Printing History: December 1996 First printing First Printing for MATLAB 5
J une 1997 Second printing Revised for MATLAB 5.1
J anuary 1998 Third printing Revised for MATLAB 5.2
J anuary 1999 Fourth printing Revised for MATLAB 5.3 (Release 11)
November 2000 Fifth printing Revised for MATLAB 6 (Release 12)
J une 2001 Online only Revised for MATLAB 6.1 (Release 12.1)

## Development Environment

Starting and Quitting MATLAB
1
Starting MATLAB ..... 1-3
Starting MATLAB on Windows Platforms ..... 1-3
Starting MATLAB on UNIX Platforms ..... 1-3
Startup Directory for MATLAB ..... 1-3
Startup Options ..... 1-5
Reducing Startup Time with Toolbox Path Caching ..... 1-10
Quitting MATLAB ..... 1-15
Running a Script When Quitting MATLAB ..... 1-15
Using the Desktop
2
Desktop Tools ..... 2-4
Launch Pad ..... 2-5
Configuring the Desktop ..... 2-7
Opening and Closing Desktop Tools ..... 2-7
Resizing Windows ..... 2-9
Moving Windows ..... 2-10
Using Predefined Desktop Configurations ..... 2-16
Common Desktop Features ..... 2-17
Desktop Toolbar ..... 2-17
Context Menus ..... 2-17
Keyboard Shortcuts and Accelerators ..... 2-18
Selecting Multiple Items ..... 2-19
Using the Clipboard ..... 2-20
Accessing The MathWorks on the Web ..... 2-20
Setting Preferences ..... 2-21
General Preferences for MATLAB ..... 2-23
Running MATLAB Functions
3
The Command Window ..... 3-2
Opening the Command Window ..... 3-2
Running F unctions and Entering Variables ..... 3-2
Controlling Input and Output ..... 3-4
Running Programs ..... 3-11
Keeping a Session Log ..... 3-12
Preferences for the Command Window ..... 3-13
Command History ..... 3-17
Viewing Functions in the Command History Window ..... 3-17
Running F unctions from the Command History Window ..... 3-18
Copying F unctions from the Command History Window ..... 3-19
Getting Help
4
Types of Information ..... 4-3
Using the Help Browser ..... 4-4
Changing the Size of the Help Browser ..... 4-5
Using the Help Navigator ..... 4-7
Using the Product Filter ..... 4-7
Viewing the Contents Listing in the Help Browser ..... 4-9
Finding Documentation Using the Index ..... 4-11
Searching Documentation ..... 4-13
Bookmarking Favorite Pages ..... 4-15
Viewing Documentation in the Display Pane ..... 4-17
Browsing to Other Pages ..... 4-18
Bookmarking Pages ..... 4-18
Revisiting Pages ..... 4-19
Printing Pages ..... 4-19
Finding Terms in Displayed Pages ..... 4-19
Copying Information ..... 4-19
Evaluating a Selection ..... 4-19
Viewing the Page Source (HTML) ..... 4-20
Viewing Web Pages ..... 4-20
Preferences for the Help Browser ..... 4-21
Documentation Location - Specifying the help Directory ..... 4-22
Product Filter - Limiting the Product Documentation ..... 4-23
PDF Reader - Specifying Its Location ..... 4-23
General - Synchronizing the Contents Pane with the Displayed Page ..... 4-23
Help Fonts Preferences - Specifying F ont Name, Style, and Size ..... 4-24
Printing Documentation ..... 4-26
Printing a Page from the Help Browser ..... 4-26
Printing the PDF Version of Documentation ..... 4-26
Using Help F unctions ..... 4-28
Viewing Function Reference Pages - the doc Function ..... 4-29
Getting Help in the Command Window - the help Function ..... 4-29
Other Methods for Getting Help ..... 4-31
Product-Specific Help Features ..... 4-31
Running Demos ..... 4-31
Contacting Technical Support ..... 4-32
Providing Feedback ..... 4-32
Getting Version and License Information ..... 4-32
Accessing Documentation for Other Products ..... 4-33
Participating in the Newsgroup for MathWorks Products ..... 4-33
Workspace, Search Path, and File Operations
5
MATLAB Workspace ..... 5-3
Workspace Browser ..... 5-3
Viewing and Editing Workspace Variables Using the Array Editor ..... 5-10
Search Path ..... 5-14
How the Search Path Works ..... 5-14
Viewing and Setting the Search Path ..... 5-15
File Operations ..... 5-20
Current Directory Field ..... 5-20
Current Directory Browser ..... 5-20
Viewing and Making Changes to Directories ..... 5-22
Creating, Renaming, Copying, and Removing Directories and Files ..... 5-23
Opening, Running, and Viewing the Content of Files ..... 5-26
Finding and Replacing Content Within Files ..... 5-28
Preferences for the Current Directory Browser ..... 5-30
Importing and Exporting Data
6
Importing Text Data ..... 6-4
Using the Import Wizard with Text Data ..... 6-4
Using Import Functions with Text Data ..... 6-9
Importing Numeric Text Data ..... 6-11
Importing Delimited ASCII Data Files ..... 6-12
Importing Numeric Data with Text Headers ..... 6-13
Importing Mixed Alphabetic and Numeric Data ..... 6-14
Exporting ASCII Data ..... 6-16
Exporting Delimited ASCII Data Files ..... 6-17
Using the diary Command to Export Data ..... 6-18
Importing Binary Data ..... 6-20
Using the Import Wizard with Binary Data Files ..... 6-20
Using Import Functions with Binary Data ..... 6-22
Exporting Binary Data ..... 6-25
Exporting MATLAB Graphs in AVI Format ..... 6-27
Working with HDF Data ..... 6-29
Overview of MATLAB HDF Support ..... 6-30
MATLAB HDF Function Calling Conventions ..... 6-31
Importing HDF Data into the MATLAB Workspace ..... 6-33
Exporting MATLAB Data in an HDF File ..... 6-41
Including Metadata in an HDF File ..... 6-47
Using the MATLAB HDF Utility API ..... 6-49
Using Low-Level File I/O Functions ..... 6-51
Opening Files ..... 6-52
Reading Binary Data ..... 6-54
Writing Binary Data ..... 6-55
Controlling Position in a File ..... 6-56
Reading Strings Line-By-Line from Text Files ..... 6-58
Reading F ormatted ASCII Data ..... 6-59
Writing F ormatted Text Files ..... 6-61
Closing a File ..... 6-62
Editing and Debugging M-Files
7
Starting the Editor/Debugger ..... 7-3
Creating a New M-File in the Editor/Debugger ..... 7-4
Opening Existing M-Files in the Editor/Debugger ..... 7-5
Opening the Editor Without Starting MATLAB ..... 7-6
Closing the Editor/Debugger ..... 7-6
Creating and Editing M-Files with the Editor/Debugger ..... 7-8
Appearance of an M-File ..... 7-8
Navigating in an M-File ..... 7-11
Saving M-Files ..... 7-15
Running M-Files from the Editor/Debugger ..... 7-15
Printing an M-File ..... 7-16
Closing M-Files ..... 7-16
Debugging M-Files ..... 7-17
Types of Errors ..... 7-17
Finding Errors ..... 7-17
Debugging Example - The Collatz Problem ..... 7-18
Using Debugging Features ..... 7-22
Preferences for the Editor/Debugger ..... 7-35
General Preferences for the Editor/Debugger ..... 7-36
F ont \& Colors Preferences for the Editor/Debugger ..... 7-37
Display Preferences for the Editor/Debugger ..... 7-38
K eyboard and Indenting Preferences for the E ditor/Debugger ..... 7-40
Printing Preferences for the Editor/Debugger ..... 7-42
Improving M-File Performance - the Profiler
8
What Is Profiling? ..... 8-3
Using the Profiler ..... 8-4
The profile Function ..... 8-4
An Example Using the Profiler ..... 8-6
Viewing Profiler Results ..... 8-7
Viewing Profile Reports ..... 8-7
Profile Plot ..... 8-12
Saving Profile Reports ..... 8-13

