Lecture 2: Making Sequences of Good Decisions Given a Model of the World

Emma Brunskill

CS234 Reinforcement Learning

Spring 2024
In a Markov decision process, a large discount factor $\gamma$ means that short term rewards are much more influential than long term rewards. [Enter your answer in participation poll ]

- True
- False
- Don’t know

Question for today’s lecture (not for poll): Can we construct algorithms for computing decision policies so that we can guarantee with additional computation / iterations, we monotonically improve the decision policy? Do all algorithms satisfy this property?
In a Markov decision process, a large discount factor $\gamma$ means that short term rewards are much more influential than long term rewards. [Enter your answer in the poll]

- True
- False
- Don’t know

False. A large $\gamma$ implies we weigh delayed / long term rewards more. $\gamma = 0$ only values immediate rewards.

Question for today’s lecture (not for poll): Can we construct algorithms for computing decision policies so that we can guarantee with additional computation / iterations, we monotonically improve the decision policy? Do all algorithms satisfy this property?

Yes it is possible! We will see this today. Not all of them do.
Class Tasks and Updates

- Homework 1 out shortly. Due Friday April 12 at 6pm.
- Office hours will start Friday. See Ed for days, times of group and 1:1 office hours, and we will update the calendar on the website with locations shortly.
Today’s Plan

- Last Time:
  - Introduction
  - Components of an agent: model, value, policy
- This Time:
  - Making good decisions given a Markov decision process
- Next Time:
  - Policy evaluation when don’t have a model of how the world works
Today: Given a model of the world

- Markov Processes (last time)
- Markov Reward Processes (MRPs) (continue from last time)
- Markov Decision Processes (MDPs)
- Evaluation and Control in MDPs

\[
\text{dynamics } p(s'|s,a) \\
\text{reward mode}
\]
Return & Value Function

- **Definition of Horizon \((H)\)**
  - Number of time steps in each episode
  - Can be infinite
  - Otherwise called **finite** Markov reward process

- **Definition of Return, \(G_t\) (for a MRP)**
  - Discounted sum of rewards from time step \(t\) to horizon \(H\)

\[
G_t = r_t + \gamma r_{t+1} + \gamma^2 r_{t+2} + \cdots + \gamma^{H-1} r_{t+H-1}
\]

- **Definition of State Value Function, \(V(s)\) (for a MRP)**
  - Expected return from starting in state \(s\)

\[
V(s) = \mathbb{E}[G_t|s_t = s] = \mathbb{E}[r_t + \gamma r_{t+1} + \gamma^2 r_{t+2} + \cdots + \gamma^{H-1} r_{t+H-1}|s_t = s]
\]
Computing the Value of an Infinite Horizon Markov Reward Process

- Markov property provides structure
- MRP value function satisfies

\[ V(s) = R(s) + \gamma \sum_{s' \in S} P(s'|s)V(s') \]

Where:
- **Immediate reward**: \( R(s) \)
- **Discounted sum of future rewards**: \( \gamma \sum_{s' \in S} P(s'|s)V(s') \)
For finite state MRP, we can express $V(s)$ using a matrix equation

$$
\begin{pmatrix}
V(s_1) \\
\vdots \\
V(s_N)
\end{pmatrix}
= 
\begin{pmatrix}
R(s_1) \\
\vdots \\
R(s_N)
\end{pmatrix}
+ \gamma
\begin{pmatrix}
P(s_1|s_1) & \cdots & P(s_N|s_1) \\
P(s_1|s_2) & \cdots & P(s_N|s_2) \\
\vdots & \ddots & \vdots \\
P(s_1|s_N) & \cdots & P(s_N|s_N)
\end{pmatrix}
\begin{pmatrix}
V(s_1) \\
\vdots \\
V(s_N)
\end{pmatrix}
$$

$$
V = R + \gamma PV
$$

$$
V - \gamma PV = R
$$

$$
V (I - \gamma P) = R
$$

$$
V = (I - \gamma P)^{-1} R
$$
For finite state MRP, we can express \( V(s) \) using a matrix equation:

\[
\begin{pmatrix}
V(s_1) \\
\vdots \\
V(s_N)
\end{pmatrix} =
\begin{pmatrix}
R(s_1) \\
\vdots \\
R(s_N)
\end{pmatrix} + \gamma
\begin{pmatrix}
P(s_1|s_1) & \cdots & P(s_N|s_1) \\
P(s_1|s_2) & \cdots & P(s_N|s_2) \\
\vdots & \ddots & \vdots \\
P(s_1|s_N) & \cdots & P(s_N|s_N)
\end{pmatrix}
\begin{pmatrix}
V(s_1) \\
\vdots \\
V(s_N)
\end{pmatrix}
\]

\[
V = R + \gamma PV
\]

\[
V - \gamma PV = R
\]

\[
(I - \gamma P)V = R
\]

\[
V = (I - \gamma P)^{-1} R
\]

