Lecture 2: Making Sequences of Good Decisions Given a Model of the World

Emma Brunskill

CS234 Reinforcement Learning

Winter 2022
In a Markov decision process, a large discount factor $\gamma$ means that short term rewards are much more influential than long term rewards. [Enter your answer in participation poll ]

- True
- False
- Don’t know
In a Markov decision process, a large discount factor $\gamma$ means that short term rewards are much more influential than long term rewards. [Enter your answer in the poll]

- True
- False
- Don’t know

False. A large $\gamma$ implies we weigh delayed / long term rewards more. $\gamma = 0$ only values immediate rewards.
Class Tasks and Updates

- Quiz 0 due Friday at 6pm Stanford time
- Homework 1 out today. Due Friday January 14 at 6pm Stanford time
- Office hours have started. See Ed for days, times of group and 1:1 office hours!
Today’s Plan

- Last Time:
  - Introduction
  - Components of an agent: model, value, policy

- This Time:
  - Making good decisions given a Markov decision process

- Next Time:
  - Policy evaluation when don’t have a model of how the world works
Models, Policies, Values

- **Model**: Mathematical models of dynamics and reward
- **Policy**: Function mapping states to actions $\pi : S \rightarrow A$
- **Value function**: future rewards from being in a state and/or action when following a particular policy
Today: Given a model of the world

- Markov Processes
- Markov Reward Processes (MRPs)
- Markov Decision Processes (MDPs)
- Evaluation and Control in MDPs
MDPs can model a huge number of interesting problems and settings
- Bandits: single state MDP
- Optimal control mostly about continuous-state MDPs
- Partially observable MDPs = MDP where state is history
Recall: Markov Property

- Information state: sufficient statistic of history
- State $s_t$ is Markov if and only if:
  $$p(s_{t+1}|s_t, a_t) = p(s_{t+1}|h_t, a_t)$$
- Future is independent of past given present
Markov Process or Markov Chain

- Memoryless random process
  - Sequence of random states with Markov property
- Definition of Markov Process
  - $S$ is a (finite) set of states ($s \in S$)
  - $P$ is dynamics/transition model that specifies $p(s_{t+1} = s' | s_t = s)$
- Note: no rewards, no actions
- If finite number ($N$) of states, can express $P$ as a matrix

$$P = \begin{pmatrix}
  P(s_1 | s_1) & P(s_2 | s_1) & \cdots & P(s_N | s_1) \\
  P(s_1 | s_2) & P(s_2 | s_2) & \cdots & P(s_N | s_2) \\
  \vdots & \vdots & \ddots & \vdots \\
  P(s_1 | s_N) & P(s_2 | s_N) & \cdots & P(s_N | s_N)
\end{pmatrix}$$
Example: Mars Rover Markov Chain Transition Matrix, \( P \)

\[
P = \begin{pmatrix}
0.6 & 0.4 & 0 & 0 & 0 & 0 & 0 & 0 \\
0.4 & 0.2 & 0.4 & 0 & 0 & 0 & 0 & 0 \\
0 & 0.4 & 0.2 & 0.4 & 0 & 0 & 0 & 0 \\
0 & 0 & 0.4 & 0.2 & 0.4 & 0 & 0 & 0 \\
0 & 0 & 0 & 0.4 & 0.2 & 0.4 & 0 & 0 \\
0 & 0 & 0 & 0 & 0.4 & 0.2 & 0.4 & 0 \\
0 & 0 & 0 & 0 & 0 & 0.4 & 0.2 & 0.4 \\
0 & 0 & 0 & 0 & 0 & 0 & 0.4 & 0.6
\end{pmatrix}
\]
### Example: Mars Rover Markov Chain Episodes

<table>
<thead>
<tr>
<th>$S_1$</th>
<th>$S_2$</th>
<th>$S_3$</th>
<th>$S_4$</th>
<th>$S_5$</th>
<th>$S_6$</th>
<th>$S_7$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.4</td>
<td>0.4</td>
<td>0.4</td>
<td>0.4</td>
<td>0.4</td>
<td>0.4</td>
<td>0.4</td>
</tr>
<tr>
<td>0.4</td>
<td>0.4</td>
<td>0.4</td>
<td>0.4</td>
<td>0.4</td>
<td>0.4</td>
<td>0.4</td>
</tr>
</tbody>
</table>