## 9

Process of Interfacing to an SCS ..... 9-3
Viewing or Selecting the Source Control System ..... 9-4
F unction Alternative for Viewing the SCS ..... 9-5
Setting Up the Source Control System ..... 9-6
F or SourceSafe Only - Mirroring MATLAB Hierarchy ..... 9-6
For ClearCase on UNIX Only - Set a View and
Check Out a Directory ..... 9-6
Checking Files into the Source Control System ..... 9-7
Function Alternative for Checking In Files ..... 9-8
Checking Files Out of the SCS ..... 9-9
F unction Alternative for Checking Out Files ..... 9-10
Undoing the Check-Out ..... 9-10
Using Notebook
10
Notebook Basics ..... 10-3
Creating an M-Book ..... 10-3
Entering MATLAB Commands in an M-Book ..... 10-6
Protecting the Integrity of Your Workspace ..... 10-6
Ensuring Data Consistency ..... 10-7
Defining MATLAB Commands as Input Cells ..... 10-8
Defining Cell Groups ..... 10-8
Defining Autoinit Input Cells ..... 10-10
Defining Calc Zones ..... 10-10
Converting an Input Cell to Text ..... 10-11
Evaluating MATLAB Commands ..... 10-12
Evaluating Cell Groups ..... 10-13
Evaluating a Range of Input Cells ..... 10-14
Evaluating a Calc Zone ..... 10-14
Evaluating an Entire M-Book ..... 10-15
Using a Loop to Evaluate Input Cells Repeatedly ..... 10-15
Converting Output Cells to Text ..... 10-16
Deleting Output Cells ..... 10-17
Printing and Formatting an M-Book ..... 10-18
Printing an M-Book ..... 10-18
Modifying Styles in the M-Book Template ..... 10-18
Choosing Loose or Compact Format ..... 10-19
Controlling Numeric Output Format ..... 10-20
Controlling Graphic Output ..... 10-20
Configuring Notebook ..... 10-24
Notebook Command Reference ..... 10-26
Bring MATLAB to Front Command ..... 10-26
Define Autoinit Cell Command ..... 10-26
Define Calc Zone Command ..... 10-27
Define Input Cell Command ..... 10-27
Evaluate Calc Zone Command ..... 10-28
Evaluate Cell Command ..... 10-28
Evaluate Loop Command ..... 10-29
Evaluate M-Book Command ..... 10-30
Group Cells Command ..... 10-30
Hide Cell Markers Command ..... 10-31
Notebook Options Command ..... 10-31
Purge Output Cells Command ..... 10-31
Toggle Graph Output for Cell Command ..... 10-31
Undefine Cells Command ..... 10-32
Ungroup Cells Command ..... 10-32

