

# EE107 Spring 2019

## Lecture 4

## Serial Busses

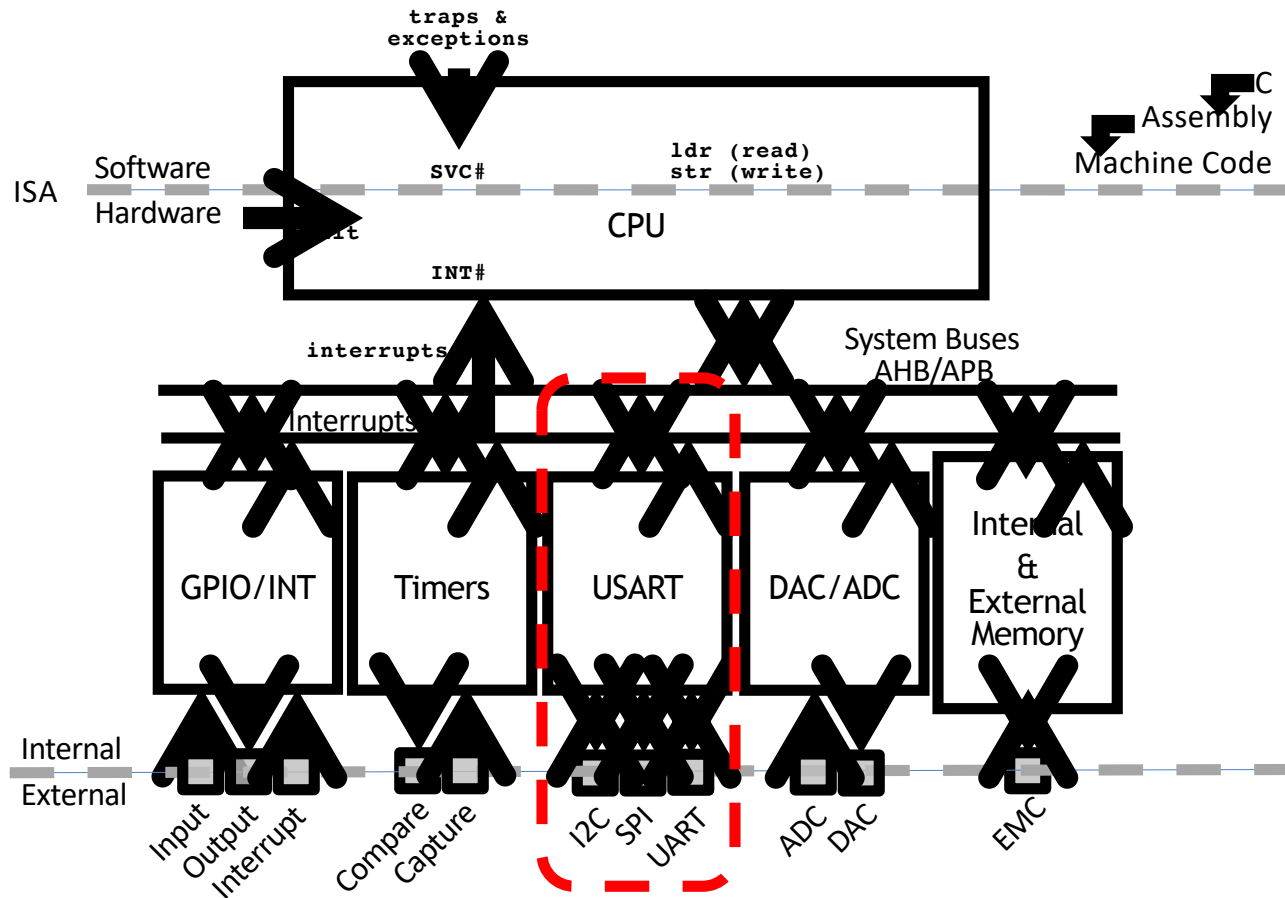

## Embedded Networked Systems

Sachin Katti

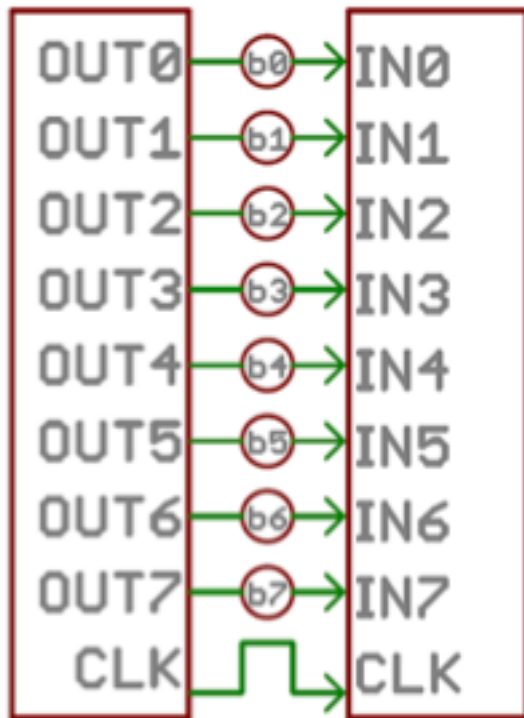

# Serial Buses in our project

- UART serial bus for sending debug messages to your development host
- I2C serial bus for communicating with sensors (e.g., the accelerometer)
- SPI serial bus for communicating with the Bluetooth Low Energy radio