Example: Sample episodes starting from $S_4$

- $s_4, s_5, s_6, s_7, s_7, \ldots$
- $s_4, s_4, s_5, s_4, s_5, s_6, \ldots$
- $s_4, s_3, s_2, s_1, \ldots$
Markov Reward Process (MRP)

- Markov Reward Process is a Markov Chain + rewards
- Definition of Markov Reward Process (MRP)
  - $S$ is a (finite) set of states ($s \in S$)
  - $P$ is dynamics/transition model that specifies $P(s_{t+1} = s'|s_t = s)$
  - $R$ is a reward function $R(s_t = s) = \mathbb{E}[r_t|s_t = s]$
  - Discount factor $\gamma \in [0, 1]$
- Note: no actions
- If finite number ($N$) of states, can express $R$ as a vector
Example: Mars Rover MRP

Reward: +1 in $s_1$, +10 in $s_7$, 0 in all other states

$$R = [+1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 10]$$
Definition of Horizon \((H)\)
- Number of time steps in each episode
- Can be infinite
- Otherwise called \textit{finite} Markov reward process

Definition of Return, \(G_t\) (for a MRP)
- Discounted sum of rewards from time step \(t\) to horizon \(H\)

\[
G_t = r_t + \gamma r_{t+1} + \gamma^2 r_{t+2} + \cdots + \gamma^{H-1} r_{t+H-1}
\]

Definition of State Value Function, \(V(s)\) (for a MRP)
- Expected return from starting in state \(s\)

\[
V(s) = \mathbb{E}[G_t|s_t = s] = \mathbb{E}[r_t + \gamma r_{t+1} + \gamma^2 r_{t+2} + \cdots + \gamma^{H-1} r_{t+H-1}|s_t = s]
\]
Discount Factor

- Mathematically convenient (avoid infinite returns and values)
- Humans often act as if there’s a discount factor $\gamma < 1$
- $\gamma = 0$: Only care about immediate reward
- $\gamma = 1$: Future reward is as beneficial as immediate reward
- If episode lengths are always finite ($H < \infty$), can use $\gamma = 1$
Markov property provides structure
MRP value function satisfies

\[ V(s) = R(s) + \gamma \sum_{s' \in S} P(s'|s) V(s') \]

Immediate reward
Discounted sum of future rewards
For finite state MRP, we can express $V(s)$ using a matrix equation:

$$
\begin{pmatrix}
V(s_1) \\
\vdots \\
V(s_N)
\end{pmatrix}
= 
\begin{pmatrix}
R(s_1) \\
\vdots \\
R(s_N)
\end{pmatrix}
+ \gamma 
\begin{pmatrix}
P(s_1|s_1) & \cdots & P(s_N|s_1) \\
P(s_1|s_2) & \cdots & P(s_N|s_2) \\
\vdots & \ddots & \vdots \\
P(s_1|s_N) & \cdots & P(s_N|s_N)
\end{pmatrix}
\begin{pmatrix}
V(s_1) \\
\vdots \\
V(s_N)
\end{pmatrix}
$$

$$
V = R + \gamma P V
$$

$$
V - \gamma P V = R
$$

$$
(I - \gamma P) V = R
$$

$$
V = (I - \gamma P)^{-1} R
$$
For finite state MRP, we can express \( V(s) \) using a matrix equation

\[
\begin{pmatrix}
V(s_1) \\
\vdots \\
V(s_N)
\end{pmatrix} =
\begin{pmatrix}
R(s_1) \\
\vdots \\
R(s_N)
\end{pmatrix} + \gamma
\begin{pmatrix}
P(s_1|s_1) & \cdots & P(s_N|s_1) \\
P(s_1|s_2) & \cdots & P(s_N|s_2) \\
\vdots & \ddots & \vdots \\
P(s_1|s_N) & \cdots & P(s_N|s_N)
\end{pmatrix}
\begin{pmatrix}
V(s_1) \\
\vdots \\
V(s_N)
\end{pmatrix}
\]

\[
V = R + \gamma PV
\]

\[
V - \gamma PV = R
\]

\[
(I - \gamma P)V = R
\]

\[
V = (I - \gamma P)^{-1}R
\]

- Solving directly requires taking a matrix inverse \( \sim O(N^3) \)
- Note that \( (I - \gamma P) \) is invertible
Iterative Algorithm for Computing Value of a MRP