## Mathematics

Matrices and Linear Algebra
11
Function Summary ..... 11-3
Matrices in MATLAB ..... 11-5
Creation ..... 11-5
Addition and Subtraction ..... 11-7
Vector Productsand Transpose ..... 11-7
Matrix Multiplication ..... 11-9
The Identity Matrix ..... 11-11
The Kronecker Tensor Product ..... 11-11
Vector and Matrix Norms ..... 11-12
Solving Linear Systems of Equations ..... 11-13
Overview ..... 11-13
Square Systems ..... 11-15
Overdetermined Systems ..... 11-15
Underdetermined Systems ..... 11-18
Inverses and Determinants ..... 11-21
Overview ..... 11-21
Pseudoinverses ..... 11-22
Cholesky, LU, and QR Factorizations ..... 11-25
Cholesky Factorization ..... 11-25
LU Factorization ..... 11-26
QR Factorization ..... 11-28
Matrix Powers and Exponentials ..... 11-32
Eigenvalues ..... 11-35
Singular Value Decomposition ..... 11-39
Polynomials ..... 12-3
Polynomial Function Summary ..... 12-3
Representing Polynomials ..... 12-4
Polynomial Roots ..... 12-4
Characteristic Polynomials ..... 12-5
Polynomial Evaluation ..... 12-5
Convolution and Deconvolution ..... 12-6
Polynomial Derivatives ..... 12-6
Polynomial Curve Fitting ..... 12-7
Partial Fraction Expansion ..... 12-8
Interpolation ..... 12-10
Interpolation Function Summary ..... 12-10
One-Dimensional Interpolation ..... 12-11
Two-Dimensional Interpolation ..... 12-13
Comparing Interpolation Methods ..... 12-14
Interpolation and Multidimensional Arrays ..... 12-16
Triangulation and Interpolation of Scattered Data ..... 12-19
Tessellation and Interpolation of Scattered Data in Higher Dimensions ..... 12-27
Selected Bibliography ..... 12-38
Data Analysis and Statistics
13
Column-Oriented Data Sets ..... 13-4
Basic Data Analysis Functions ..... 13-8
Function Summary ..... 13-8
Covariance and Correlation Coefficients ..... 13-11
Finite Differences ..... 13-12
Data Preprocessing ..... 13-14
Missing Values ..... 13-14
Removing Outliers ..... 13-15
Regression and Curve Fitting ..... 13-17
Polynomial Regression ..... 13-18
Linear-in-the-Parameters Regression ..... 13-19
Multiple Regression ..... 13-21
Case Study: Curve Fitting ..... 13-22
Polynomial Fit ..... 13-22
Analyzing Residuals ..... 13-24
Exponential Fit ..... 13-27
Error Bounds ..... 13-30
The Basic Fitting Interface ..... 13-31
Difference Equations and Filtering ..... 13-40
Fourier Analysis and the Fast Fourier Transform (FFT) ..... 13-43
Function Summary ..... 13-43
Introduction ..... 13-44
Magnitude and Phase of Transformed Data ..... 13-49
FFT Length Versus Speed ..... 13-50
Function Functions
14
Function Summary ..... 14-3
Representing Functions in MATLAB ..... 14-4
Plotting Mathematical Functions ..... 14-6
Minimizing Functions and Finding Zeros ..... 14-9
Minimizing Functions of One Variable ..... 14-9
Minimizing Functions of Several Variables ..... 14-10
Setting Minimization Options ..... 14-11
Finding Zeros of Functions ..... 14-12
Tips ..... 14-15
Troubleshooting ..... 14-15
Converting Your Optimization Code to MATLAB Version 5 Syntax ..... 14-16
Numerical Integration (Quadrature) ..... 14-19
Example: Computing the Length of a Curve ..... 14-19
Example: Double Integration ..... 14-20
Differential Equations
15
Initial Value Problems for ODEs and DAEs ..... 15-3
ODE Function Summary ..... 15-3
Introduction to Initial Value ODE Problems ..... 15-6
Initial Value Problem Solvers ..... 15-6
Representing ODE Problems ..... 15-10
Improving ODE Solver Performance ..... 15-16
Examples: Applying the ODE Initial Value Problem Solvers ..... 15-31
Questions and Answers, and Troubleshooting ..... 15-50
Boundary Value Problems for ODEs ..... 15-57
BVP Function Summary ..... 15-57
Introduction to Boundary Value ODE Problems ..... 15-59
Boundary Value Problem Solver ..... 15-60
Representing BVP Problems ..... 15-63
Using Continuation to Make a Good Initial Guess ..... 15-68
Improving BVP Solver Performance ..... 15-75
Partial Differential Equations ..... 15-82
PDE Function Summary ..... 15-82
Introduction to PDE Problems ..... 15-83
MATLAB Partial Differential Equation Solver ..... 15-84
Representing PDE Problems ..... 15-88
Improving PDE Solver Performance ..... 15-93
Example: Electrodynamics Problem ..... 15-94
Selected Bibliography ..... 15-99
Sparse Matrices
16
Function Summary ..... 16-3
Introduction ..... 16-6
Sparse Matrix Storage ..... 16-6
General Storage Information ..... 16-7
Creating Sparse M atrices ..... 16-7
Importing Sparse Matrices from Outside MATLAB ..... 16-12
Viewing Sparse Matrices ..... 16-13
Information About Nonzero Elements ..... 16-13
Viewing Sparse Matrices Graphically ..... 16-15
The find Function and Sparse Matrices ..... 16-16
Example: Adjacency Matrices and Graphs ..... 16-17
Introduction to Adjacency M atrices ..... 16-17
Graphing Using Adjacency Matrices ..... 16-18
The Bucky Ball ..... 16-18
An Airflow Model ..... 16-23
Sparse Matrix Operations ..... 16-25
Computational Considerations ..... 16-25
Standard Mathematical Operations ..... 16-25
Permutation and Reordering ..... 16-26
Factorization ..... 16-30
Simultaneous Linear Equations ..... 16-36
Eigenvalues and Singular Values ..... 16-39
Selected Bibliography ..... 16-42

