This week’s section handout has practice with strings, data structures such as Grids, Vectors, Stacks and Queues as well as review of Big-Oh Notation.

1. CrazyCaps (CodeStepByStep)
Write a function named `crazyCaps` that accepts a string reference as a parameter and changes that string to have its capitalization altered such that the characters at even indexes are all in lowercase and odd indexes are all in uppercase. For example, if a variable `s` stores "Hey!! THERE!", the call of `crazyCaps(s)` should change `s` to store "hEy!! tHeRe!".

2. Mirror (CodeStepByStep)
Write a function `mirror` that accepts a reference to a grid of integers as a parameter and flips the grid along its diagonal, so that each index `[i][j]` contains what was previously at index `[j][i]` in the grid. You may assume the grid is square, that is, it has the same number of rows as columns. For example, the grid below at left would be altered to give it the new grid state at right:

```
{{ 6, 1, 9, 4},
 { -2, 5, 8, 12},
 {14, 39, -6, 18},
{21, 55, 73, -3}}  -->  {{ 6, -2, 14, 21},
 { 1, 5, 39, 55},
 { 9, 8, -6, 73},
 { 4, 12, 18, -3}}
```

3. Rotate Clockwise (CodeStepByStep)
Write a function `rotateClockwise90Degrees` that accepts a reference to a grid of integers as a parameter and rotates the Grid 90 degrees clockwise. You may assume the grid is square, that is, it has the same number of rows as columns. For example, the grid below at the left would be altered to give it the new grid state at right.

```
{{ 6, 1, 9, 4},
 { -2, 5, 8, 12},
 {14, 39, -6, 18},
{21, 55, 73, -3}}  -->  {{ 21, 14, -2, 6 },
 { 55, 39, 5, 1 },
 { 73, -6, 8, 9 },
 { -3, 18, 12, 4 }}
```

4. Cumulative (CodeStepByStep)
Write a function named `cumulative` that accepts a reference to a Vector of integers as a parameter and modifies it so each element contains the sum of the original vector up through that index. For example, if a Vector variable `v` stores `{1, 1, 2, 3, 5}`, the call of `cumulative(v)`; should modify it to store `{1, 2, 4, 7, 12}`. Don’t do more than one pass through the original vector.

5. Stretch (CodeStepByStep)
Write a function named `stretch` that accepts a reference to a vector of integers as a parameter and modifies it to be twice as large, replacing every integer with a pair of integers, each half the original. If a number in the original vector is odd, then the first number in the new pair should be one higher than the second so that the sum equals the original number. For example, passing the vector `{18, 7, 4, 24, 11}` should modify the vector to contain `{9, 9, 4, 3, 2, 2, 12, 12, 6, 5}`.

Thanks to Aaron Broder, Marty Stepp, Victoria Kirst, Jerry Cain, and other past CS106B and X instructors and TAs for contributing problems on this handout.
6. Big-Oh Analysis
Give a tight bound on the nearest runtime complexity for each of the following code fragments in Big-Oh, in terms of the variable N. In other words, find the growth rate of the code’s runtime as N grows.

// a)
int sum = 0;
for (int i = 1; i <= N + 2; i++) {
    sum++;
}
for (int j = 1; j <= N * 2; j++) {
    sum += 5;
}
cout << sum << endl;

// b)
int sum = 0;
for (int i = 1; i <= N - 5; i++) {
    for (int j = 1; j <= N - 5; j += 2) {
        sum++;
    }
}
cout << sum << endl;

// c)
int sum = N;
for (int i = 0; i < 1000000; i++) {
    for (int j = 1; j <= i + 4; j++) {
        sum += N;
    }
    for (int j = 1; j <= i; j++) {
        sum += N;
    }
}
cout << sum << endl;

// d)
HashSet<int> set1;
for (int i = 1; i <= N; i++) {
    set1.add(i);
}
Set<int> set2;
for (int i = 1; i <= N; i++) {
    set1.remove(i);
    set2.add(i + N);
}
cout << “done!” << endl;

7. Oh? More Big-Oh?
Give a tight bound on the nearest runtime complexity for each of the following code fragments in Big-Oh, in terms of the variable N. In other words, find the growth rate of the code’s runtime as N grows.