- Dynamic programming
- Initialize $V_0(s) = 0$ for all $s$
- For $k = 1$ until convergence
  - For all $s$ in $S$
    
    $$V_k(s) = R(s) + \gamma \sum_{s' \in S} P(s'|s) V_{k-1}(s')$$

- Computational complexity: $O(|S|^2)$ for each iteration ($|S| = N$)
Markov Decision Process (MDP)

- Markov Decision Process is Markov Reward Process + actions
- Definition of MDP
  - $S$ is a (finite) set of Markov states $s \in S$
  - $A$ is a (finite) set of actions $a \in A$
  - $P$ is dynamics/transition model for each action, that specifies $P(s_{t+1} = s' | s_t = s, a_t = a)$
  - $R$ is a reward function
    $$ R(s_t = s, a_t = a) = \mathbb{E}[r_t | s_t = s, a_t = a] $$
    - Discount factor $\gamma \in [0, 1]$
  - MDP is a tuple: $(S, A, P, R, \gamma)$

---

1Reward is sometimes defined as a function of the current state, or as a function of the (state, action, next state) tuple. Most frequently in this class, we will assume reward is a function of state and action
Example: Mars Rover MDP

<table>
<thead>
<tr>
<th>$S_1$</th>
<th>$S_2$</th>
<th>$S_3$</th>
<th>$S_4$</th>
<th>$S_5$</th>
<th>$S_6$</th>
<th>$S_7$</th>
</tr>
</thead>
</table>

$P(s'|s, a_1) = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix}$

$P(s'|s, a_2) = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}$

- 2 deterministic actions
MDP Policies

- Policy specifies what action to take in each state
  - Can be deterministic or stochastic
- For generality, consider as a conditional distribution
  - Given a state, specifies a distribution over actions
- Policy: $\pi(a|s) = P(a_t = a|s_t = s)$

\[ \text{deterministic } S \rightarrow A \]
MDP + Policy

- MDP + \( \pi(a|s) \) = Markov Reward Process

- Precisely, it is the MRP \((S, R^\pi, P^\pi, \gamma)\), where

\[
R^\pi(s) = \sum_{a \in A} \pi(a|s) R(s,a)
\]

\[
P^\pi(s'|s) = \sum_{a \in A} \pi(a|s) P(s'|s, a)
\]

- Implies we can use same techniques to evaluate the value of a policy for a MDP as we could to compute the value of a MRP, by defining a MRP with \( R^\pi \) and \( P^\pi \)
MDP Policy Evaluation, Iterative Algorithm

- Initialize $V_0(s) = 0$ for all $s$
- For $k = 1$ until convergence
  - For all $s$ in $S$

$$V^\pi_k(s) = \sum_a \pi(a|s) \left[ r(s,a) + \gamma \sum_{s' \in S} p(s'|s,a) V^\pi_{k-1}(s') \right]$$

- This is a **Bellman backup** for a particular policy
- Note that if the policy is deterministic then the above update simplifies to

$$V^\pi_k(s) = r(s, \pi(s)) + \gamma \sum_{s' \in S} p(s'|s, \pi(s)) V^\pi_{k-1}(s')$$
Dynamics: $p(s_6 | s_6, a_1) = 0.5$, $p(s_7 | s_6, a_1) = 0.5$, ...

Reward: for all actions, +1 in state $s_1$, +10 in state $s_7$, 0 otherwise

Let $\pi(s) = a_1 \forall s$, assume $V_k = [1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 10]$ and $k = 1$, $\gamma = 0.5$

Compute $V_{k+1}(s_6)$

Select answer on participation poll:

- 0
- 2.5
- 10
- I don’t know
We will shortly be interested in not just evaluating the value of a single policy, but finding an optimal policy. Given this it is informative to think about properties of the potential policy space.

First for the Mars rover example [7 discrete states (location of rover); 2 actions: Left or Right]

- How many deterministic policies are there?
- Select answer on the participation poll: 2 / 14 / $2^2$ / $2^7$ / Not sure
- Is the optimal policy (one with highest value) for a MDP unique?
- Select answer on the participation poll: Yes / No / Not sure
Lecture Break

- At start of next module section will go through check your understanding results and discuss MDP control
Check Your Understanding L2N1: MDP 1 Iteration of Policy Evaluation, Mars Rover Example