## Programming and Data Types

M-File Programming
17
MATLAB Programming: A Quick Start ..... 17-3
Kinds of M-Files ..... 17-3
What's in an M-File? ..... 17-4
Providing Help for Your Programs ..... 17-4
Creating M-Files: Accessing Text Editors ..... 17-5

return ..... 17-42
Subfunctions ..... 17-43
Private Functions ..... 17-45
Subscripting and Indexing ..... 17-46
Subscripting ..... 17-46
Advanced Indexing ..... 17-51
String Evaluation ..... 17-54
eval ..... 17-54
feval ..... 17-54
Command/F unction Duality ..... 17-56
Empty Matrices ..... 17-57
Operating on an Empty Matrix ..... 17-57
Using Empty Matrices with If or While ..... 17-58
Errors and Warnings ..... 17-59
Error Handling with eval and lasterr ..... 17-59
Displaying Error and Warning Messages ..... 17-60
Dates and Times ..... 17-62
Date Formats ..... 17-62
Current Date and Time ..... 17-67
Obtaining User Input ..... 17-69
Prompting for Keyboard Input ..... 17-69
Pausing During Execution ..... 17-69
Shell Escape Functions ..... 17-70
Optimizing MATLAB Code ..... 17-71
Vectorizing Loops ..... 17-71
Preallocating Arrays ..... 17-73
Making Efficient Use of Memory ..... 17-74
Character Arrays (Strings)
18
Character Arrays ..... 18-5
Creating Character Arrays ..... 18-5
Creating Two-Dimensional Character Arrays ..... 18-6
Converting Characters to Numeric Values ..... 18-7
Cell Arrays of Strings ..... 18-8
Converting to a Cell Array of Strings ..... 18-8
String Comparisons ..... 18-10
Comparing Strings For Equality ..... 18-10
Comparing for Equality Using Operators ..... 18-11
Categorizing Characters Within a String ..... 18-12
Searching and Replacing ..... 18-13
String/Numeric Conversion ..... 18-15
Array/String Conversion ..... 18-16
Multidimensional Arrays
19Multidimensional Arrays19-3
Creating Multidimensional Arrays ..... 19-4
Accessing Multidimensional Array Properties ..... 19-8
Indexing ..... 19-9
Reshaping ..... 19-10
Permuting Array Dimensions ..... 19-12
Computing with Multidimensional Arrays ..... 19-14
Operating on Vectors ..... 19-14
Operating Element-by-Element ..... 19-14
Operating on Planes and Matrices ..... 19-15
Organizing Data in Multidimensional Arrays ..... 19-16
Multidimensional Cell Arrays ..... 19-18
Multidimensional Structure Arrays ..... 19-19
Applying Functions to Multidimensional Structure Arrays ..... 19-20
Structures and Cell Arrays
20
Structures ..... 20-4
Building Structure Arrays ..... 20-5
Accessing Data in Structure Arrays ..... 20-7
Finding the size of Structure Arrays ..... 20-10
Adding Fields to Structures ..... 20-10
Deleting Fields from Structures ..... 20-10
Applying Functions and Operators ..... 20-10
Writing Functions to Operate on Structures ..... 20-11
Organizing Data in Structure Arrays ..... 20-12
Nesting Structures ..... 20-17
Cell Arrays ..... 20-19
Creating Cell Arrays ..... 20-20
Obtaining Data from Cell Arrays ..... 20-23
Deleting Cells ..... 20-24
Reshaping Cell Arrays ..... 20-25
Replacing Lists of Variables with Cell Arrays ..... 20-25
Applying Functions and Operators ..... 20-27
Organizing Data in Cell Arrays ..... 20-27
Nesting Cell Arrays ..... 20-29
Converting Between Cell and Numeric Arrays ..... 20-30
Cell Arrays of Structures ..... 20-31
Function Handles
21
Benefits of Using Function Handles ..... 21-3
A Simple Function Handle ..... 21-5
Constructing a Function Handle ..... 21-7
Maximum Length of a Function Name ..... 21-7
Evaluating a Function Through Its Handle ..... 21-9
Function Evaluation and Overloading ..... 21-9
Examples of Function Handle Evaluation ..... 21-10
Displaying F unction Handle Information ..... 21-13
Fields Returned by the Functions Command ..... 21-14
Types of Function Handles ..... 21-17
Function Handle Operations ..... 21-21
Converting Function Handles to Function Names ..... 21-21
Converting Function Names to Function Handles ..... 21-22
