</tr>
</tbody>
</table>

```javascript
function LineGeometryExample() {
    let gw = GWindow(GWINDOW_WIDTH, GWINDOW_HEIGHT);
    let line = GLine(0, 0, 100, 100);
    gw.add(line);
    line.setLocation(200, 50);
    line.setStartPoint(200, 150);
    line.setEndPoint(300, 50);
}
```
The JavaScript Event Model

• Graphical applications usually make it possible for the user to control the action of a program by using an input device such as a mouse. Programs that support this kind of user control are called *interactive programs*.

• User actions such as mouse clicks and keystrokes are called *events*. Programs that respond to events are *event-driven*.

• In modern interactive programs, user input doesn’t occur at predictable times. A running program doesn’t tell the user when to click the mouse. The user decides when to click the mouse, and the program reacts. Because events are not controlled by the program, they are said to be *asynchronous*.

• In JavaScript program, you write a function that acts as a *listener* for a particular event type. When the event occurs, that listener is called.
First-Class Functions

• Writing listener functions requires you to make use of one of JavaScript’s most important features, which is summed up in the idea that functions in JavaScript are treated as data values just like any others.

• Given a function in JavaScript, you can assign it to a variable, pass it as a parameter, or return it from another function.

• Functions that can be treated like any other data value are called first-class functions.

• The textbook includes examples of how first-class functions can be used to write a program that generates a table of values for a client-supplied function. The focus here is using first-class functions as listeners.
Declaring Functions using Assignment

• The syntax for function definitions you have been using all along is really just a convenient shorthand for assigning a function to a variable. Thus, instead of writing

```javascript
function fahrenheitToCelsius(f) {
  return 5 / 9 * (f - 32);
}
```

JavaScript allows you to write

```javascript
let fahrenheitToCelsius = function(f) {
  return 5 / 9 * (f - 32);
};
```

• Note this second form is a declaration and requires a semicolon.
Closures

- The assignment syntax has a few advantages over the more familiar definition for functions defined at the highest level of a program.

- The real advantage of declaring functions in this way comes when you declare one function as a local variable inside another function. In that case, the inner function not only includes the code in the function body but also has access to the outer function’s local variables.

- This combination of a function definition and the collection of local variables available in the stack frame in which the new function is defined is called a closure.

- Closures are essential to writing interactive programs in JavaScript, so it’s worth going through some examples in detail.
A Simple Interactive Example

• The first interactive example in the text is `DrawDots`:

```javascript
function DrawDots() {
    let gw = GWindow(GWINDOW_WIDTH, GWINDOW_HEIGHT);
    let clickAction = function(e) {
        let dot = GOval(e.getX() - DOT_SIZE / 2,
                        e.getY() - DOT_SIZE / 2,
                        DOT_SIZE, DOT_SIZE);
        dot.setFilled(true);
        gw.add(dot);
    };
    gw.addEventListener("click", clickAction);
}
```

• The key to understanding this program is the `clickAction` function, which defines what to do when the mouse is clicked.

• It is imperative we note that `clickAction` has access to the `gw` variable in `DrawDots` because `gw` is included in the closure.
Registering an Event Listener

• The last line in the `DrawDots` function is

```javascript
gw.addEventListener("click", clickAction);
```

which tells the graphics window (`gw`) to call `clickAction` whenever a mouse click occurs in the window.

• The definition of `clickAction` is

```javascript
let clickAction = function(e) {
  let dot = GOval(e.getX() - DOT_SIZE / 2,
                 e.getY() - DOT_SIZE / 2,
                 DOT_SIZE, DOT_SIZE);
  dot.setFilled(true);
  gw.add(dot);
};
```
Callback Functions

• The `clickAction` function in the `DrawDots.js` program is representative of all functions that handle mouse events. The `DrawDots.js` program passes the function to the graphics window using the `addEventListener` method. When the user clicks the mouse, the graphics window, in essence, calls the client back with the message that a click occurred. For this reason, such functions are known as *callback functions*.

• The parameter `e` supplied to the `clickAction` function is a data structure called a *mouse event*, which gives information about the specifics of the event that triggered the action.

• The programs in the text use only two methods that are part of the mouse event object: `getX()` and `getY()`. These methods return the `x` and `y` coordinates of the mouse click in the coordinate system of the graphics window.
Mouse Events

- The following table shows the different mouse-event types:

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;click&quot;</td>
<td>The user clicks the mouse in the window.</td>
</tr>
<tr>
<td>&quot;dblclk&quot;</td>
<td>The user double-clicks the mouse.</td>
</tr>
<tr>
<td>&quot;mousedown&quot;</td>
<td>The user presses the mouse button.</td>
</tr>
<tr>
<td>&quot;mouseup&quot;</td>
<td>The user releases the mouse button.</td>
</tr>
<tr>
<td>&quot;mousemove&quot;</td>
<td>The user moves the mouse with the button up.</td>
</tr>
<tr>
<td>&quot;drag&quot;</td>
<td>The user drags the mouse with the button down.</td>
</tr>
</tbody>
</table>

- Certain user actions can generate more than one mouse event. For example, clicking the mouse generates a "mousedown" event, a "mouseup" event, and a "click" event, in that order.

- Events trigger no action unless a client is listening for that event type. The DrawDots.js program listens only for the "click" event and is therefore never notified about any of the other event types that occur.
A Simple Line-Drawing Program

In all likelihood, you have at some point used an application that allows you to draw lines with the mouse. In JavaScript, the necessary code fits easily on a single slide.

```javascript
const GWINDOW_WIDTH = 500;
const GWINDOW_HEIGHT = 300;

function DrawLines() {
    let gw = GWindow(GWINDOW_WIDTH, GWINDOW_HEIGHT);
    let line = null;

    let mousedownAction = function(e) {
        line = GLine(e.getX(), e.getY(), e.getX(), e.getY());
        gw.add(line);
    };
    let dragAction = function(e) {
        line.setEndPoint(e.getX(), e.getY());
    };

    gw.addEventListener("mousedown", mousedownAction);
    gw.addEventListener("drag", dragAction);
}
```
Simulating the **DrawLines** Program

– The two calls to `addEventListener` register the listeners.
– Depressing the mouse button generates a "mousedown" event.
– The `mousedownAction` call adds a zero-length line to the canvas.
– Dragging the mouse generates a series of "drag" events.
– Each `dragAction` call extends the line to the new position.
– Releasing the mouse stops the dragging operation.
– Repeating these steps adds new lines to the canvas.