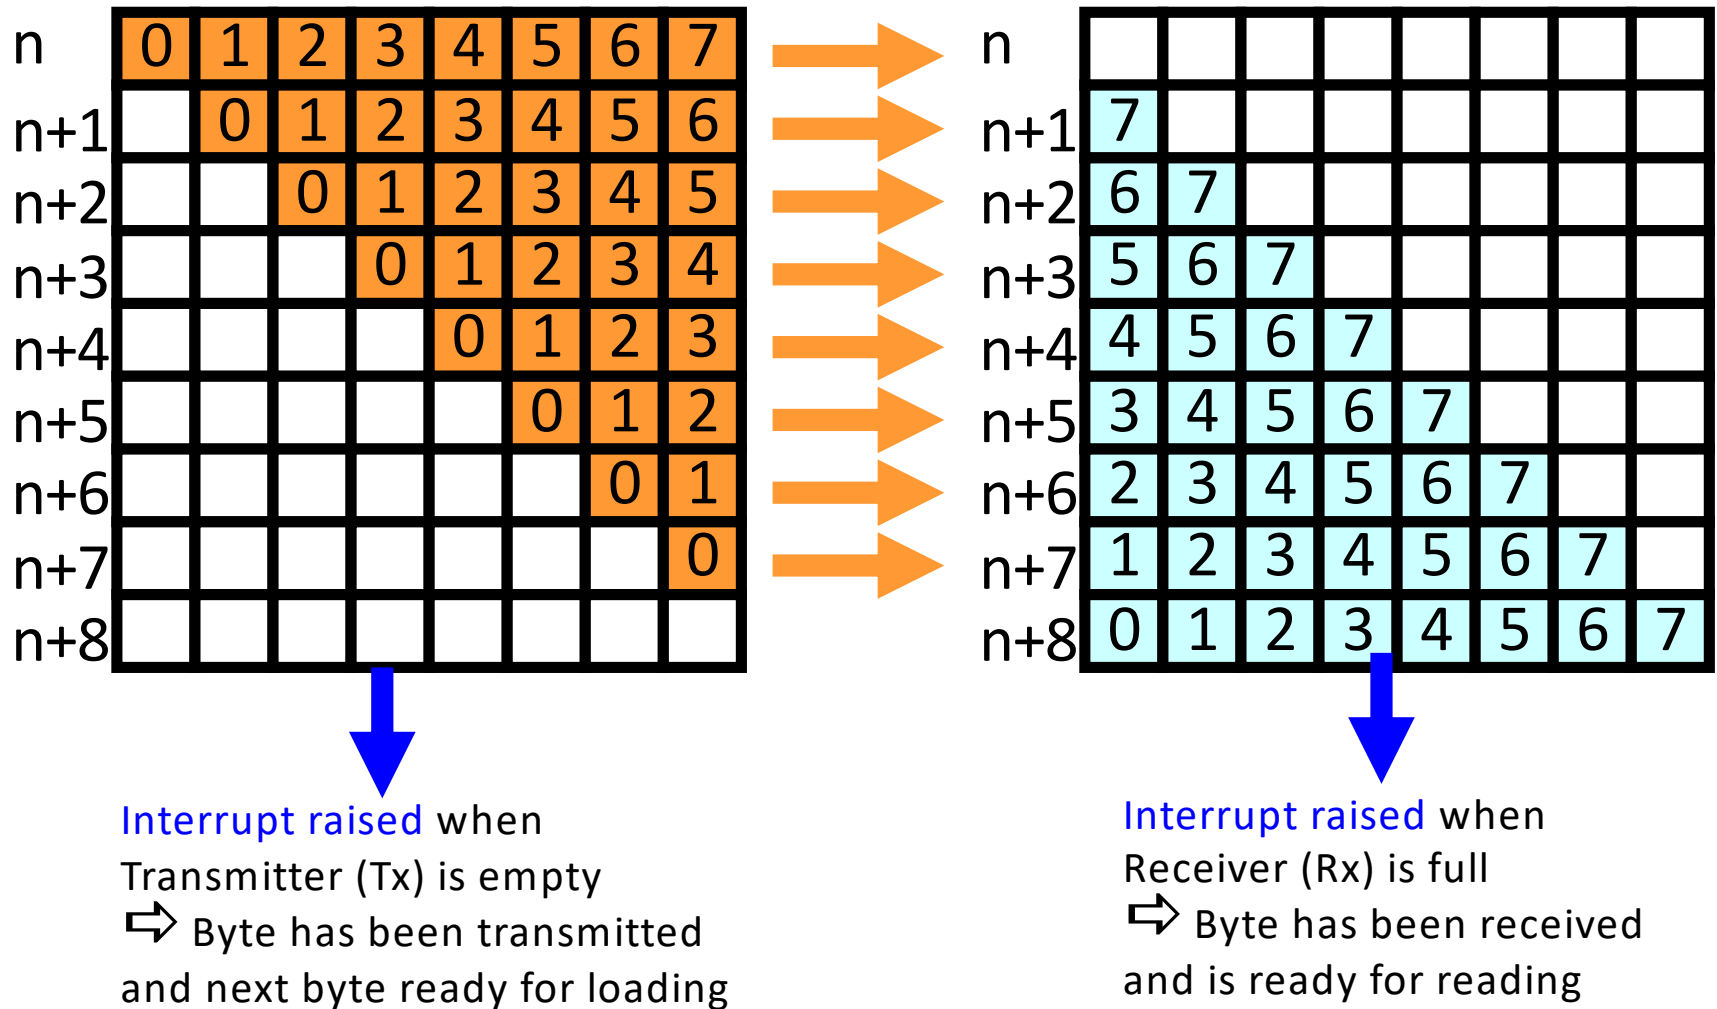

# Serial Interfaces

# Parallel Bus VS Serial Bus

# Simplistic View of Serial Port Operation

# Serial Bus Interface Motivations

- Motivation
  - Without using a lot of I/O lines
    - I/O lines require I/O pads which cost \$\$\$ and size
    - I/O lines require PCB area which costs \$\$\$ and size
  - Connect different systems together
    - Two embedded systems
    - A desktop and an embedded system
  - Connect different chips together in the same embedded system
    - MCU to peripheral
    - MCU to MCU
  - Often at relatively low data rates
  - But sometimes at higher data rates
- So, what are our options?
  - Universal Synchronous/Asynchronous Receiver Transmitter
  - Also known as USART (pronounced: “you-sart”)

# Serial Bus Design Space

- Number of wires required?
- Asynchronous or synchronous?
- How fast can it transfer data?
- Can it support more than two endpoints?
- Can it support more than one master (i.e. txn initiator)?
- How do we support flow control?
- How does it handle errors/noise?
- How far can signals travel?