Testing for Data Type ..... 21-23
Testing for Equality ..... 21-23
Saving and Loading Function Handles ..... 21-25
Handling Error Conditions ..... 21-26
Handles to Nonexistent Functions ..... 21-26
Including Path In the Function Handle Constructor ..... 21-26
Evaluating a Nonscalar Function Handle ..... 21-27
Historical Note - Evaluating Function Names ..... 21-28
Classes and Objects: An Overview ..... 22-3
F eatures of Object-Oriented Programming ..... 22-3
MATLAB Data Class Hierarchy ..... 22-4
Creating Objects ..... 22-4
Invoking Methods on Objects ..... 22-5
Private Methods ..... 22-6
Helper Functions ..... 22-6
Debugging Class Methods ..... 22-6
Setting Up Class Directories ..... 22-7
Data Structure ..... 22-8
Tips for C+ and J ava Programmers ..... 22-8
Designing User Classes in MATLAB ..... 22-9
The MATLAB Canonical Class ..... 22-9
The Class Constructor Method ..... 22-10
Examples of Constructor Methods ..... 22-11
Identifying Objects Outside the Class Directory ..... 22-11
The display Method ..... 22-12
Accessing Object Data ..... 22-13
The set and get Methods ..... 22-13
Indexed Reference Using subsref and subsasgn ..... 22-14
Handling Subscripted Reference ..... 22-14
Handling Subscripted Assignment ..... 22-17
Object Indexing Within Methods ..... 22-17
Defining end Indexing for an Object ..... 22-18
Indexing an Object with Another Object ..... 22-19
Converter Methods ..... 22-20
Overloading Operators and Functions ..... 22-21
Overloading Operators ..... 22-21
Overloading F unctions ..... 22-23
Example - A Polynomial Class ..... 22-24
Polynom Data Structure ..... 22-24
Polynom Methods ..... 22-24
The Polynom Constructor Method ..... 22-24
Converter Methods for the Polynom Class ..... 22-25
The Polynom display Method ..... 22-28
The Polynom subsref Method ..... 22-28
Overloading Arithmetic Operators for polynom ..... 22-29
Overloading F unctions for the Polynom Class ..... 22-31
Listing Class Methods ..... 22-33
Building on Other Classes ..... 22-35
Simple Inheritance ..... 22-35
Multiple Inheritance ..... 22-36
Aggregation ..... 22-37
Example - Assets and Asset Subclasses ..... 22-38
Inheritance Model for the Asset Class ..... 22-38
Asset Class Design ..... 22-39
Other Asset Methods ..... 22-39
The Asset Constructor Method ..... 22-39
The Asset get Method ..... 22-41
The Asset set Method ..... 22-41
The Asset subsref Method ..... 22-42
The Asset subsasgn Method ..... 22-43
The Asset display Method ..... 22-44
The Asset fieldcount Method ..... 22-45
Designing the Stock Class ..... 22-45
The Stock Constructor Method ..... 22-46
The Stock get Method ..... 22-48
The Stock set Method ..... 22-48
The Stock subsref Method ..... 22-49
The Stock subsasgn Method ..... 22-51
The Stock display Method ..... 22-52
Example - The Portfolio Container ..... 22-54
Designing the Portfolio Class ..... 22-54
The Portfolio Constructor Method ..... 22-55
The Portfolio display Method ..... 22-56
The Portfolio pie3 Method ..... 22-57
Creating a Portfolio ..... 22-58
Saving and Loading Objects ..... 22-60
M odifying Objects During Save or Load ..... 22-60
Example - Defining saveobj and loadobj for Portfolio ..... 22-61
Summary of Code Changes ..... 22-61
The saveobj Method ..... 22-62
The loadobj Method ..... 22-62
Changing the Portfolio Constructor ..... 22-63
The Portfolio subsref Method ..... 22-64
Object Precedence ..... 22-65
Specifying Precedence of User-Defined Classes ..... 22-66
How MATLAB Determines Which Method to Call ..... 22-67
Selecting a Method ..... 22-67
Querying Which Method MATLAB Will Call ..... 22-70
External Interfaces and the MATLAB API

# Development Environment 

The MATLAB ${ }^{\circledR}$ development environment is a set of tools to help you use MATLAB functions and files. Many of these tools are graphical user interfaces.

