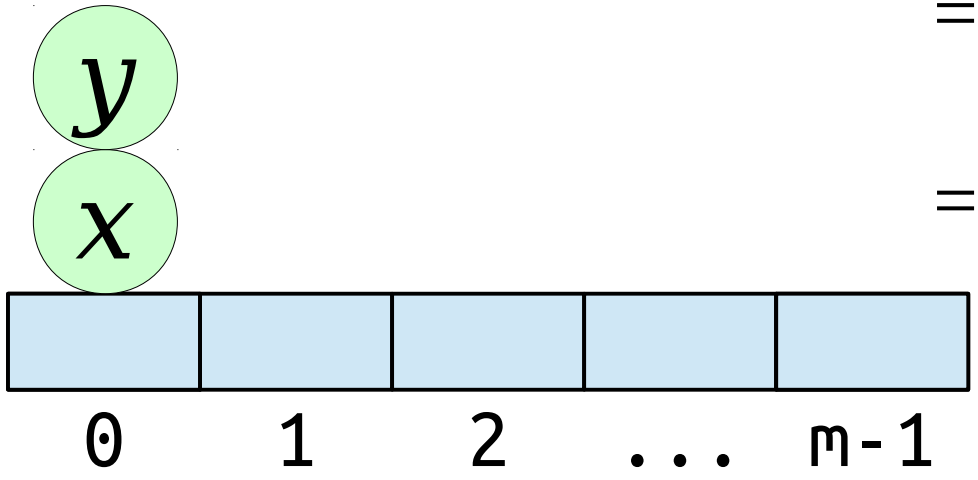
&= \sum_{i=0}^{m-1} \frac{1}{m^2} \\
&= \frac{1}{m}
\end{aligned}$$



This is the same as if $h$ were a truly random function.

For more on hashing outside of Theoryland, check out ***this Stack Exchange post***.

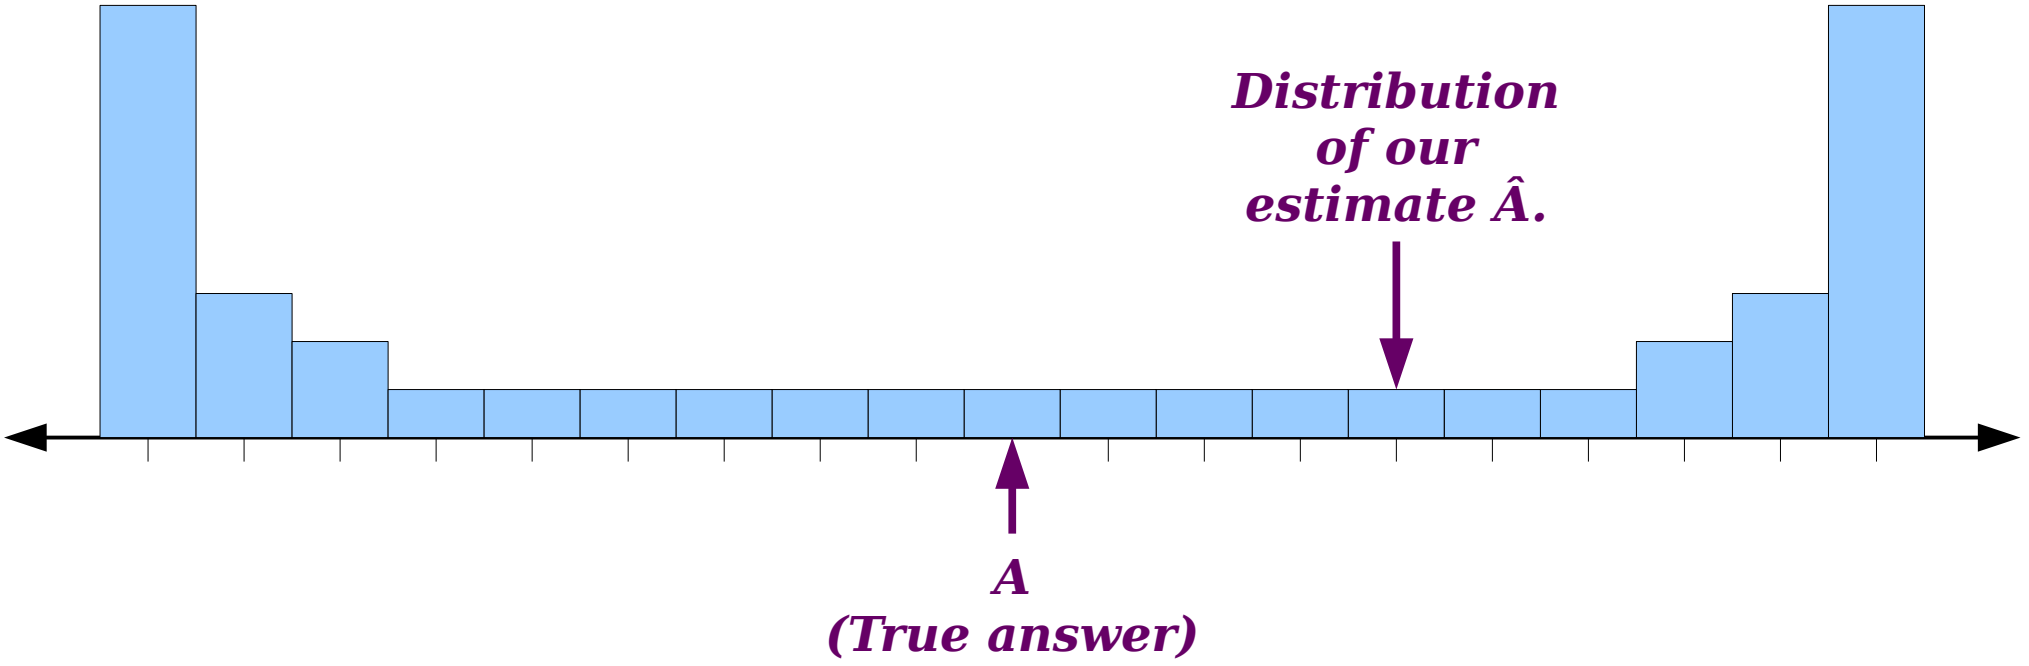
# Approximating Quantities

What makes for a good
“approximate” solution?

Let $\boldsymbol{A}$ be the true answer. Let $\boldsymbol{\hat{A}}$ be a random variable denoting our estimate.

This would not make for a good estimate. However, we have $E[\hat{A}] = A$.

***Observation 1:*** Being correct in expectation isn't sufficient.

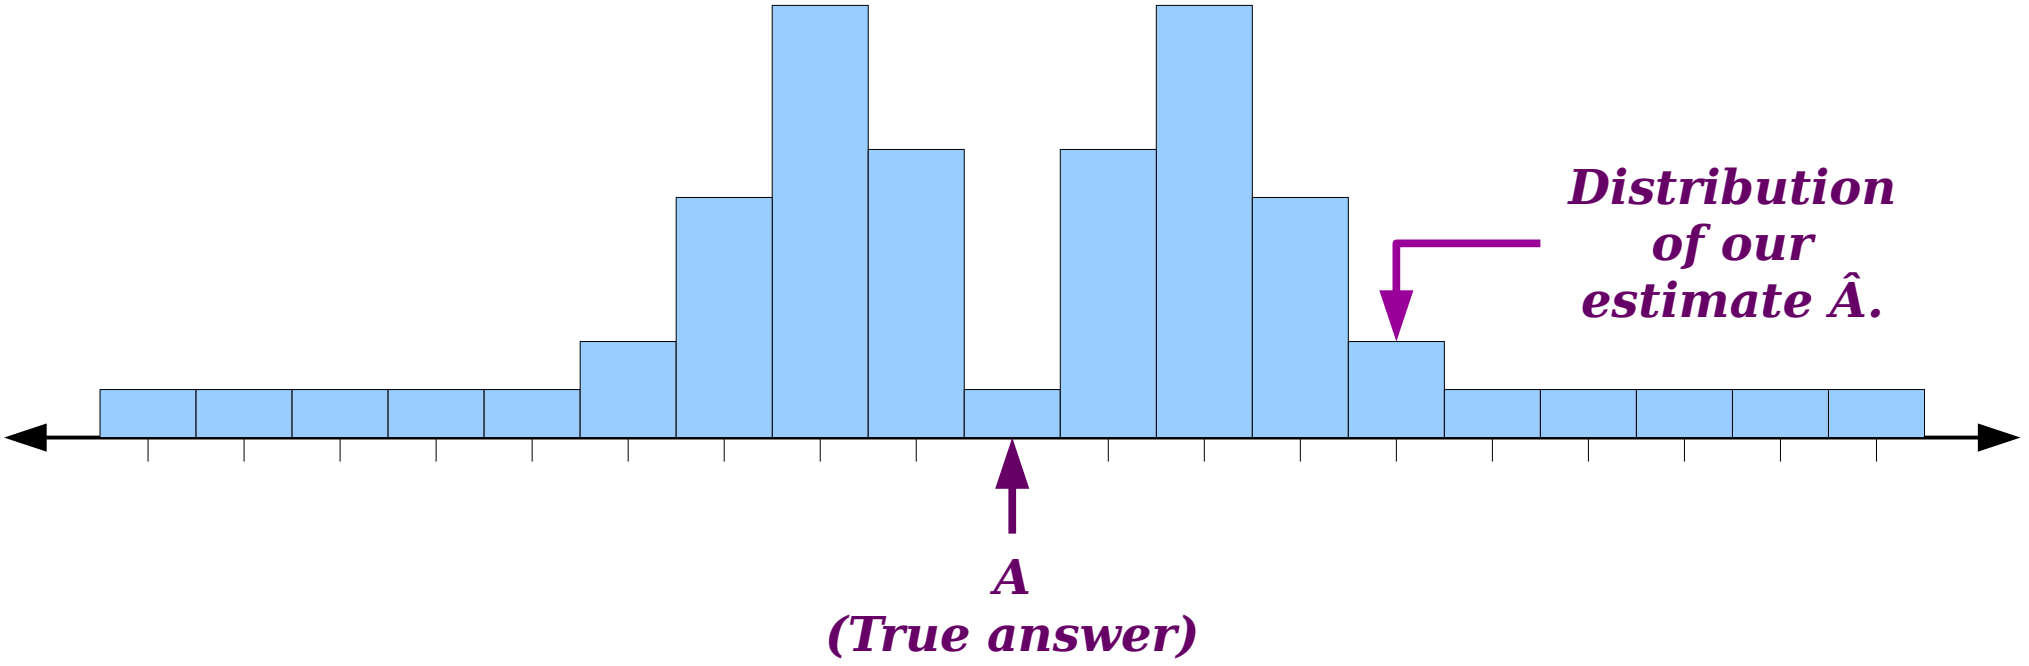


What does it mean for an approximation to be "good"?

Let $A$ be the true answer. Let $\hat{A}$ be a random variable denoting our estimate.

It's unlikely that we'll get the right answer, but we're probably going to be close.

***Observation 2:*** The difference $|\hat{A} - A|$ between our estimate and the truth should ideally be small.

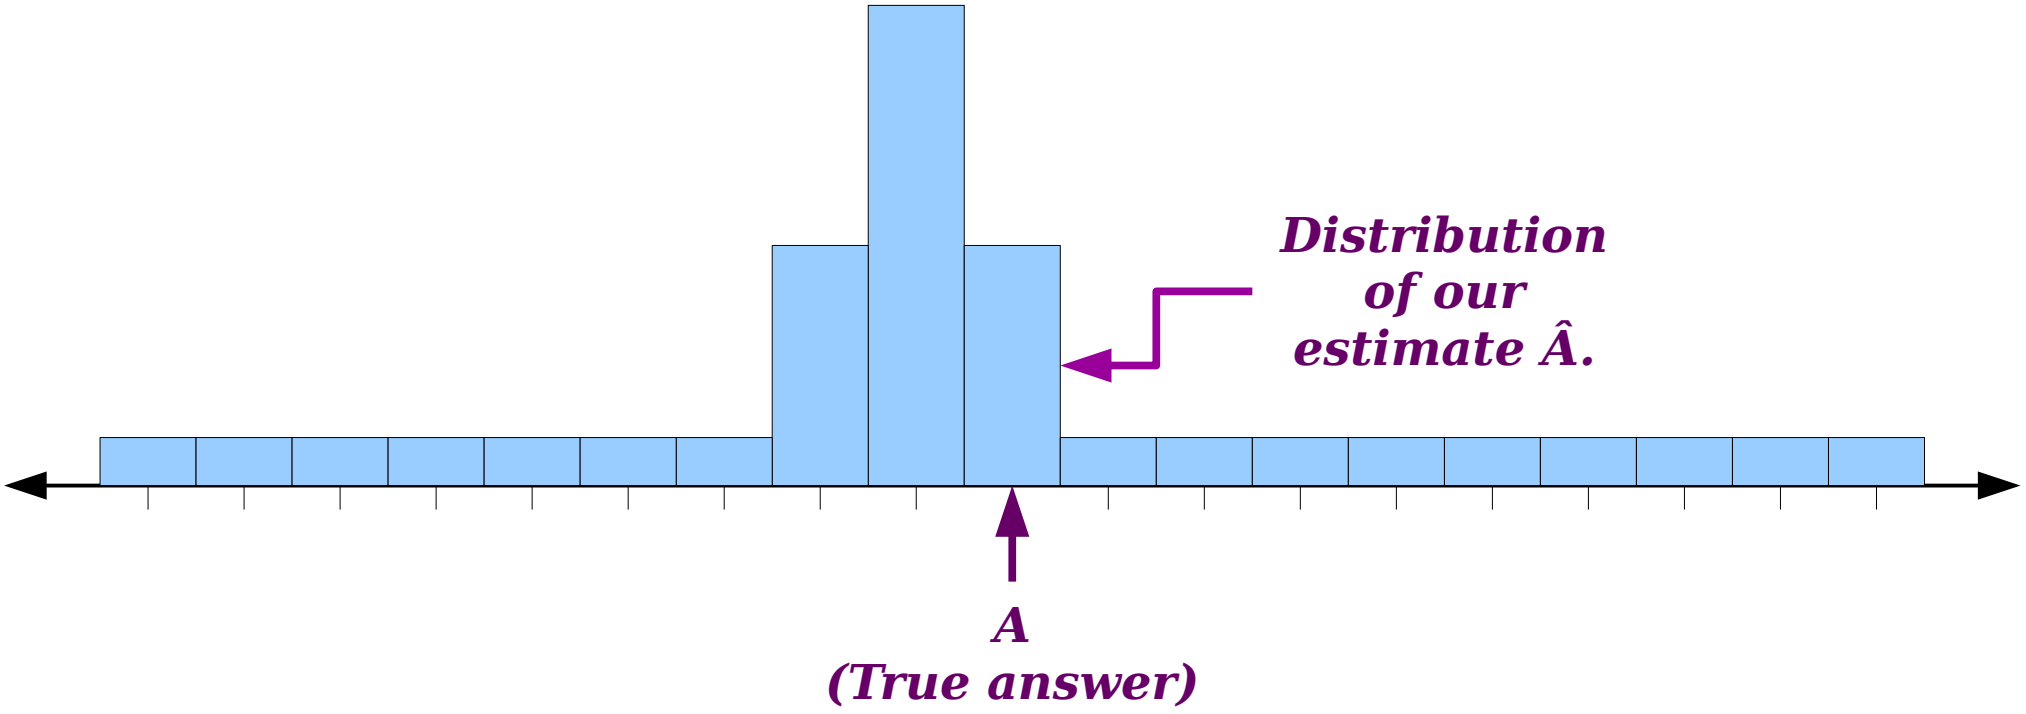


What does it mean for an approximation to be "good"?