# Serial Bus Examples

	S/A	Type	Duplex	#Devices	Speed (kbps)	Distance (ft)	Wires
RS232	A	Peer	Full	2	20	30	2+
RS422	A	Multi-drop	Half	10	10000	4000	1+
RS485	A	Multi-point	Half	32	10000	4000	2
I2C	S	Multi-master	Half	?	3400	<10	2
SPI	S	Multi-master	Full	?	>1000	<10	3+
Microwire	S	Master/slave	Full	?	>625	<10	3+
1-Wire	A	Master/slave	half	?	16	1000	1+

# UART Uses

- PC serial port is a UART!
- Serializes data to be sent over serial cable
  - De-serializes received data

# UART Uses

- Used to be commonly used for internet access

# UART

- Universal Asynchronous Receiver/Transmitter
- Hardware that translates between parallel and serial forms
- Commonly used in conjunction with communication standards such as EIA, RS-232, RS-422 or RS-485

# Protocol

- Each character is sent as
  - a logic *low* **start** bit
  - a configurable number of data bits (usually 7 or 8, sometimes 5)
  - an optional parity bit
  - *one or more logic high* **stop** bits
  - with a particular bit timing (“baud”)

# UART Example

- Send the ASCII letter 'W' (1010111)

# UART Hardware Connection

# UART Character Reception

Start bit says a character is coming,  
receiver resets its timers

Receiver uses a timer (counter) to time when it samples.  
Transmission rate (i.e., bit width) must be known!

# UART Character Reception

If receiver samples too quickly, see what happens...

# UART Character Reception

If receiver samples too slowly, see what happens...

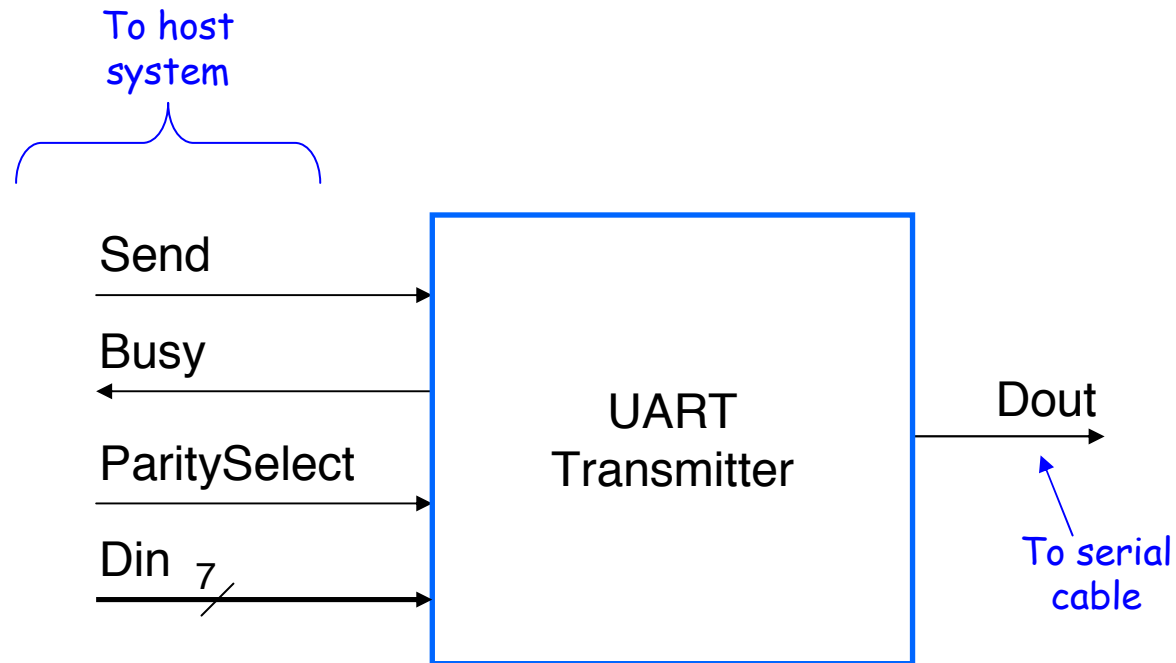

Receiver resynchronizes on every start bit.  
Only has to be accurate enough to read 9 bits.