## Fundamentals

- "Starting and Quitting MATLAB" - How to run MATLAB, and startup and shutdown options.
- "Using the Desktop" - The MATLAB desktop is what you first see when you start MATLAB. It manages the other tools, including the Launch Pad, which is described here.
- "Running MATLAB Functions" - Working in the Command Window and Command History window.
- "Getting Help" - The Help browser, help functions, printed documentation, and other ways to get help.

## Additional Development Environment Tools

- "Workspace, Search Path, and File Operations" - Use the Workspace browser, Array Editor, search path tool, Current Directory browser, and equivalent functions.
- "Importing and Exporting Data" - Techniques for bringing data created by other applications into the MATLAB workspace, including the Import Wizard, and packaging MATLAB workspace variables for use by other applications.
- "Editing and Debugging M-Files" - MATLAB's graphical Editor/Debugger and debugging functions for creating and changing M-files (program files containing MATLAB functions).
- "Improving M-File Performance - the Profiler" - Tool that measures where an $M$-file is spending its time. Use it help you make speed improvements.
- "Interfacing with Source Control Systems" - Access your source control system from within MATLAB, Simulink, and Stateflow.
- "Using Notebook" - Access MATLAB's numeric computation and visualization software from within a word processing environment (Microsoft Word).

## Starting and Quitting MATLAB

Starting MATLAB ..... 1-3
Starting MATLAB on Windows Platforms ..... 1-3
Starting MATLAB on UNIX Platforms ..... 1-3
Startup Directory for MATLAB ..... 1-3
Startup Options ..... 1-5
Reducing Startup Time with Toolbox Path Caching ..... 1-10
Quitting MATLAB ..... 1-15
Running a Script When Quitting MATLAB ..... 1-15

These sections describe how to start and quit MATLAB, including options associated with starting and quitting.

- "Starting MATLAB on Windows Platforms" on page 1-3
- "Starting MATLAB on UNIX Platforms" on page 1-3
- "Startup Directory for MATLAB" on page 1-3
- "Startup Options" on page 1-5
- "Reducing Startup Time with Toolbox Path Caching" on page 1-10
- "Quitting MATLAB" on page 1-15
- "Running a Script When Quitting MATLAB" on page 1-15

## Starting MATLAB

Instructions for starting MATLAB depend on your platform. For a list of supported platforms, see the system requirements in theInstallation Guidefor your platform or the Products section of the MathWorks Web site, http://www.mathworks.com.

## Starting MATLAB on Windows Platforms

Tostart MATLAB on a Microsoft Windows platform, double-dick theMATLAB shortcut icon on your Windows desktop. The shortcut was automatically created by the installer in the installation directory.

If you start MATLAB from a DOS window, type matlab at the DOS prompt.
After starting MATLAB, the MATLAB desktop opens - see Chapter 2, "Using the Desktop."

If you use a virus scanner, your settings may slow down MATLAB startup. For example, if you use McAfee VirusScan, set the options to scan program files only.

## Starting MATLAB on UNIX Platforms

To start MATLAB on a UNIX platform, type matlab at the operating system prompt.

After starting MATLAB, the MATLAB desktop opens - see Chapter 2, "Using the Desktop." On UNIX platforms, if the DISPLAY environment variable is not set or is invalid, the desktop will not display. On some UNIX platforms, the desktop is not supported - see the R12 Rel ease Notes for details.

## Startup Directory for MATLAB

The initial current directory in MATLAB depends on your platform and installation. Y ou can start MATLAB in a different directory.

## Startup Directory on Windows Platforms

On Windows platforms, when you installed MATLAB, the default startup directory was set to \$matlabroot \work, where \$matlabroot is the directory where MATLAB files are installed.

## Startup Directory on UNIX Platforms

On UNIX platforms, the initial current directory is the directory you are in on your UNIX file system when you invoke MATLAB.

## Changing the Startup Directory

You can start MATLAB in a different directory from the default. The directory you specify will be the current working directory when MATLAB starts. To do so:

1 Create a startup.m file - see "Using the Startup File for MATLAB, startup.m" on page 1-5.

2 In the startup.m file, include the cd function to change to the new directory.
3 Put the startup.m file in the current startup directory.
For Windows Platforms Only. For Windows platforms, you can follow thesesteps to change the startup directory:

1 Right-click on the MATLAB shortcut icon and select Properties from the context menu.

The Properties dialog box for matlab. exe opens to the Shortcut page.
2 E nter the new startup directory in the Start in field and click OK.
The next time you start MATLAB using that shortcut icon, the current directory will be the one you specified in step 2.
You can make multiple shortcuts to start MATLAB, each with its own startup directory, and each startup directory having different startup options.

## Startup Options

You can define startup options for MATLAB, which instruct MATLAB to perform certain operations upon startup. There aretwo ways to specify startup options for MATLAB:

- "Using the Startup File for MATLAB, startup.m" on page 1-5
- "Adding Startup Options for Windows Platforms" on page 1-5 or "Adding Startup Options for UNIX Platforms" on page 1-7

## Using the Startup File for MATLAB, startup.m

At startup, MATLAB automatically executes the master M-file matlabrc.m and, if it exists, startup.m. The file matlabrc.m, which lives in the local directory, is reserved for use by The MathWorks, and on multiuser systems, by your system manager.