Let $A$ be the true answer. Let $\hat{A}$ be a random variable denoting our estimate.

This estimate skews low, but it's very close to the true value.

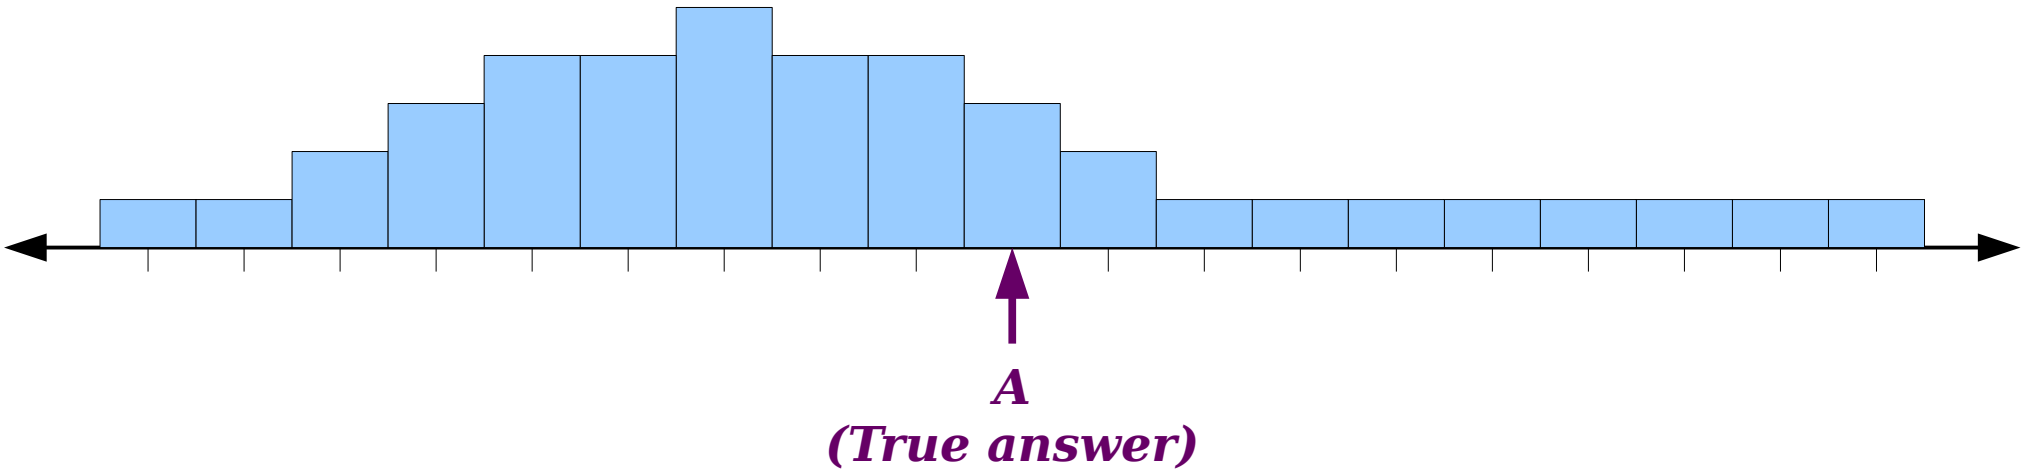
***Observation 3:*** An estimate doesn't have to be unbiased to be useful.



What does it mean for an approximation to be "good"?

Let $A$ be the true answer. Let $\hat{A}$ be a random variable denoting our estimate.

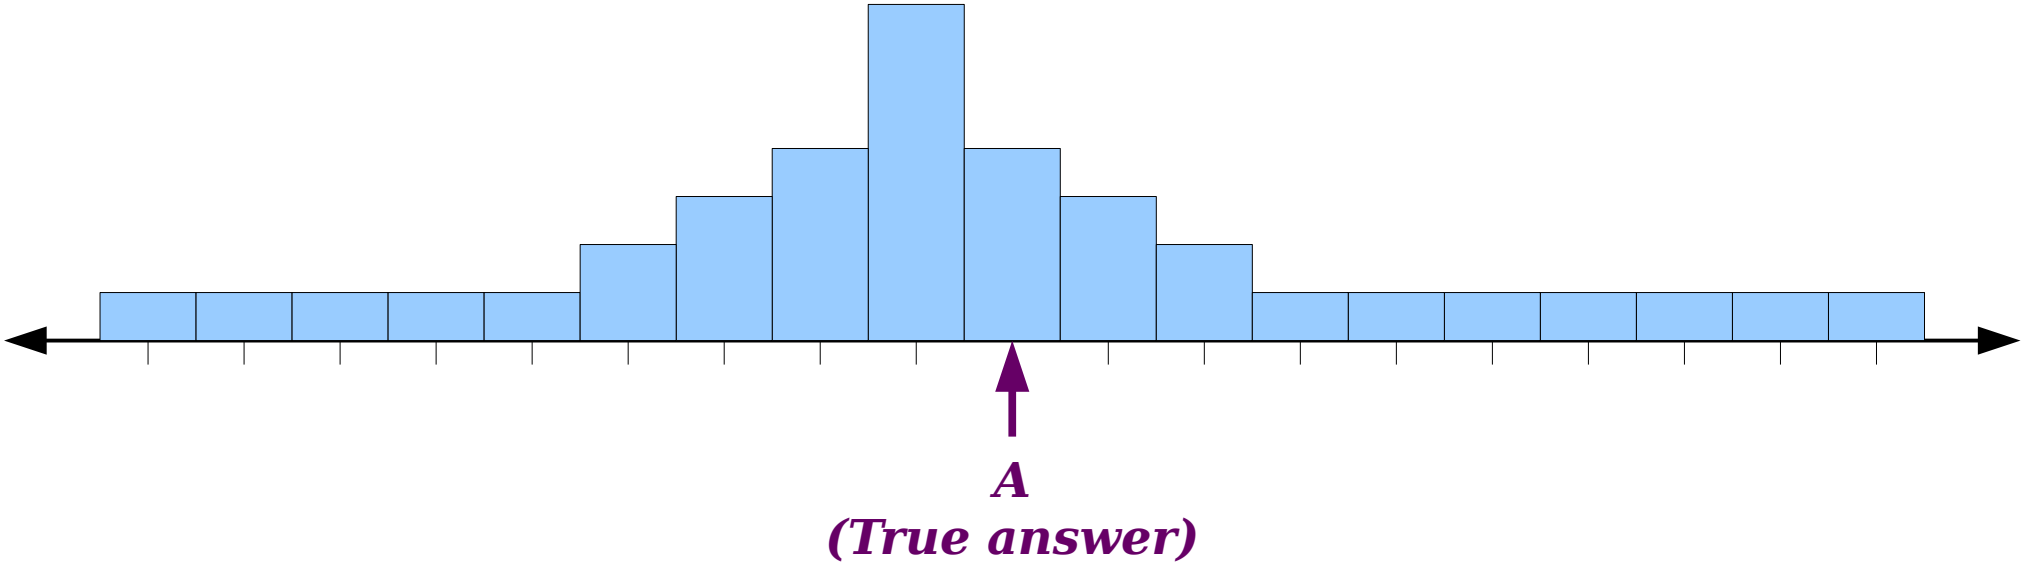
**Memory used: 16MB**



What does it mean for an approximation to be “good”?

Let $A$ be the true answer. Let $\hat{A}$ be a random variable denoting our estimate.

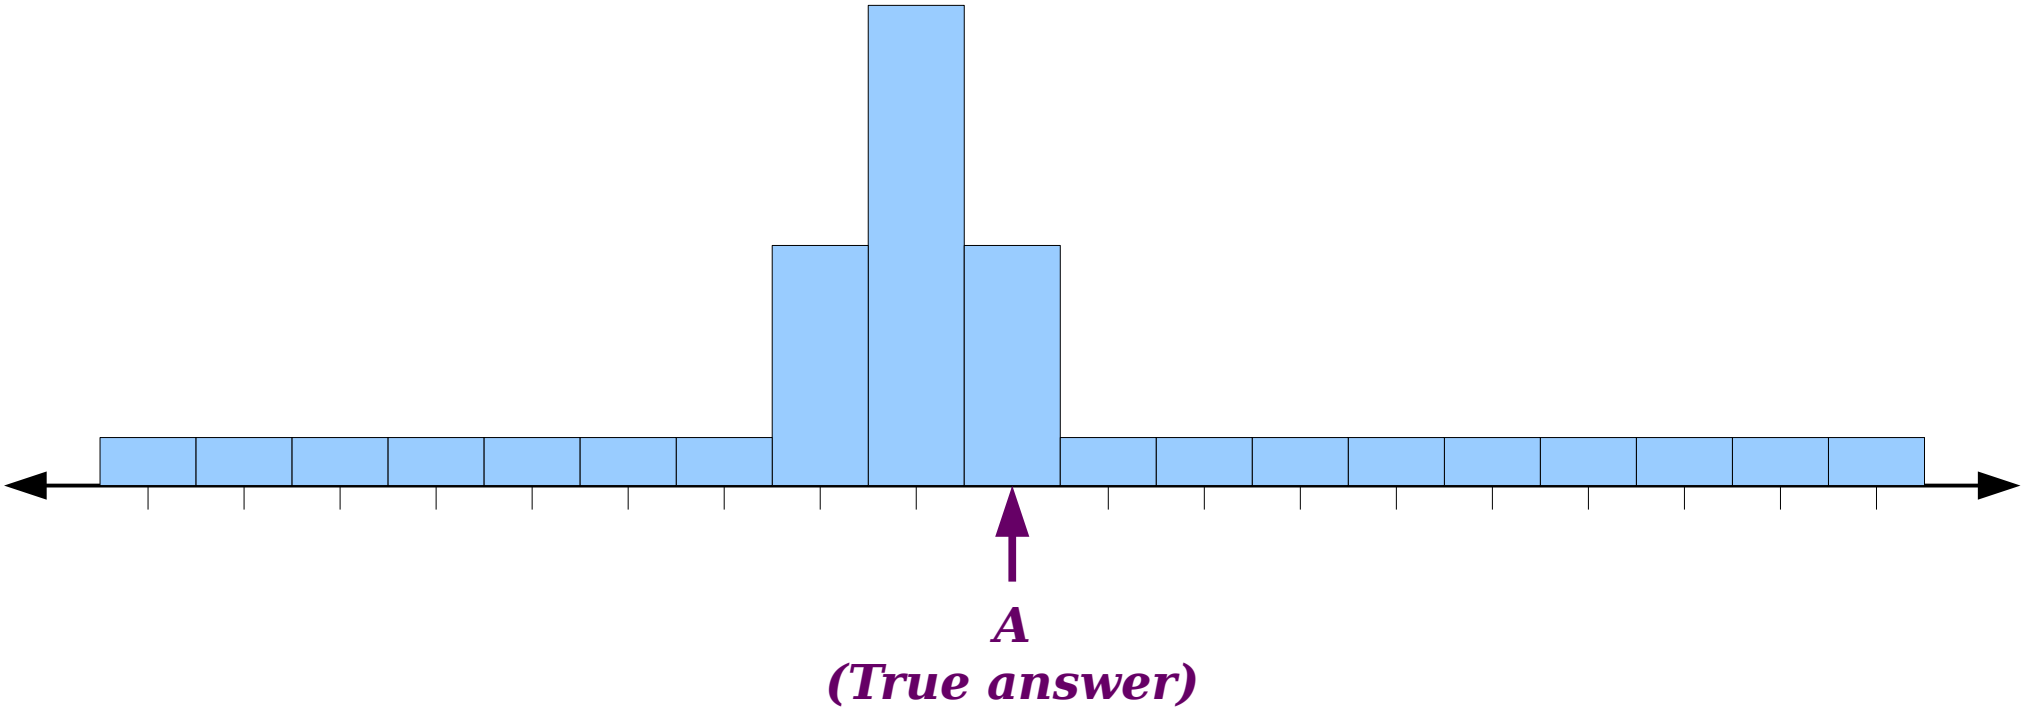
**Memory used: 32MB**



What does it mean for an approximation to be “good”?

Let $A$ be the true answer. Let $\hat{A}$ be a random variable denoting our estimate.

