CS107, Lecture 8
C Generics – Void *
CS107 Topic 4: How can we use our knowledge of memory and data representation to write code that works with any data type?
Learning Goals

• Learn how to write C code that works with any data type.
• Learn about how to use void * and avoid potential pitfalls.
Lecture Plan

• **Overview**: Generics
• Generic Swap
• Generics Pitfalls
• Generic Array Swap
• Generic Stack

cp -r /afs(ir/class/cs107/lecture-code/lect8)
Lecture Plan

- Overview: Generics
- Generic Swap
- Generics Pitfalls
- Generic Array Swap
- Generic Stack
Generics

• We always strive to write code that is as general-purpose as possible.
• Generic code reduces code duplication and means you can make improvements and fix bugs in one place rather than many.
• Generics is used throughout C for functions to sort any array, search any array, free arbitrary memory, and more.
• How can we write generic code in C?
Lecture Plan

• **Overview**: Generics
• **Generic Swap**
• Generics Pitfalls
• Generic Array Swap
• Generic Stack
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    int x = 2;
    int y = 5;
    swap_int(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    int x = 2;
    int y = 5;
    swap_int(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
You’re asked to write a function that swaps two numbers.

```c
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    int x = 2;
    int y = 5;
    swap_int(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
```
You’re asked to write a function that swaps two numbers.

```c
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    int x = 2;
    int y = 5;
    swap_int(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
```
You’re asked to write a function that swaps two numbers.

```c
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    int x = 2;
    int y = 5;
    swap_int(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
```
You’re asked to write a function that swaps two numbers.

```c
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    int x = 2;
    int y = 5;
    swap_int(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
```
You're asked to write a function that swaps two numbers.

```c
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    int x = 2;
    int y = 5;
    swap_int(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
```
You’re asked to write a function that swaps two numbers.

```c
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    int x = 2;
    int y = 5;
    swap_int(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
```
You’re asked to write a function that swaps two numbers.

```c
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    int x = 2;
    int y = 5;
    swap_int(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
```
“Oh, when I said ‘numbers’ I meant shorts, not ints.”
void swap_short(short *a, short *b) {
    short temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    short x = 2;
    short y = 5;
    swap_short(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
void swap_short(short *a, short *b) {
    short temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    short x = 2;
    short y = 5;
    swap_short(&x, &y);
    // want x = 5, y = 2
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
“You know what, I goofed. We’re going to use strings. Could you write something to swap those?” 😤
void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    char *x = "2";
    char *y = "5";
    swap_string(&x, &y);
    // want x = 5, y = 2
    printf("x = %s, y = %s\n", x, y);
    return 0;
}
void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    char *x = "2";
    char *y = "5";
    swap_string(&x, &y);
    // want x = 5, y = 2
    printf("x = %s, y = %s\n", x, y);
    return 0;
}
void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    char *x = "2";
    char *y = "5";
    swap_string(&x, &y);
    // want x = 5, y = 2
    printf("x = %s, y = %s\n", x, y);
    return 0;
}
void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    char *x = "2";
    char *y = "5";
    swap_string(&x, &y);
    // want x = 5, y = 2
    printf("x = %s, y = %s\n", x, y);
    return 0;
}
void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    char *x = "2";
    char *y = "5";
    swap_string(&x, &y);
    // want x = 5, y = 2
    printf("x = %s, y = %s\n", x, y);
    return 0;
}
void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    char *x = "2";
    char *y = "5";
    swap_string(&x, &y);
    // want x = 5, y = 2
    printf("x = %s, y = %s\n", x, y);
    return 0;
}
void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    char *x = "2";
    char *y = "5";
    swap_string(&x, &y);
    // want x = 5, y = 2
    printf("x = %s, y = %s\n", x, y);
    return 0;
}
void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    char *x = "2";
    char *y = "5";
    swap_string(&x, &y);
    // want x = 5, y = 2
    printf("x = %s, y = %s\n", x, y);
    return 0;
}
void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}