# UART Character Reception

- Receiver also verifies that stop bit is '1'
  - If not, reports “framing error” to host system
- New start bit can appear immediately after stop bit
  - Receiver will resynchronize on each start bit

# Let us design a UART transmitter

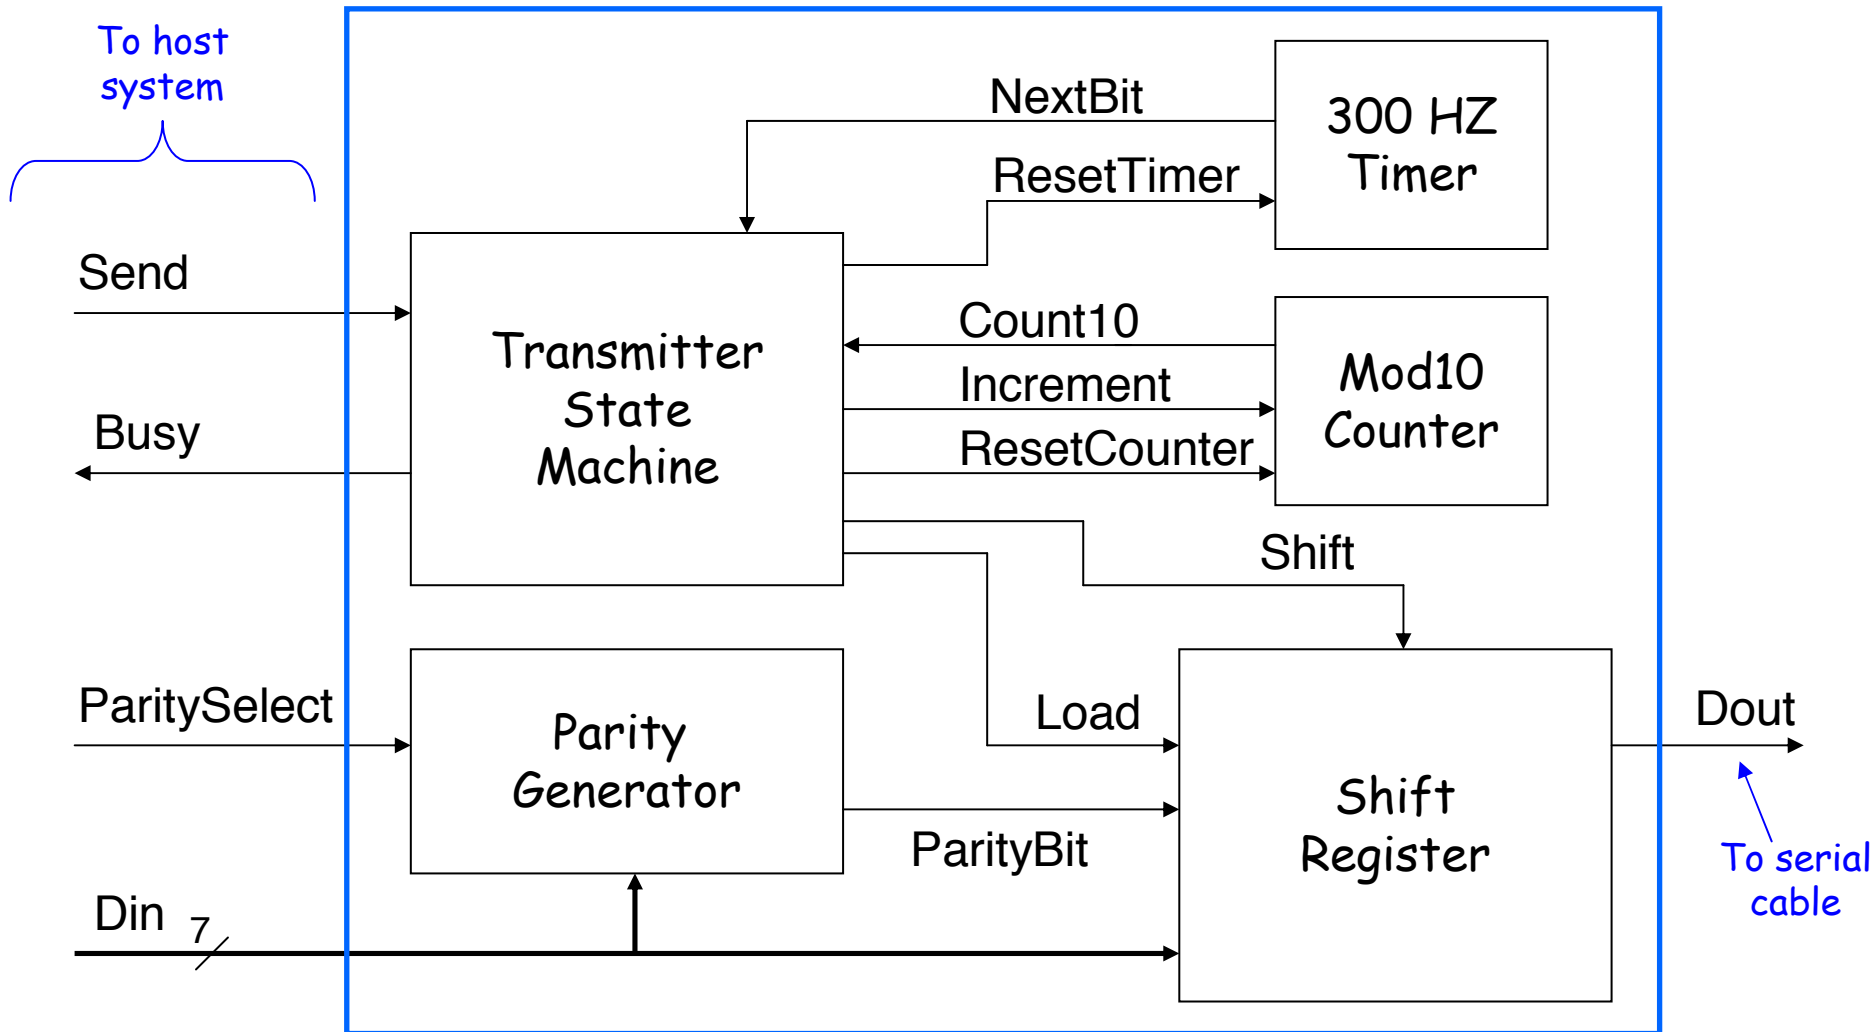

# Transmitter/System Handshaking

- System asserts Send and holds it high when it wants to send a byte
- UART asserts Busy signal in response
- When UART has finished transfer, UART de-asserts Busy signal
- System de-asserts Send signal