// a)
int sum = 0;
for (int i = 1; i <= N - 2; i++) {
    for (int j = 1; j <= i + 4; j++) {
        sum++;
    }
    sum++;
}
cout << sum << endl;

// c)
Vector<int> list;
for (int i = 0; i < N; i++) {
    list.insert(0, i * i);
}
Set<int> set;
for (int k : list) {
    set.add(k);
}
cout << “done!” << endl;

// b)
int sum = 0;
for (int i = 1; i <= N * 2; i++) {
    for (int j = 1; j <= i / 2; j += 2) {
        for (int k = 0; k < N * N; k++) {
            sum++;
        }
    }
}
cout << sum << endl;

// d)
int sum = 0;
for (int i = 1; i <= 100000; i++) {
    for (int j = 1; j <= i; j++) {
        for (int k = 1; k <= N; k++) {
            sum++;
        }
    }
}
cout << sum << endl;
8. Keith Numbers (CodeStepByStep)

A Keith Number is defined as any \( n \)-digit integer that appears in the sequence that starts off with the number's \( n \) digits and then continues such that each subsequent number is the sum of the preceding \( n \). All one-digit numbers are trivially Keith numbers, but there are more interesting ones as well. For example, the number 7385 is a Keith number because of the following sequence:

7, 3, 8, 5, 23, 39, 75, 142, 279, 535, 1031, 1987, 3832, 7385

Keith numbers are computationally hard to calculate; there are only about 100 known right now. Write a function `findKeithNumbers` that takes a minimum and maximum value and finds all Keith numbers between those values (inclusive). For each number, it should print the sequence that proves it is a Keith number. For example, if you call `findKeithNumbers(1, 1000)`, it should print:

1: \{1\}
2: \{2\}
3: \{3\}
4: \{4\}
5: \{5\}
6: \{6\}
7: \{7\}
8: \{8\}
9: \{9\}
14: \{1, 4, 5, 9, 14\}
19: \{1, 9, 10, 19\}
28: \{2, 8, 10, 18, 28\}
47: \{4, 7, 11, 18, 29, 47\}
61: \{6, 1, 7, 8, 15, 23, 38, 61\}
75: \{7, 5, 12, 17, 29, 46, 75\}
197: \{1, 9, 7, 17, 33, 57, 107, 197\}
742: \{7, 4, 2, 13, 19, 34, 66, 119, 219, 404, 742\}

9. Reorder (CodeStepByStep)

Write a function named reorder that takes a queue of integers that are already sorted by absolute value, and modifies it so that the integers are sorted normally. The only auxiliary data structure you can use is a single `Stack<int>`. For example, passing the queue `{1, -2, 3, 4, -5, -6, 7}` changes it to `{­6, ­5, -2, 1, 3, 4, 7}`.

10. CheckBalance (CodeStepByStep)

Write a function named `checkBalance` that accepts a string of source code and uses a Stack to check whether the braces/parentheses are balanced. Every ( or { must be closed by a ) or } in the opposite order. Return the index at which an imbalance occurs, or -1 if the string is balanced. If any ( or { are never closed, return the string's length.

Here are some example calls:

```
// index 0123456789012345678901234567890
checkBalance("if (a(4) > 9) \{ foo(a(2)); }\") // returns -1 because balanced
checkBalance("for (i=0;i&lt;a(3);i++) \{ foo(); }\") // returns 14 because } out of order
checkBalance("while (true) foo(); \{ ()\}") // returns 20 because } doesn't match any {
checkBalance("if (x) \{\") // returns 8 because { is never closed
```

**Constraints**: Use a single stack as auxiliary storage.
