Solutions for Section #3

Solution 1: String Split

    /*
     * Function: split
     * --------------
     * Returns an array of the supplied string when exploded around
     * all of the characters within the supplied delimiter.
     */
    function split(str, delimiters) {
        let start = 0,
            fragments = [];
        for (let i = 0; i <= str.length; i++) {
            if (i === str.length || delimiters.indexOf(str.charAt(i)) !== -1) {
                let fragment = str.substring(start, i);
                fragments.push(fragment);
                start = i + 1;
            }
        }
        return fragments;
    }

Some thought questions to ensure you understand the solution:

- Why does the for loop test rely on <= instead of <?
- What’s the best description you have for what i is tracking on behalf of the algorithm?
- The internal if test checks to see if i === str.length first before advancing on to check the return value of indexOf. Why does it do that?

Solution 2: Strings, Arrays, and Disguised Algorithms

a) The provided code—batty variable names notwithstanding—is an implementation of Kadane’s algorithm, which uses a technique called dynamic programming to compute the largest subarray sum in an array of integers.

    perplexity([-2, 1, -3, 4, -1, 2, 1, -5, 7, -10]);

produces the following

<p>| | | | | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>1</td>
<td>1</td>
<td>4</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>6</td>
<td>8</td>
</tr>
</tbody>
</table>
b) The provided code is a key contribution to the implementation of the Knuth-Morris-Pratt algorithm, which works to find a particular substring within a larger string. In particular, result[i] stores the length of the longest proper prefix of str.substring(0, i + 1) that’s also a proper suffix. result[9], for instance, say that the first four characters of str match the last four characters of str.

| 0 | 1 | 2 | 0 | 1 | 2 | 3 | 3 | 3 | 4 |

Solution 3: Keith Numbers
/*
 * Predicate Function: isKeithNumber
 * ---------------------------------
 * Returns true if and only if the supplied integer,
 * assumed to be positive, is a Keith number.
 * It does so by maintaining as much of the Fibonacci-like
 * sequence needed to generate the next sequence number,
 * and stops when the most recently introduced number either
 * equals n (yay!) or exceeds it (opposite of yay!)
 */
function isKeithNumber(n) {
  if (n <= 0) return false;
  let partials = createDigitsArray(n);
  while (partials[partials.length - 1] < n) {
    let sum = sumArray(partials); // see Lecture 08 slides
    partials.push(sum);
    partials.shift();
  }
  return partials[partials.length - 1] === n;
}

/**
 * Function: createDigitsArray
 * ---------------------------
 * Accepts an integer called n (assumed to be positive)
 * and produces an array of all of its digits, in order,
 * such that the most significant digit is in the leading
 * position and the least significant digit is in
 * the final position.
 */
function createDigitsArray(n) {
  let digits = [];
  while (n > 0) {
    let digit = n % 10;
    digits.push(digit);
    n = Math.floor(n/10);
  }
  digits.reverse();
  return digits;
}

Some thought questions to ensure you understand the solution:
• What does the use of array throughout the implementation of `isKeithNumber` buy you? What would have been the alternative?
• How would the implementation of `isKeithNumber` need to change had the implementation of `createDigitsArray` not reversed the digits array just before returning it?
• What’s the advantage of calling `shift` on the `partials` array within `isKeithNumber`? Had the shift call been omitted, how could the implementation of `isKeithNumber` change to account for the omission?
• Note that the while loop test within `isKeithNumber` uses `<` instead of `<=`. What would have happened had you accidentally used `<=` instead?

Solution 4: RNA, Codons, and Data Structures

```javascript
/**
 * Predicate Function: mappingIsValid
 * ----------------------------------
 * Returns true if the supplied gene is a valid encoding
 * of the supplied amino acid sequence, and false otherwise.
 */
function mappingIsValid(gene, sequence) {
    if (gene.length !== 3 * (sequence.length + 2)) return false;
    let start = gene.substring(0, 3);
    if (start !== START_CODON) return false;
    gene = gene.substring(3);
    for (let i = 0; i < sequence.length; i++) {
        let codons = MAPPINGS[sequence[i]];
        let codon = gene.substring(0, 3);
        if (codons.indexOf(codon) === -1) return false;
        gene = gene.substring(3);
    }
    let stop = gene;
    return STOP_CODONS.indexOf(stop) !== -1;
}
```