The file startup.m is for you to use to specify startup options. You can modify the default search path, predefine variables in your workspace, or define Handle Graphics ${ }^{\circledR}$ defaults. For example, creating a startup.m file with the line
addpath \home\me\mytools
cd \home\me\mytools
adds \home $\backslash$ me $\backslash$ mytools to your default search path and makes that directory the current directory upon startup.

On Windows platforms, place the startup.m file in
\$matlabroot \toolbox\local, where \$matlabroot is the directory in which MATLAB is installed.

On UNIX workstations, place the startup.m file in the directory named matlab off of your home directory, for example, ~/matlab.

## Adding Startup 0 ptions for W indows Platforms

You can add selected startup options (also called command flags) to the target path for your Windows shortcut for MATLAB, or include the option if you start MATLAB from a DOS window. To do so:

1 Right-click on theMATLAB shortcuticon and select Properties from the context menu.

The Properties dialog box for matlab. exe opens to the Shortcut panel.
2 In the Target field, after the target path for matlab.exe, add one or more of the allowable startup options listed here.

| Option | Description |
| :--- | :--- |
| / automation | Start MATLAB as an automation server, <br> minimized and without the MATLAB splash <br> screen. For more information, see "Client/Server <br> Applications" in the External Interfaces Guide. |
| /c licensefile | Set LM_LICENSE_FILE to licensefile. It can <br> have the form port@host. |
| /logfile logfilename | Automatically write output from MATLAB to the <br> specified log file. |
| /minimize | Start MATLAB minimized and without the <br> MATLAB splash screen. |
| /nosplash | Start MATLAB without displaying the MATLAB <br> splash screen. |
| /r M_file | Automatically run the specified M-file <br> immediately after MATLAB starts. This is also <br> referred to as calling MATLAB in batch mode. |
| /regserver | Modify the Windows registry with the <br> appropriate ActiveX entries for MATLAB. For <br> more information, see "Client/Server <br> Applications" in the External Interfaces Guide |
| /unregserver | Modify the Windows registry to remove the <br> ActiveX entries for MATLAB. Use this option to <br> reset the registry. For more information, see <br> "Client/Server Applications" in the External <br> Interfaces Guide |

## 3 Click OK.

Example - Setting the Startup Options to Automatically Run an M-File. To start MATLAB and automatically run the file results.m, use this target path for your Windows shortcut.

```
D:\matlabr12\bin\win32\matlab.exe /r results
```

Startup Options If You Run MATLAB from a DOS Window. If you run MATLAB from a DOS window, include the startup options listed in the preceding table after the matlab startup function.

For example, to start MATLAB and automatically run the file results.m, type matlab /r results

## Adding Startup 0 ptions for UNIX Platforms

Include startup options (also called command flags) after the matlab startup function. The startup options for UNIX are listed in the following table

| Option | Description |
| :--- | :--- |
| - arch | Run MATLAB assuming architecture arch. |
| -arch/ext | Run the version of MATLAB with the <br> extension ext if it exists, assuming <br> architecture arch. |
| -c licensefile | Set LM_LICENSE_FILE to licensefile. It can <br> have the form port@host. |
| - Ddebugger [options] | Start MATLAB with the specified debugger. |
| -debug | Turn on MATLAB internal debugging. |
| -display Xserver | Send X commands to Xserver. |
| - ext | Run the version of MATLAB with the <br> extension ext, if it exists. |
| -h or -help | Displays startup options. |

| Option | Description (Continued) |
| :--- | :--- |
| -mwvisual visualid | Specify the default X visual to use for figure <br> windows. |
| -n | Print environment variables only. |
| -nodesktop | Start MATLAB without bringing up the <br> MATLAB desktop. Use this option to run <br> without an X-window, for example, in VT100 <br> mode, or in batch processing mode. N otethat if <br> you pipe to MATLAB using the > constructor, <br> the nodesktop option is used automatically. |
|  | With nodesktop, you can still use most <br> development environment tools by starting <br> them with a function. Specifically use: |
|  | - edit to open the Editor/Debugger <br> - helpbrowser to open the Help browser |
|  | - filebrowser to open the Current Directory |
| browser |  |

| Option | Description (Continued) |
| :--- | :--- |
| -nojvm | Start MATLAB without loading the J ava VM. <br>  <br>  <br>  <br>  <br> This minimizes memory usage and improves <br> initial startup speed. With noj vm, you cannot <br> use the desktop, nor any of the tools that <br> requireJ ava. The restrictions are the same as <br> those described under UNIX Platform <br> Limitations in the R12 Re ease Notes. |
| -nosplash | Start MATLAB without displaying the splash <br> screen during startup. |

For example, to start MATLAB without the splash screen, type matlab -nosplash

## Reducing Startup Time with Toolbox Path Caching

If you run MATLAB from a network server, you can significantly reduce your startup time by using the MATLAB tool box path cache. The tool box path cache stores search path information on all tool box directories under the MATLAB root directory. During startup, MATLAB obtains this information from the cache rather than by reading it from the remote file system.