int main(int argc, char *argv[]) {
    char *x = "2";
    char *y = "5";
    swap_string(&x, &y);
    // want x = 5, y = 2
    printf("x = %s, y = %s\n", x, y);
    return 0;
}
“Awesome! Thanks.”
“Awesome! Thanks. We also have 20 custom struct types. Could you write swap for those too?”
What if we could write one function to swap two values of any single type?

```c
void swap_int(int *a, int *b) { ... }
void swap_float(float *a, float *b) { ... }
void swap_size_t(size_t *a, size_t *b) { ... }
void swap_double(double *a, double *b) { ... }
void swap_string(char **a, char **b) { ... }
void swap_mystruct(mystruct *a, mystruct *b) { ... }
...
```
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

void swap_short(short *a, short *b) {
    short temp = *a;
    *a = *b;
    *b = temp;
}

void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}
void swap_int(int *a, int *b) {
    int temp = *a;
    *a = *b;
    *b = temp;
}

void swap_short(short *a, short *b) {
    short temp = *a;
    *a = *b;
    *b = temp;
}

void swap_string(char **a, char **b) {
    char *temp = *a;
    *a = *b;
    *b = temp;
}

All 3:
• Take pointers to values to swap
• Create temporary storage to store one of the values
• Move data at b into where a points
• Move data in temporary storage into where b points
void swap(pointer to data1, pointer to data2) {
    store a copy of data1 in temporary storage
    copy data2 to location of data1
    copy data in temporary storage to location of data2
}
void swap(pointer to data1, pointer to data2) {
store a copy of data1 in temporary storage
copy data2 to location of data1
copy data in temporary storage to location of data2
}

Problem: each type may need a different size temp!
void swap(pointer to data1, pointer to data2) {
    store a copy of data1 in temporary storage
    copy data2 to location of data1
    copy data in temporary storage to location of data2
}

*data1Ptr = *data2ptr;

*data1Ptr = *data2ptr;

*data1Ptr = *data2ptr;

**Problem:** each type needs to copy a different amount of data!
void swap(pointer to data1, pointer to data2) {
    store a copy of data1 in temporary storage
    copy data2 to location of data1
    copy data in temporary storage to location of data2
}

Problem: each type needs to copy a different amount of data!
C knows the size of temp, and knows how many bytes to copy, because of the variable types.
Is there a way to make a version that doesn’t care about the variable types?
void swap(pointer to data1, pointer to data2) {
    store a copy of data1 in temporary storage
    copy data2 to location of data1
    copy data in temporary storage to location of data2
}
void swap(pointer to data1, pointer to data2) {
    store a copy of data1 in temporary storage
    copy data2 to location of data1
    copy data in temporary storage to location of data2
}

Generic Swap
void swap(void *data1ptr, void *data2ptr) {
    store a copy of data1 in temporary storage
    copy data2 to location of data1
    copy data in temporary storage to location of data2
}
void swap(void *data1ptr, void *data2ptr) {
    // store a copy of data1 in temporary storage
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}

Generic Swap
void swap(void *data1ptr, void *data2ptr) {
    // store a copy of data1 in temporary storage
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}

If we don’t know the data type, we don’t know how many bytes it is. Let’s take that as another parameter.
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    // store a copy of data1 in temporary storage
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}

If we don’t know the data type, we don’t know how many bytes it is. Let’s take that as another parameter.
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    // store a copy of data1 in temporary storage
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    void temp; ???
    // store a copy of data1 in temporary storage
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}

Now, how can we copy in what data1ptr points to into temp?
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    temp = *data1ptr; ???
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}

Now, how can we copy in what data1ptr points to into temp?
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    temp = *data1ptr; ???
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}

We can’t dereference a void * (or set an array equal to something). C doesn’t know what it points to! Therefore, it doesn’t know how many bytes there it should be looking at.
memcpy is a function that copies a specified amount of bytes at one address to another address.

```c
void *memcpy(void *dest, const void *src, size_t n);
```

It copies the next n bytes that src points to to the location contained in dest. (It also returns dest). It does not support regions of memory that overlap.

```c
int x = 5;
int y = 4;
memcpy(&x, &y, sizeof(x)); // like x = y
```
**memmove**

*memmove* is the same as *memcpy*, but supports overlapping regions of memory. (Unlike its name implies, it still “copies”).

```c
void *memmove(void *dest, const void *src, size_t n);
```

It copies the next n bytes that *src* points to to the location contained in *dest*. (It also returns *dest*).
When might `memmove` be useful?
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    temp = *data1ptr; ???
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}

We can’t dereference a **void** *. C doesn’t know what it points to! Therefore, it doesn’t know how many bytes there it should be looking at.
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    temp = *data1ptr; ???
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}

How can \texttt{memcpy} or \texttt{memmove} help us here?

