Introduction to Information Retrieval

CS276: Information Retrieval and Web Search
Christopher Manning and Pandu Nayak

Lecture 14: Learning to Rank
Machine learning for IR ranking?

- We’ve looked at methods for ranking documents in IR
  - Cosine similarity, inverse document frequency, BM25, proximity, pivoted document length normalization, (will look at) Pagerank, ...

- We’ve looked at methods for classifying documents using supervised machine learning classifiers
  - Rocchio, kNN, SVMs, etc.

- Surely we can also use *machine learning* to rank the documents displayed in search results?
  - Sounds like a good idea
  - A.k.a. “machine-learned relevance” or “learning to rank”
Machine Learned Ranking (MLR)/Search Relevance Researcher and Engineers at Clients of PromptHire, Inc.

Location: San Francisco Bay Area - Burlingame (San Francisco Bay Area)

Type: Full-time
Experience: Mid-Senior level
Functions: Research, Engineering
Industries: Internet
Posted: November 16, 2008 by Sangeeta Narayan

LinkedIn Exclusive — this job is available only on LinkedIn

Job Description

A typical candidate has made a not-trivial contribution into one of the major web search engine.
Specific areas of expertise include
* machine learned ranking -- ranking features and training technologies
* query independent search quality -- acquisition and analysis of high quality web-content
* query and content classification
Machine learning for IR ranking

- This “good idea” has been actively researched – and actively deployed by major web search engines – in the last 7–10 years

- Why didn’t it happen earlier?
  - Modern supervised ML has been around for about 20 years...
  - Naïve Bayes has been around for about 50 years...
There’s some truth to the fact that the IR community wasn’t very connected to the ML community.

But there were a whole bunch of precursors:

Why weren’t early attempts very successful/influential?

- Sometimes an idea just takes time to be appreciated...
- **Limited training data**
  - Especially for real world use (as opposed to writing academic papers), it was very hard to gather test collection queries and relevance judgments that are representative of real user needs and judgments on documents returned
  - This has changed, both in academia and industry
- Poor machine learning techniques
- Insufficient customization to IR problem
- Not enough features for ML to show value
Why wasn’t ML much needed?

- Traditional ranking functions in IR used a very small number of features, e.g.,
  - Term frequency
  - Inverse document frequency
  - Document length

- It was easy possible to tune weighting coefficients by hand
  - And people did
  - You students do it in PA3
Why is ML needed now?

- Modern systems – especially on the Web – use a great number of features:
  - Arbitrary useful features – not a single unified model
    - Log frequency of query word in anchor text?
    - Query word in color on page?
    - # of images on page?
    - # of (out) links on page?
    - PageRank of page?
    - URL length?
    - URL contains “~”?  
    - Page edit recency?
    - Page loading speed

- The *New York Times* in 2008-06-03 quoted Amit Singhal as saying Google was using over 200 such features (“signals”)

Simple example: 
Using classification for ad hoc IR

- Collect a training corpus of \((q, d, r)\) triples
  - Relevance \(r\) is here binary (but may be multiclass, with 3–7 values)
  - Document is represented by a feature vector
    - \(x = (\alpha, \omega)\) \(\alpha\) is cosine similarity, \(\omega\) is minimum query window size
      - \(\omega\) is the shortest text span that includes all query words
    - Query term proximity is an important new weighting factor
  - Train a machine learning model to predict the class \(r\) of a document-query pair

<table>

Simple example: Using classification for ad hoc IR

- A linear score function is then
  \[ \text{Score}(d, q) = \text{Score}(\alpha, \omega) = a\alpha + b\omega + c \]
- And the linear classifier is
  Decide relevant if \( \text{Score}(d, q) > \theta \)

- ... just like when we were doing text classification
Simple example:
Using classification for ad hoc IR
More complex example of using classification for search ranking  [Nallapati 2004]

- We can generalize this to classifier functions over more features
- We can use methods we have seen previously for learning the linear classifier weights
An SVM classifier for information retrieval

[Nallapati 2004]