Solving directly requires taking a matrix inverse \( \sim O(N^3) \)

Requires that \( (I - \gamma P) \) is invertible
Iterative Algorithm for Computing Value of a MRP

- Dynamic programming
- Initialize $V_0(s) = 0$ for all $s$
- For $k = 1$ until convergence
  - For all $s$ in $S$
    - $V_k(s) = R(s) + \gamma \sum_{s' \in S} P(s'|s) V_{k-1}(s')$

Computational complexity: $O(|S|^2)$ for each iteration ($|S| = N$)
Markov Decision Process (MDP)

- Markov Decision Process is Markov Reward Process + actions

Definition of MDP

- $S$ is a (finite) set of Markov states $s \in S$
- $A$ is a (finite) set of actions $a \in A$
- $P$ is dynamics/transition model for each action, that specifies
  $P(s_{t+1} = s'|s_t = s, a_t = a)$
- $R$ is a reward function
  \[ R(s_t = s, a_t = a) = \mathbb{E}[r_t|s_t = s, a_t = a] \]

- Discount factor $\gamma \in [0, 1]$

- MDP is a tuple: $(S, A, P, R, \gamma)$

---

1Reward is sometimes defined as a function of the current state, or as a function of the (state, action, next state) tuple. Most frequently in this class, we will assume reward is a function of state and action
Example: Mars Rover MDP

2 deterministic actions
Policy specifies what action to take in each state

- Can be deterministic or stochastic

For generality, consider as a conditional distribution

- Given a state, specifies a distribution over actions

Policy: $\pi(a|s) = P(a_t = a|s_t = s)$
MDP + Policy

- MDP + \( \pi(a|s) \) = Markov Reward Process
- Precisely, it is the MRP \((S, R^\pi, P^\pi, \gamma)\), where

\[
R^\pi(s) = \sum_{a \in A} \pi(a|s)R(s, a)
\]

\[
P^\pi(s'|s) = \sum_{a \in A} \pi(a|s)P(s'|s, a)
\]

- Implies we can use same techniques to evaluate the value of a policy for a MDP as we could to compute the value of a MRP, by defining a MRP with \( R^\pi \) and \( P^\pi \)
MDP Policy Evaluation, Iterative Algorithm

- Initialize $V_0(s) = 0$ for all $s$
- For $k = 1$ until convergence
  - For all $s$ in $S$
    - $V_{\pi}^k(s) = \sum_a \pi(a|s) \left[ R(s, a) + \gamma \sum_{s' \in S} p(s'|s, a) V_{\pi}^{k-1}(s') \right]$

This is a **Bellman backup** for a particular policy

- Note that if the policy is deterministic then the above update simplifies to

$$V_{\pi}^k(s) = R(s, \pi(s)) + \gamma \sum_{s' \in S} p(s'|s, \pi(s)) V_{\pi}^{k-1}(s')$$
Exercise L2E1: MDP 1 Iteration of Policy Evaluation, Mars Rover Example

- Dynamics: \( p(s_6|s_6, a_1) = 0.5, p(s_7|s_6, a_1) = 0.5, \ldots \)
- Reward: for all actions, +1 in state \( s_1 \), +10 in state \( s_7 \), 0 otherwise
- Let \( \pi(s) = a_1 \ \forall s \), assume \( V_k = [1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 10] \) and \( k = 1, \gamma = 0.5 \)
- Compute \( V_{k+1}(s_6) \)

See answer at the end of the slide deck. If you’d like practice, work this out and then check your answers.
We will shortly be interested in not just evaluating the value of a single policy, but finding an optimal policy. Given this it is informative to think about properties of the potential policy space.

First for the Mars rover example [7 discrete states (location of rover); 2 actions: Left or Right]

How many deterministic policies are there?