# Transmitter Block Diagram

# Discussion Questions

- How fast can we run a UART?
- What are the limitations?
- Why do we need start/stop bits?
- How many data bits can be sent?
  - 19200 baud rate, no parity, 8 data bits, 1 stop bit

# I2C bus in our projects

- Communication with the accelerometer
  - Read from the accelerometer
- Pros
  - Simple wire connection
  - Two wires bus that can connect multiple peripherals with the MCU
- Cons
  - Complexity is significantly higher

# How to operate the accel?

<https://www.youtube.com/watch?v=eqZgxR6eRjo>

# I2C Details

- Two lines
  - Serial data line (SDA)
  - Serial clock line (SCL)
- Only two wires for connecting multiple devices

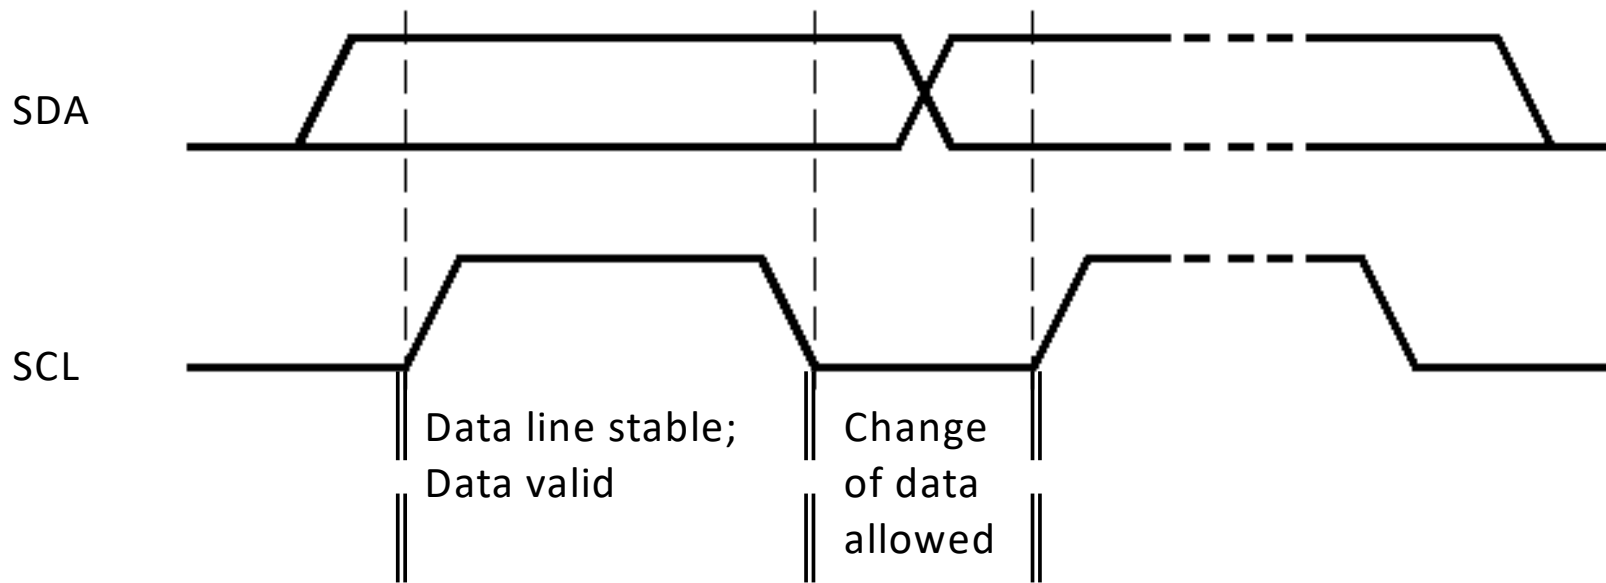

# I2C Details

- Each I2C device recognized by a unique address
- Each I2C device can be either a transmitter or receiver
- I2C devices can be masters or slaves for a data transfer
  - Master (usually a microcontroller): Initiates a data transfer on the bus, generates the clock signals to permit that transfer, and terminates the transfer
  - Slave: Any device addressed by the master at that time

# Bit Transfer on the I<sup>2</sup>C Bus

- In normal data transfer, the data line only changes state when the clock is low

