Chapter 5 Algorithmic Verification (of General Formulas)

Algorithmic Verification of Finite-state Systems

Given finite-state program P, i.e., each $x \in V$ assumes only finitely many values in all P-computations.

Example: MUX-PET1 (Fig. 3.4) is finite-state
$$s=1,2$$
 $y_1={\tt T},{\tt F}$ $y_2={\tt T},{\tt F}$ π can assume at most 36 different values.

We present an algorithm (decision procedure) for establishing properties specified by an <u>arbitrary</u> (quantifier-free) temporal formula.

Example: Program mux-pet1 (Fig. 3.4)

(Peterson's Algorithm for mutual exclusion)

local y_1, y_2 : boolean where $y_1 = F, y_2 = F$

s: integer where s = 1

 ℓ_0 : loop forever do

 $P_1::$ $\begin{bmatrix} \ell_1: & \text{noncritical} \\ \ell_2: & (y_1, s) := (\mathtt{T}, \ 1) \\ \ell_3: & \text{await} \ (\lnot y_2) \lor (s \neq 1) \\ \ell_4: & \text{critical} \\ \ell_5: & y_1 := \mathtt{F} \end{bmatrix}$

 m_0 : loop forever do

 $egin{bmatrix} m_1 : & \text{noncritical} \ m_2 : & (y_2, \, s) := (\mathtt{T}, \, 2) \ m_3 : & \text{await} \, (\lnot y_1) \lor (s \neq 2) \ m_4 : & \text{critical} \ m_5 : & y_2 := \mathtt{F} \ \end{bmatrix}$

Overview

Given a temporal formula φ

1) Is φ satisfiable? i.e., is there a model σ such that $\sigma \models \varphi$?

Apply algorithm for φ :

YES: φ satisfiable produce a model σ satisfying φ

NO: $\frac{\varphi \text{ unsatisfiable}}{\text{there exists no model } \sigma \text{ satisfying } \varphi}$

2) Is φ valid? [Is $\neg \varphi$ unsatisfiable?]

Apply algorithm for $\neg \varphi$:

YES: $\frac{\neg \varphi \text{ satisfiable} = \varphi \text{ not valid}}{\text{produce a model } \sigma \text{ satisfying } \neg \varphi}$ (counterexample)

NO: $\neg \varphi$ unsatisfiable = φ is valid

Overview (Cont'd)

Given a temporal formula φ and a <u>finite-state</u> program P

3) Is φ *P*-satisfiable?

i.e., is there a *P*-computation σ such that $\sigma \models \varphi$?

Apply algorithm for φ and P:

YES: φ *P*-satisfiable produce a *P*-computation σ satisfying φ

NO: φ *P*-unsatisfiable there exists no such computation

Overview (Cont'd)

Given a temporal formula φ and a finite-state program P

4) Is φ *P*-valid? [Is $\neg \varphi$ *P*-unsatisfiable?]

Apply algorithm for $\neg \varphi$ and P:

YES: $\frac{\neg \varphi \ P\text{-satisfiable}}{\text{(Computation produced is a counterexample)}} = \frac{\varphi \text{ not } P\text{-valid}}{\text{(Computation produced is a counterexample)}}$

NO: $\neg \varphi P$ -unsatisfiable = φ is P-valid

Idea of algorithm

Construct a directed graph ("tableau") T_{φ} that exactly embeds all models of φ , i.e., σ is embedded in T_{φ} iff $\sigma \models \varphi$.

Embedding in a graph

In the <u>simplest version</u>, the nodes of the graph are labelled by <u>assertions</u>. A model

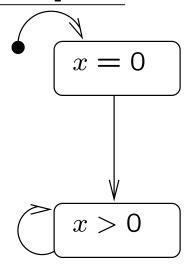

$$\sigma$$
: $s_0, s_1, \ldots s_i, \ldots$

is embedded in the graph if there exists a path

$$\pi$$
: $n_0, n_1, \ldots n_i, \ldots$

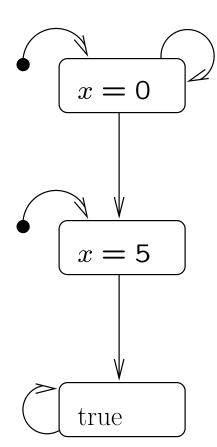

(where n_0 is an initial node) such that for all $i \geq 0$, s_i satisfies the assertion A_i labeling node n_i , i.e., $s_i \models A_i$.