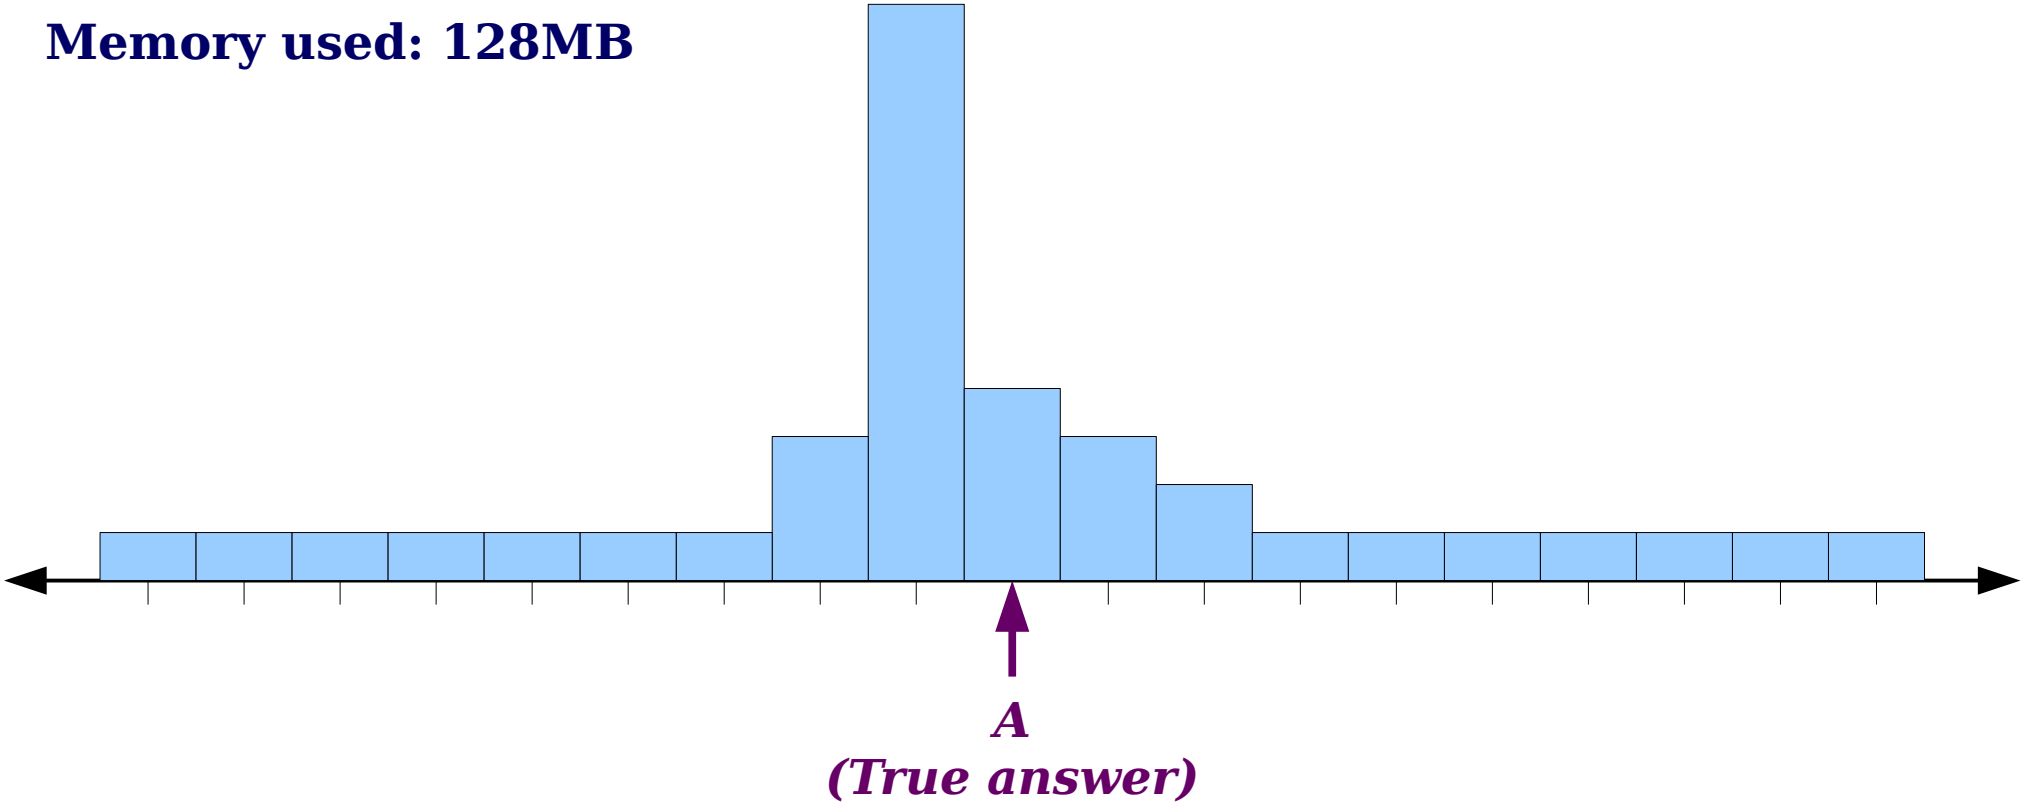
**Memory used: 64MB**



What does it mean for an approximation to be “good”?

Let $A$ be the true answer. Let $\hat{A}$ be a random variable denoting our estimate.

**Memory used: 128MB**



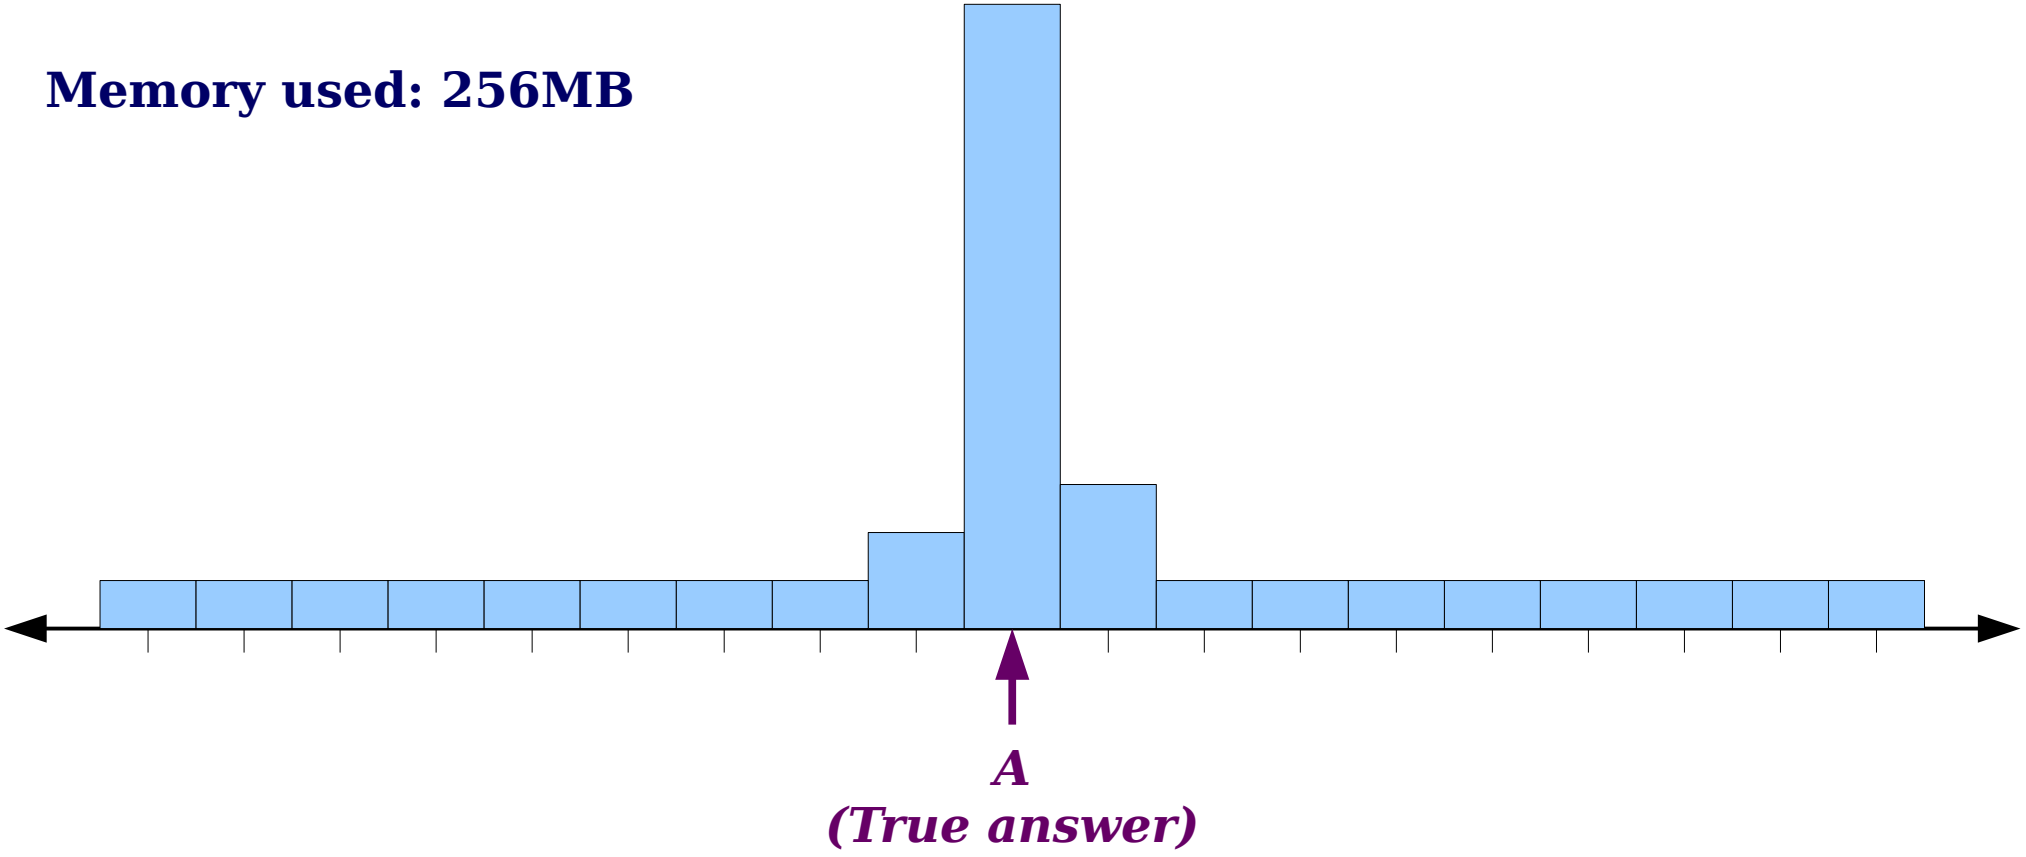
What does it mean for an approximation to be “good”?

Let $A$ be the true answer. Let $\hat{A}$ be a random variable denoting our estimate.

The more resources we allocate, the better our estimate should be.

***Observation 4:*** A good approximation should be tunable.

**Memory used: 256MB**



What does it mean for an approximation to be “good”?

Suppose there are two tunable values

$\varepsilon \in (0, 1]$
$\delta \in (0, 1]$

where $\varepsilon$ represents ***accuracy*** and $\delta$ represents ***confidence***.

***Goal:*** Make an estimator $\hat{A}$ for some quantity $A$ where

With probability at least $1 - \delta$,

$$|\hat{A} - A| \leq \varepsilon \cdot size(input)$$

for some measure of the size of the input.

---

What does it mean for an approximation to be “good”?

Suppose there are two tunable values

$\varepsilon \in (0, 1]$
$\delta \in (0, 1]$

where $\varepsilon$ represents ***accuracy*** and $\delta$ represents ***confidence***.

***Goal:*** Make an estimator $\hat{A}$ for some quantity $A$ where

With probability at least $1 - \delta$, ← ***Probably***

***Goal:*** Make an estimator $\hat{A}$ for some quantity $A$ where

With probability at least $1 - \delta$, ← ***Probably***

$|A - \hat{A}| \leq \varepsilon \cdot size(input)$ ← ***Approximately Correct***

for some measure of the size of the input.

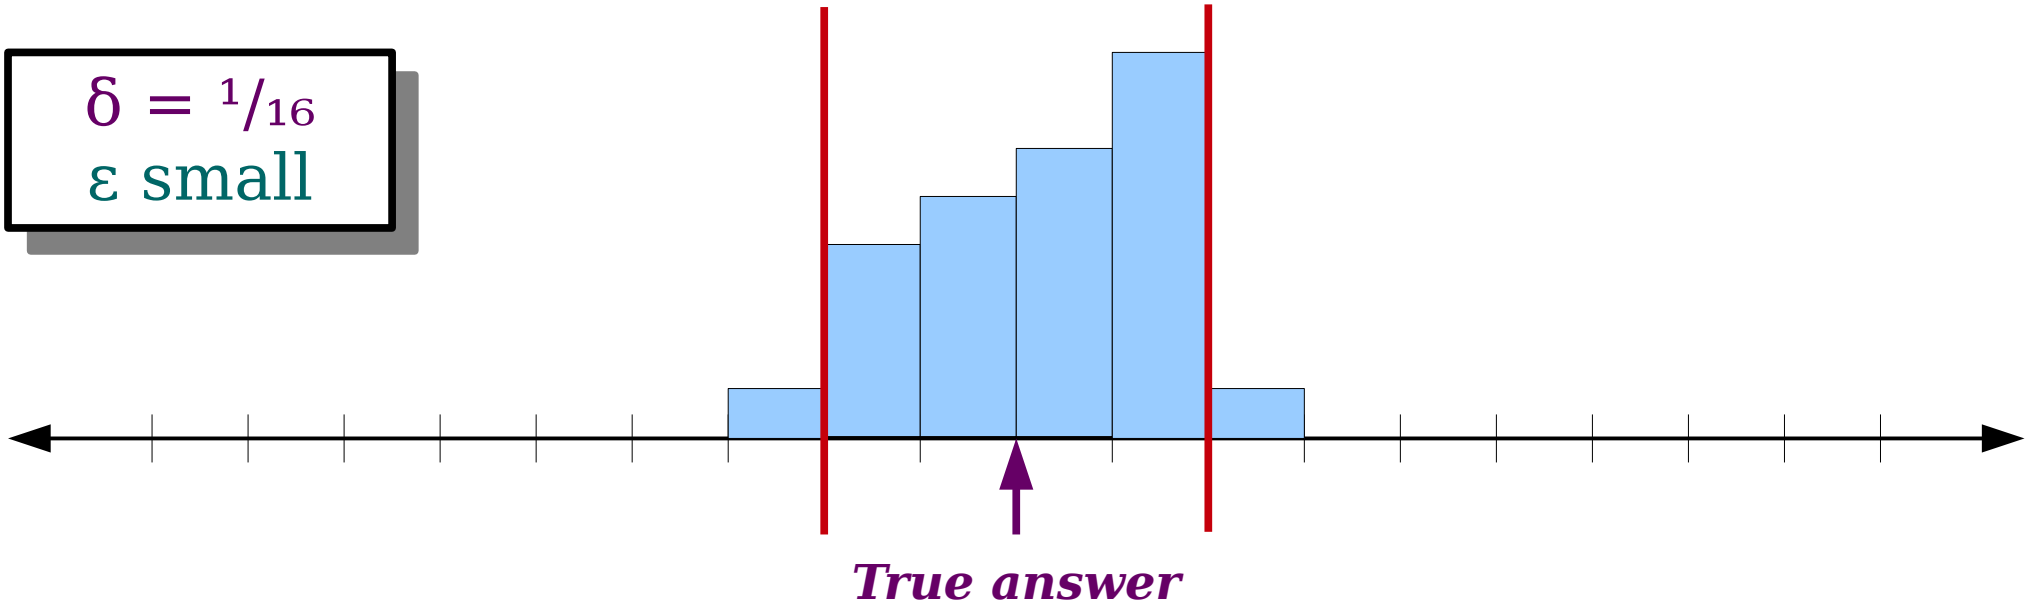
$\delta = 1/16$

$\varepsilon$ small



What does it mean for an approximation to be “good”?