- Let relevance score \( g(r|d,q) = w \cdot f(d,q) + b \)
- SVM training: want \( g(r|d,q) \leq -1 \) for nonrelevant documents and \( g(r|d,q) \geq 1 \) for relevant documents
- SVM testing: decide relevant iff \( g(r|d,q) \geq 0 \)

- Features are *not* word presence features (how would you deal with query words not in your training data?) but scores like the summed (log) tf of all query terms
- Unbalanced data (which can result in trivial always-say-nonrelevant classifiers) is dealt with by undersampling nonrelevant documents during training (just take some at random)  
  [there are other ways of doing this – cf. Cao et al. later]
An SVM classifier for information retrieval
[Nallapati 2004]

- Experiments:
  - 4 TREC data sets
  - Comparisons with Lemur, a state-of-the-art open source IR engine (Language Model (LM)-based – see IIR ch. 12)
  - Linear kernel normally best or almost as good as quadratic kernel, and so used in reported results
  - 6 features, all variants of tf, idf, and tf.idf scores
An SVM classifier for information retrieval
[Nallapati 2004]

<table>
<thead>
<tr>
<th>Train \ Test</th>
<th>Disk 3</th>
<th>Disk 4-5</th>
<th>WT10G (web)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TREC Disk 3</td>
<td>0.1785</td>
<td>0.2503</td>
<td>0.2666</td>
</tr>
<tr>

</tr>
<tr>
<td>Lemur</td>
<td>0.1646</td>
<td>0.2355</td>
<td>0.2675</td>
</tr>
</tbody>
</table>

- At best the results are about equal to Lemur
  - Actually a little bit below
- Paper’s advertisement: Easy to add more features
  - This is illustrated on a homepage finding task on WT10G:
    - Baseline Lemur 52% success@10, baseline SVM 58%
    - SVM with URL-depth, and in-link features: 78% success@10
“Learning to rank”

- Classification probably isn’t the right way to think about approaching ad hoc IR:
  - Classification problems: Map to an unordered set of classes
  - Regression problems: Map to a real value [Start of PA4]
  - Ordinal regression problems: Map to an *ordered* set of classes
    - A fairly obscure sub-branch of statistics, but what we want here

- This formulation gives extra power:
  - Relations between relevance levels are modeled
  - Documents are good versus other documents for query given collection; not an absolute scale of goodness
“Learning to rank”

- Assume a number of categories $\mathbf{C}$ of relevance exist
  - These are totally ordered: $c_1 < c_2 < \ldots < c_J$
  - This is the ordinal regression setup
- Assume training data is available consisting of document-query pairs represented as feature vectors $\psi_i$ and relevance ranking $c_i$

- We could do **point-wise learning**, where we try to map items of a certain relevance rank to a subinterval (e.g., Crammer et al. 2002 PRank)
- But most work does **pair-wise learning**, where the input is a pair of results for a query, and the class is the relevance ordering relationship between them
Point-wise learning

- Goal is to learn a threshold to separate each rank
Pairwise learning: The Ranking SVM

[Herbrich et al. 1999, 2000; Joachims et al. 2002]

- Aim is to classify instance pairs as correctly ranked or incorrectly ranked
  - This turns an ordinal regression problem back into a binary classification problem in an expanded space
- We want a ranking function \( f \) such that
  \[
  c_i > c_k \iff f(\psi_i) > f(\psi_k)
  \]
- ... or at least one that tries to do this with minimal error
- Suppose that \( f \) is a linear function
  \[
  f(\psi_i) = \mathbf{w} \cdot \psi_i
  \]
The Ranking SVM

[Herbrich et al. 1999, 2000; Joachims et al. 2002]

- Ranking Model: $f(\psi_i)$
The Ranking SVM

[Herbrich et al. 1999, 2000; Joachims et al. 2002]