Examples:

embeds all sequences that satisfy

$$(x = 0) \land \bigcirc \square(x > 0)$$

embeds all sequences that satisfy

$$(x = 0) W (x = 5)$$

Example: Construct a graph that embeds exactly all sequences that satisfy

$$p \Rightarrow p \mathcal{W} q$$

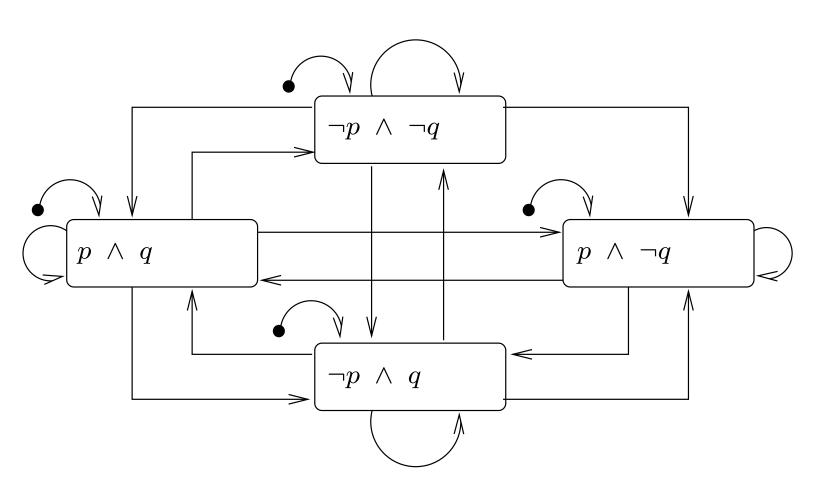

Tableau: Motivation

Note that $\Box(p \land \neg q)$ is embedded in the graph (as it should be since $\Box(p \land \neg q)$ implies $(p \Rightarrow p \ \mathcal{W} \ q)$.

How do we construct a graph that embeds all sequences that satisfy $p \Rightarrow p \ \mathcal{U} \ q$?

Now sequences that satisfy $\square(p \land \neg q)$ should be excluded.

Temporal Tableau vs. ω -Automata

To be able to embed exactly all sequences that satisfy a formula like $p \Rightarrow p \ \mathcal{U} \ q$, we need some additional conditions on embeddings. The two most popular ways of doing this are:

1. ω -Automata:

Add Muller or Streett-like acceptance conditions and interpret the graph as an ω -automaton.

2. Temporal Tableau:

In addition to assertions, label the nodes with <u>temporal</u> <u>formulas</u> that determine not only what happens in the current state but also what must happen in the future (i.e., that make promises) and then exclude paths that don't fulfill their promises.

Now we will only use the temproal tableau and we will not further consider the ω -automata approach. We distinguish between 2 types of Temporal Tableaux:

Atom Tableau and Particle Tableau.

Satisfiability of a temporal formula

We consider temporal formulas that consist of

Note: In this class we will only deal with future temporal operators. The book covers both past and future temporal operators.

Atom Tableau Closure

The closure of a formula
$$\varphi$$
 Φ_{φ}

is the smallest set of formulas satisfying:

- $\varphi \in \Phi_{\varphi}$
- For every $\psi \in \Phi_{\varphi}$ and subformula ξ of ψ ,

$$\xi \in \Phi_{\varphi}$$

- For every $\psi \in \Phi_{\varphi}$, $\neg \psi \in \Phi_{\varphi}$ ($\neg \neg \psi$ is considered identical to ψ)
- ullet For every ψ of the form

$$\square \psi_1$$
, $\diamondsuit \psi_1$, $\psi_1 \mathcal{U} \psi_2$, $\psi_1 \mathcal{W} \psi_2$,

if
$$\psi \in \Phi_{\varphi}$$
 then $\bigcirc \psi \in \Phi_{\varphi}$

Definition: Formulas in Φ_{φ} are called the closure formulas of φ

Example: The closure of

$$\varphi_0: \Leftrightarrow p$$

is
$$\Phi_{\varphi_0}$$
: $\{ \diamondsuit p, p, \bigcirc \diamondsuit p, \neg \diamondsuit p, \neg p, \neg \bigcirc \diamondsuit p \}$.