# Frequency Estimation

# Frequency Estimators

- A ***frequency estimator*** is a data structure supporting the following operations:
  - ***increment***($x$), which increments the number of times that $x$ has been seen, and
  - ***estimate***($x$), which returns an estimate of the frequency of $x$.
- Using BSTs, we can solve this in space $\Theta(n)$ with worst-case $O(\log n)$ costs on the operations.
- Using hash tables, we can solve this in space $\Theta(n)$ with expected $O(1)$ costs on the operations.

# Frequency Estimators

- Frequency estimation has many applications:
  - Search engines: Finding frequent search queries.
  - Network routing: Finding common source and destination addresses.
- In these applications, $\Theta(n)$ memory can be impractical.
- ***Goal:*** Get *approximate* answers to these queries in sublinear space.

# The Count-Min Sketch

# How to Build an Estimator

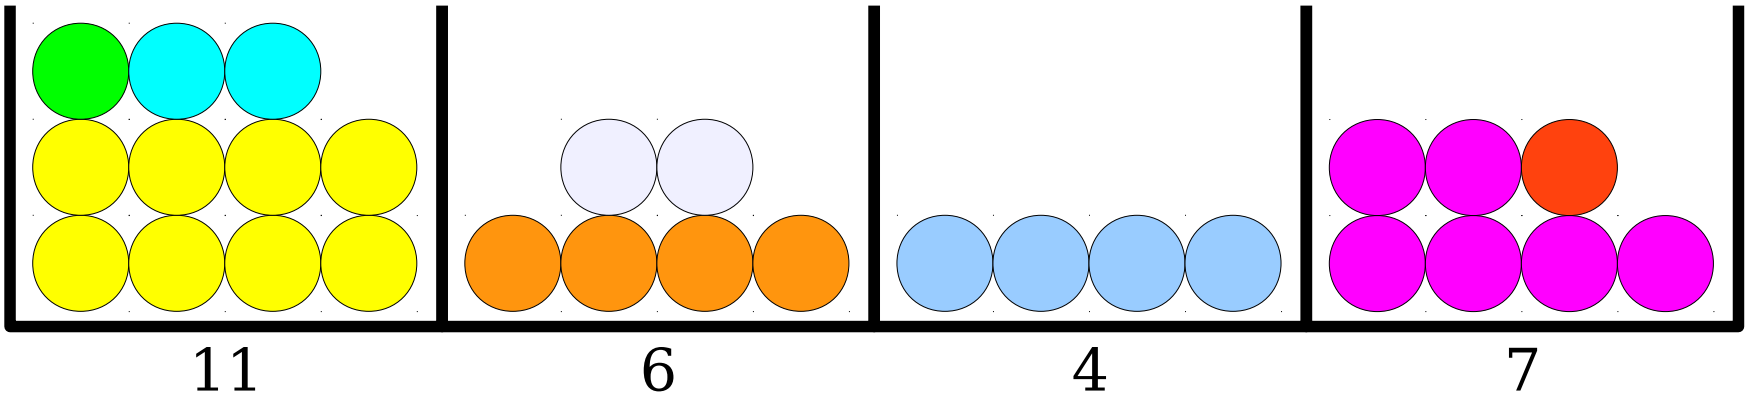
1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

# How to Build an Estimator

1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

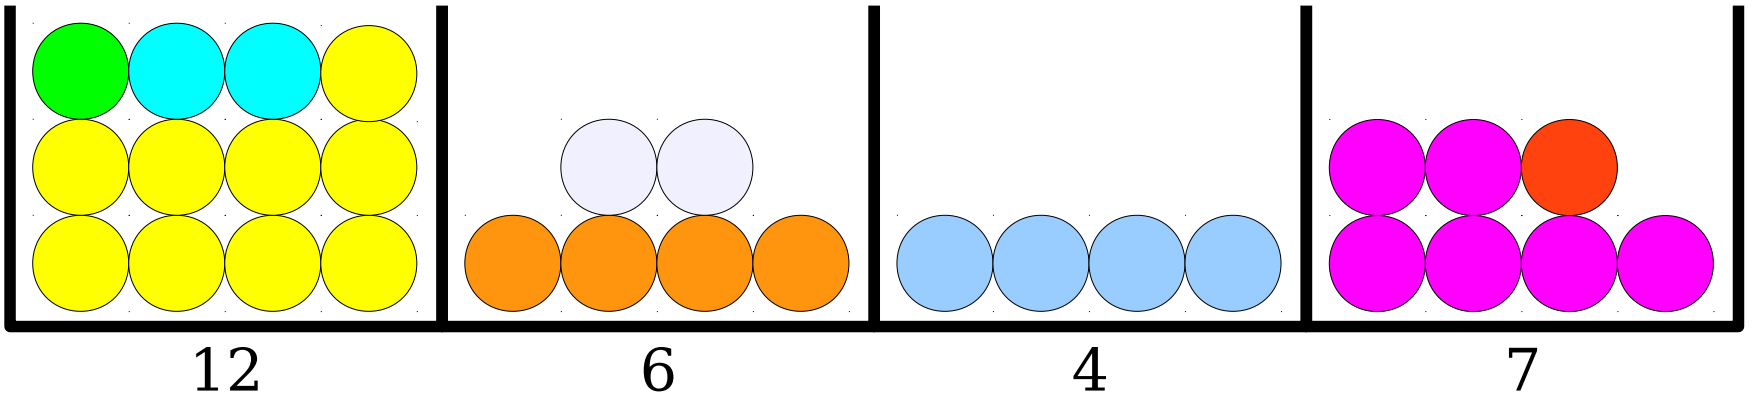
# Revisiting the Exact Solution

- In the exact solution to the frequency estimation problem, we maintained a single counter for each distinct element. This is too space-inefficient.
- ***Idea:*** Store a fixed number of counters and assign a counter to each $x_i \in \mathscr{U}$. Multiple $x_i$'s might be assigned to the same counter.
- To ***increment***($x$), increment the counter for $x$.
- To ***estimate***($x$), read the value of the counter for $x$.



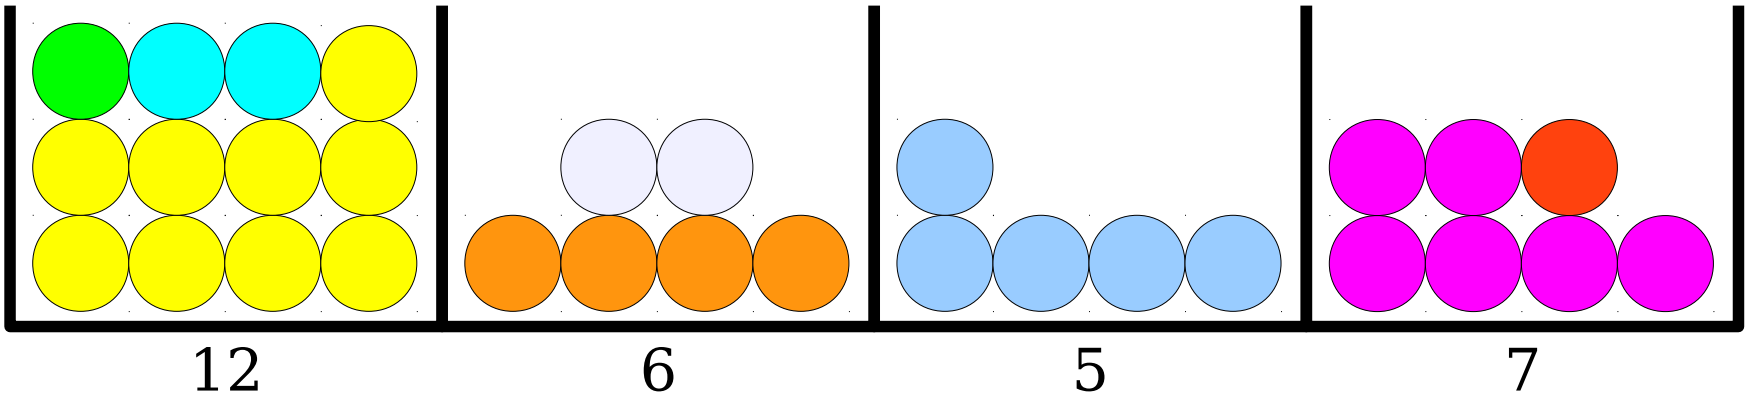
# Revisiting the Exact Solution

- In the exact solution to the frequency estimation problem, we maintained a single counter for each distinct element. This is too space-inefficient.
- ***Idea:*** Store a fixed number of counters and assign a counter to each $x_i \in \mathscr{U}$. Multiple $x_i$'s might be assigned to the same counter.
- To ***increment***($x$), increment the counter for $x$.
- To ***estimate***($x$), read the value of the counter for $x$.



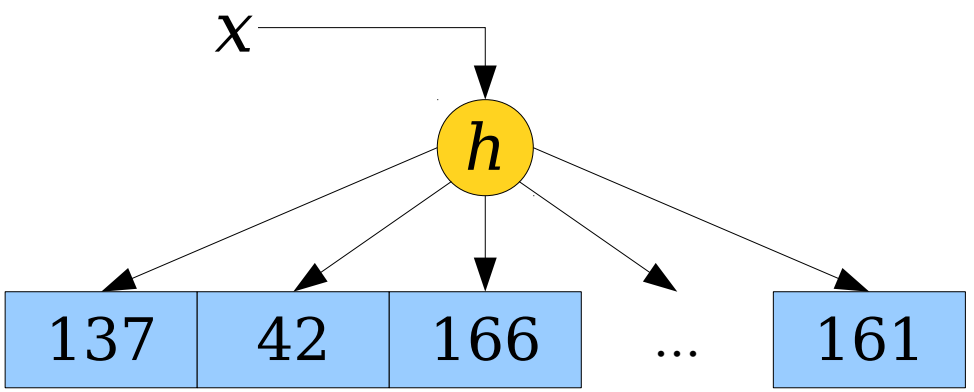
# Revisiting the Exact Solution

- In the exact solution to the frequency estimation problem, we maintained a single counter for each distinct element. This is too space-inefficient.
- ***Idea:*** Store a fixed number of counters and assign a counter to each $x_i \in \mathscr{U}$. Multiple $x_i$'s might be assigned to the same counter.
- To ***increment***($x$), increment the counter for $x$.
- To ***estimate***($x$), read the value of the counter for $x$.



# Our Initial Structure

- We can model "assigning each $x_i$ to a counter" by using hash functions.
- Choose, from a family of 2-independent hash functions $\mathscr{H}$, a uniformly-random hash function $h : \mathscr{U} \to [w]$.
- Create an array `count` of $w$ counters, each initially zero.
  - We'll choose $w$ later on.
- To ***increment***(x), increment `count`[$h(x)$].
- To ***estimate***(x), return `count`[$h(x)$].



# Analyzing our Structure

For each $x_i \in \mathscr{U}$, let $\boldsymbol{a}_i$ denote the number of times we've seen $x_i$.

Similarly, let $\hat{\boldsymbol{a}}_i$ denote our estimated value of the frequency of $x_i$.

***Goal:*** Show that the error in our estimate $(\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i)$ is probably close to zero.

***Idea:*** Think of our element frequencies $\boldsymbol{a}_1$, $\boldsymbol{a}_2$, $\boldsymbol{a}_3$, … as a vector

$$\boldsymbol{a} = [\boldsymbol{a}_1, \boldsymbol{a}_2, \boldsymbol{a}_3, \ldots].$$

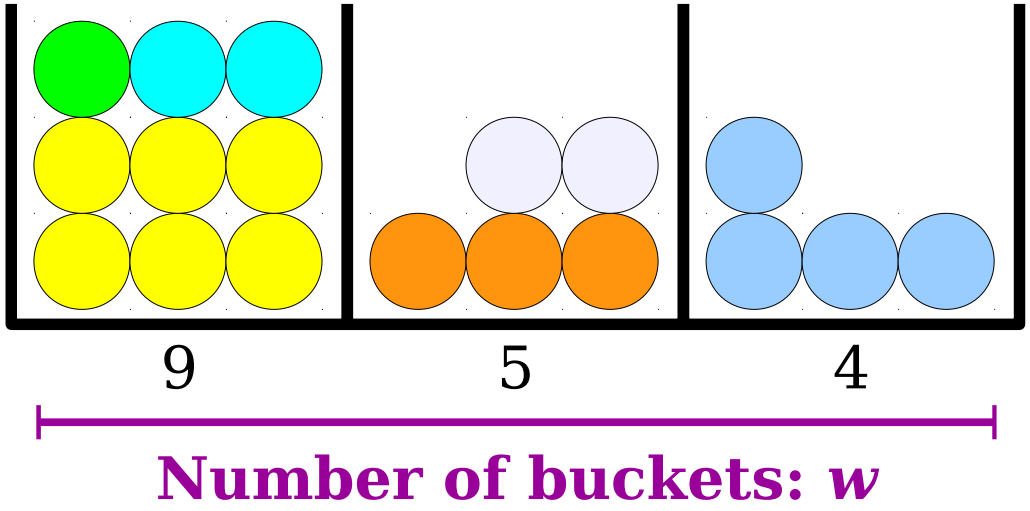
The total number of objects is the sum of the vector entries.

This is called the ***$L_1$ norm*** of $\boldsymbol{a}$, and is denoted $\|\boldsymbol{a}\|_1$:

$$\|\boldsymbol{a}\|_1 = \sum_i |\boldsymbol{a}_i|$$

There are $\|\boldsymbol{a}\|_1$ total elements distributed across $w$ buckets. We're using a 2-independent hash family.

