Fibonacci Heaps
Outline for Today

- **Recap from Last Time**
  - Quick refresher on binomial heaps and lazy binomial heaps.

- **The Need for decrease-key**
  - An important operation in many graph algorithms.

- **Fibonacci Heaps**
  - A data structure efficiently supporting decrease-key.

- **Representational Issues**
  - Some of the challenges in Fibonacci heaps.
Recap from Last Time
(Lazy) Binomial Heaps

- Last time, we covered the *binomial heap* and a variant called the *lazy binomial heap*.
- These are priority queue structures designed to support efficient *melding*.
- Elements are stored in a collection of *binomial trees*.
Draw what happens if we enqueue the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we *enqueue* the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we **enqueue** the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we *enqueue* the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we enqueue the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we **enqueue** the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Eager Binomial Heap

Draw what happens if we enqueue the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.

Lazy Binomial Heap
Draw what happens if we *enqueue* the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we *enqueue* the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we *enqueue* the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we *enqueue* the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we *enqueue* the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we enqueue the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we **enqueue** the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we *enqueue* the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Draw what happens if we *enqueue* the numbers 1, 2, 3, 4, 5, 6, 7, 8, and 9 into each heap.
Eager Binomial Heap

Lazy Binomial Heap

Operation Costs

- Eager Binomial Heap:
  - enqueue: $O(\log n)$
  - meld: $O(\log n)$
  - find-min: $O(\log n)$
  - extract-min: $O(\log n)$

- Lazy Binomial Heap:
  - enqueue: $O(1)$
  - meld: $O(1)$
  - find-min: $O(1)$
  - extract-min: $O(\log n)^*$

*amortized

Intuition: Each extract-min has to do a bunch of cleanup for the earlier enqueue operations, but then leaves us with few trees.
New Stuff!
The Need for *decrease-key*
The *decrease-key* Operation

- Some priority queues support the operation \textit{decrease-key}(v, k), which works as follows:

  \textit{Given a pointer to an element v, lower its key (priority) to k. It is assumed that k is less than the current priority of v.}

- This operation is crucial in efficient implementations of Dijkstra's algorithm and Prim's MST algorithm.
Dijkstra and *decrease-key*

- Dijkstra's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min*es, and
  - $O(m)$ total *decrease-key*es.
Dijkstra and \textit{decrease-key}

- Dijkstra's algorithm can be implemented with a priority queue using
  - $O(n)$ total \textit{enqueue}s,
  - $O(n)$ total \textit{extract-mins}, and
  - $O(m)$ total \textit{decrease-keys}. 

![Graph](image)
Dijkstra and *decrease-key*

- Dijkstra's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min*fs, and
  - $O(m)$ total *decrease-key*fs.
Dijkstra and *decrease-key*

- Dijkstra's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min*es, and
  - $O(m)$ total *decrease-keys*.

![Graph](image-url)
Dijkstra and *decrease-key*

- Dijkstra's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min*s, and
  - $O(m)$ total *decrease-key*s.
Dijkstra's algorithm can be implemented with a priority queue using

- $O(n)$ total \textit{enqueue}s,
- $O(n)$ total \textit{extract-mins}, and
- $O(m)$ total \textit{decrease-keys}.
Dijkstra's algorithm can be implemented with a priority queue using:

- $O(n)$ total enqueue operations,
- $O(n)$ total extract-min operations, and
- $O(m)$ total decrease-key operations.
Dijkstra and *decrease-key*

- Dijkstra's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min*es, and
  - $O(m)$ total *decrease-key*es.
Dijkstra and \textit{decrease-key}

- Dijkstra's algorithm can be implemented with a priority queue using
  - $O(n)$ total \textit{enqueue}s,
  - $O(n)$ total \textit{extract-min}s, and
  - $O(m)$ total \textit{decrease-key}s.
Dijkstra and *decrease-key*

- Dijkstra's algorithm can be implemented with a priority queue using

  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min*es, and
  - $O(m)$ total *decrease-keys*.