Example: The closure of

$$\varphi_1$$
: $\Box p \land \Diamond \neg p$

is $\Phi_{\varphi_1} = \Phi_{\varphi_1}^+ \cup \Phi_{\varphi_1}^-$:

$$\{ \quad \varphi_1, \quad \Box p, \quad \diamondsuit \neg p, \quad p, \quad \bigcirc \Box p, \quad \bigcirc \diamondsuit \neg p$$

$$\neg \varphi_1, \ \neg \Box p, \ \neg \diamondsuit \neg p, \ \neg p, \ \neg \bigcirc \Box p, \ \neg \bigcirc \diamondsuit \neg p$$

Example: The closure of

$$\varphi_2$$
: $\square \underbrace{(\neg p \lor (p \mathcal{W} q))}_{\psi}$

is
$$\Phi_{\varphi_2} = \Phi_{\varphi_2}^+ \cup \Phi_{\varphi_2}^-$$
:

$$\{ \varphi_2, \quad \psi, \quad p, \qquad p \mathcal{W} q, \quad q, \quad \bigcirc \varphi_2, \quad \bigcirc (p \mathcal{W} q), \}$$

$$\neg \varphi_2, \ \neg \psi, \ \neg p, \ \neg (p \mathcal{W} q), \ \neg q, \ \neg \bigcirc \varphi_2, \ \neg \bigcirc (p \mathcal{W} q) \}$$

Size of Closure

The size of the closure is bounded by

$$|\Phi_{\varphi}| \le 4|\varphi|$$

where

$$|\Phi_{\varphi}|$$
 – # of formulas

$$|\varphi|$$
 - size of formula
(# of occ. of connectives, operators
+ # of occ. of propositions, variables)

Typically a temporal operator contributes 4 formulas to the closure, e.g., for $\square p$:

$$p, \neg p$$

Atoms (Motivation)

Atoms are maximal "consistent" subsets of closure formulas that may hold together at some position in the model.

How do we identify consistent subsets?

Intuition: Based on the "Expansion Congruences".

We decompose temporal formulas into what must hold <u>current state</u>, and/or what must hold in the next state.

$$\Box p \approx p \land \bigcirc \Box p$$

$$\diamondsuit p \approx p \lor \bigcirc \diamondsuit p$$

$$p \mathcal{U} q \approx q \lor [p \land \bigcirc (p \mathcal{U} q)]$$

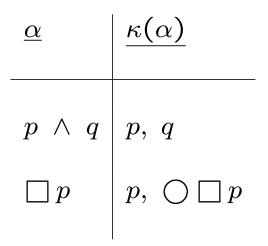

$$p \mathcal{W} q \approx q \vee [p \wedge \bigcirc (p \mathcal{W} q)]$$

For this purpose, we classify formulas as

- \bullet α -formulas (conjunctive flavor) and
- β -formulas (disjunctive flavor)

based on the top-level connective/operator of the formula.

$\underline{\alpha}$ -formulas

intended meaning:

An α -formula holds at position j iff all $\kappa(\alpha)$ -formulas hold at j

Example:

 $\ \square\ p$ holds at position j in σ iff both p and $\bigcirc\ \square\ p$ hold at j

β -formulas

\underline{eta}	$\left \frac{\kappa_1(\beta)}{} \right $	$\kappa_2(\beta)$
$p \lor q$	igg p	q
$\diamondsuit p$	$\mid p \mid$	$\bigcirc \diamondsuit p$
$p \ \mathcal{U} \ q$	igg q	$p, \bigcirc (p \ \mathcal{U} \ q)$ $p, \bigcirc (p \ \mathcal{W} \ q)$
$p \ \mathcal{W} \ q$	igg q	$p, \bigcirc (p \ \mathcal{W} \ q)$