# Start and Stop Conditions

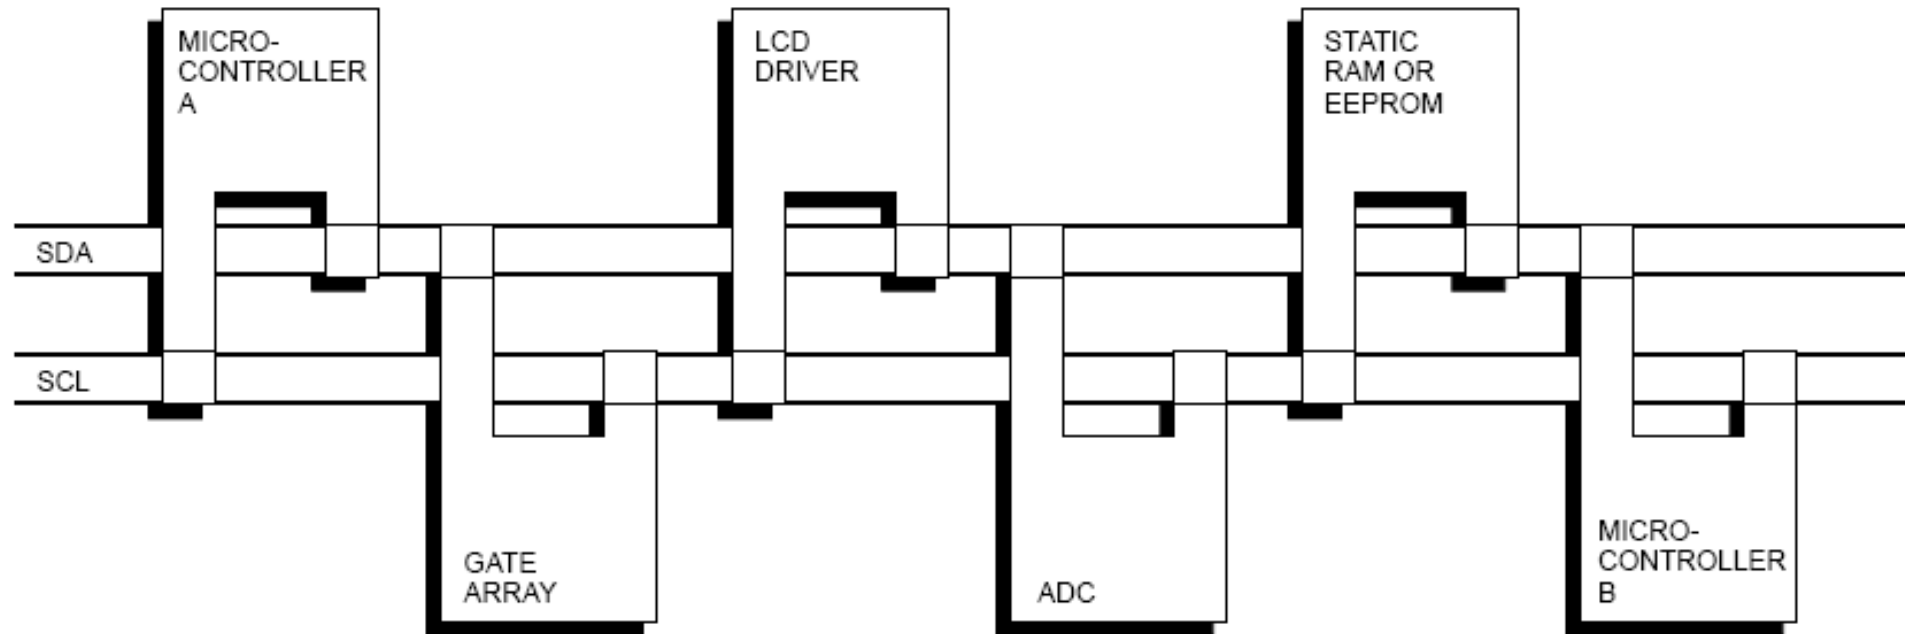

- A transition of the data line while the clock line is high is defined as either a start or a stop condition.
- Both start and stop conditions are generated by the bus master
- The bus is considered busy after a start condition, until a stop condition occurs

# I<sup>2</sup>C Addressing

- Each node has a unique 7 (or 10) bit address
- Peripherals often have fixed and programmable address portions
- Addresses starting with 0000 or 1111 have special functions:-
  - 00000000 Is a General Call Address
  - 00000001 Is a Null (CBUS) Address
  - 1111XXX Address Extension
  - 11111111 Address Extension – Next Bytes are the Actual Address

# I2C-Connected System

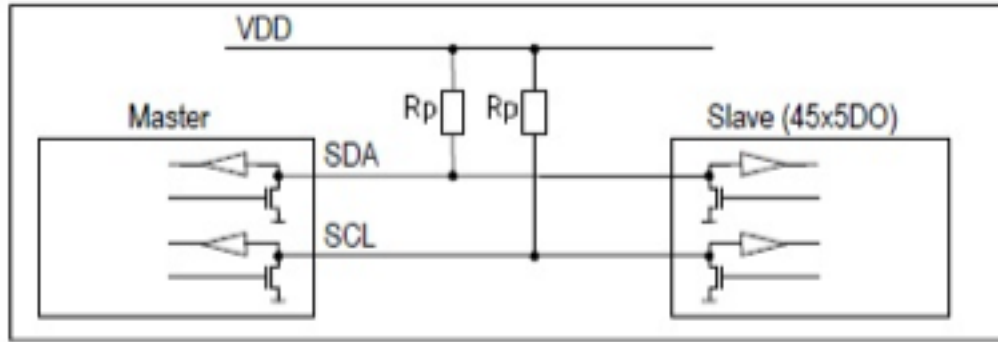

Example I2C-connected system with two microcontrollers

*(Source: I2C Specification, Philips)*

# Master-Slave Relationships

- Who is the master?
  - master-transmitters
  - master-receivers
- Suppose microcontroller A wants to send information to microcontroller B
  - A (master) addresses B (slave)
  - A (master-transmitter), sends data to B (slave-receiver)
  - A terminates the transfer.
- If microcontroller A wants to receive information from microcontroller B
  - A (master) addresses microcontroller B (slave)
  - A (master-receiver) receives data from B (slave-transmitter)
  - A terminates the transfer
- In both cases, the master (microcontroller A) generates the timing and terminates the transfer

# Exercise: How fast can I2C run?

- How fast can you run it?
- Assumptions
  - 0's are driven
  - 1's are "pulled up"
- Some working figures
  - $R_p = 10 \text{ k}\Omega$
  - $C_{cap} = 100 \text{ pF}$
  - $V_{DD} = 5 \text{ V}$
  - $V_{in\_high} = 3.5 \text{ V}$
- Recall for RC circuit
  - $V_{cap}(t) = V_{DD}(1 - e^{-t/\tau})$
  - Where  $\tau = RC$

# Exercise: Bus bit rate vs Useful data rate

- An I2C “transactions” involves the following bits
  - $\langle S \rangle \langle A6:A0 \rangle \langle R/W \rangle \langle A \rangle \langle D7:D0 \rangle \langle A \rangle \langle F \rangle$
- Which of these actually carries useful data?
  - $\langle S \rangle \langle A6:A0 \rangle \langle R/W \rangle \langle A \rangle \langle D7:D0 \rangle \langle A \rangle \langle F \rangle$
- So, if a bus runs at 400 kHz
  - What is the clock period?
  - What is the data throughput (i.e. data-bits/second)?
  - What is the bus “efficiency”?