Select answer on the participation poll: 2 / 14 / $7^2$ / $2^7$ / Not sure

Is the optimal policy (one with highest value) for a MDP unique?

Select answer on the participation poll: Yes / No / Not sure
7 discrete states (location of rover)
2 actions: Left or Right
How many deterministic policies are there?
$2^7$

Is the highest reward policy for a MDP always unique? No, there may be two policies with the same (maximal) value function.
Compute the optimal policy

\[ \pi^*(s) = \arg \max_{\pi} V^\pi(s) \]

There exists a unique optimal value function

Optimal policy for a MDP in an infinite horizon problem is deterministic
Compute the optimal policy

\[ \pi^*(s) = \arg \max_\pi V^\pi(s) \]

There exists a unique optimal value function

Optimal policy for a MDP in an infinite horizon problem (agent acts forever is
  
  - Deterministic
  - Stationary (does not depend on time step)
  - Unique? Not necessarily, may have two policies with identical (optimal) values
One option is searching to compute best policy
Number of deterministic policies is $|A|^{|S|}$
Policy iteration is generally more efficient than enumeration
Set $i = 0$

Initialize $\pi_0(s)$ randomly for all states $s$

While $i == 0$ or $\|\pi_i - \pi_{i-1}\|_1 > 0$ (L1-norm, measures if the policy changed for any state):

- $V^{\pi_i} \leftarrow$ MDP V function policy evaluation of $\pi_i$
- $\pi_{i+1} \leftarrow$ Policy improvement
- $i = i + 1$
New Definition: State-Action Value $Q$

- State-action value of a policy

$$Q^\pi(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a) V^\pi(s')$$

- Take action $a$, then follow the policy $\pi$
Compute state-action value of a policy $\pi_i$

For $s$ in $S$ and $a$ in $A$:

$$Q^{\pi_i}(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V^{\pi_i}(s')$$

Compute new policy $\pi_{i+1}$, for all $s \in S$

$$\pi_{i+1}(s) = \arg \max_a Q^{\pi_i}(s, a) \quad \forall s \in S$$

if $\pi_i = \pi_{i+1}$ then $Q^{\pi_i} = Q^{\pi_{i+1}}$
Set $i = 0$

Initialize $\pi_0(s)$ randomly for all states $s$

While $i == 0$ or $\|\pi_i - \pi_{i-1}\|_1 > 0$ (L1-norm, measures if the policy changed for any state):

- $V^{\pi_i} \leftarrow$ MDP V function policy evaluation of $\pi_i$
- $\pi_{i+1} \leftarrow$ Policy improvement
- $i = i + 1$

$$\pi_{i+1}(s) = \arg\max_a Q(s, a)$$
Delving Deeper Into Policy Improvement Step

\[ Q^{\pi_i}(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a) V^{\pi_i}(s') \]
Delving Deeper Into Policy Improvement Step

\[ Q^{\pi_i}(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V^{\pi_i}(s') \]

\[ \max_a Q^{\pi_i}(s, a) \geq R(s, \pi_i(s)) + \gamma \sum_{s' \in S} P(s'|s, \pi_i(s)) V^{\pi_i}(s') = V^{\pi_i}(s) \]

\[ \pi_{i+1}(s) = \arg \max_a Q^{\pi_i}(s, a) \]

- Suppose we take \( \pi_{i+1}(s) \) for one action, then follow \( \pi_i \) forever
  - Our expected sum of rewards is at least as good as if we had always followed \( \pi_i \)
- But new proposed policy is to always follow \( \pi_{i+1} \) ...
Monotonic Improvement in Policy

- **Definition**
  \[ V^{\pi_1} \geq V^{\pi_2} : V^{\pi_1}(s) \geq V^{\pi_2}(s), \forall s \in S \]

- **Proposition:** \( V^{\pi_{i+1}} \geq V^{\pi_i} \) with strict inequality if \( \pi_i \) is suboptimal, where \( \pi_{i+1} \) is the new policy we get from policy improvement on \( \pi_i \).
Proof: Monotonic Improvement in Policy

\[ V^\pi_i(s) \leq \max_a Q^\pi_i(s, a) \]

\[ = \max_a R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a) V^\pi_i(s') \]

\[ = R(s, \pi_i(s)) + \gamma \sum_s P(s' | s, \pi_i(s)) \max_{a'} Q^\pi_i(s', a') \]