Intended meaning:

A β -formula holds at position j iff $\kappa_1(\beta)$ -formula holds at j or all $\kappa_2(\beta)$ -formulas hold at j (or both)

Example:

 $p \ \mathcal{U} \ q$ holds at position j iff q holds at j or both p and $\bigcap (p \ \mathcal{U} \ q)$ hold at j

12-20

Atoms

atom over φ (φ -atom) is a subset $A \subseteq \Phi_{\varphi}$ satisfying the following requirements:

- R_{sat} : state(A), the conjunction of all state formulas in A is satisfiable
- R_{\neg} : For every $\psi \in \Phi_{\varphi}$, $\psi \in A$ iff $\neg \psi \notin A$
- R_{α} : For every α -formula $\psi \in \Phi_{\varphi}$, $\psi \in A$ iff $\kappa(\psi) \subseteq A$ [e.g., $\square p \in A$ iff both $p \in A$ and $\bigcap \square p \in A$]
- R_{β} : For every β -formula $\psi \in \Phi_{\varphi}$, $\psi \in A$ iff $\kappa_{1}(\psi) \in A$, or $\kappa_{2}(\psi) \subseteq A$ (or both) [e.g., $p\mathcal{U}q \in A$ iff $q \in A$ or $\{p, \bigcirc (p\mathcal{U}q)\} \subseteq A$]

Note: Due to R_{\neg} , φ -atom must contain ψ or $\neg \psi$ for every ψ of Φ_{φ} . Thus the number of formulas in an atom is always half the number of formulas in the closure.

Example:

$$\varphi_1: \quad \Box p \land \Diamond \neg p$$

closure

$$\Phi_{\varphi_1}: \{\varphi_1, \ \square \ p, \ \diamondsuit \neg p, \ \bigcirc \ \square \ p, \ \diamondsuit \neg p, \ p \\ \neg \varphi_1, \ldots\}$$

A:
$$\{\varphi_1, \ \Box p, \ \diamondsuit \neg p, \ \bigcirc \ \Box p, \ \bigcirc \ \diamondsuit \neg p, \ p\}$$
 is an atom

$$B\colon \ \{\varphi_1, \ \Box p, \ \diamondsuit \neg p, \ \bigcirc \Box p, \ \neg \bigcirc \diamondsuit \neg p, \ \neg p\}$$

$$\uparrow \qquad \uparrow \qquad \uparrow$$

is not an atom since by α -table,

$$\square p \in B \quad \text{iff} \quad \{p, \ \bigcirc \ \square \ p\} \subseteq B$$

Basic Formula

<u>Definition</u>: A <u>formula</u> is called <u>basic</u> if it is an atomic formula (i.e., no operators or connectives) or a formula of the form $\bigcirc \psi$

Example:

$$\varphi_0$$
: $\diamondsuit p$

basic formulas in Φ_{φ_0} :

$$p, \bigcirc \Diamond p$$

Example:

$$\varphi_1: \square p \land \lozenge \neg p$$

basic formulas in Φ_{φ_1} :

$$p, \quad \bigcirc \Box p, \quad \bigcirc \diamondsuit \neg p$$

Example:

$$\varphi_2$$
: $\square (\neg p \lor (p \mathcal{W} q))$

basic formulas in Φ_{φ_2} :

$$p, q, \bigcirc \varphi_2, \bigcirc (p \mathcal{W} q)$$

Why important?

In an atom, the positive/negative presence of the basic formulas uniquely determine the rest of the atom.

Thus, if a closure has b basic formulas, then there are 2^b distinct atoms.