- Then (combining \(c_i > c_k\) iff \(f(\psi_i) > f(\psi_k)\) and \(f(\psi_i) = w \cdot \psi_i\):
  \[
  c_i > c_k \iff w \cdot (\psi_i - \psi_k) > 0
  \]
- Let us then create a new instance space from such pairs:
  \[
  \Phi_u = \Phi(d_i, d_k, q) = \psi_i - \psi_k
  \]
  \[
  z_u = +1, 0, -1 \text{ as } c_i >,=,< c_k
  \]
- We can build model over just cases for which \(z_u = -1\)
- From training data \(S = \{\Phi_u\}\), we train an SVM
Two queries in the original space
Two queries in the pairwise space
The Ranking SVM

[Herbrich et al. 1999, 2000; Joachims et al. 2002]

- The SVM learning task is then like other examples that we saw before

- Find \( \mathbf{w} \) and \( \xi_u \geq 0 \) such that
  - \( \frac{1}{2} \mathbf{w}^T \mathbf{w} + C \sum \xi_u \) is minimized, and
  - for all \( \Phi_u \) such that \( z_u < 0 \), \( \mathbf{w} \cdot \Phi_u \geq 1 - \xi_u \)

- We can just do the negative \( z_u \), as ordering is antisymmetric

- You can again use libSVM or SVMlight (or other SVM libraries) to train your model (SVMrank specialization)
Aside: The SVM loss function

The minimization

$$\min_w \frac{1}{2} w^T w + C \sum \xi_u$$

and for all $\Phi_u$ such that $z_u < 0$, $w \cdot \Phi_u \geq 1 - \xi_u$

can be rewritten as

$$\min_w (1/2C)w^T w + \sum \xi_u$$

and for all $\Phi_u$ such that $z_u < 0$, $\xi_u \geq 1 - (w \cdot \Phi_u)$

Now, taking $\lambda = 1/2C$, we can reformulate this as

$$\min_w \sum [1 - (w \cdot \Phi_u)]_+ + \lambda w^T w$$

Where $[\cdot]_+$ is the positive part (0 if a term is negative)
Aside: The SVM loss function

- The reformulation

\[ \min_w \sum [1 - (w \cdot \Phi_u)]_+ + \lambda w^T w \]

- shows that an SVM can be thought of as having an empirical "hinge" loss combined with a weight regularizer (smaller weights are preferred)
Adapting the Ranking SVM for (successful) Information Retrieval

[Yunbo Cao, Jun Xu, Tie-Yan Liu, Hang Li, Yalou Huang, Hsiao-Wuen Hon SIGIR 2006]

- A Ranking SVM model already works well
  - Using things like vector space model scores as features
  - As we shall see, it outperforms standard IR in evaluations
- But it does not model important aspects of practical IR well
- This paper addresses two customizations of the Ranking SVM to fit an IR utility model
The ranking SVM fails to model the IR problem well ...

1. Correctly ordering the most relevant documents is crucial to the success of an IR system, while misordering less relevant results matters little
   - The ranking SVM considers all ordering violations as the same

2. Some queries have many (somewhat) relevant documents, and other queries few. If we treat all pairs of results for queries equally, queries with many results will dominate the learning
   - But actually queries with few relevant results are at least as important to do well on
Experiments use LETOR test collection

  - From Microsoft Research Asia
  - An openly available standard test collection with pregenerated features, baselines, and research results for learning to rank

- It’s availability has really driven research in this area

- OHSUMED, MEDLINE subcollection for IR
  - 350,000 articles
  - 106 queries
  - 16,140 query-document pairs
  - 3 class judgments: Definitely relevant (DR), Partially Relevant (PR), Non-Relevant (NR)

- TREC GOV collection (predecessor of GOV2, cf. IIR p. 142)
  - 1 million web pages
  - 125 queries
Principal components projection of 2 queries
[solid = q12, open = q50; circle = DR, square = PR, triangle = NR]
Ranking scale importance discrepancy

[r3 = Definitely Relevant, r2 = Partially Relevant, r1 = Nonrelevant]
Number of training documents per query discrepancy [solid = q12, open = q50]
IR Evaluation Measures

- Some evaluation measures strongly weight doing well in highest ranked results:
  - MAP (Mean Average Precision)
  - NDCG (Normalized Discounted Cumulative Gain)