![Graph with weights](image-url)
Prim and \textit{decrease-key}

- Prim's algorithm can be implemented with a priority queue using:
  - O($n$) total \textit{enqueue}s,
  - O($n$) total \textit{extract-min}s, and
  - O($m$) total \textit{decrease-key}s.
Prim and *decrease-key*

- Prim's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min* s, and
  - $O(m)$ total *decrease-key* s.
Prim and *decrease-key*

- Prim's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*s,
  - $O(n)$ total *extract-min*s, and
  - $O(m)$ total *decrease-key*s.
Prim and *decrease-key*

- Prim's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min*ns, and
  - $O(m)$ total *decrease-key*ns.
Prim and *decrease-key*

- Prim's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*s,
  - $O(n)$ total *extract-min*s, and
  - $O(m)$ total *decrease-key*s.
Prim and *decrease-key*

- Prim's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min*es, and
  - $O(m)$ total *decrease-key*s.

![Graph Diagram]
Prim and *decrease-key*

- Prim's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min* s, and
  - $O(m)$ total *decrease-key* s.
Prim and **decrease-key**

- Prim's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min*ss, and
  - $O(m)$ total *decrease-key*ss.
Prim and \textit{decrease-key}

- Prim's algorithm can be implemented with a priority queue using:
  - \(O(n)\) total \textit{enqueues},
  - \(O(n)\) total \textit{extract-mins}, and
  - \(O(m)\) total \textit{decrease-keys}.

![Graph](image)
Prim and *decrease-key*

- Prim's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*es,
  - $O(n)$ total *extract-min*ns, and
  - $O(m)$ total *decrease-key*ns.

![Graph with Prim's algorithm example]
Prim and *decrease-key*

- Prim's algorithm can be implemented with a priority queue using
  - $O(n)$ total *enqueue*,
  - $O(n)$ total *extract-mins*, and
  - $O(m)$ total *decrease-keys*.
Prim and **decrease-key**

- Prim's algorithm can be implemented with a priority queue using
  - \(O(n)\) total *enqueue*es,
  - \(O(n)\) total *extract-min* s, and
  - \(O(m)\) total *decrease-key* s.
- Prim's algorithm runtime is
  \[
  O(n T_{\text{enq}} + n T_{\text{ext}} + m T_{\text{dec}})
  \]
Standard Approaches

- In a binary heap, **enqueue**, **extract-min**, and **decrease-key** can be made to work in time $O(\log n)$ time each.

- Cost of Dijkstra's / Prim's algorithm:
  
  $$O(n T_{enq} + n T_{ext} + m T_{dec})$$
  
  $$= O(n \log n + n \log n + m \log n)$$
  
  $$= O(m \log n)$$
Standard Approaches

- In a lazy binomial heap, \textit{enqueue} takes amortized time O(1), and \textit{extract-min} and \textit{decrease-key} take amortized time O(\log n).

- Cost of Dijkstra's / Prim's algorithm:

  \[
  O(n T_{\text{enq}} + n T_{\text{ext}} + m T_{\text{dec}})
  \]

  \[
  = O(n + n \log n + m \log n)
  \]

  \[
  = O(m \log n)
  \]
Where We're Going

- The *Fibonacci heap* has these amortized runtimes:
  - `enqueue`: $O(1)$
  - `extract-min`: $O(\log n)$.  
  - `decrease-key`: $O(1)$.

- Cost of Prim's or Dijkstra's algorithm:
  \[
  O(n \ T_{\text{enq}} + n \ T_{\text{ext}} + m \ T_{\text{dec}})
  \]
  \[
  = O(n + n \log n + m)
  \]
  \[
  = O(m + n \log n)
  \]

- This is theoretically optimal for a comparison-based priority queue in Dijkstra's or Prim's algorithms.
The Challenge of \textit{decrease-key}
How might we implement *decrease-key* in a lazy binomial heap?
How might we implement *decrease-key* in a lazy binomial heap?
How might we implement \textit{decrease-key} in a lazy binomial heap?

*What We Used to Do*

This system assumes we can assign an “order” to each tree. That’s easy with binomial trees. That’s harder with our new trees. What should we do here?

*What We Used to Do*
**Problem:** What do we do in an *extract-min*?

**Idea 1:** A tree has order $k$ if it has $2^k$ nodes.

**Idea 2:** A tree has order $k$ if its root has $k$ children.

**What We Used to Do**
What do we do in an extract-min?

(1) To do a **decrease-key**, cut the node from its parent.
(2) Do **extract-min** as usual, using child count as order.
To do a decrease-key, cut the node from its parent.

Do extract-min as usual, using child count as order.