Systematic Construction of Atoms

Suppose we know only the presence/absence of the basic formulas - the full atom A can be constructed following the definition of atom

Example:
$$\varphi_1$$
: $\square p \land \diamondsuit \neg p$

Suppose we know

$$\bigcirc \square p, \bigcirc \diamondsuit \neg p \in A \qquad \neg p \in A \text{ (i.e., } p \not\in A)$$

The full atom can be constructed as follows

•
$$\neg p \in A \rightarrow \text{place } \neg \square p \text{ in } A$$

•
$$\neg p \in A \rightarrow \text{place } \diamondsuit \neg p \text{ in } A$$

•
$$\neg \Box p \in A \rightarrow \text{place } \neg (\underline{\Box p \land \Diamond \neg p}) \text{ in } A$$

Final atom A:

$$\{ \underline{\neg p, \bigcirc p, \bigcirc \diamondsuit \neg p}, \underline{\neg p, \diamondsuit \neg p, \neg \varphi_1} \}$$
 chosen follow from independently the rules

Example:

$$\varphi_2$$
: $\Box (\neg p \lor (p \mathcal{W} q))$

 Φ_{φ_2} has four basic formulas

$$p, q, \bigcirc \varphi_2, \bigcirc (pWq)$$

Two atoms are:

$$\{ \neg p, \neg q, \bigcirc \varphi_2, \bigcirc (p \mathcal{W} q), \neg (p \mathcal{W} q), \neg p \lor (p \mathcal{W} q), \varphi_2 \}$$

$$\{ \neg p, q, \bigcirc \varphi_2, \bigcirc (pWq), pWq, \neg p \lor (pWq), \varphi_2 \}$$

chosen independently

follow from the rules

Atom Construction

- let p_1, p_2, \ldots, p_b be all basic formulas in Φ_{φ}
- construct all 2^b combinations

$$\left\{\begin{array}{c} p_1 \\ \neg p_1 \end{array}\right\}, \ldots, \left\{\begin{array}{c} p_b \\ \neg p_b \end{array}\right\}$$

• complete each combination into a full atom using the α -table and the β -table.

Example: φ_0 : $\diamondsuit p$

$$\Phi_{\varphi_0}: \{ \diamondsuit p, p, \bigcirc \diamondsuit p, \neg \diamondsuit p, \neg p, \neg \bigcirc \diamondsuit p \}$$

Basic formulas: $\{p, \bigcirc \Diamond p\}$

Atoms:

$$A_1: \{\underline{p}, \bigcirc \Diamond p, \Diamond p \}$$

$$A_2: \{\underline{\neg p}, \bigcirc \Diamond p, \Diamond p \}$$

$$A_3: \{\underline{p}, \neg \bigcirc \Diamond p, \Diamond p \}$$

$$A_4: \{\underline{\neg p}, \neg \bigcirc \diamondsuit p, \neg \diamondsuit p \}$$

Example:

Generate all atoms of

$$\varphi_1: \Box p \land \Diamond \neg p$$

basic formulas

$$p \quad \bigcirc \Box p \quad \bigcirc \diamondsuit \neg p$$

8 possible combinations = 8 atoms

$$A_{0}: \{ \neg p, \ \neg \bigcirc \square p, \ \neg \bigcirc \diamondsuit \neg p, \ \neg \square p, \ \diamondsuit \neg p, \ \neg \varphi_{1} \}$$

$$A_{1}: \{ p, \ \neg \bigcirc \square p, \ \neg \bigcirc \diamondsuit \neg p, \ \neg \square p, \ \neg \diamondsuit \neg p, \ \neg \varphi_{1} \}$$

$$A_{2}: \{ \neg p, \ \neg \bigcirc \square p, \ \bigcirc \diamondsuit \neg p, \ \neg \square p, \ \diamondsuit \neg p, \ \neg \varphi_{1} \}$$

$$A_{3}: \{ p, \ \neg \bigcirc \square p, \ \bigcirc \diamondsuit \neg p, \ \neg \square p, \ \diamondsuit \neg p, \ \neg \varphi_{1} \}$$

$$A_{4}: \{ \neg p, \ \bigcirc \square p, \ \neg \bigcirc \diamondsuit \neg p, \ \neg \square p, \ \diamondsuit \neg p, \ \neg \varphi_{1} \}$$

$$A_{5}: \{ p, \ \bigcirc \square p, \ \neg \bigcirc \diamondsuit \neg p, \ \square p, \ \neg \diamondsuit \neg p, \ \neg \varphi_{1} \}$$

$$A_{6}: \{ \neg p, \ \bigcirc \square p, \ \bigcirc \diamondsuit \neg p, \ \square p, \ \diamondsuit \neg p, \ \varphi_{1} \}$$

$$A_{7}: \{ p, \ \bigcirc \square p, \ \bigcirc \diamondsuit \neg p, \ \square p, \ \diamondsuit \neg p, \ \varphi_{1} \}$$

chosen independently

follow from the rules

Tableau Construction T_{φ}

Given formula φ , construct directed graph T_{φ} (tableau of φ):