# Serial Peripheral Interconnect (SPI)

- Another kind of serial protocol in embedded systems (proposed by Motorola)
- Four-wire protocol
  - SCLK — Serial Clock
  - MOSI/SIMO — Master Output, Slave Input
  - MISO/SOMI — Master Input, Slave Output
  - SS — Slave Select
- Single master device and with one or more slave devices
- Higher throughput than I2C and can do “stream transfers”
- No arbitration required
- But
  - Requires more pins
  - Has no hardware flow control
  - No slave acknowledgment (master could be talking to thin air and not even know it)

# What is SPI?

- Serial Bus protocol
- Fast, Easy to use, Simple
- Everyone supports it

# SPI Basics

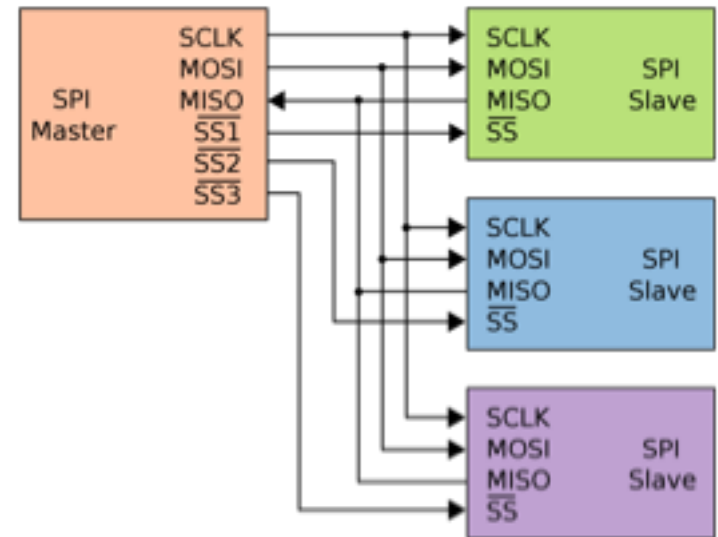

- A communication protocol using 4 wires
  - Also known as a 4 wire bus
- Used to communicate across small distances
- Multiple Slaves, Single Master
- Synchronized

# SPI Capabilities

- Always Full Duplex
  - Communicating in two directions at the same time
  - Transmission need not be meaningful
- Multiple Mbps transmission speed
- Transfers data in 4 to 16 bit characters
- Multiple slaves
  - Daisy-chaining possible

# SPI Protocol

- Wires:
  - Master Out Slave In (MOSI)
  - Master In Slave Out (MISO)
  - System Clock (SCLK)
  - Slave Select 1...N
- Master Set Slave Select low
- Master Generates Clock
- Shift registers shift in and out data

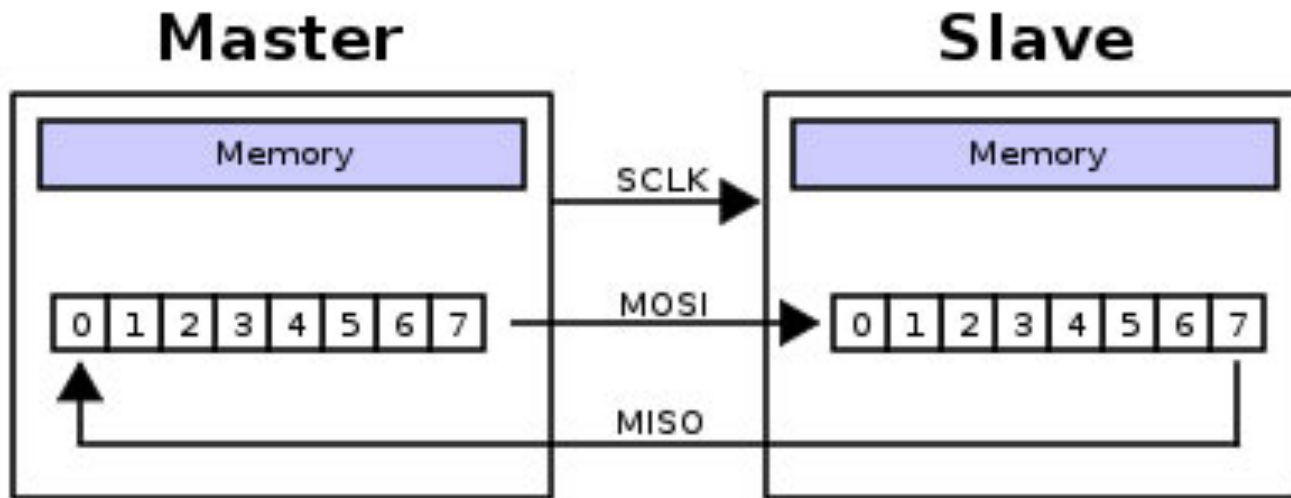

# SPI Wires in Detail

- MOSI – Carries data out of Master to Slave
- MISO – Carries data from Slave to Master
  - Both signals happen for every transmission
- SS\_BAR – Unique line to select a slave
- SCLK – Master produced clock to synchronize data transfer