\[ = R(s, \pi_i(s)) + \gamma \sum_{s'} P(s' | s, \pi_i(s)) \max_{a'} Q^\pi_i(s', a') \]

\[ = V^{\pi_{i+1}}(s) \]
Proof: Monotonic Improvement in Policy

\[ V^{\pi_i}(s) \leq \max_a Q^{\pi_i}(s, a) \]

\[ = \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V^{\pi_i}(s') \]

\[ = R(s, \pi_{i+1}(s)) + \gamma \sum_{s' \in S} P(s'|s, \pi_{i+1}(s))V^{\pi_i}(s') \quad \text{by the definition of } \pi_{i+1} \]

\[ \leq R(s, \pi_{i+1}(s)) + \gamma \sum_{s' \in S} P(s'|s, \pi_{i+1}(s)) \left( \max_{a'} Q^{\pi_i}(s', a') \right) \]

\[ = R(s, \pi_{i+1}(s)) + \gamma \sum_{s' \in S} P(s'|s, \pi_{i+1}(s)) \left( R(s', \pi_{i+1}(s')) + \gamma \sum_{s'' \in S} P(s''|s', \pi_{i+1}(s'))V^{\pi_i}(s'') \right) \]

\[ \vdots \]

\[ = V^{\pi_{i+1}}(s) \]
Check Your Understanding L2N3: Policy Iteration (PI)

Note: all the below is for finite state-action spaces

Set \( i = 0 \)

Initialize \( \pi_0(s) \) randomly for all states \( s \)

While \( i == 0 \) or \( \|\pi_i - \pi_{i-1}\|_1 > 0 \) (L1-norm, measures if the policy changed for any state):

- \( V^{\pi_i} \leftarrow \text{MDP V function policy evaluation of } \pi_i \)
- \( \pi_{i+1} \leftarrow \text{Policy improvement} \)
- \( i = i + 1 \)

If policy doesn’t change, can it ever change again?

Select on participation poll: Yes / No / Not sure

Is there a maximum number of iterations of policy iteration?

Select on participation poll: Yes / No / Not sure
Results for Check Your Understanding L2N3 Policy Iteration

- Note: all the below is for finite state-action spaces
- Set $i = 0$
- Initialize $\pi_0(s)$ randomly for all states $s$
- While $i == 0$ or $\|\pi_i - \pi_{i-1}\|_1 > 0$ (L1-norm, measures if the policy changed for any state):
  - $V^{\pi_i} \leftarrow$ MDP V function policy evaluation of $\pi_i$
  - $\pi_{i+1} \leftarrow$ Policy improvement
  - $i = i + 1$

- If policy doesn’t change, can it ever change again?
  No

- Is there a maximum number of iterations of policy iteration?
  $|A|^{|S|}$ since that is the maximum number of policies, and as the policy improvement step is monotonically improving, each policy can only appear in one round of policy iteration unless it is an optimal policy.
Suppose for all \( s \in S \), \( \pi_{i+1}(s) = \pi_i(s) \)

Then for all \( s \in S \), \( Q^{\pi_{i+1}}(s, a) = Q^{\pi_i}(s, a) \)

Recall policy improvement step

\[
Q^{\pi_i}(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V^{\pi_i}(s')
\]

\[
\pi_{i+1}(s) = \arg\max_a Q^{\pi_i}(s, a)
\]

\[
\pi_{i+2}(s) = \arg\max_a Q^{\pi_{i+1}}(s, a) = \arg\max_a Q^{\pi_i}(s, a)
\]

Therefore policy cannot ever change again

(assuming \( \pi^* \) is unique per \( s \))
Policy iteration computes infinite horizon value of a policy and then improves that policy.

Value iteration is another technique:
- Idea: Maintain optimal value of starting in a state $s$ if have a finite number of steps $k$ left in the episode.
- Iterate to consider longer and longer episodes.
Bellman Equation and Bellman Backup Operators

- Value function of a policy must satisfy the Bellman equation

\[ V^\pi(s) = R^\pi(s) + \gamma \sum_{s' \in S} P^\pi(s'|s)V^\pi(s') \]

- Bellman backup operator
  - Applied to a value function
  - Returns a new value function
  - Improves the value if possible

\[ BV(s) = \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} p(s'|s, a)V(s') \right] \]

- \( BV \) yields a value function over all states \( s \)
Value Iteration (VI)