***Reasonable guess:*** each bin has $\|\boldsymbol{a}\|_1 / w$ elements in it, so $\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i \leq \|\boldsymbol{a}\|_1 / w$



***Question:*** Intuitively, what should we expect our approximation error to be?

# How to Build an Estimator

1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

# How to Build an Estimator

2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

# Analyzing this Structure

- Let's look at $\hat{\boldsymbol{a}}_i$ = `count`$[h(x_i)]$ for some choice of $x_i$.
- For each element $x_j$:
  - If $h(x_i) = h(x_j)$, then $x_j$ contributes $\boldsymbol{a}_j$ to `count`$[h(x_i)]$.
  - If $h(x_i) \neq h(x_j)$, then $x_j$ contributes 0 to `count`$[h(x_i)]$.

# Analyzing this Structure

- Let's look at $\hat{\boldsymbol{a}}_i$ = `count`$[h(x_i)]$ for some choice of $x_i$.
- For each element $x_j$:
  - If $h(x_i) = h(x_j)$, then $x_j$ contributes $\boldsymbol{a}_j$ to `count`$[h(x_i)]$.
  - If $h(x_i) \neq h(x_j)$, then $x_j$ contributes 0 to `count`$[h(x_i)]$.
- To pin this down precisely, let's define a set of random variables $X_1$, $X_2$, …, as follows:

$$X_j = \begin{cases} 1 & \text{if } h(x_i) = h(x_j) \\ 0 & \text{otherwise} \end{cases}$$

Each of these variables is called an ***indicator random variable***, since it "indicates" whether some event occurs.

# Analyzing this Structure

- Let's look at $\hat{\boldsymbol{a}}_i$ = `count`$[h(x_i)]$ for some choice of $x_i$.
- For each element $x_j$:
  - If $h(x_i) = h(x_j)$, then $x_j$ contributes $\boldsymbol{a}_j$ to `count`$[h(x_i)]$.
  - If $h(x_i) \neq h(x_j)$, then $x_j$ contributes 0 to `count`$[h(x_i)]$.
- To pin this down precisely, let's define a set of random variables $X_1$, $X_2$, …, as follows:

$$X_j = \begin{cases} 1 & \text{if } h(x_i) = h(x_j) \\ 0 & \text{otherwise} \end{cases}$$

- The value of $\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i$ is then given by

$$\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i = \sum_{j \neq i} \boldsymbol{a}_j X_j$$

$$\mathrm{E}[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i] \quad = \quad \mathrm{E}[\sum_{j \neq i} \boldsymbol{a}_j X_j]$$

$$\mathrm{E}[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i] = \mathrm{E}[\sum_{j \neq i} \boldsymbol{a}_j X_j]$$

$$= \sum_{j \neq i} \mathrm{E}[\boldsymbol{a}_j X_j]$$

This follows from ***linearity of expectation***. We'll use this property extensively over the next few days.

$$
\begin{aligned}
\mathrm{E}[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i] &= \mathrm{E}\left[\sum_{j \neq i} \boldsymbol{a}_j X_j\right] \\
&= \sum_{j \neq i} \mathrm{E}[\boldsymbol{a}_j X_j] \\
&= \sum_{j \neq i} \boldsymbol{a}_j \mathrm{E}[X_j]
\end{aligned}
$$

The values of $\boldsymbol{a}_j$ are not random. The randomness comes from our choice of hash function.

$$
\begin{aligned}
\mathrm{E}[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i] &= \mathrm{E}[\sum_{j \neq i} \boldsymbol{a}_j X_j] \\
&= \sum_{j \neq i} \mathrm{E}[\boldsymbol{a}_j X_j] \\
&= \sum_{j \neq i} \boldsymbol{a}_j \mathrm{E}[X_j]
\end{aligned}
$$

$$\begin{aligned} \mathrm{E}[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i] &= \mathrm{E}[\sum_{j \neq i} \boldsymbol{a}_j X_j] \\ &= \sum_{j \neq i} \mathrm{E}[\boldsymbol{a}_j X_j] \\ &= \sum_{j \neq i} \boldsymbol{a}_j \mathrm{E}[X_j] \end{aligned}$$

$$

# How to Build an Estimator

1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

# How to Build an Estimator

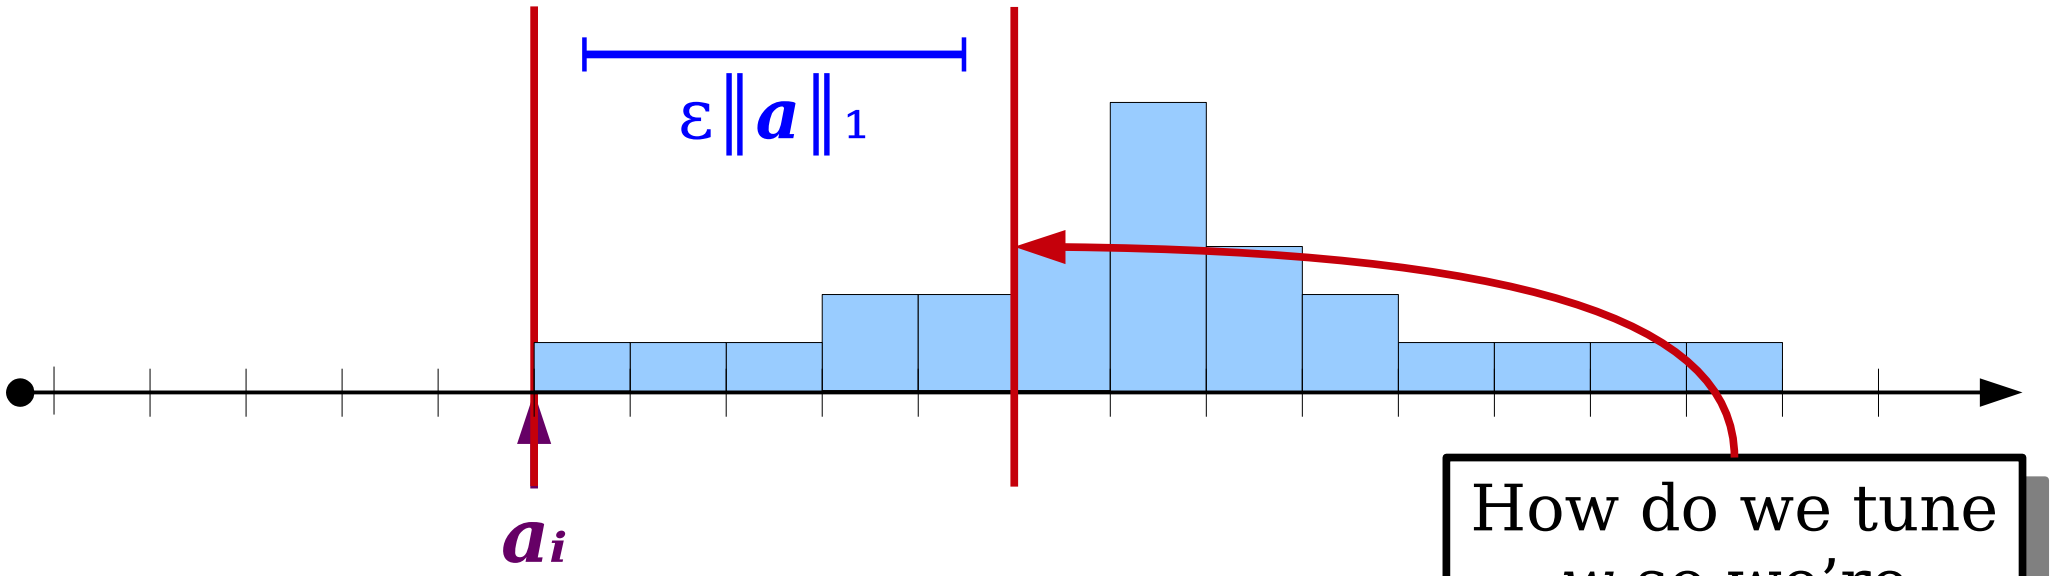
1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

***Goal:*** Make an estimator $\hat{a}$ for some quantity $a$ where

With probability at least $1 - \delta$, — ***Probably***

$|\hat{a} - a| \leq \varepsilon \cdot size(input)$ — ***Approximately Correct***

for some measure of the size of the input.



How do we tune $w$ so we're likely to fall in this range?

$$\mathrm{E}[\hat{a}_i - a_i] \leq \frac{\|a\|_1}{w}$$

$$\Pr\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$\Pr\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i > \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

We don't know the exact distribution of this random variable.

However, we have a ***one-sided error***: our estimate can never be lower than the true value. This means that $\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i \geq 0$.

***Markov's inequality*** says that if $X$ is a nonnegative random variable, then

$$\Pr[X > c] < \frac{\mathrm{E}[X]}{c}.$$

$$\Pr\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i > \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$< \frac{\mathrm{E}\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right]}{\varepsilon \left\|\boldsymbol{a}\right\|_1}$$

We don't know the exact distribution of this random variable.

However, we have a ***one-sided error***: our estimate can never be lower than the true value. This means that $\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i \geq 0$.

$$< \quad \frac{\mathrm{E}\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right]}{\varepsilon \left\|\boldsymbol{a}\right\|_1}$$

$$\mathrm{E}\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right] \quad \leq \quad \frac{\left\|\boldsymbol{a}\right\|_1}{w}$$

$$\Pr\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i > \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$< \frac{\mathrm{E}\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right]}{\varepsilon \left\|\boldsymbol{a}\right\|_1}$$

$$\leq \frac{\left\|\boldsymbol{a}\right\|_1}{w} \cdot \frac{1}{\varepsilon \left\|\boldsymbol{a}\right\|_1}$$

$$\mathrm{E}\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right] \leq \frac{\left\|\boldsymbol{a}\right\|_1}{w}$$

$$\Pr\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i > \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$< \frac{\mathrm{E}\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right]}{\varepsilon \left\|\boldsymbol{a}\right\|_1}$$

$$\leq \frac{\left\|\boldsymbol{a}\right\|_1}{w} \cdot \frac{1}{\varepsilon \left\|\boldsymbol{a}\right\|_1}$$

$$
\begin{aligned}
& \Pr\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i > \varepsilon \left\|\boldsymbol{a}\right\|_1\right] \\
< \quad & \frac{\mathrm{E}\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right]}{\varepsilon \left\|\boldsymbol{a}\right\|_1} \\
\leq \quad & \frac{\left\|\boldsymbol{a}\right\|_1}{w} \cdot \frac{1}{\varepsilon \left\|\boldsymbol{a}\right\|_1} \\
= \quad & \frac{1}{\varepsilon\, w}
\end{aligned}
$$

***Goal:*** Make an estimator $\hat{a}$ for some quantity $a$ where

With probability at least $1 - \delta$, — ***Probably***

$|\hat{a} - a| \leq \varepsilon \cdot size(input)$ — ***Approximately Correct***

for some measure of input size.

$$\Pr[\hat{a}_i - a_i > \varepsilon \|a\|_1] \leq \frac{1}{\varepsilon w}$$

***Initial Idea:***

Pick $w = \varepsilon^{-1} \cdot \delta^{-1}$. Then

$$\Pr[\hat{a}_i - a_i > \varepsilon \|a\|_1] < \delta$$

Suppose we're counting 1,000 distinct items.

If we want our estimate to be within $\varepsilon \|a\|_1$ of the true value with 99.9% probability, how much memory do we need?

***Answer:*** **$1{,}000 \cdot \varepsilon^{-1}$.**

***Can we do better?***

# How to Build an Estimator

for some measure of input size.

***Probably***

***Approximately Correct***

$$\Pr[\hat{a}_i - a_i > \varepsilon \|a\|_1] \leq \frac{1}{\varepsilon w}$$

***Revised Idea:*** Pick $w = e \cdot \varepsilon^{-1}$. Then

$$\Pr[\hat{a}_i - a_i > \varepsilon \|a\|_1] < e^{-1}$$

This simple data structure, by itself, is likely to be wrong.

What happens if we run a bunch of copies of this approach in parallel?

# Running in Parallel

- Let's suppose that we run ***d*** independent copies of this data structure. Each has its own independently randomly chosen hash function.
- To ***increment***(*x*) in the overall structure, we call ***increment***(*x*) on each of the underlying data structures.
- The probability that at least one of them provides a good estimate is quite high.
- ***Question:*** How do you know which one?

| *Estimator 1:* | *Estimator 2:* | *Estimator 3:* | *Estimator 4:* | *Estimator 5:* |
|---|---|---|---|---|
| 137 | 271 | 166 | 103 | 261 |

# Recognizing the Answer

- ***Recall:*** Each estimate $\hat{a}_i$ is the sum of two independent terms:
  - The actual value $a_i$.
  - Some "noise" terms from other elements colliding with $x_i$.
- Since the noise terms are always nonnegative, larger values of $\hat{a}_i$ are less accurate than smaller values of $\hat{a}_i$.
- ***Idea:*** Take, as our estimate, the minimum value of $\hat{a}_i$ from all of the data structures.

# Recognizing the Answer

- Suppose we have $d$ independent copies of our estimator.
- Let $\hat{\boldsymbol{a}}_{ij}$ be the estimate returned by the $j$th copy of the estimator.
- Our overall estimate is therefore

$$\min \{\hat{\boldsymbol{a}}_{ij}\}$$

- ***Question:*** How likely is this to be within our magic window around the true value?

Let $\hat{\boldsymbol{a}}_{ij}$ be the estimate from the $j$th copy of the data structure.

Our final estimate is $\min \{\hat{\boldsymbol{a}}_{ij}\}$

$$\Pr\left[\min\left\{\hat{\boldsymbol{a}}_{ij}\right\} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

Let $\hat{\boldsymbol{a}}_{ij}$ be the estimate from the $j$th copy of the data structure.

Our final estimate is $\min\{\hat{\boldsymbol{a}}_{ij}\}$

$$\Pr\left[\min\left\{\hat{\boldsymbol{a}}_{ij}\right\} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

The only way the minimum estimate is inaccurate is if *every* estimate is inaccurate.

Let $\hat{\boldsymbol{a}}_{ij}$ be the estimate from the $j$th copy of the data structure.

Our final estimate is $\min\{\hat{\boldsymbol{a}}_{ij}\}$

$$\Pr\left[\min\left\{\hat{\boldsymbol{a}}_{ij}\right\} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$= \quad \Pr\left[\bigwedge_j \left(\hat{\boldsymbol{a}}_{ij} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right)\right]$$

The only way the minimum estimate is inaccurate is if *every* estimate is inaccurate.