# SPI uses a “shift register” model of communications

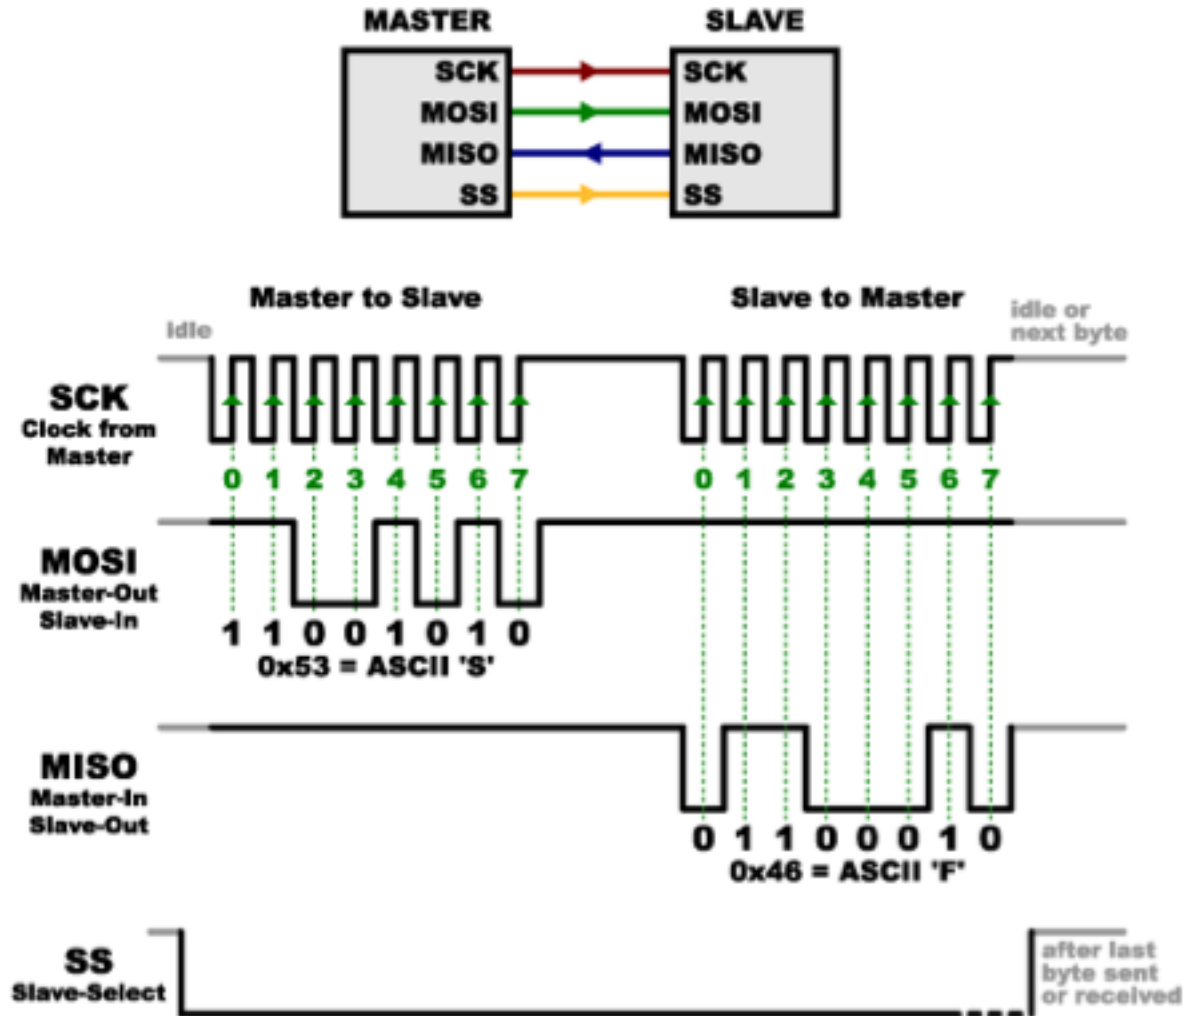

Master shifts out data to Slave, and shifts in data from Slave

[http://upload.wikimedia.org/wikipedia/commons/thumb/b/bb/SPI\\_8-bit\\_circular\\_transfer.svg/400px-SPI\\_8-bit\\_circular\\_transfer.svg.png](http://upload.wikimedia.org/wikipedia/commons/thumb/b/bb/SPI_8-bit_circular_transfer.svg/400px-SPI_8-bit_circular_transfer.svg.png)

# SPI Communication

# SPI clocking: there is no “standard way”

- Four clocking “modes”
  - Two phases
  - Two polarities
- Master and *selected* slave must be in the same mode
- During transfers with slaves A and B, Master must
  - Configure clock to Slave A’s clock mode
  - Select Slave A
  - Do transfer
  - Deselect Slave A
  - Configure clock to Slave B’s clock mode
  - Select Slave B
  - Do transfer
  - Deselect Slave B
- Master reconfigures clock mode on-the-fly!

# SPI timing diagram

Timing Diagram – Showing Clock polarities and phases

<http://www.maxim-ic.com.cn/images/appnotes/3078/3078Fig02.gif>

# SPI Pros and Cons

- Pros:
  - Fast and easy
    - Fast for point-to-point connections
    - Easily allows streaming/Constant data inflow
    - No addressing/Simple to implement
  - Everyone supports it
- Cons:
  - SS makes multiple slaves very complicated
  - No acknowledgement ability
  - No inherent arbitration
  - No flow control