- Set $k = 1$
- Initialize $V_0(s) = 0$ for all states $s$
- Loop until convergence: (for ex. $\|V_{k+1} - V_k\|_\infty \leq \epsilon$)
  - For each state $s$
    \[
    V_{k+1}(s) = \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a) V_k(s') \right]
    \]
  - View as Bellman backup on value function
    \[
    V = 0 \forall s \\
    V_{k+1}(s) = \max_a r(s, a) \\
    V_{k+1} = BV_k
    \]
    \[
    \pi_{k+1}(s) = \arg \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a) V_k(s') \right]
    \]
Bellman backup operator $B^\pi$ for a particular policy is defined as

$$B^\pi V(s) = R^\pi(s) + \gamma \sum_{s' \in S} P^\pi(s'|s)V(s')$$

Policy evaluation amounts to computing the fixed point of $B^\pi$

To do policy evaluation, repeatedly apply operator until $V$ stops changing

$$V^\pi = B^\pi B^\pi \cdots B^\pi V$$
Policy Iteration as Bellman Operations

- Bellman backup operator $B^\pi$ for a particular policy is defined as
  \[ B^\pi V(s) = R^\pi(s) + \gamma \sum_{s' \in S} P^\pi(s'|s)V(s') \]

- To do policy improvement
  \[ \pi_{k+1}(s) = \arg \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V^{\pi_k}(s') \right] \]
Going Back to Value Iteration (VI)

- Set $k = 1$
- Initialize $V_0(s) = 0$ for all states $s$
- Loop until convergence: (for ex. $\|V_{k+1} - V_k\|_\infty \leq \epsilon$)
  - For each state $s$
    $$V_{k+1}(s) = \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s') \right]$$
  - Equivalently, in Bellman backup notation
    $$V_{k+1} = BV_k$$
- To extract optimal policy if can act for $k + 1$ more steps,
  $$\pi(s) = \arg \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_{k+1}(s') \right]$$
Let $O$ be an operator, and $|x|$ denote (any) norm of $x$

If $|OV - OV'| \leq |V - V'|$, then $O$ is a contraction operator
Yes, if discount factor $\gamma < 1$, or end up in a terminal state with probability 1

Bellman backup is a contraction if discount factor, $\gamma < 1$

If apply it to two different value functions, distance between value functions shrinks after applying Bellman equation to each
Proof: Bellman Backup is a Contraction on $V$ for $\gamma < 1$

Let $\| V - V' \| = \max_s |V(s) - V'(s)|$ be the infinity norm.

$$\| BV_k - BV_j \| = \max_a \left( R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s') \right) - \max_{a'} \left( R(s, a') + \gamma \sum_{s' \in S} P(s'|s, a') V_j(s') \right)$$

$$= \max_a \gamma \| E_s, P(s'|s, a) (V_k(s') - V_j(s')) \|$$

$$= \max_a \gamma \| V_k - V_j \|$$

$$= \gamma \| V_k - V_j \|$$

$$= \gamma \| V_{k-1} - V_j \|$$

$$\vdots$$

$$V_0 \rightarrow V_1 \rightarrow V_2 \rightarrow V_3 \rightarrow V_4 \rightarrow \ldots$$
Proof: Bellman Backup is a Contraction on $V$ for $\gamma < 1$

Let $\|V - V'\| = \max_s |V(s) - V'(s)|$ be the infinity norm

\[\|BV_k - BV_j\| = \max_a \left( R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a)V_k(s') \right) - \max_{a'} \left( R(s, a') + \gamma \sum_{s' \in S} P(s' | s, a')V_j(s') \right) \]

\[\leq \max_a \left( R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a)V_k(s') - R(s, a) - \gamma \sum_{s' \in S} P(s' | s, a)V_j(s') \right) \]

\[= \max_a \gamma \sum_{s' \in S} P(s' | s, a)(V_k(s') - V_j(s')) \]

\[\leq \max_a \gamma \sum_{s' \in S} P(s' | s, a)\|V_k - V_j\| \]

\[= \max_a \gamma \|V_k - V_j\| \sum_{s' \in S} P(s' | s, a) \]

\[= \gamma \|V_k - V_j\| \]

Note: Even if all inequalities are equalities, this is still a contraction if $\gamma < 1$
Prove value iteration converges to a unique solution for discrete state and action spaces with $\gamma < 1$

Does the initialization of values in value iteration impact anything?