**Question:** How efficient is this?
Claim: Our trees can end up with very unusual shapes.

Find a series of operations that gives rise to a heap containing a single tree with this shape.
Our trees can end up with very unusual shapes.
Claim: Our trees can end up with very unusual shapes.

1. enqueue $2^k + 1$ nodes.
2. Do an extract-min.
3. Use decrease-key and extract-min to prune the tree.
**Claim:** Because tree shapes aren’t well-constrained, we can force *extract-min* to take amortized time $\Omega(n^{1/2})$.

**Intuition:** *extract-min* is only fast if it compacts nodes into a few trees.

There are $\Theta(n^{1/2})$ trees here. What happens if we repeatedly *enqueue* and *extract-min* a small value?
**Claim:** Because tree shapes aren’t well-constrained, we can force *extract-min* to take amortized time $\Omega(n^{1/2})$.

**Intuition:** *extract-min* is only fast if it compacts nodes into a few trees.

There are $\Theta(n^{1/2})$ trees here. What happens if we repeatedly *enqueue* and *extract-min* a small value?
**Claim:** Because tree shapes aren’t well-constrained, we can force *extract-min* to take amortized time $\Omega(n^{1/2})$.

**Intuition:** *extract-min* is only fast if it compacts nodes into a few trees.

There are $\Theta(n^{1/2})$ trees here. What happens if we repeatedly *enqueue* and *extract-min* a small value?
Intuition: `extract-min` is only fast if it compacts nodes into a few trees.

There are $\Theta(n^{1/2})$ trees here. What happens if we repeatedly `enqueue` and `extract-min` a small value?

CLAIM: Because tree shapes aren’t well-constrained, we can force `extract-min` to take amortized time $\Omega(n^{1/2})$. 

(Do a bunch of work to compact the trees, which doesn’t accomplish anything.)
**Intuition:** *extract-min* is only fast if it compacts nodes into a few trees.

There are $\Theta(n^{1/2})$ trees here. What happens if we repeatedly *enqueue* and *extract-min* a small value?

There are $\Theta(n^{1/2})$ trees here. What happens if we repeatedly *enqueue* and *extract-min* a small value?

Each operation does $\Theta(n^{1/2})$ work, and doesn’t make any future operations any better.
With $n$ nodes, it’s possible to have $\Omega(n^{1/2})$ trees of distinct orders.

**Question:** Why didn’t this happen before?
Binomial tree sizes grow exponentially. With $n$ nodes, we can have at most $O(\log n)$ trees of distinct orders.

**Question:** Why didn’t this happen before?
**Intuition:** Allow trees to get somewhat imbalanced, slowly propagating information to the root.

**Rule:** Nodes can lose at most one child. If a node loses two children, cut it from its parent.

**Goal:** Make tree sizes grow exponentially with order, but still allow for subtrees to be cut out quickly.
**Goal:** Make tree sizes grow exponentially with order, but still allow for subtrees to be cut out quickly.

**Intuition:** Allow trees to get somewhat imbalanced, slowly propagating information to the root.

**Rule:** Nodes can lose at most one child. If a node loses two children, cut it from its parent.

**Question:** Does this guarantee exponential tree size?
Maximally-Damaged Trees

• Here’s a binomial tree of order 4. That is, the root has four children.

• **Question**: Using our marking scheme, how many nodes can we remove without changing the order of the tree?

• Equivalently: how many nodes can we remove without removing any direct children of the root?
Maximally-Damaged Trees
Maximally-Damaged Trees
Maximally-Damaged Trees
Maximally-Damaged Trees

We can't cut any nodes from this tree without making the root node have order 0.
Maximally-Damaged Trees
Maximally-Damaged Trees

We can't cut any of the root's children without decreasing its order.
We can't cut any of the root's children without decreasing its order.

However, we can cut this node, leaving the root node with two children.
Maximally-Damaged Trees
Maximally-Damaged Trees
Maximally-Damaged Trees

As before, we can't cut any of the root's children without decreasing its order.
Maximally-Damaged Trees

As before, we can't cut any of the root's children without decreasing its order.