- **Dynamics:** \( p(s_6|s_6, a_1) = 0.5, p(s_7|s_6, a_1) = 0.5, \ldots \)
- **Reward:** for all actions, +1 in state \( s_1 \), +10 in state \( s_7 \), 0 otherwise
- Let \( \pi(s) = a_1 \ \forall s \), assume \( V_k = [1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 10] \) and \( k = 1, \gamma = 0.5 \)

\[
V_k^\pi(s) = r(s, \pi(s)) + \gamma \sum_{s' \in S} p(s'|s, \pi(s)) V_k^\pi(s')
\]

\[
V_{k+1}(s_6) = r(s_6, a_1) + \gamma * 0.5 * V_k(s_6) + \gamma * 0.5 * V_k(s_7)
\]

\[
V_{k+1}(s_6) = 0 + 0.5 * 0.5 * 0 + .5 * 0.5 * 10
\]

\[
V_{k+1}(s_6) = 2.5
\]
7 discrete states (location of rover)
2 actions: Left or Right
How many deterministic policies are there? \(2^7\)
Is the highest reward policy for a MDP always unique? No, there may be two policies with the same (maximal) value function.
MDP Control

- Compute the optimal policy
  \[ \pi^*(s) = \arg \max_{\pi} V^\pi(s) \]
- There exists a unique optimal value function
- Optimal policy for a MDP in an infinite horizon problem is deterministic
Compute the optimal policy

$$\pi^*(s) = \arg \max_{\pi} V^\pi(s)$$

There exists a unique optimal value function

Optimal policy for a MDP in an infinite horizon problem (agent acts forever) is

- Deterministic
- Stationary (does not depend on time step)
- Unique? Not necessarily, may have two policies with identical (optimal) values
One option is searching to compute best policy

- Number of deterministic policies is $|A|^{|S|}$

- Policy iteration is generally more efficient than enumeration
MDP Policy Iteration (PI)

- Set $i = 0$
- Initialize $\pi_0(s)$ randomly for all states $s$
- While $i == 0$ or $\|\pi_i - \pi_{i-1}\|_1 > 0$ (L1-norm, measures if the policy changed for any state): 
  - $V^{\pi_i} \leftarrow$ MDP V function policy evaluation of $\pi_i$
  - $\pi_{i+1} \leftarrow$ Policy improvement
  - $i = i + 1$
New Definition: State-Action Value $Q$

- State-action value of a policy

$$Q^\pi(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V^\pi(s')$$

- Take action $a$, then follow the policy $\pi$
Policy Improvement

- Compute state-action value of a policy $\pi_i$
  - For $s$ in $S$ and $a$ in $A$:
    $$Q^{\pi_i}(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V^{\pi_i}(s')$$

- Compute new policy $\pi_{i+1}$, for all $s \in S$
  $$\pi_{i+1}(s) = \arg\max_a Q^{\pi_i}(s, a) \quad \forall s \in S$$

Emma Brunskill (CS234 Reinforcement Learning)  
Lecture 2: Making Sequences of Good Decisions Given a Model of the World  
Winter 2022  36 / 66
MDP Policy Iteration (PI)

- Set $i = 0$
- Initialize $\pi_0(s)$ randomly for all states $s$
- While $i == 0$ or $\|\pi_i - \pi_{i-1}\|_1 > 0$ (L1-norm, measures if the policy changed for any state):
  - $V^{\pi_i} \leftarrow$ MDP V function policy evaluation of $\pi_i$
  - $\pi_{i+1} \leftarrow$ Policy improvement
  - $i = i + 1$
Delving Deeper Into Policy Improvement Step

\[ Q^{\pi_i}(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s' \mid s, a) V^{\pi_i}(s') \]
Delving Deeper Into Policy Improvement Step

\[
Q^{\pi_i}(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V^{\pi_i}(s')
\]

\[
\max_a Q^{\pi_i}(s, a) \geq R(s, \pi_i(s)) + \gamma \sum_{s' \in S} P(s'|s, \pi_i(s))V^{\pi_i}(s') = V^{\pi_i}(s)
\]

\[
\pi_{i+1}(s) = \arg \max_a Q^{\pi_i}(s, a)
\]

- Suppose we take \(\pi_{i+1}(s)\) for one action, then follow \(\pi_i\) forever
  - Our expected sum of rewards is at least as good as if we had always followed \(\pi_i\)
- But new proposed policy is to always follow \(\pi_{i+1}\) ...
Monotonic Improvement in Policy

- Definition

\[ V^{\pi_1} \geq V^{\pi_2} : V^{\pi_1}(s) \geq V^{\pi_2}(s), \forall s \in S \]