\texttt{void *memcpy(void *dest, const void *src, size_t n)};

\texttt{void *memmove(void *dest, const void *src, size_t n)};
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}

We can copy the bytes ourselves into temp! This is equivalent to \texttt{temp = *data1ptr} in non-generic versions, but this works for \textit{any} type of \textit{any} size.
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    // copy data in temporary storage to location of data2
}

How can we copy data2 to the location of data1?
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    *data1ptr = *data2ptr; ???
    // copy data in temporary storage to location of data2
}

How can we copy data2 to the location of data1?
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    memcpy(data1ptr, data2ptr, nbytes);
    // copy data in temporary storage to location of data2
}

How can we copy data2 to the location of data1?
memcpy!
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    memcpy(data1ptr, data2ptr, nbytes);
    // copy data in temporary storage to location of data2
}

How can we copy temp’s data to the location of data2?
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    memcpy(data1ptr, data2ptr, nbytes);
    // copy data in temporary storage to location of data2
    memcpy(data2ptr, temp, nbytes);
}

How can we copy temp’s data to the location of data2? memcpy!
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    memcpy(data1ptr, data2ptr, nbytes);
    // copy data in temporary storage to location of data2
    memcpy(data2ptr, temp, nbytes);
}

int x = 2;
int y = 5;
swap(&x, &y, sizeof(x));
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    memcpy(data1ptr, data2ptr, nbytes);
    // copy data in temporary storage to location of data2
    memcpy(data2ptr, temp, nbytes);
}

short x = 2;
short y = 5;
swap(&x, &y, sizeof(x));
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    memcpy(data1ptr, data2ptr, nbytes);
    // copy data in temporary storage to location of data2
    memcpy(data2ptr, temp, nbytes);
}

char *x = "2";
char *y = "5";
swap(&x, &y, sizeof(x));
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    // store a copy of data1 in temporary storage
    memcpy(temp, data1ptr, nbytes);
    // copy data2 to location of data1
    memcpy(data1ptr, data2ptr, nbytes);
    // copy data in temporary storage to location of data2
    memcpy(data2ptr, temp, nbytes);
}

mystruct x = {...};
mystruct y = {...};
swap(&x, &y, sizeof(x));
C Generics

- We can use `void *` and `memcpy` to handle memory as generic bytes.
- If we are given where the data of importance is, and how big it is, we can handle it!

```c
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {
    char temp[nbytes];
    memcpy(temp, data1ptr, nbytes);
    memcpy(data1ptr, data2ptr, nbytes);
    memcpy(data2ptr, temp, nbytes);
}
```
Lecture Plan

• Overview: Generics
• Generic Swap
• **Generics Pitfalls**
• Generic Array Swap
• Generic Stack
Void * Pitfalls

• **void** *s are powerful, but dangerous - C cannot do as much checking!

• E.g. with **int**, C would never let you swap *half* of an int. With **void** *s*, this can happen! (*How?  Let’s find out!*)
Demo: Void *s Gone Wrong
Void * Pitfalls

• Void * has more room for error because it manipulates arbitrary bytes without knowing what they represent. This can result in some strange memory Frankensteins!
• **Overview:** Generics
• Generic Swap
• Generics Pitfalls
• **Generic Array Swap**
• Generic Stack
You’re asked to write a function that swaps the first and last elements in an array of numbers.

```c
void swap_ends_int(int *arr, size_t nelems) {
    int tmp = arr[0];
    arr[0] = arr[nelems - 1];
    arr[nelems - 1] = tmp;
}

int main(int argc, char *argv[]) {
    int nums[] = {5, 2, 3, 4, 1};
    size_t nelems = sizeof(nums) / sizeof(nums[0]);
    swap_ends_int(nums, nelems);
    // want nums[0] = 1, nums[4] = 5
    printf("nums[0] = %d, nums[4] = %d\n", nums[0], nums[4]);
    return 0;
}
```