However, any nodes below the second layer are fair game to be eliminated.
Maximally-Damaged Trees
Maximally-Damaged Trees
Maximally-Damaged Trees
Maximally-Damaged Trees

We can't cut this node without triggering a cascading cut, so we're done.
Maximally-Damaged Trees
Maximally-Damaged Trees
We can start chopping away at these nodes!

\[ \Phi = t + m \]

where

- \( t \) is the number of trees and
- \( m \) is the number of marked nodes.
Idea: Factor the number of marked nodes into our potential to offset the cost of cascading cuts.

\[ \Phi = t + m \]

where

\( t \) is the number of trees and \( m \) is the number of marked nodes.
Factor the number of marked nodes into our potential to offset the cost of cascading cuts.

\[ \Phi = t + m \]

where

- \( t \) is the number of trees and
- \( m \) is the number of marked nodes.

**Idea:** Factor the number of marked nodes into our potential to offset the cost of cascading cuts.
**Idea:** Factor the number of marked nodes into our potential to offset the cost of cascading cuts.

\[ \Phi = t + m \]

where

- \( t \) is the number of trees and
- \( m \) is the number of marked nodes.
\[ \Phi = t + m \]

where

\( t \) is the number of trees and \( m \) is the number of marked nodes.

**Idea:** Factor the number of marked nodes into our potential to offset the cost of cascading cuts.
Idea: Factor the number of marked nodes into our potential to offset the cost of cascading cuts.

\[ \Phi = t + m \]

where

\( t \) is the number of trees and \( m \) is the number of marked nodes.

Idea: Factor the number of marked nodes into our potential to offset the cost of cascading cuts.
**Idea:** Factor the number of marked nodes into our potential to offset the cost of cascading cuts.

\[ \Phi = t + m \]

where

- \( t \) is the number of trees and
- \( m \) is the number of marked nodes.
Idea: Factor the number of marked nodes into our potential to offset the cost of cascading cuts.

$$\Phi = t + m$$

where

$t$ is the number of trees and
$m$ is the number of marked nodes.
\[ \Phi = t + m \]

where

- \( t \) is the number of trees and
- \( m \) is the number of marked nodes.

**Idea:** Factor the number of marked nodes into our potential to offset the cost of cascading cuts.

Suppose this operation did \( C \) total cuts.

Actual cost: \( O(C) \)
\[ \Delta \Phi: +1 \]

Amortized cost: \( O(C) \).

\[ \text{Actual cost: } O(C) \]
\[ \Delta \Phi: +1 \]
\[ \text{Amortized cost: } O(C). \]
Idea 2: Each decrease-key hurts twice: once in a cascading cut, and once in an extract-min.

\[ \Phi = t + m \]

where

\[ t \] is the number of trees and
\[ m \] is the number of marked nodes.
Idea 2: Each *decrease-key* hurts twice: once in a cascading cut, and once in an *extract-min*.

\[ \Phi = t + 2m \]

where

- \( t \) is the number of trees and
- \( m \) is the number of marked nodes.
Idea 2: Each \textit{decrease-key} hurts twice: once in a cascading cut, and once in an \textit{extract-min}.

\[ \Phi = t + 2m \]

where \( t \) is the number of trees and \( m \) is the number of marked nodes.
\[ \Phi = t + 2m \]

where

\( t \) is the number of trees and \( m \) is the number of marked nodes.

**Idea 2:** Each *decrease-key* hurts twice: once in a cascading cut, and once in an *extract-min*. 
**Idea 2:** Each *decrease-key* hurts twice: once in a cascading cut, and once in an *extract-min*.

\[ \Phi = t + 2m \]

*where*

\( t \) is the number of trees and \( m \) is the number of marked nodes.
Idea 2: Each $\text{decrease-key}$ hurts twice: once in a cascading cut, and once in an $\text{extract-min}$. 

$\Phi = t + 2m$

where

$t$ is the number of trees and $m$ is the number of marked nodes.

Actual cost: $O(1)$

$\Delta \Phi: +3.$

Amortized cost: $O(1)$. 
\( \Phi = t + 2m \)

*where*

\( t \) is the number of trees and \( m \) is the number of marked nodes.

**Idea 2:** Each *decrease-key* hurts twice: once in a cascading cut, and once in an *extract-min*. 
Idea 2: Each *decrease-key* hurts twice: once in a cascading cut, and once in an *extract-min*.

\[
\Phi = t + 2m \\
\text{where} \\
t \text{ is the number of trees and} \\
m \text{ is the number of marked nodes.}
\]
**Idea 2:** Each *decrease-key* hurts twice: once in a cascading cut, and once in an *extract-min*.

\[ \Phi = t + 2m \]

*where*

- \( t \) is the number of trees and

\[ \Phi = t + 2m \]

where

\( t \) is the number of trees and \( m \) is the number of marked nodes.
\( \Phi = t + 2m \)

\textit{where}

\( t \) is the number of trees and \( m \) is the number of marked nodes.