Let $\hat{\boldsymbol{a}}_{ij}$ be the estimate from the $j$th copy of the data structure.

Our final estimate is $\min\{\hat{\boldsymbol{a}}_{ij}\}$

$$\Pr\left[\min\left\{\hat{\boldsymbol{a}}_{ij}\right\} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$= \quad \Pr\left[\bigwedge_j \left(\hat{\boldsymbol{a}}_{ij} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right)\right]$$

Each copy of the data structure is independent of the others.

Let $\hat{\boldsymbol{a}}_{ij}$ be the estimate from the $j$th copy of the data structure.

Our final estimate is $\min\{\hat{\boldsymbol{a}}_{ij}\}$

$$\Pr\left[\min\left\{\hat{\boldsymbol{a}}_{ij}\right\} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$= \Pr\left[\bigwedge_j \left(\hat{\boldsymbol{a}}_{ij} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right)\right]$$

$$= \prod_j \Pr\left[\hat{\boldsymbol{a}}_{ij} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

Each copy of the data structure is independent of the others.

Let $\hat{\boldsymbol{a}}_{ij}$ be the estimate from the $j$th copy of the data structure.

Our final estimate is $\min\{\hat{\boldsymbol{a}}_{ij}\}$

$$\Pr\left[\min\left\{\hat{\boldsymbol{a}}_{ij}\right\} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$= \Pr\left[\bigwedge_j \left(\hat{\boldsymbol{a}}_{ij} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right)\right]$$

$$= \prod_j \Pr\left[\hat{\boldsymbol{a}}_{ij} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$\Pr\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right] \;<\; e^{-1}$$

Let $\hat{\boldsymbol{a}}_{ij}$ be the estimate from the $j$th copy of the data structure.

Our final estimate is $\min\{\hat{\boldsymbol{a}}_{ij}\}$

$$\Pr\left[\min\left\{\hat{\boldsymbol{a}}_{ij}\right\} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$= \Pr\left[\bigwedge_j \left(\hat{\boldsymbol{a}}_{ij} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right)\right]$$

$$= \prod_j \Pr\left[\hat{\boldsymbol{a}}_{ij} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$< \prod_j e^{-1}$$

$$\Pr\left[\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right] \;<\; e^{-1}$$

Let $\hat{\boldsymbol{a}}_{ij}$ be the estimate from the $j$th copy of the data structure.

Our final estimate is $\min\{\hat{\boldsymbol{a}}_{ij}\}$

$$\Pr\left[\min\left\{\hat{\boldsymbol{a}}_{ij}\right\} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$= \Pr\left[\bigwedge_j \left(\hat{\boldsymbol{a}}_{ij} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right)\right]$$

$$= \prod_j \Pr\left[\hat{\boldsymbol{a}}_{ij} - \boldsymbol{a}_i \;>\; \varepsilon \left\|\boldsymbol{a}\right\|_1\right]$$

$$< \prod_j e^{-1}$$

$$= e^{-d}$$

Let $\hat{\boldsymbol{a}}_{ij}$ be the estimate from the $j$th copy of the data structure.

Our final estimate is $\min\{\hat{\boldsymbol{a}}_{ij}\}$

***Goal:*** Make an estimator $\hat{\boldsymbol{a}}$ for some quantity $\boldsymbol{a}$ where

With probability at least $1 - \delta$, — ***Probably***

$|\hat{\boldsymbol{a}} - \boldsymbol{a}| \leq \varepsilon \cdot size(input)$ — ***Approximately Correct***

for some measure of input size.

$$\Pr\left[\min\left\{\hat{\boldsymbol{a}}_{ij}\right\} - \boldsymbol{a}_i > \varepsilon \left\|\boldsymbol{a}\right\|_1\right] < e^{-d}$$

***Idea:*** Choose $d = -\ln \delta$. (Equivalently: $d = \ln \delta^{-1}$.) Then

$$\Pr\left[\min\left\{\hat{\boldsymbol{a}}_{ij}\right\} - \boldsymbol{a}_i > \varepsilon \left\|\boldsymbol{a}\right\|_1\right] < \delta$$

# The Count-Min Sketch

- This data structure is called the ***count-min sketch***.
- Given parameters ε and δ, choose

$$w = \lceil e / \varepsilon \rceil \qquad d = \lceil \ln \delta^{-1} \rceil$$

- Create an array `count` of size $w \times d$ and for each row $i$, choose a hash function $h_i : \mathscr{U} \to [w]$ uniformly and independently from a 2-independent family of hash functions $\mathscr{H}$.
- To ***increment***(x), increment `count`$[i][h_i(x)]$ for each row $i$.
- To ***estimate***(x), return the minimum value of `count`$[i][h_i(x)]$ across all rows $i$.

# The Count-Min Sketch

- Update and query times are $\Theta(d)$, which is $\Theta(\log \delta^{-1})$.
- Space usage: $\Theta(\varepsilon^{-1} \cdot \log \delta^{-1})$ counters.
  - This is a major improvement over our earlier approach that used $\Theta(\varepsilon^{-1} \cdot \delta^{-1})$ counters.
  - This can be *significantly* better than just storing a raw frequency count!
- Provides an estimate to within $\varepsilon \| \boldsymbol{a} \|_1$ with probability at least $1 - \delta$.

Time-Out for Announcements!

# Problem Sets

- Solutions to PS3 are now up on the course website.
  - Take a few minutes to read over them – it never hurts to get a different perspective on the solutions to the problems!
- PS4 is due a week from Tuesday. We recommend starting early so you have time to think things over.

# Project Checkpoints

- As a reminder, you should be working on the project checkpoint, which is due a week from today.
- Take some time to think through the questions we sent you. Some of them are fairly open-ended and might require you to go looking in the literature for future work. Let us know if you need any help!

Back to CS166!

# An Alternative: Count Sketches

# The Motivation

- *(Note: This is historically backwards; count sketches came before count-min sketches.)*
- In a count-min sketch, errors arise when multiple elements collide.
- Errors are strictly additive; the more elements collide in a bucket, the worse the estimate for those elements.
- ***Question:*** Can we try to offset the "badness" that results from the collisions?

# How to Build an Estimator

1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

# How to Build an Estimator

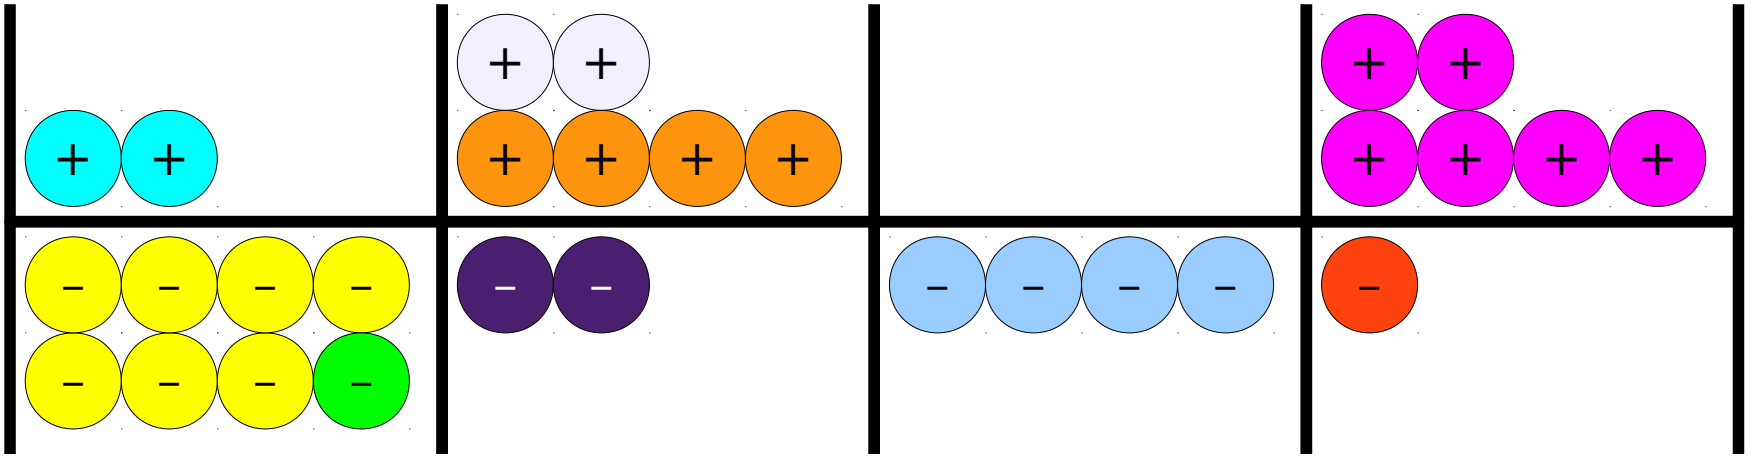
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

# The Setup

- As before, for some parameter $w$, we'll create an array `count` of length $w$.
- As before, choose a hash function $h : \mathscr{U} \to [w]$ from a family $\mathscr{H}$.
- For each $x_i \in \mathscr{U}$, assign $x_i$ either +1 or -1.
- To ***increment***($x$), go to `count`[$h(x)$] and add ±1 as appropriate.
- To ***estimate***($x$), return `count`[$h(x)$], multiplied by ±1 as appropriate.



# The Setup

- As before, for some parameter $w$, we'll create an array `count` of length $w$.
- As before, choose a hash function $h : \mathscr{U} \to [w]$ from a family $\mathscr{H}$.
- For each $x_i \in \mathscr{U}$, assign $x_i$ either +1 or -1.
- To ***increment***($x$), go to `count`[$h(x)$] and add ±1 as appropriate.
- To ***estimate***($x$), return `count`[$h(x)$], multiplied by ±1 as appropriate.

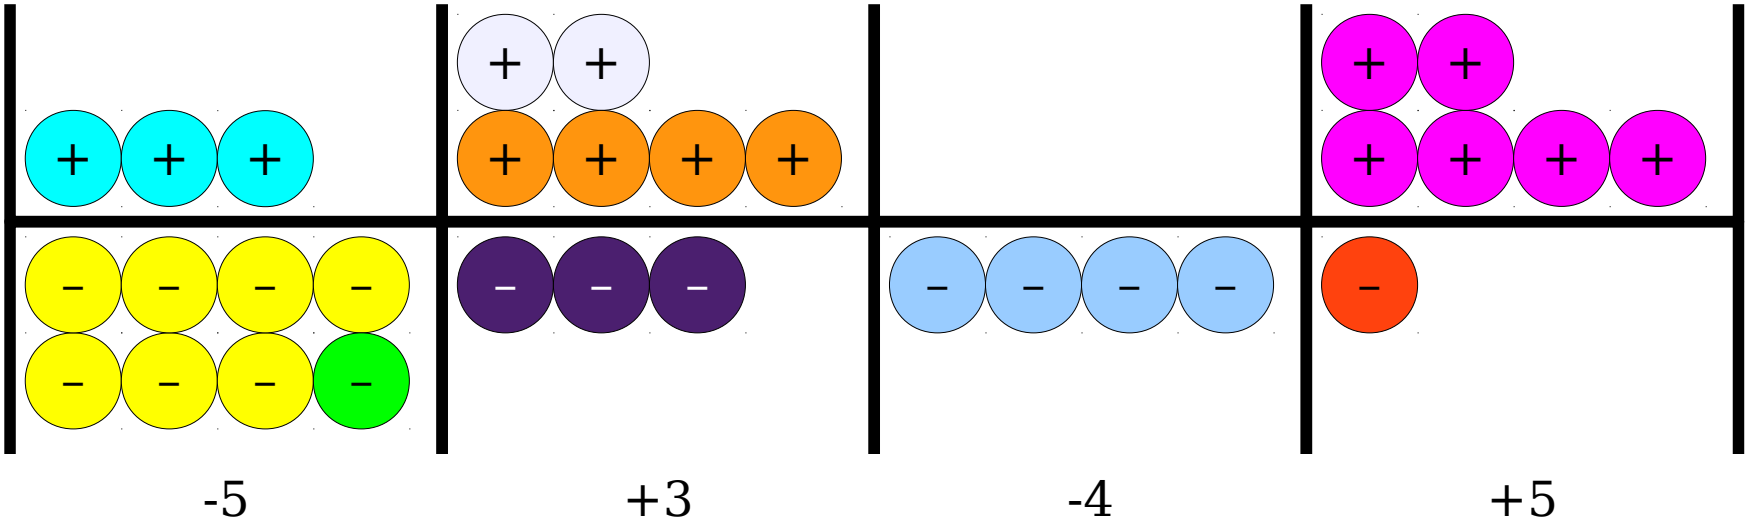
- To ***increment***($x$), go to `count`[$h(x)$] and add ±1 as appropriate.
- To ***estimate***($x$), return `count`[$h(x)$], multiplied by ±1 as appropriate.

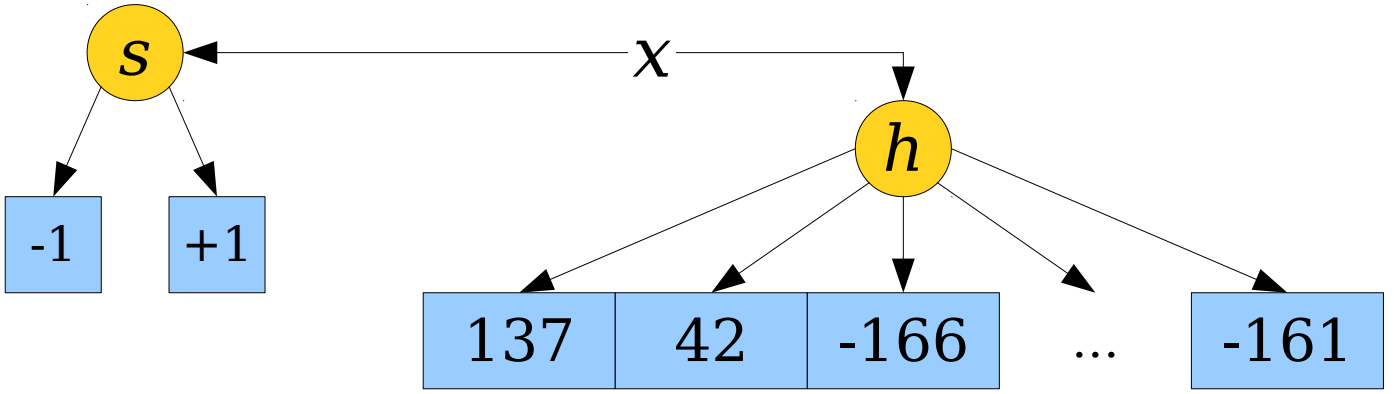


# The Intuition

- Think about what introducing the ±1 term does when collisions occur.
- If an element $x$ collides with a frequent element $y$, we're not going to get a good estimate for $x$ (but we wouldn't have gotten one anyway).
- If $x$ collides with multiple infrequent elements, the collisions between those elements will partially offset one another and leave a better estimate for $x$.