- NDCG has been especially popular in machine learned relevance research
  - It handles multiple levels of relevance (MAP doesn’t)
  - It seems to have the right kinds of properties in how it scores system rankings
Normalized Discounted Cumulative Gain (NDCG) evaluation measure

- Query: $q_i$
- DCG at position $m$: 
  \[ N_i = Z_i \sum_{j=1}^{m} (2^{r(j)} - 1)/\log(1 + j) \]
- NDCG at position $m$: average over queries
- Example
  - (3, 3, 2, 2, 1, 1, 1) \quad \text{rank } r
  - (7, 7, 3, 3, 1, 1, 1) \quad \text{gain } 2^{r(j)} - 1
  - (1, 0.63, 0.5, 0.43, 0.39, 0.36, 0.33) \quad \text{discount } 1/\log(1 + j)
  - (7, 11.41, 12.91, 14.2, 14.59, 14.95, 15.28) \quad \sum_{j=1}^{m} (2^{r(j)} - 1)/\log(1 + j)
- $Z_i$ normalizes against best possible result for query, the above, versus lower scores for other rankings
  - Necessarily: High ranking number is good (more relevant)
Recap: Two Problems with Direct Application of the Ranking SVM

- Cost sensitivity: negative effects of making errors on top ranked documents

  
  d: definitely relevant, p: partially relevant, n: not relevant

  ranking 1: p d p n n n n
  ranking 2: d p n p n n n

- Query normalization: number of instance pairs varies according to query

  q1: d p p n n n n
  q2: d d p p p n n n n n

  q1 pairs: 2*(d, p) + 4*(d, n) + 8*(p, n) = 14
  q2 pairs: 6*(d, p) + 10*(d, n) + 15*(p, n) = 31
These problems are solved with a new Loss function

\[
\min_{\tilde{w}} L(\tilde{w}) = \sum_{i=1}^{l} \tau_{k(i)} \mu_{q(i)} \left[ 1 - z_i \langle \tilde{w}, \tilde{x}_i^{(1)} - \tilde{x}_i^{(2)} \rangle \right] + \lambda \left\| \tilde{w} \right\|^2
\]

- \( \tau \) weights for type of rank difference
  - Estimated empirically from effect on NDCG
- \( \mu \) weights for size of ranked result set
  - Linearly scaled versus biggest result set
Optimization (Gradient Descent)
Optimization (Quadratic Programming)

\[
\begin{align*}
\min_{\vec{w}} L &= \sum_{i=1}^{\ell} \tau_{k(i)} u_{q(i)} \left[ 1 - z_i \langle \vec{w}, \vec{x}_i^{(1)} - \vec{x}_i^{(2)} \rangle \right]_+ + \lambda \|\vec{w}\|^2, \\
\min_{\vec{w}} M(\vec{w}) &= \frac{1}{2} \|\vec{w}\|^2 + \sum_{i=1}^{\ell} C_i \xi_i \\
\text{subject to } \xi_i \geq 0, \quad z_i \langle \vec{w}, \vec{x}_i^{(1)} - \vec{x}_i^{(2)} \rangle \geq 1 - \xi_i \quad i = 1, \cdots, \ell \\
\text{where } C_i &= \frac{\tau_{k(i)} u_{q(i)}}{2\lambda} \\
\max_{\alpha} L_D &= \sum_{i=1}^{\ell} \alpha_i - \frac{1}{2} \sum_{i=1}^{\ell} \sum_{i'=1}^{\ell} \alpha_i \alpha_{i'} z_i z_{i'} \langle \vec{x}_i^{(1)} - \vec{x}_i^{(2)}, \vec{x}_{i'}^{(1)} - \vec{x}_{i'}^{(2)} \rangle \\
\text{subject to } 0 \leq \alpha_i \leq C_i \quad i = 1, \cdots, \ell
\end{align*}
\]
Experiments

- OHSUMED (from LETOR)
- Features:
  - 6 that represent versions of tf, idf, and tf.idf factors
  - BM25 score (*IIR* sec. 11.4.3)
Experimental Results (OHSUMED)
MSN Search [now Bing]