- Proposition: \( V^{\pi_{i+1}} \geq V^{\pi_i} \) with strict inequality if \( \pi_i \) is suboptimal, where \( \pi_{i+1} \) is the new policy we get from policy improvement on \( \pi_i \)
Proof: Monotonic Improvement in Policy

\[ V^\pi_i(s) \leq \max_a Q^\pi_i(s, a) \]

\[ = \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V^\pi_i(s') \]

\[ = R(s, \pi_{i+1}(s)) + \gamma \sum_{s'} P(s'|s, \pi_{i+1}(s)) \max_a Q^\pi_i(s'|a) \]

\[ = R(s, \pi_{i+1}(s)) + \gamma \sum_{s'} P(s'|s, \pi_{i+1}(s)) \left[ r(s', \pi_{i+1}(s')) + \gamma \sum_{s''} P(s''|s', \pi_{i+1}(s')) V^\pi_i(s'') \right] \]

\[ = V^\pi_{i+1}(s) \]
Proof: Monotonic Improvement in Policy

\[ V^{\pi_i}(s) \leq \max_a Q^{\pi_i}(s, a) \]

\[ = \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V^{\pi_i}(s') \]

\[ = R(s, \pi_{i+1}(s)) + \gamma \sum_{s' \in S} P(s'|s, \pi_{i+1}(s)) V^{\pi_{i+1}}(s') \quad \text{/by the definition of } \pi_{i+1} \]

\[ \leq R(s, \pi_{i+1}(s)) + \gamma \sum_{s' \in S} P(s'|s, \pi_{i+1}(s)) \left( \max_{a'} Q^{\pi_i}(s', a') \right) \]

\[ = R(s, \pi_{i+1}(s)) + \gamma \sum_{s' \in S} P(s'|s, \pi_{i+1}(s)) \left( R(s', \pi_{i+1}(s')) + \gamma \sum_{s'' \in S} P(s''|s', \pi_{i+1}(s')) V^{\pi_i}(s'') \right) \]

\[ \vdots \]

\[ = V^{\pi_{i+1}}(s) \]
Check Your Understanding L2N3: Policy Iteration (PI)

- Note: all the below is for finite state-action spaces
- Set $i = 0$
- Initialize $\pi_0(s)$ randomly for all states $s$
- While $i == 0$ or $||\pi_i - \pi_{i-1}||_1 > 0$ (L1-norm, measures if the policy changed for any state):
  - $V^{\pi_i} \leftarrow$ MDP V function policy evaluation of $\pi_i$
  - $\pi_{i+1} \leftarrow$ Policy improvement
  - $i = i + 1$

- If policy doesn’t change, can it ever change again?
- Select on participation poll: Yes / No / Not sure
- Is there a maximum number of iterations of policy iteration?
- Select on participation poll: Yes / No / Not sure
Results for Check Your Understanding L2N3 Policy Iteration

- Note: all the below is for finite state-action spaces
- Set $i = 0$
- Initialize $\pi_0(s)$ randomly for all states $s$
- While $i == 0$ or $\|\pi_i - \pi_{i-1}\|_1 > 0$ (L1-norm, measures if the policy changed for any state):
  - $V^{\pi_i} \leftarrow$ MDP V function policy evaluation of $\pi_i$
  - $\pi_{i+1} \leftarrow$ Policy improvement
  - $i = i + 1$

- If policy doesn’t change, can it ever change again?
  No

- Is there a maximum number of iterations of policy iteration?
  $|A|^{|S|}$ since that is the maximum number of policies, and as the policy improvement step is monotonically improving, each policy can only appear in one round of policy iteration unless it is an optimal policy.
Check Your Understanding Explanation of Policy Not Changing

- Suppose for all $s \in S$, $\pi_{i+1}(s) = \pi_i(s)$
- Then for all $s \in S$, $Q^{\pi_i+1}(s, a) = Q^{\pi_i}(s, a)$
- Recall policy improvement step

$$Q^{\pi_i}(s, a) = R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V^{\pi_i}(s')$$

$$\pi_{i+1}(s) = \arg \max_a Q^{\pi_i}(s, a)$$

$$\pi_{i+2}(s) = \arg \max_a Q^{\pi_i+1}(s, a) = \arg \max_a Q^{\pi_i}(s, a)$$

Therefore policy cannot ever change again
Policy iteration computes infinite horizon value of a policy and then improves that policy.