Wait – we just wrote a generic swap function. Let’s use that!
You’re asked to write a function that swaps the first and last elements in an array of numbers.

```c
void swap_ends_int(int *arr, size_t nelems) {
    swap(arr, arr + nelems - 1, sizeof(*arr));
}

int main(int argc, char *argv[]) {
    int nums[] = {5, 2, 3, 4, 1};
    size_t nelems = sizeof(nums) / sizeof(nums[0]);
    swap_ends_int(nums, nelems);
    // want nums[0] = 1, nums[4] = 5
    printf("nums[0] = %d, nums[4] = %d\n", nums[0], nums[4]);
    return 0;
}
```

Wait – we just wrote a generic swap function. Let’s use that!
Let’s write out what some other versions would look like (just in case).

```c
void swap_ends_int(int *arr, size_t nelems) {
    swap(arr, arr + nelems - 1, sizeof(*arr));
}

void swap_ends_short(short *arr, size_t nelems) {
    swap(arr, arr + nelems - 1, sizeof(*arr));
}

void swap_ends_string(char **arr, size_t nelems) {
    swap(arr, arr + nelems - 1, sizeof(*arr));
}

void swap_ends_float(float *arr, size_t nelems) {
    swap(arr, arr + nelems - 1, sizeof(*arr));
}
```

The code seems to be the same regardless of the type!
Let’s write a version of swap_ends that works for any type of array.

```c
void swap_ends(void *arr, size_t nelems) {
    swap(arr, arr + nelems - 1, sizeof(*arr));
}
```

Is this generic? Does this work?
Let’s write a version of swap_ends that works for any type of array.

```c
void swap_ends(void *arr, size_t nelems) {
    swap(arr, arr + nelems - 1, sizeof(*arr));
}
```

Is this generic? Does this work?

**Unfortunately not.** First, we no longer know the element size. Second, pointer arithmetic depends on the type of data being pointed to. With a void *, we lose that information!
Let’s write a version of swap_ends that works for any type of array.

```c
void swap_ends(void *arr, size_t nelems) {
    swap(arr, arr + nelems - 1, sizeof(*arr));
}
```

We need to know the element size, so let’s add a parameter.
Let’s write a version of swap_ends that works for any type of array.

```c
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {
    swap(arr, arr + nelems - 1, elem_bytes);
}
```

We need to know the element size, so let’s add a parameter.
Pointer Arithmetic

\[ \text{arr} + \text{nelems} - 1 \]

Let’s say \( \text{nelems} = 4 \). How many bytes beyond \( \text{arr} \) is this?

If it’s an array of...

\text{Int}?
Let’s say nelems = 4. How many bytes beyond arr is this?

If it’s an array of...

**Int:** adds 3 places to arr, and 3 * sizeof(int) = 12 bytes
Let’s say nelems = 4. How many bytes beyond arr is this?

If it’s an array of...

Int: adds 3 **places** to arr, and 3 * sizeof(int) = 12 bytes

Short?
Let’s say nelems = 4. How many bytes beyond arr is this?

If it’s an array of...

**Int:** adds 3 places to arr, and 3 * sizeof(int) = 12 bytes

**Short:** adds 3 places to arr, and 3 * sizeof(short) = 6 bytes
Let’s say `nelems = 4`. How many bytes beyond `arr` is this?

If it’s an array of...

- **Int**: adds 3 places to `arr`, and $3 \times \text{sizeof} \text{(int)} = 12$ bytes
- **Short**: adds 3 places to `arr`, and $3 \times \text{sizeof} \text{(short)} = 6$ bytes
- **Char ***: adds 3 places to `arr`, and $3 \times \text{sizeof} \text{(char *)} = 24$ bytes

In each case, we need to know the element size to do the arithmetic.
Let’s write a version of `swap_ends` that works for any type of array.

```c
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {
    swap(arr, arr + nelems - 1, elem_bytes);
}
```

How many bytes past `arr` should we go to get to the last element?