- Second experiment with MSN search
- Collection of 2198 queries
- 6 relevance levels rated:
  - Definitive 8990
  - Excellent 4403
  - Good 3735
  - Fair 20463
  - Bad 36375
  - Detrimental 310
Experimental Results (MSN search)
Alternative: Optimizing Rank-Based Measures
[Yue et al. SIGIR 2007]

- If we think that NDCG is a good approximation of the user’s utility function from a result ranking
- Then, let’s directly optimize this measure
  - As opposed to some proxy (weighted pairwise prefs)

- But, there are problems ...
  - Objective function no longer decomposes
    - Pairwise prefs decomposed into each pair
  - Objective function is flat or discontinuous
Discontinuity Example

- NDCG computed using rank positions
- Ranking via retrieval scores
- Slight changes to model parameters
  - Slight changes to retrieval scores
  - No change to ranking
  - No change to NDCG

\[
\begin{array}{c|c|c|c}
\text{Retrieval Score} & d_1 & d_2 & d_3 \\
\hline
\text{Rank} & 1 & 2 & 3 \\
\text{Relevance} & 0 & 1 & 0 \\
\end{array}
\]

\[\text{NDCG} = 0.63\]

NDCG discontinuous w.r.t model parameters!
Structural SVMs [Tsochantaridis et al., 2007]

- Structural SVMs are a generalization of SVMs where the output classification space is not binary or one of a set of classes, but some complex object (such as a sequence or a parse tree)
- Here, it is a complete (weak) ranking of documents for a query
- The Structural SVM attempts to predict the complete ranking for the input query and document set
- The true labeling is a ranking where the relevant documents are all ranked in the front, e.g.,
  \[ y = \text{[green] [green] [green] [red] [red] [red]} \]
- An incorrect labeling would be any other ranking, e.g.,
  \[ y' = \text{[green] [red] [green] [red] [red]} \]
- There are an intractable number of rankings, thus an intractable number of constraints!
Structural SVM training

[Tsochantaridis et al., 2007]

Structural SVM training proceeds incrementally by starting with a working set of constraints, and adding in the most violated constraint at each iteration.

Original SVM Problem
- Exponential constraints
- Most are dominated by a small set of “important” constraints

Structural SVM Approach
- Repeatedly finds the next most violated constraint...
- ...until a set of constraints which is a good approximation is found
Other machine learning methods for learning to rank

- Of course!
- I’ve only presented the use of SVMs for machine learned relevance, but other machine learning methods have also been used successfully
  - Boosting: RankBoost
  - Ordinal Regression loglinear models
  - Neural Nets: RankNet, RankBrain
  - (Gradient-boosted) Decision Trees
The Limitations of Machine Learning

- Everything that we have looked at (and most work in this area) produces *linear* models over features.
- This contrasts with most of the clever ideas of traditional IR, which are *nonlinear* scalings and combinations (products, etc.) of basic measurements.
  - log term frequency, idf, tf.idf, pivoted length normalization
- At present, ML is good at weighting features, but not as good at coming up with nonlinear scalings.
  - Designing the basic features that give good signals for ranking remains the domain of human creativity.
  - Or maybe we can do it with deep learning 😊
Why is machine learning used heavily for Google's ad ranking and less for their search ranking?

A lot of people I've talked to at Google have told me that the ad ranking system is largely machine learning based, while search ranking is rooted in functions that are written by humans using their intuition (with some components using machine learning).

What led to this difference?
Summary

- The idea of learning ranking functions has been around for about 20 years.
- But only more recently have ML knowledge, availability of training datasets, a rich space of features, and massive computation come together to make this a hot research area.
- It’s too early to give a definitive statement on what methods are best in this area ... it’s still advancing rapidly.
- But machine-learned ranking over many features now easily beats traditional hand-designed ranking functions in comparative evaluations [in part by using the hand-designed functions as features!]
- There is every reason to think that the importance of machine learning in IR will grow in the future.