# More Formally

- Let's have $h \in \mathscr{H}$ chosen uniformly at random from a 2-independent family of hash functions from $\mathscr{U}$. to $w$.
- Choose $s \in \mathscr{U}$ uniformly randomly and independently of $h$ from a 2-independent family from $\mathscr{U}$ to {-1, +1}.
- To ***increment***(x), add $s(x)$ to `count`$[h(x)]$.
- To ***estimate***(x), return $s(x) \cdot$ `count`$[h(x)]$.



# How to Build an Estimator

1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.

# Formalizing the Intuition

- As before, define $\hat{\boldsymbol{a}}_i$ to be our estimate of $\boldsymbol{a}_i$.
- As before, $\hat{\boldsymbol{a}}_i$ will depend on how the other elements are distributed. Unlike before, it now also depends on signs given to the elements by $s$.
- Specifically, for each other $x_j$ that collides with $x_i$, the error contribution will be

$$s(x_i) \cdot s(x_j) \cdot \boldsymbol{a}_j$$

- Why?
  - The counter for $x_i$ will have $s(x_j)\ \boldsymbol{a}_j$ added in.
  - We multiply the counter by $s(x_i)$ before returning it.

# Formalizing the Intuition

- As before, define $\hat{\boldsymbol{a}}_i$ to be our estimate of $\boldsymbol{a}_i$.
- As before, $\hat{\boldsymbol{a}}_i$ will depend on how the other elements are distributed. Unlike before, it now also depends on signs given to the elements by $s$.
- Specifically, for each other $x_j$ that collides with $x_i$, the error contribution will be

$$s(x_i) \cdot s(x_j) \cdot \boldsymbol{a}_j$$

- Or:
  - If $s(x_i)$ and $s(x_j)$ point in the same direction, the terms add to the total.
  - If $s(x_i)$ and $s(x_j)$ point in different directions, the terms subtract from the total.

# Formalizing the Intuition

- In our quest to learn more about $\hat{\boldsymbol{a}}_i$, let's have $X_j$ be a random variable indicating whether $x_i$ and $x_j$ collided with one another:

$$X_j = \begin{cases} 1 & \text{if } h(x_i) = h(x_j) \\ 0 & \text{if } h(x_i) \neq h(x_j) \end{cases}$$

# Formalizing the Intuition

- In our quest to learn more about $\hat{\boldsymbol{a}}_i$, let's have $X_j$ be a random variable indicating whether $x_i$ and $x_j$ collided with one another:

$$X_j = \begin{cases} 1 & \text{if } h(x_i) = h(x_j) \\ 0 & \text{if } h(x_i) \neq h(x_j) \end{cases}$$

- We can then express $\hat{\boldsymbol{a}}_i$ in terms of the signed contributions from the items it collides with:

$$\hat{\boldsymbol{a}}_i = \sum_j \boldsymbol{a}_j s(x_i) s(x_j) X_j$$

This is how much the collision impacts our estimate.

We only care about items we collided with.

# Formalizing the Intuition

- In our quest to learn more about $\hat{\boldsymbol{a}}_i$, let's have $X_j$ be a random variable indicating whether $x_i$ and $x_j$ collided with one another:

$$X_j = \begin{cases} 1 & \text{if } h(x_i) = h(x_j) \\ 0 & \text{if } h(x_i) \neq h(x_j) \end{cases}$$

- We can then express $\hat{\boldsymbol{a}}_i$ in terms of the signed contributions from the items it collides with:

$$\hat{\boldsymbol{a}}_i = \sum_j \boldsymbol{a}_j s(x_i) s(x_j) X_j = \boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j$$

This is how much the collision impacts our estimate.

We only care about items we collided with.

$$\mathrm{E}[\hat{\boldsymbol{a}}_i] \;=\; \mathrm{E}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j]$$

$$\begin{aligned} \mathrm{E}[\hat{\boldsymbol{a}}_i] &= \mathrm{E}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\ &= \mathrm{E}[\boldsymbol{a}_i] + \mathrm{E}[\sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \end{aligned}$$

Hey, it's linearity of expectation!

$$
\begin{aligned}
\mathrm{E}[\hat{\boldsymbol{a}}_i] &= \mathrm{E}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \mathrm{E}[\boldsymbol{a}_i] + \mathrm{E}[\sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \boldsymbol{a}_i + \sum_{j \neq i} \mathrm{E}[\boldsymbol{a}_j s(x_i) s(x_j) X_j]
\end{aligned}
$$

Remember that $\boldsymbol{a}_i$ and the like aren't random variables.

$$
\begin{aligned}
\mathrm{E}[\hat{\boldsymbol{a}}_i] &= \mathrm{E}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \mathrm{E}[\boldsymbol{a}_i] + \mathrm{E}[\sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \boldsymbol{a}_i + \sum_{j \neq i} \mathrm{E}[\boldsymbol{a}_j s(x_i) s(x_j) X_j]
\end{aligned}
$$

We chose the hash functions $h$ and $s$ independently of one another.

$$
X_j = \begin{cases} 1 & \text{if } h(x_i) = h(x_j) \\ 0 & \text{if } h(x_i) \neq h(x_j) \end{cases}
$$

$$
\begin{aligned}
\mathrm{E}[\hat{\boldsymbol{a}}_i] &= \mathrm{E}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \mathrm{E}[\boldsymbol{a}_i] + \mathrm{E}[\sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \boldsymbol{a}_i + \sum_{j \neq i} \mathrm{E}[\boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \boldsymbol{a}_i + \sum_{j \neq i} \mathrm{E}[s(x_i) s(x_j)] \mathrm{E}[\boldsymbol{a}_j X_j]
\end{aligned}
$$

We chose the hash functions $h$ and $s$ independently of one another.

$$
X_j = \begin{cases} 1 & \text{if } h(x_i) = h(x_j) \\ 0 & \text{if } h(x_i) \neq h(x_j) \end{cases}
$$

$$
\begin{aligned}
\mathrm{E}[\hat{\boldsymbol{a}}_i] &= \mathrm{E}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \mathrm{E}[\boldsymbol{a}_i] + \mathrm{E}[\sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \boldsymbol{a}_i + \sum_{j \neq i} \mathrm{E}[\boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \boldsymbol{a}_i + \sum_{j \neq i} \mathrm{E}[s(x_i) s(x_j)] \mathrm{E}[\boldsymbol{a}_j X_j] \\
&= \boldsymbol{a}_i + \sum_{j \neq i} \mathrm{E}[s(x_i)] \mathrm{E}[s(x_j)] \mathrm{E}[\boldsymbol{a}_j X_j]
\end{aligned}
$$

Since $s$ is drawn from a 2-independent family of hash functions, we know $s(x_i)$ and $s(x_j)$ are independent random variables.

$$
\begin{aligned}
\mathrm{E}[\hat{\boldsymbol{a}}_i] &= \mathrm{E}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \mathrm{E}[\boldsymbol{a}_i] + \mathrm{E}[\sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \boldsymbol{a}_i + \sum_{j \neq i} \mathrm{E}[\boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \boldsymbol{a}_i + \sum_{j \neq i} \mathrm{E}[s(x_i) s(x_j)] \mathrm{E}[\boldsymbol{a}_j X_j] \\
&= \boldsymbol{a}_i + \sum_{j \neq i} \mathrm{E}[s(x_i)] \mathrm{E}[s(x_j)] \mathrm{E}[\boldsymbol{a}_j X_j]
\end{aligned}
$$

---

$\mathrm{E}[s(x_i)] =$

$$

# How to Build an Estimator

1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

# How to Build an Estimator

1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

# A Hitch

- In the count-min sketch, we used Markov's inequality to bound the probability that we get a bad estimate.
- This worked because we had a ***one-sided error***: the distance $\hat{a}_i - a_i$ from the true answer was nonnegative.
- However, with the count sketch, we have a ***two-sided error***: $\hat{a}_i - a_i$ can be negative in the count sketch because collisions can *decrease* the estimate $\hat{a}_i$ below the true value $a_i$.
- We'll need to use a different technique to bound the error.

# Chebyshev to the Rescue

- ***Chebyshev's inequality*** states that for any random variable $X$ with finite variance, given any $c > 0$, we have

$$\Pr\left[\ |X - \mathrm{E}[X]| > c\ \right] < \frac{\mathrm{Var}[X]}{c^2}.$$

- If we can get the variance of $\hat{\boldsymbol{a}}_i$, we can bound the probability that we get a bad estimate with our data structure.

$$\mathrm{Var}[\hat{\boldsymbol{a}}_i] \quad = \quad \mathrm{Var}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j]$$

$$\mathrm{Var}[\hat{\boldsymbol{a}}_i] \;=\; \mathrm{Var}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j]$$

$$\mathrm{Var}[a + X] = \mathrm{Var}[X]$$

$$\mathrm{Var}[\hat{\boldsymbol{a}}_i] = \mathrm{Var}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j]$$

$$= \mathrm{Var}[\sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j]$$

$$\mathrm{Var}[a + X] = \mathrm{Var}[X]$$

$$\mathrm{Var}[\hat{\boldsymbol{a}}_i] = \mathrm{Var}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j]$$

$$= \mathrm{Var}[\sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j]$$

In general, Var is *not* a linear operator.

However, if the terms in the sum are ***pairwise uncorrelated***, then Var is linear.

***Lemma:*** The terms in this sum are uncorrelated. *(Prove this!)*

$$\begin{aligned}
\mathrm{Var}[\hat{\boldsymbol{a}}_i] &= \mathrm{Var}[\boldsymbol{a}_i + \sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \mathrm{Var}[\sum_{j \neq i} \boldsymbol{a}_j s(x_i) s(x_j) X_j] \\
&= \sum_{j \neq i} \mathrm{Var}[\boldsymbol{a}_j s(x_i) s(x_j) X_j]
\end{aligned}$$

&= \frac{1}{w} \sum_{j \neq i} \boldsymbol{a}_j^2
\end{aligned}
$$

I know this might look really dense, but many of these substeps end up being really useful techniques. These ideas generalize, I promise.

Think of $[\boldsymbol{a}_1, \boldsymbol{a}_2, \boldsymbol{a}_3, \ldots]$ as a vector.

What does the following quantity represent?

$$\sum_j \boldsymbol{a}_j^2$$

$$\mathrm{Var}[\hat{\boldsymbol{a}}_i] = \frac{1}{w} \sum_{j \neq i} \boldsymbol{a}_j^2$$

Think of $[\boldsymbol{a}_1, \boldsymbol{a}_2, \boldsymbol{a}_3, \ldots]$ as a vector.

What does the following quantity represent?

$$\sum_j \boldsymbol{a}_j^2$$

This is the square of the magnitude of the vector!

$$\mathrm{Var}[\hat{\boldsymbol{a}}_i] = \frac{1}{w} \sum_{j \neq i} \boldsymbol{a}_j^2$$

Think of $[\boldsymbol{a}_1, \boldsymbol{a}_2, \boldsymbol{a}_3, \ldots]$ as a vector.

What does the following quantity represent?

$$\sum_j \boldsymbol{a}_j^2$$

This is the square of the magnitude of the vector!

The magnitude of a vector is called its ***L₂ norm*** and is denoted $\|\boldsymbol{a}\|_2$.

$$\|\boldsymbol{a}\|_2 \quad = \quad \sqrt{\sum_j \boldsymbol{a}_i^2}$$

$$\mathrm{Var}[\hat{\boldsymbol{a}}_i] \quad = \quad \frac{1}{w} \sum_{j \neq i} \boldsymbol{a}_j^2$$

Think of $[\boldsymbol{a}_1, \boldsymbol{a}_2, \boldsymbol{a}_3, \ldots]$ as a vector.

What does the following quantity represent?

$$\sum_j \boldsymbol{a}_j^2$$

This is the square of the magnitude of the vector!

The magnitude of a vector is called its ***L₂ norm*** and is denoted $\|\boldsymbol{a}\|_2$.

$$\|\boldsymbol{a}\|_2 = \sqrt{\sum_j \boldsymbol{a}_i^2}$$

Therefore, our above sum is $\|\boldsymbol{a}\|_2^2$.

$$\mathrm{Var}[\hat{\boldsymbol{a}}_i] = \frac{1}{w}\sum_{j \neq i} \boldsymbol{a}_j^2$$

Think of $[\boldsymbol{a}_1, \boldsymbol{a}_2, \boldsymbol{a}_3, \ldots]$ as a vector.

What does the following quantity represent?

$$\sum_j \boldsymbol{a}_j^2$$

This is the square of the magnitude of the vector!

The magnitude of a vector is called its ***L₂ norm*** and is denoted $\|\boldsymbol{a}\|_2$.

$$\|\boldsymbol{a}\|_2 = \sqrt{\sum_j \boldsymbol{a}_i^2}$$

Therefore, our above sum is $\|\boldsymbol{a}\|_2^2$.

$$\text{Var}[\hat{\boldsymbol{a}}_i] = \frac{1}{w}\sum_{j \neq i} \boldsymbol{a}_j^2 \leq \frac{\|\boldsymbol{a}\|_2^2}{w}$$

Think of $[a_1, a_2, a_3, \ldots]$ as a vector.

What does the following quantity represent?

$$\sum_j a_j^2$$

This is the square of the mag

The magnitude of a vector is c
is denoted $\|a$

**_Great exercise:_** Prove that the $L_2$ norm of a vector is never greater than the $L_1$ norm.

$$\|a\|_2 = \sqrt{\sum_j a_i^2}$$

Therefore, our above sum is $\|a\|_2^2$.