`(nelems - 1) * elem_bytes`
Let’s write a version of swap_ends that works for any type of array.

```c
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {
    swap(arr, arr + (nelems - 1) * elem_bytes, elem_bytes);
}
```

How many bytes past `arr` should we go to get to the last element?

`(nelems - 1) * elem_bytes`
Let’s write a version of swap_ends that works for any type of array.

```c
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {
    swap(arr, arr + (nelems - 1) * elem_bytes, elem_bytes);
}
```

But C still can’t do arithmetic with a `void*`. We need to tell it to not worry about it, and just add bytes. **How can we do this?**
Let’s write a version of swap_ends that works for any type of array.

```c
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {
    swap(arr, (char *)arr + (nelems - 1) * elem_bytes, elem_bytes);
}
```

But C still can’t do arithmetic with a void*. We need to tell it to not worry about it, and just add bytes. How can we do this?

char * pointers already add bytes!
You’re asked to write a function that swaps the first and last elements in an array of numbers. Well, now it can swap for an array of anything!

```c
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {
    swap(arr, (char *)arr + (nelems - 1) * elem_bytes, elem_bytes);
}
```
You’re asked to write a function that swaps the first and last elements in an array of numbers. Well, now it can swap for an array of anything!

```c
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {
    swap(arr, (char *)arr + (nelems - 1) * elem_bytes, elem_bytes);
}
```

```c
int nums[] = {5, 2, 3, 4, 1};
size_t nelems = sizeof(nums) / sizeof(nums[0]);
swap_ends(nums, nelems, sizeof(nums[0]));
```
You’re asked to write a function that swaps the first and last elements in an array of numbers. Well, now it can swap for an array of anything!

```c
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {
    swap(arr, (char *)arr + (nelems - 1) * elem_bytes, elem_bytes);
}
```

```c
short nums[] = {5, 2, 3, 4, 1};
size_t nelems = sizeof(nums) / sizeof(nums[0]);
swap_ends(nums, nelems, sizeof(nums[0]));
```
You’re asked to write a function that swaps the first and last elements in an array of numbers. Well, now it can swap for an array of anything!

```c
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {
    swap(arr, (char *)arr + (nelems - 1) * elem_bytes, elem_bytes);
}
```

```c
char *strs[] = {"Hi", "Hello", "Howdy"};
size_t nelems = sizeof(strs) / sizeof(strs[0]);
swap_ends(strs, nelems, sizeof(strs[0]));
```
You’re asked to write a function that swaps the first and last elements in an array of numbers. Well, now it can swap for an array of anything!

```c
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {
    swap(arr, (char *)arr + (nelems - 1) * elem_bytes, elem_bytes);
}
```

```c
typedef struct mystruct { ...
    ...
} mystruct;

mystruct structs[] = ...
size_t nelems = ...
swap_ends(structs, nelems, sizeof(structs[0]));
```
Demo: Void *s Gone Wrong
Lecture Plan

• **Overview:** Generics
• Generic Swap
• Generics Pitfalls
• **Announcements**
• Generic Array Swap
• **Generic Stack**
Stacks

- C generics are particularly powerful in helping us create generic data structures.
- Let’s see how we might go about making a Stack in C.
A **Stack** is a data structure representing a stack of things.

Objects can be **pushed** on top of or **popped** from the top of the stack.

Only the top of the stack can be accessed; no other objects in the stack are visible.

Main operations:

- **`push(value)`**: add an element to the top of the stack
- **`pop()`**: remove and return the top element in the stack
- **`peek()`**: return (but do not remove) the top element in the stack
A stack is often implemented using a **linked list** internally.

- "bottom" = tail of linked list
- "top" = head of linked list  *(why not the other way around?)*

```cpp
Stack<int> s;
    s.push(42);
    s.push(-3);
    s.push(17);
```

**Problem:** C is not object-oriented! We can't call methods on variables.
Demo: Int Stack

int_stack.c
What modifications are necessary to make a generic stack?
typedef struct int_node {
    struct int_node *next;
    int data;
} int_node;

typedef struct int_stack {
    int nelems;
    int_node *top;
} int_stack;

How might we modify the Stack data representation itself to be generic?
Stack Structs

typedef struct int_node {
    struct int_node *next;
    int data;
} int_node;

typedef struct int_stack {
    int nelems;
    int_node *top;
} int_stack;