Value iteration is another technique:
- Idea: Maintain optimal value of starting in a state $s$ if have a finite number of steps $k$ left in the episode.
- Iterate to consider longer and longer episodes.
Bellman Equation and Bellman Backup Operators

- Value function of a policy must satisfy the Bellman equation

\[ V^\pi(s) = R^\pi(s) + \gamma \sum_{s' \in S} P^\pi(s'|s)V^\pi(s') \]

- Bellman backup operator
  - Applied to a value function
  - Returns a new value function
  - Improves the value if possible

\[ BV(s) = \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} p(s'|s, a)V(s') \right] \]

- \( BV \) yields a value function over all states \( s \)
Value Iteration (VI)

- Set $k = 1$
- Initialize $V_0(s) = 0$ for all states $s$
- Loop until convergence: (for ex. $\| V_{k+1} - V_k \|_\infty \leq \epsilon$)
  - For each state $s$
    $$ V_{k+1}(s) = \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s') \right] $$
    View as Bellman backup on value function
    $$ V_{k+1} = BV_k $$
    $$ \pi_{k+1}(s) = \arg \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s') \right] $$
Bellman backup operator $B^\pi$ for a particular policy is defined as

$$B^\pi V(s) = R^\pi(s) + \gamma \sum_{s' \in S} P^\pi(s'|s)V(s')$$

Policy evaluation amounts to computing the fixed point of $B^\pi$

To do policy evaluation, repeatedly apply operator until $V$ stops changing

$$V^\pi = B^\pi B^\pi \cdots B^\pi V$$
Bellman backup operator $B^\pi$ for a particular policy is defined as

$$B^\pi V(s) = R^\pi(s) + \gamma \sum_{s' \in S} P^\pi(s'|s)V(s')$$

To do policy improvement

$$\pi_{k+1}(s) = \arg\max_a \left[R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V^\pi_k(s') \right]$$
Going Back to Value Iteration (VI)

- Set \( k = 1 \)
- Initialize \( V_0(s) = 0 \) for all states \( s \)
- Loop until [finite horizon, convergence]:
  - For each state \( s \)
    \[
    V_{k+1}(s) = \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s') \right]
    \]
  - Equivalently, in Bellman backup notation
    \[
    V_{k+1} = BV_k
    \]
  - To extract optimal policy if can act for \( k + 1 \) more steps,
    \[
    \pi(s) = \arg \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_{k+1}(s') \right]
    \]
Let $O$ be an operator, and $|x|$ denote (any) norm of $x$

If $|OV - OV'| \leq |V - V'|$, then $O$ is a contraction operator
Yes, if discount factor $\gamma < 1$, or end up in a terminal state with probability 1

Bellman backup is a contraction if discount factor, $\gamma < 1$

If apply it to two different value functions, distance between value functions shrinks after applying Bellman equation to each
Proof: Bellman Backup is a Contraction on $V$ for $\gamma < 1$

Let $\| V - V' \| = \max_s |V(s) - V'(s)|$ be the infinity norm

$$\| BV_k - BV_j \| = \max_a \left( R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a) V_k(s') \right) - \max_{a'} \left( R(s, a') + \gamma \sum_{s' \in S} P(s' | s, a') V_j(s') \right)$$

$$\leq \max_a \| R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a) (V_k(s') - V_j(s')) \|$$

$$= \max_a \| \gamma \sum_{s' \in S} P(s' | s, a) \| \| V_k - V_j \|$$

$$\leq \max_a \| V_k - V_j \| \| \sum_{s' \in S} P(s' | s, a) \|$$

$$= \gamma \| V_k - V_j \|$$

$$\gamma < 1$$
Proof: Bellman Backup is a Contraction on $V$ for $\gamma < 1$

Let $\|V - V'\| = \max_s |V(s) - V'(s)|$ be the infinity norm

$$
\|BV_k - BV_j\| = \max_a \left\| \left( R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a)V_k(s') \right) - \max_{a'} \left( R(s, a') + \gamma \sum_{s' \in S} P(s' | s, a')V_j(s') \right) \right\|

\leq \max_a \left\| \left( R(s, a) + \gamma \sum_{s' \in S} P(s' | s, a)V_k(s') - R(s, a) - \gamma \sum_{s' \in S} P(s' | s, a)V_j(s') \right) \right\|

