

## Properties of Joint Distributions

---

### Expectation with Multiple RVs

Expectation over a joint isn't nicely defined because it is not clear how to compose the multiple variables. However, expectations over functions of random variables (for example sums or multiplications) are nicely defined:  $E[g(X, Y)] = \sum_{x,y} g(x, y)p(x, y)$  for any function  $g(X, Y)$ . When you expand that result for the function  $g(X, Y) = X + Y$  you get a beautiful result:

$$\begin{aligned} E[X + Y] &= E[g(X, Y)] = \sum_{x,y} g(x, y)p(x, y) = \sum_{x,y} [x + y]p(x, y) \\ &= \sum_{x,y} xp(x, y) + \sum_{x,y} yp(x, y) \\ &= \sum_x x \sum_y p(x, y) + \sum_y y \sum_x p(x, y) \\ &= \sum_x xp(x) + \sum_y yp(y) \\ &= E[X] + E[Y] \end{aligned}$$

This can be generalized to multiple variables:

$$E \left[ \sum_{i=1}^n X_i \right] = \sum_{i=1}^n E[X_i]$$

### Independence with Multiple RVs

#### Discrete

Two discrete random variables  $X$  and  $Y$  are called independent if:

$$P(X = x, Y = y) = P(X = x)P(Y = y) \text{ for all } x, y$$

Intuitively: knowing the value of  $X$  tells us nothing about the distribution of  $Y$ . If two variables are not independent, they are called dependent. This is a similar conceptually to independent events, but we are dealing with multiple *variables*. Make sure to keep your events and variables distinct.

#### Continuous

Two continuous random variables  $X$  and  $Y$  are called independent if:

$$P(X \leq a, Y \leq b) = P(X \leq a)P(Y \leq b) \text{ for all } a, b$$

This can be stated equivalently as:

$$\begin{aligned} F_{X,Y}(a, b) &= F_X(a)F_Y(b) \text{ for all } a, b \\ f_{X,Y}(a, b) &= f_X(a)f_Y(b) \text{ for all } a, b \end{aligned}$$

More generally, if you can factor the joint density function then your continuous random variables are independent:

$$f_{X,Y}(x, y) = h(x)g(y) \text{ where } -\infty < x, y < \infty$$

## Example 2

Let  $N$  be the # of requests to a web server/day and that  $N \sim Poi(\lambda)$ . Each request comes from a human (probability =  $p$ ) or from a “bot” (probability =  $(1-p)$ ), independently. Define  $X$  to be the # of requests from humans/day and  $Y$  to be the # of requests from bots/day.

Since requests come in independently, the probability of  $X$  conditioned on knowing the number of requests is a Binomial. Specifically:

$$(X|N) \sim Bin(N, p)$$

$$(Y|N) \sim Bin(N, 1-p)$$

Calculate the probability of getting exactly  $i$  human requests and  $j$  bot requests. Start by expanding using the chain rule:

$$P(X = i, Y = j) = P(X = i, Y = j | X + Y = i + j)P(X + Y = i + j)$$

We can calculate each term in this expression:

$$P(X = i, Y = j | X + Y = i + j) = \binom{i+j}{i} p^i (1-p)^j$$

$$P(X + Y = i + j) = e^{-\lambda} \frac{\lambda^{i+j}}{(i+j)!}$$

Now we can put those together and simplify:

$$P(X = i, Y = j) = \binom{i+j}{i} p^i (1-p)^j e^{-\lambda} \frac{\lambda^{i+j}}{(i+j)!}$$

As an exercise you can simplify this expression into two independent Poisson distributions.

## Symmetry of Independence

Independence is symmetric. That means that if random variables  $X$  and  $Y$  are independent,  $X$  is independent of  $Y$  and  $Y$  is independent of  $X$ . This claim may seem meaningless but it can be very useful. Imagine a sequence of events  $X_1, X_2, \dots$ . Let  $A_i$  be the event that  $X_i$  is a “record value” (eg it is larger than all previous values). Is  $A_{n+1}$  independent of  $A_n$ ? It is easier to answer that  $A_n$  is independent of  $A_{n+1}$ . By symmetry of independence both claims must be true.