**Problem:** each node can no longer store the data itself, because it could be any size!
typedef struct int_node {
    struct int_node *next;
    void *data;
} int_node;

typedef struct stack {
    int nelems;
    int elem_size_bytes;
    node *top;
} stack;

Solution: each node stores a pointer, which is always 8 bytes, to the data somewhere else. We must also store the data size in the Stack struct.
Stack Functions

• `int_stack_create()`: creates a new stack on the heap and returns a pointer to it

• `int_stack_push(int_stack *s, int data)`: pushes data onto the stack

• `int_stack_pop(int_stack *s)`: pops and returns topmost stack element
int_stack *int_stack_create() {
    int_stack *s = malloc(sizeof(int_stack));
    s->nelems = 0;
    s->top = NULL;
    return s;
}

From previous slide:
typedef struct stack {
    int nelems;
    int elem_size_bytes;
    node *top;
} stack;
Generic stack_create

```c
stack *stack_create(int elem_size_bytes) {
  stack *s = malloc(sizeof(stack));
  s->nelems = 0;
  s->top = NULL;
  s->elem_size_bytes = elem_size_bytes;
  return s;
}
```
```c
void int_stack_push(int_stack *s, int data) {
    int_node *new_node = malloc(sizeof(int_node));
    new_node->data = data;

    new_node->next = s->top;
    s->top = new_node;
    s->nelems++;
}
```

**From previous slide:**

```
typedef struct stack {
    int nelems;
    int elem_size_bytes;
    node *top;
} stack;
```

```
typedef struct node {
    struct node *next;
    void *data;
} node;
```
void int_stack_push(int_stack *s, int data) {
    int_node *new_node = malloc(sizeof(int_node));
    new_node->data = data;
    new_node->next = s->top;
    s->top = new_node;
    s->nelems++;
}

Problem 1: we can no longer pass the data itself as a parameter, because it could be any size!
Generic stack_push

void int_stack_push(int_stack *s, const void *data) {
    int_node *new_node = malloc(sizeof(int_node));
    new_node->data = data;

    new_node->next = s->top;
    s->top = new_node;
    s->nelems++;
}

Solution 1: pass a pointer to the data as a parameter instead.
void int_stack_push(int_stack *s, const void *data) {
    int_node *new_node = malloc(sizeof(int_node));
    new_node->data = data;
    new_node->next = s->top;
    s->top = new_node;
    s->nelems++;
}

**Problem 2:** we cannot copy the existing data pointer into new_node. The data structure must manage its own copy that exists for its entire lifetime. The provided copy may go away!
int main() {
    stack *int_stack = stack_create(sizeof(int));
    add_one(int_stack);
    // now stack stores pointer to invalid memory for 7!
}

void add_one(stack *s) {
    int num = 7;
    stack_push(s, &num);
}
void stack_push(stack *s, const void *data) {
    node *new_node = malloc(sizeof(node));
    new_node->data = malloc(s->elem_size_bytes);
    memcpy(new_node->data, data, s->elem_size_bytes);
    new_node->next = s->top;
    s->top = new_node;
    s->nelems++;
};
int int_stack_pop(int_stack *s) {
    if (s->nelems == 0) {
        error(1, 0, "Cannot pop from empty stack");
    }
    int_node *n = s->top;
    int value = n->data;

    s->top = n->next;

    free(n);
    s->nelems--;

    return value;
}
**Generic stack_pop**

```c
#include "int_stack.h"

int int_stack_pop(int_stack *s) {
    if (s->nelems == 0) {
        error(1, 0, "Cannot pop from empty stack");
    }
    int_node *n = s->top;
    int value = n->data;
    s->top = n->next;
    free(n);
    s->nelems--;
    return value;
}
```

**Problem:** we can no longer return the data itself, because it could be any size!
```c
void *int_stack_pop(int_stack *s) {
    if (s->nelems == 0) {
        error(1, 0, "Cannot pop from empty stack");
    }
    int_node *n = s->top;
    void *value = n->data;

    s->top = n->next;
    free(n);
    s->nelems--;

    return value;
}
```