Is the value of the policy extracted from value iteration at each round guaranteed to monotonically improve (if executed in the real infinite horizon problem), like policy iteration?
Value Iteration for Finite Horizon $H$

$V_k = \text{optimal value if making } k \text{ more decisions}$

$\pi_k = \text{optimal policy if making } k \text{ more decisions}$

- Initialize $V_0(s) = 0$ for all states $s$
- For $k = 1 : H$
  - For each state $s$
    
    $$V_{k+1}(s) = \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V_k(s') \right]$$

    $$\pi_{k+1}(s) = \arg \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V_k(s') \right]$$
Alternatively can estimate by simulation
- Generate a large number of episodes
- Average returns
- Concentration inequalities bound how quickly average concentrates to expected value
- Requires no assumption of Markov structure
Example: Mars Rover

<table>

- Reward: +1 in $s_1$, +10 in $s_7$, 0 in all other states
- Sample returns for sample 4-step ($H=4$) episodes, $\gamma = 1/2$
  - $s_4, s_5, s_6, s_7$: $0 + \frac{1}{2} \times 0 + \frac{1}{4} \times 0 + \frac{1}{8} \times 10 = 1.25$
Example: Mars Rover

Reward: +1 in $s_1$, +10 in $s_7$, 0 in all other states

Sample returns for sample 4-step ($H=4$) episodes, start state $s_4$, $\gamma = 1/2$

- $s_4, s_5, s_6, s_7$: $0 + \frac{1}{2} \times 0 + \frac{1}{4} \times 0 + \frac{1}{8} \times 10 = 1.25$
- $s_4, s_4, s_5, s_4$: $0 + \frac{1}{2} \times 0 + \frac{1}{4} \times 0 + \frac{1}{8} \times 0 = 0$
- $s_4, s_3, s_2, s_1$: $0 + \frac{1}{2} \times 0 + \frac{1}{4} \times 0 + \frac{1}{8} \times 1 = 0.125$
Question: Finite Horizon Policies

- Set $k = 1$
- Initialize $V_0(s) = 0$ for all states $s$
- Loop until $k == H$:
  - For each state $s$
    \[
    V_{k+1}(s) = \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s')
    \]
    \[
    \pi_{k+1}(s) = \arg \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s')
    \]

Is optimal policy stationary (independent of time step) in finite horizon tasks?
Set $k = 1$

Initialize $V_0(s) = 0$ for all states $s$

Loop until $k == H$:
  - For each state $s$

$$V_{k+1}(s) = \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s')$$

$$\pi_{k+1}(s) = \arg \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s')$$

Is optimal policy stationary (independent of time step) in finite horizon tasks?
In general no.
Value vs Policy Iteration

- **Value iteration:**
  - Compute optimal value for horizon $= k$
    - Note this can be used to compute optimal policy if horizon $= k$
  - Increment $k$

- **Policy iteration**
  - Compute infinite horizon value of a policy
  - Use to select another (better) policy
  - Closely related to a very popular method in RL: policy gradient
RL Terminology: Models, Policies, Values

- **Model**: Mathematical models of dynamics and reward
- **Policy**: Function mapping states to actions
- **Value function**: future rewards from being in a state and/or action when following a particular policy
What You Should Know

- Define MP, MRP, MDP, Bellman operator, contraction, model, Q-value, policy
- Be able to implement
  - Value Iteration
  - Policy Iteration
- Give pros and cons of different policy evaluation approaches
- Be able to prove contraction properties
- Limitations of presented approaches and Markov assumptions
  - Which policy evaluation methods require the Markov assumption?
Where We Are

- **Last Time:**
  - Introduction
  - Components of an agent: model, value, policy
- **This Time:**
  - Making good decisions given a Markov decision process
- **Next Time:**
  - Policy evaluation when don’t have a model of how the world works
Dynamics: \( p(s_6|s_6, a_1) = 0.5, \ p(s_7|s_6, a_1) = 0.5, \ldots \)

Reward: for all actions, +1 in state \( s_1 \), +10 in state \( s_7 \), 0 otherwise

Let \( \pi(s) = a_1 \ \forall s \), assume \( V_k = [1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 10] \) and \( k = 1, \gamma = 0.5 \)