= \max_a \left\| \gamma \sum_{s' \in S} P(s' | s, a)(V_k(s') - V_j(s')) \right\|

\leq \max_a \left\| \gamma \sum_{s' \in S} P(s' | s, a)\|V_k - V_j\| \right\|

= \max_a \left\| \gamma \|V_k - V_j\| \sum_{s' \in S} P(s' | s, a) \right\|

= \gamma \|V_k - V_j\|

Note: Even if all inequalities are equalities, this is still a contraction if $\gamma < 1$
Opportunities for Out-of-Class Practice

- Prove value iteration converges to a unique solution for discrete state and action spaces with $\gamma < 1$
- Does the initialization of values in value iteration impact anything?
Value Iteration for Finite Horizon $H$

$V_k = \text{optimal value if making } k \text{ more decisions}$

$\pi_k = \text{optimal policy if making } k \text{ more decisions}$

- Initialize $V_0(s) = 0$ for all states $s$
- For $k = 1 : H$
  - For each state $s$
    
    $$V_{k+1}(s) = \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V_k(s') \right]$$

    $$\pi_{k+1}(s) = \arg \max_a \left[ R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V_k(s') \right]$$
Alternatively can estimate by simulation
- Generate a large number of episodes
- Average returns
- Concentration inequalities bound how quickly average concentrates to expected value
- Requires no assumption of Markov structure
Example: Mars Rover

- Reward: +1 in $s_1$, +10 in $s_7$, 0 in all other states
- Sample returns for sample 4-step ($H=4$) episodes, $\gamma = 1/2$
  - $s_4, s_5, s_6, s_7$: $0 + \frac{1}{2} \times 0 + \frac{1}{4} \times 0 + \frac{1}{8} \times 10 = 1.25$

$L = \gamma^0, \gamma^1, \gamma^2, \gamma^3$
**Example: Mars Rover**

- **Reward:** +1 in $s_1$, +10 in $s_7$, 0 in all other states
- **Sample returns for sample 4-step ($H=4$) episodes, start state $s_4$, $\gamma = 1/2$**
  - $s_4, s_5, s_6, s_7$: $0 + \frac{1}{2} \times 0 + \frac{1}{4} \times 0 + \frac{1}{8} \times 10 = 1.25$
  - $s_4, s_4, s_5, s_4$: $0 + \frac{1}{2} \times 0 + \frac{1}{4} \times 0 + \frac{1}{8} \times 0 = 0$
  - $s_4, s_3, s_2, s_1$: $0 + \frac{1}{2} \times 0 + \frac{1}{4} \times 0 + \frac{1}{8} \times 1 = 0.125$
Set $k = 1$

Initialize $V_0(s) = 0$ for all states $s$

Loop until $k == H$:
- For each state $s$

\[
V_{k+1}(s) = \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s')
\]

\[
\pi_{k+1}(s) = \arg \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a) V_k(s')
\]

Is optimal policy stationary (independent of time step) in finite horizon tasks?
Set $k = 1$

Initialize $V_0(s) = 0$ for all states $s$

Loop until $k == H$:
  
  For each state $s$

  $$V_{k+1}(s) = \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V_k(s')$$

  $$\pi_{k+1}(s) = \arg \max_a R(s, a) + \gamma \sum_{s' \in S} P(s'|s, a)V_k(s')$$

Is optimal policy stationary (independent of time step) in finite horizon tasks?

In general no.
Value vs Policy Iteration

- **Value iteration:**
  - Compute optimal value for horizon $= k$
  - Note this can be used to compute optimal policy if horizon $= k$
  - Increment $k$

- **Policy iteration**
  - Compute infinite horizon value of a policy
  - Use to select another (better) policy
  - Closely related to a very popular method in RL: policy gradient

Emma Brunskill (CS234 Reinforcement Learning) Lecture 2: Making Sequences of Good Decisions Given a Model of the World Winter 2022
What You Should Know

- Define MP, MRP, MDP, Bellman operator, contraction, model, Q-value, policy
- Be able to implement
  - Value Iteration
  - Policy Iteration
- Give pros and cons of different policy evaluation approaches
- Be able to prove contraction properties
- Limitations of presented approaches and Markov assumptions
  - Which policy evaluation methods require the Markov assumption?
Where We Are

• Last Time:
  • Introduction
  • Components of an agent: model, value, policy

• This Time:
  • Making good decisions given a Markov decision process

• Next Time:
  • Policy evaluation when don’t have a model of how the world works