While it’s possible to return the heap address of the element, this means the client would be responsible for freeing it. Ideally, the data structure should manage its own memory here.
void stack_pop(stack *s, void *addr) {
    if (s->nelems == 0) {
        error(1, 0, "Cannot pop from empty stack");
    }
    node *n = s->top;
    memcpy(addr, n->data, s->elem_size_bytes);
    s->top = n->next;

    free(n->data);
    free(n);
    s->nelems--;
}

**Solution:** have the caller pass a memory location as a parameter and copy the data to that location.
Using Generic Stack

```c
int_stack *intstack = int_stack_create();
for (int i = 0; i < TEST_STACK_SIZE; i++) {
    int_stack_push(intstack, i);
}
```

We must now pass the *address* of an element to push onto the stack, rather than the element itself.
Using Generic Stack

stack *intstack = stack_create(sizeof(int));
for (int i = 0; i < TEST_STACK_SIZE; i++) {
    stack_push(intstack, &i);
}
Using Generic Stack

int_stack *intstack = int_stack_create();
int_stack_push(intstack, 7);

We must now pass the *address* of an element to push onto the stack, rather than the element itself.
Using Generic Stack

stack *intstack = stack_create(sizeof(int));
int num = 7;
stack_push(intstack, &num);

We must now pass the address of an element to push onto the stack, rather than the element itself.
// Pop off all elements
while (intstack->nelems > 0) {
    printf("%d\n", int_stack_pop(intstack));
}
// Pop off all elements
int popped_int;
while (intstack->nelems > 0) {
    int_stack_pop(intstack, &popped_int);
    printf("%d\n", popped_int);
}
Demo: Generic Stack
Recap

- **void** * is a variable type that represents a generic pointer “to something”.
- We cannot perform pointer arithmetic with or dereference a **void** *.
- We can use `memcpy` or `memmove` to copy data from one memory location to another.
- To do pointer arithmetic with a **void** *, we must first cast it to a **char** *.
- **void** * and generics are powerful but dangerous because of the lack of type checking, so we must be extra careful when working with generic memory.

• Generic Stack

Next time: More Generics, and Function Pointers
Question Break!

Post any questions or topics you’d like to review on the Ed thread for today’s lecture.
Extra Practice
Exercise: You’re asked to provide an implementation for a function called `rotate` with the following prototype:

```c
void rotate(void *front, void *separator, void *end);
```

The expectation is that `front` is the base address of an array, `end` is the past-the-end address of the array, and `separator` is the address of some element in between. `rotate` moves all elements in between `front` and `separator` to the end of the array, and all elements between `separator` and `end` move to the front.
int array[7] = {1, 2, 3, 4, 5, 6, 7};
rotate(array, array + 3, array + 7);
Exercise: A properly implemented **rotate** will prompt the following program to generate the provided output.

```c
int main(int argc, char *argv[]) {
    int array[10] = {1, 2, 3, 4, 5, 6, 7, 8, 9, 10};
    print_int_array(array, 10); // intuit implementation 😊
    rotate(array, array + 5, array + 10);
    print_int_array(array, 10);
    rotate(array, array + 1, array + 10);
    print_int_array(array, 10);
    rotate(array + 4, array + 5, array + 6);
    print_int_array(array, 10);
    return 0;
}
```

**Output:**

```
myth52:~/lect8$ ./rotate
Array: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10
Array: 6, 7, 8, 9, 10, 1, 2, 3, 4, 5
Array: 7, 8, 9, 10, 1, 2, 3, 4, 5, 6
Array: 7, 8, 9, 10, 2, 1, 3, 4, 5, 6
myth52:~/lect8$
```
Demo: Array Rotation
Exercise: A properly implemented `rotate` will prompt the following program to generate the provided output.

And here’s that properly implemented function!

```c
void rotate(void *front, void *separator, void *end) {
    int width = (char *)end - (char *)front;
    int prefix_width = (char *)separator - (char *)front;
    int suffix_width = width - prefix_width;

    char temp[prefix_width];
    memcpy(temp, front, prefix_width);
    memmove(front, separator, suffix_width);
    memcpy((char *)end - prefix_width, temp, prefix_width);
}
```