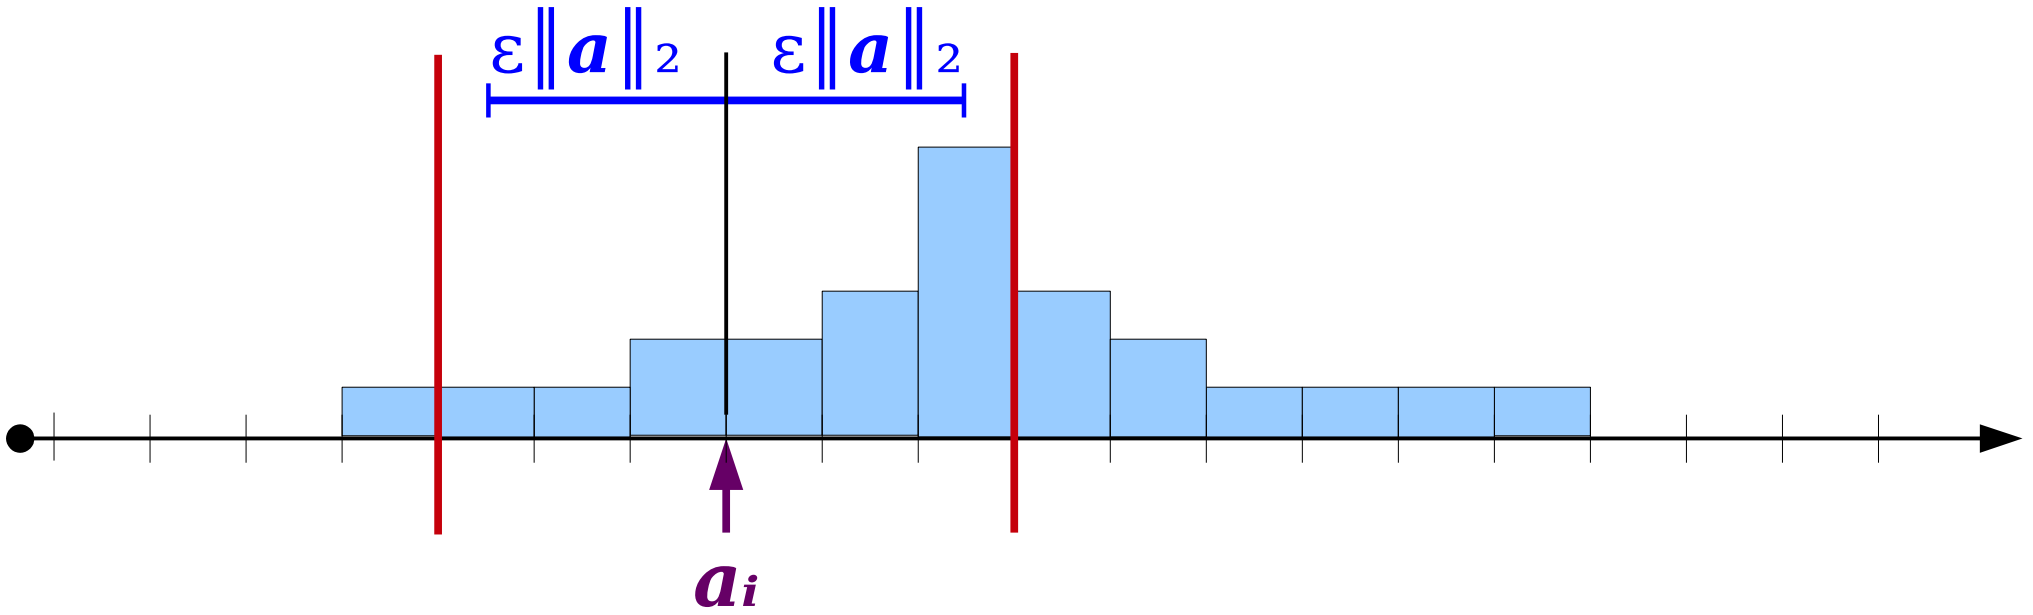
$$\text{Var}[\hat{a}_i] = \frac{1}{w}\sum_{j \neq i} a_j^2 \leq \frac{\|a\|_2^2}{w}$$

***Goal:*** Make an estimator $\hat{a}$ for some quantity $a$ where

With probability at least $1 - \delta$, ← ***Probably***

$|\hat{a} - a| \leq \varepsilon \cdot size(input)$ ← ***Approximately Correct***

for some measure of the size of the input.



$$\mathrm{Var}[\hat{a}_i] \leq \frac{\|a\|_2^2}{w}$$

$$\Pr\left[\left|\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right| > \varepsilon \|\boldsymbol{a}\|_2\right]$$

$$\Pr\left[\left|\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right| > \varepsilon \left\|\boldsymbol{a}\right\|_2\right]$$

Chebyshev's inequality says that

$$\Pr\left[\ |X - \mathrm{E}[X]| > c\ \right] < \frac{\mathrm{Var}[X]}{c^2}.$$

$$\Pr\left[\left|\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right| > \varepsilon \|\boldsymbol{a}\|_2\right]$$

$$< \quad \frac{\mathrm{Var}[\hat{\boldsymbol{a}}_i]}{(\varepsilon \|\boldsymbol{a}\|_2)^2}$$

Chebyshev's inequality says that

$$\Pr\left[\ |X - \mathrm{E}[X]| > c\ \right] < \frac{\mathrm{Var}[X]}{c^2}.$$

$$\Pr\left[\left|\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right| > \varepsilon \|\boldsymbol{a}\|_2\right]$$

$$< \quad \frac{\mathrm{Var}[\hat{\boldsymbol{a}}_i]}{(\varepsilon \|\boldsymbol{a}\|_2)^2}$$

$$\mathrm{Var}[\hat{\boldsymbol{a}}_i] \quad \leq \quad \frac{\|\boldsymbol{a}\|_2^2}{w}$$

$$\Pr\left[\left|\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right| > \varepsilon \|\boldsymbol{a}\|_2\right]$$

$$< \quad \frac{\mathrm{Var}[\hat{\boldsymbol{a}}_i]}{\left(\varepsilon \|\boldsymbol{a}\|_2\right)^2}$$

$$\leq \quad \frac{\|\boldsymbol{a}\|_2^2}{w} \cdot \frac{1}{\left(\varepsilon \|\boldsymbol{a}\|_2\right)^2}$$

$$\mathrm{Var}[\hat{\boldsymbol{a}}_i] \quad \leq \quad \frac{\|\boldsymbol{a}\|_2^2}{w}$$

$$
\begin{aligned}
& \Pr\left[\left|\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right| > \varepsilon \|\boldsymbol{a}\|_2\right] \\
< \quad & \frac{\operatorname{Var}[\hat{\boldsymbol{a}}_i]}{\left(\varepsilon \|\boldsymbol{a}\|_2\right)^2} \\
\leq \quad & \frac{\|\boldsymbol{a}\|_2^2}{w} \cdot \frac{1}{\left(\varepsilon \|\boldsymbol{a}\|_2\right)^2} \\
= \quad & \frac{1}{w\varepsilon^2}
\end{aligned}
$$

***Goal:*** Make an estimator $\hat{a}$ for some quantity $a$ where

With probability at least $1 - \delta$, ← ***Probably***

$|\hat{a} - a| \leq \varepsilon \cdot size(input)$ ← ***Approximately Correct***

for some measure of input size.

$$\Pr\left[\left|\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right| > \varepsilon \left\|\boldsymbol{a}\right\|_2\right] \leq \frac{1}{w\varepsilon^2}$$

Pick $w = e \cdot \varepsilon^{-2}$. Then

$$\Pr\left[\left|\hat{\boldsymbol{a}}_i - \boldsymbol{a}_i\right| > \varepsilon \left\|\boldsymbol{a}\right\|_2\right] \leq e^{-1}.$$

We now have a single estimator with a not-so-great chance of giving a good estimate.

How do we fix this?

# How to Build an Estimator

1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

# How to Build an Estimator

1. Design a simple data structure that, intuitively, gives you a good estimate.
2. Use a ***sum of indicator variables*** and ***linearity of expectation*** to prove that, on expectation, the data structure is pretty close to correct.
3. Use a ***concentration inequality*** to show that the data structure's output is close to its expectation.
4. Run multiple copies of the data structure in parallel to amplify the success probability.

# Running in Parallel

- Let's suppose that we run ***d*** independent copies of this data structure. Each has its own independently randomly chosen hash function.
- To ***increment***(*x*) in the overall structure, we call ***increment***(*x*) on each of the underlying data structures.
- The probability that at least one of them provides a good estimate is quite high.
- ***Question:*** How do you know which one?

| *Estimator 1:* | *Estimator 2:* | *Estimator 3:* | *Estimator 4:* | *Estimator 5:* |
|---|---|---|---|---|
| 137 | 271 | 166 | 103 | 261 |

# Working with the Median

- ***Claim:*** If we output the median estimate given by the data structures, we have high probability of giving the right answer.
- ***Intuition:*** The only way we report an answer more than $\varepsilon||\boldsymbol{a}||_2$ is if at least half of the data structures output an answer that is more than $\varepsilon||\boldsymbol{a}||_2$ from the true answer.
- Each individual data structure is wrong with probability at most $e^{-1}$, so this is highly unlikely.

# The Setup

- Let $X$ denote a random variable equal to the number of data structures that produce an answer *not* within $\varepsilon||\boldsymbol{a}||_2$ of the true answer.
- Since each independent data structure has failure probability at most $1 / e$, we can upper-bound $X$ with a Binom($d$, $1 / e$) variable.
- We want to know $\Pr[X > d / 2]$.
- How can we determine this?

# Chernoff Bounds

- The ***Chernoff bound*** says that if $X \sim \text{Binom}(n, p)$ and $p < 1/2$, then

$$\Pr[X > n/2] < e^{\frac{-n(1/2-p)^2}{2p}}$$

# Chernoff Bounds

- The ***Chernoff bound*** says that if $X \sim \text{Binom}(n, p)$ and $p < 1/2$, then

$$\Pr[X > n/2] < e^{\frac{-n(1/2-p)^2}{2p}}$$

- In our case, $X \sim \text{Binom}(d, 1/e)$, so we know that

$$\Pr[X > \frac{d}{2}] \leq e^{\frac{-d(1/2-1/e)^2}{2(1/e)}}$$

# Chernoff Bounds

- The ***Chernoff bound*** says that if $X \sim \text{Binom}(n, p)$ and $p < 1/2$, then

$$\Pr[X > n/2] < e^{\frac{-n(1/2-p)^2}{2p}}$$

- In our case, $X \sim \text{Binom}(d, 1/e)$, so we know that

$$\Pr[X > \frac{d}{2}] \leq e^{\frac{-d(1/2-1/e)^2}{2(1/e)}}$$

$$= e^{-k \cdot d} \quad \textit{(for some constant } k\textit{)}$$

# Chernoff Bounds

- The ***Chernoff bound*** says that if $X \sim \text{Binom}(n, p)$ and $p < 1/2$, then

$$\Pr[X > n/2] < e^{\frac{-n(1/2-p)^2}{2p}}$$

- In our case, $X \sim \text{Binom}(d, 1/e)$, so we know that

$$\Pr[X > \frac{d}{2}] \leq e^{\frac{-d(1/2-1/e)^2}{2(1/e)}}$$

$$= e^{-k \cdot d} \quad \textit{(for some constant } k\textit{)}$$

- Therefore, choosing $d = k^{-1} \cdot \log \delta^{-1}$ ensures that $\Pr[X > d / 2] \leq \delta$.

# Chernoff Bounds

- The ***Chernoff bound*** says that if $X \sim \text{Binom}(n, p)$ and $p < 1/2$, then

$$\Pr[X > n/2] < e^{\frac{-n(1/2-p)^2}{2p}}$$

- In our case, $X \sim \text{Binom}(d, 1/e)$, so we know that

$$\Pr[X > \frac{d}{2}] \leq e^{\frac{-d(1/2-1/e)^2}{2(1/e)}}$$

$$= e^{-k \cdot d} \quad \textit{(for some constant } k\textit{)}$$

- Therefore, choosing $d = k^{-1} \cdot \log \delta^{-1}$ ensures that $\Pr[X > d / 2] \leq \delta$.
- Therefore, the success probability is at least $1 - \delta$.

# Chernoff Bounds

- The ***Chernoff bound*** says that if $X \sim \text{Binom}(n, p)$ and $p < 1/2$, then

$$\Pr[X > n/2] < e^{\frac{-n(1/2-p)^2}{2p}}$$

- In our case, $X \sim \text{Binom}(d, 1/e)$, so we know that

$$e^{\frac{-d(1/2-1/e)^2}{2(1/e)}}$$

$$e^{-k \cdot d} \quad \textit{(for some constant } k\textit{)}$$

The specific constant factor here matters, since it's an exponent! To implement this data structure, you'll need to work out the exact value.

- Therefore, choosing $d = k^{-1} \cdot \log \delta^{-1}$ ensures that $\Pr[X > d / 2] \leq \delta$.
- Therefore, the success probability is at least $1 - \delta$.

# The Overall Construction

- The ***count sketch*** is the data structure given as follows.
- Given ε and δ, choose

$$w = \lceil e / \varepsilon^2 \rceil \qquad d = \Theta(\log \delta^{-1})$$

- Create an array `count` of $w \times d$ counters.
- Choose hash functions $h_i$ and $s_i$ for each of the $d$ rows.
- To ***increment***(x), add $s_i(x)$ to `count`$[i][h_i(x)]$ for each row $i$.
- To ***estimate***(x), return the median of $s_i(x) \cdot$ `count`$[i][h_i(x)]$ for each row $i$.

# The Final Analysis

- With probability at least 1 – δ, all estimates are accurate to within a factor of $\varepsilon \| \boldsymbol{a} \|_2$.
- Space usage is $\Theta(w \cdot d)$, which we've seen to be $\Theta(\varepsilon^{-2} \cdot \log \delta^{-1})$.
- Updates and queries run in time $\Theta(\delta^{-1})$.
- Trades factor of $\varepsilon^{-1}$ space for an accuracy guarantee relative to $\| \boldsymbol{a} \|_2$ versus $\| \boldsymbol{a} \|_1$.
- ***Question to ponder:*** Which would you prefer if your elements are more uniform? Which would you prefer if a few elements are extremely common?

# Next Time

- ***Hashing Strategies***
  - There are a lot of hash tables out there. What do they look like?
- ***Linear Probing***
  - The original hashing strategy!
- ***Analyzing Linear Probing***
  - ...is way, way more complicated than you probably would have thought. But it's beautiful! And a great way to learn about randomized data structures!