\textbf{Idea 2:} Each \textit{decrease-key} hurts twice: once in a cascading cut, and once in an \textit{extract-min}.
Idea 2: Each \textit{decrease-key} hurts twice: once in a cascading cut, and once in an \textit{extract-min}.

\[ \Phi = t + 2m \]

\textit{where}

\( t \) is the number of trees and 
\( m \) is the number of marked nodes.

Actual cost: \( O(C) \)
\( \Delta\Phi: -C + 1 \)
Amortized cost: \( O(1) \).
The Overall Analysis

- Here’s the final scorecard for the Fibonacci heap.
- These are excellent theoretical runtimes. There’s minimal room for improvement!
- Later work made all these operations worst-case efficient at a significant increase in both runtime and intellectual complexity.

<table>

Representation Issues
Representing Trees

• The trees in a Fibonacci heap must be able to do the following:
  • During a merge: Add one tree as a child of the root of another tree.
  • During a cut: Cut a node from its parent in time $O(1)$.

• **Claim**: This is trickier than it looks.

Finding this pointer might take time $\Theta(\log n)$!
The Solution
The Solution

This is going to be weird.

Sorry.
The Solution
The Solution

Each node stores a pointer to its parent.

The children of each node are in a circularly, doubly-linked list.

The parent stores a pointer to an arbitrary child.
The Solution
The Solution
To cut a node from its parent, if it isn't the representative child, just splice it out of its linked list.
The Solution
The Solution
The Solution
The Solution

Diagram:

- A
- B
- C

Connections:
- A to B
- A to C
- B to C

The Solution

If it is the representative, change the parent's representative child to be one of the node's siblings.
Awful Linked Lists

- Trees are stored as follows:
  - Each node stores a pointer to some child.
  - Each node stores a pointer to its parent.
  - Each node is in a circularly-linked list of its siblings.

- The following possible are now possible in time $O(1)$:
  - Cut a node from its parent.
  - Add another child node to a node.
Fibonacci Heap Nodes

- Each node in a Fibonacci heap stores
  - A pointer to its parent.
  - A pointer to the next sibling.
  - A pointer to the previous sibling.
  - A pointer to an arbitrary child.
  - A bit for whether it's marked.
  - Its order.
  - Its key.
  - Its element.
In Practice

• In practice, the constant factors on Fibonacci heaps make it slower than other heaps, except on huge graphs or workflows with tons of decrease-keys.

• Why?
  • Huge memory requirements per node.
  • High constant factors on all operations.
  • Poor locality of reference and caching.
In Theory

• That said, Fibonacci heaps are worth knowing about for several reasons:
  • Clever use of a two-tiered potential function shows up in lots of data structures.
  • Implementation of `decrease-key` forms the basis for many other advanced priority queues.
  • Gives the theoretically optimal comparison-based implementation of Prim's and Dijkstra's algorithms.
More to Explore

• Since the development of Fibonacci heaps, there have been a number of other priority queues with similar runtimes.
  • In 1986, a powerhouse team (Fredman, Sedgewick, Sleator, and Tarjan) invented the **pairing heap**. It’s much simpler than a Fibonacci heap, is fast in practice, but its runtime bounds are unknown!
  • In 2012, Brodal et al. invented the **strict Fibonacci heap**. It has the same time bounds as a Fibonacci heap, but in a *worst-case* rather than *amortized* sense.
  • In 2013, Chan invented the **quake heap**. It matches the asymptotic bounds of a Fibonacci heap but uses a totally different strategy.
• Also interesting to explore: if the weights on the edges in a graph are chosen from a continuous distribution, the expected number of **decrease-key**s in Dijkstra’s algorithm is $O(n \log (m / n))$. That might counsel another heap structure!
Next Time

- **Randomized Data Structures**
  - Doing well on average, broadly speaking.

- **Frequency Estimation**
  - Counting in sublinear space.

- **Count-Min Sketches**
  - A simple, elegant, fast, and widely-used data structure.