Compute \( V_{k+1}(s_6) \)

\[
V_{k+1}(s_6) = r(s_6) + \gamma \sum_{s'} p(s'|s_6, a_1) V_k(s')
\]

\[
= 0 + 0.5 \times (0.5 \times 10 + 0.5 \times 0)
\]

\[
= 2.5
\]
Check Your Understanding L2N1: MDP 1 Iteration of Policy Evaluation, Mars Rover Example

- Dynamics: \( p(s_6|s_6, a_1) = 0.5, p(s_7|s_6, a_1) = 0.5, \ldots \)
- Reward: for all actions, +1 in state \( s_1 \), +10 in state \( s_7 \), 0 otherwise
- Let \( \pi(s) = a_1 \ \forall s \), assume \( V_k = [1\ 0\ 0\ 0\ 0\ 0\ 10] \) and \( k = 1, \gamma = 0.5 \)

\[
V_k^\pi(s) = r(s, \pi(s)) + \gamma \sum_{s' \in S} p(s'|s, \pi(s)) V_{k-1}^\pi(s')
\]

\[
V_{k+1}(s_6) = r(s_6, a_1) + \gamma * 0.5 * V_k(s_6) + \gamma * 0.5 * V_k(s_7)
\]

\[
V_{k+1}(s_6) = 0 + 0.5 * 0.5 * 0 + .5 * 0.5 * 10
\]

\[
V_{k+1}(s_6) = 2.5
\]
MDPs can model a huge number of interesting problems and settings

- Bandits: single state MDP
- Optimal control mostly about continuous-state MDPs
- Partially observable MDPs = MDP where state is history
Recall: Markov Property

- Information state: sufficient statistic of history
- State $s_t$ is Markov if and only if:
  \[ p(s_{t+1}|s_t, a_t) = p(s_{t+1}|h_t, a_t) \]
- Future is independent of past given present
Markov Process or Markov Chain

- Memoryless random process
  - Sequence of random states with Markov property

- Definition of Markov Process
  - $S$ is a (finite) set of states ($s \in S$)
  - $P$ is dynamics/transition model that specifies $p(s_{t+1} = s' | s_t = s)$

- Note: no rewards, no actions

- If finite number ($N$) of states, can express $P$ as a matrix

\[
P = \begin{pmatrix}
P(s_1 | s_1) & P(s_2 | s_1) & \cdots & P(s_N | s_1) \\
P(s_1 | s_2) & P(s_2 | s_2) & \cdots & P(s_N | s_2) \\
\vdots & \vdots & \ddots & \vdots \\
P(s_1 | s_N) & P(s_2 | s_N) & \cdots & P(s_N | s_N)
\end{pmatrix}
\]
Example: Mars Rover Markov Chain Transition Matrix, $P$

\[
P = \begin{pmatrix}
0.6 & 0.4 & 0 & 0 & 0 & 0 & 0 & 0 \\
0.4 & 0.2 & 0.4 & 0 & 0 & 0 & 0 & 0 \\
0 & 0.4 & 0.2 & 0.4 & 0 & 0 & 0 & 0 \\
0 & 0 & 0.4 & 0.2 & 0.4 & 0 & 0 & 0 \\
0 & 0 & 0 & 0.4 & 0.2 & 0.4 & 0 & 0 \\
0 & 0 & 0 & 0 & 0.4 & 0.2 & 0.4 & 0 \\
0 & 0 & 0 & 0 & 0 & 0.4 & 0.2 & 0.4 \\
0 & 0 & 0 & 0 & 0 & 0 & 0.4 & 0.6
\end{pmatrix}
\]
Example: Mars Rover Markov Chain Episodes

Example: Sample episodes starting from $S_4$

- $S_4, S_5, S_6, S_7, S_7, \ldots$
- $S_4, S_4, S_5, S_4, S_5, S_6, \ldots$
- $S_4, S_3, S_2, S_1, \ldots$
Markov Reward Process (MRP)

- Markov Reward Process is a Markov Chain + rewards
- Definition of Markov Reward Process (MRP)
  - $S$ is a (finite) set of states ($s \in S$)
  - $P$ is dynamics/transition model that specifies $P(s_{t+1} = s'|s_t = s)$
  - $R$ is a reward function $R(s_t = s) = \mathbb{E}[r_t|s_t = s]$
  - Discount factor $\gamma \in [0, 1]$

- Note: no actions
- If finite number ($N$) of states, can express $R$ as a vector
Example: Mars Rover MRP

Reward: +1 in $s_1$, +10 in $s_7$, 0 in all other states