- create a <u>node</u> for each atom of φ and label the node with that atom.
- A node is initial if $\varphi \in A$.

• Create an edge: Atom A_1 is connected to atom A_2 by directed edge,

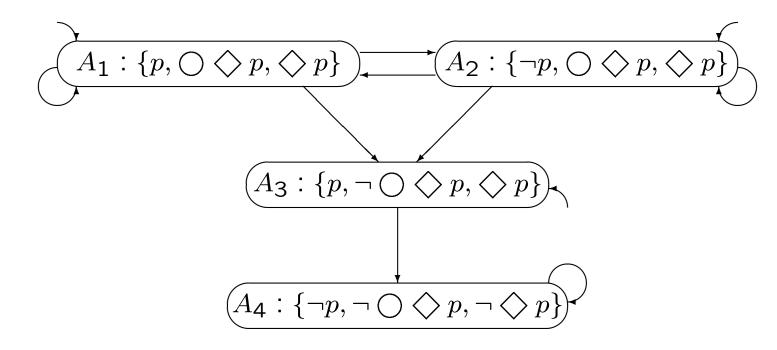

$$A_1 \longrightarrow A_2$$

If for every $\bigcirc \psi \in \Phi_{\varphi}$, $\bigcirc \psi \in A_1$ iff $\psi \in A_2$

Recall: $\neg \bigcirc \psi \approx \bigcirc \neg \psi$

Example: φ : $\diamondsuit p$

Tableau T_{φ} :

Example:

$$\varphi_1: \Box p \land \Diamond \neg p$$

Tableau T_{φ_1} (Fig 5.3)

Since

$$A_2$$
: $\{\ldots, \neg \bigcirc \Box p, \bigcirc \diamondsuit \neg p, \ldots\}$

all successors of A_2 must have

$$\{\ldots, \neg \Box p, \diamondsuit \neg p, \ldots\}$$

$$A_2 \rightarrow A_0, A_2, A_3, A_4, A_6$$

$$A_2 \not\rightarrow A_1, A_5, A_7$$

Fig. 5.3: Tableau T_{φ_1} for formula φ_1 : $\square p \land \diamondsuit \neg p$ $\neg p, \neg \bigcirc \square p, \bigcirc \diamondsuit \neg p, \\ \neg \square p, \diamondsuit \neg p, \neg \varphi_1$ A_3 : $\left\{ \begin{array}{ccc}
p, & \bigcirc & p, & \bigcirc & \neg p, \\
& & p, & \Diamond & \neg p, & \varphi_1
\end{array} \right.$ A_7 : A_6 :

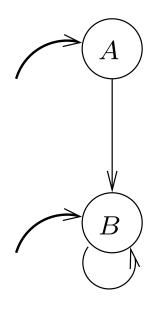

Example:

$$\varphi_2$$
: $\Box (\neg p \lor (p \mathcal{W} q))$

Let A and B be the atoms:

$$A: \{ \neg p, \neg q, \bigcirc \varphi_2, \bigcirc (p \mathcal{W} q), \\ \neg (p \mathcal{W} q), \neg p \lor (p \mathcal{W} q), \varphi_2 \}$$
$$B: \{ \neg p, q, \bigcirc \varphi_2, \bigcirc (p \mathcal{W} q), \\ p \mathcal{W} q, \neg p \lor (p \mathcal{W} q), \varphi_2 \}$$

The tableau is:

Paths induced by models

<u>Definition</u>: An infinite path

$$\pi: A_0, A_1, \dots$$

in the tableau T_{φ} is <u>induced</u> by a model

$$\sigma$$
: s_0, s_1, \ldots

if for all $j \geq 0$ and for all $\psi \in \Phi_{\varphi}$:

$$s_j \models \psi \quad \text{iff} \quad \psi \in A_j$$

$$\uparrow \quad (\sigma, j)$$

Example:

$$\varphi: \Diamond p$$

$$\Phi_{\varphi} = \{ \Diamond p, \ p, \ \bigcirc \Diamond p, \ \neg \Diamond p, \ \neg p, \ \neg \bigcirc \Diamond p \}$$

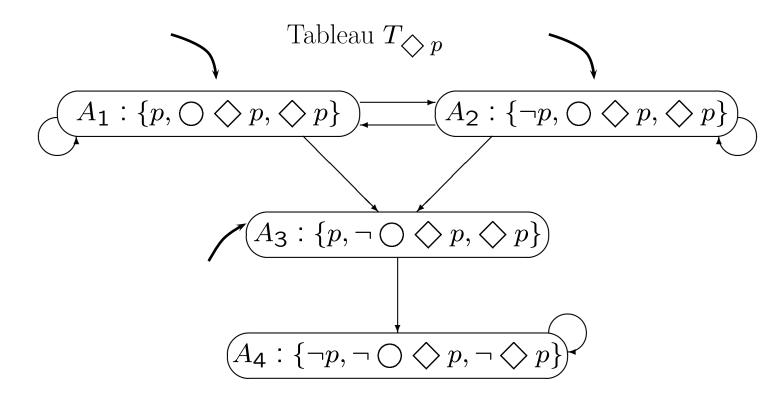

basic formulas: $\{p, \bigcirc \Diamond p\}$

Atoms:
$$A_1$$
: $\{\underline{p}, \bigcirc \Diamond \underline{p}, \Diamond p\}$

$$A_2$$
: $\{\underline{\neg p}, \bigcirc \Diamond \underline{p}, \Diamond p\}$

$$A_3$$
: $\{\underline{p}, \neg \bigcirc \Diamond \underline{p}, \Diamond p\}$

$$A_4$$
: $\{\underline{\neg p}, \neg \bigcirc \Diamond p, \neg \Diamond p\}$

Paths:

$$\frac{\sigma_1:}{\pi_1:} \quad \frac{\neg p \quad \neg p \quad \dots}{A_2 \quad A_2 \quad A_2 \quad A_3 \quad A_4 \quad A_4 \quad \dots}$$

$$\sigma_2$$
: σ_2 : σ_2 : σ_2 σ_3 σ_4 σ_5 σ_5 σ_7 σ_8 σ_9 σ

 π_1 is induced by σ_1 π_2 is induced by σ_2

Paths induced by models (Cont'd)

Claim 1 (model \rightarrow induced path):

Consider formula φ and its tableau T_{φ} . For every model σ of φ (i.e., $\sigma \models \varphi$) there exists an infinite path

$$\pi_{\sigma}$$
: A_0, A_1, \ldots

in T_{φ} such that π_{σ} is induced by σ

Converse?

The converse of claim 1 is not true:

There may be a path π in T_{φ} that is not induced by any model σ of φ .

Example: In $T_{\diamondsuit p}$,

path $\pi: A_2^{\omega}$ is not induced by model $\sigma: (\neg p)^{\omega}$, since $\neg p, \diamondsuit p \in A_2$ should hold at all positions j, but there is no σ such that

 $\diamondsuit p$ at position 0 and $\neg p$ at all positions $j \ge 0$.

Example:

$$\varphi_1$$
: $\Box p \land \Diamond \neg p$

In Fig 5.3,

$$A_{7}:\ \{\ p,\ \bigcirc\ \Box\ p,\ \bigcirc\ \diamondsuit\neg p,\ \Box\ p,\ \diamondsuit\neg p,\ \varphi_{1}\ \}$$

Path $\underline{A_7^{\omega}}$ is not induced by any model of φ_1 ,

since every $\psi \in A_7$ should hold at all positions j, but there is no σ s.t.

$$\diamondsuit \neg p$$
 at position 0 and p at all positions $j \ge 0$

How do we exclude those "bad" paths?