The tool box path cache is used only during the startup of your MATLAB session. It is especially useful if you define your MATLAB search path to include many tool box directories. It takes considerable time to acquire all of this information by scanning directories in the remote file system. Reading it from a pre-generated cache however, is significantly faster. If you have a short tool box path, there is less benefit to using the cache, but it does still provide a time savings.

If you run MATLAB on a local disk, where your files are not served from a remote system, then the cache may provide no noticeable reduction in startup time. In this case, you may want to leave the tool box path cache disabled.

## Selecting Toolbox Path Cache Preferences

To generate and enable or disable the tool box path cache, use MATLAB preferences.

1 From the MATLAB desktop, select Preferences from the File menu.
The Preferences dialog box appears.

2 In the left pane of the dialog box, click General to display the General Preferences panel in the right pane.

3 To use the cache or to regenerate the cache, select E nable toolbox cache under Toolbox caching.

With Enable toolbox cache selected, MATLAB displays summary information during startup, sends notification when it loads the tool box directories from the cache, and displays a warning if the tool box path cache cannot be found.

4 F or additional information, select Enable toolbox cache diagnostics.
With E nable toolbox cache diagnostics selected, MATLAB displays additional information at startup.

MATLAB also provides warnings whenever a tool box directory is added to the path from the remote file system at startup rather than from the cache. This occurs if the cache has not been kept up to date with changes in the tool box directories.

5 To generate a new copy of the cache, select Update Toolbox Cache. See "Generating the Tool box Path Cache" on page 1-12 for more information.

To use this, you need write access to the directory that holds the cache file. The button will be grayed out if you don't have write access.

6 Select OK.

## Generating the Toolbox Path Cache

The tool box path cache is in a MAT-file in the toolbox / local directory on the system that serves files for MATLAB. When you first install MATLAB on this system, you or your system administrator needs to generate the cache. (MATLAB does not ship with a prebuilt cache). Y ou al so need to regenerate the cache file whenever tool box directories are added or removed so that the cache does not hold out-dated path information. To do so, select Update Toolbox Cache as described in "Selecting Tool box Path Cache Preferences" on page 1-10.

Function Equivalent. To update the cache, type the following in the Command Window.
rehash toolboxcache

## Enabling Use of the Cache

When MATLAB is first installed, the tool box path cache feature is disabled. In order to make use of the cache on a distributed file system:

1 The system administrator enables caching and generates the initial toolbox path cache on the system that serves files for MATLAB. This is explained in "Generating the Tool box Path Cache" on page 1-12.

2 E ach user that intends to use tool box directory caching enables the cache on
their own system.

On a nondistributed system, the system user performs both steps.
To enable toolbox path caching, follow the instructions under "Selecting Tool box Path Cache Preferences" on page 1-10.

You can disable the use of this feature either on a user-by-user basis or on a global basis. To disable it on a per-user basis, uncheck Enable toolbox cache in the Preferences dialog box. To disable it on a global basis, remove the file toolbox_cache.mat from the toolbox/local directory.

## Updating the Cache

If you make changes to your tool box directories, your tool box path cachefile can become out of date. Depending upon the reason for this, you may or may not receive a warning that your cache needs to be updated. This section explains when you need to update your tool box path cache and how to avoid problems caused by an out-dated cache file.

Updating Cache Following a Product Install or Update. If you install a new tool box or an update from The M athWorks, it is likely that the information stored in the tool box path cache no longer accurately reflects your toolbox directories. As part of the installation process, the MATLAB installer marks the cache as being invalid.

When your cache is marked invalid, MATLAB ceases to use cache during startup, loading path information by accessing the directories through the file system instead. MATLAB issues a message at startup to warn you that your tool box path cache is out-dated and is being ignored. To resume use of the cache, you need to regenerate it using the procedure described in "Generating the Tool box Path Cache" on page 1-12.

Updating Cache Following Changes to Toolbox Directories. If you make changes to the MATLAB tool box directories (for example, by adding or deleting files), the path information in the tool box path cache file becomes out of date. When you start up your next MATLAB session, this out-dated path information will be loaded into memory from the cache. MATLAB does not issue a warning when this occurs.

If you choose to make changes that affect the tool box path, you must regenerate the cache file using the procedure described in "Generating the Tool box Path Cache" on page 1-12.

Caution The MathWorks strongly recommends that you do not do devel opment work in the tool box area when tool box path caching is enabled. If do you use the tool box area for this purpose and neglect to regenerate the cache afterwards, MATLAB will use an inaccurate record of your tool box directories in subsequent MATLAB sessions. As a result, MATLAB will be unable to locate new files that you have added.

## Quitting MATLAB

To quit MATLAB at any time, do one of the following:

- Select the close box $\begin{aligned} & \text { in the MATLAB desktop. }\end{aligned}$
- Select Exit MATLAB from the desktop File menu.
- Type quit at the Command Window prompt.

MATLAB closes immediately, without issuing a warning. If you want to see a warning, use the finishdlg.m script as described in the next paragraph.

## Running a Script When Quitting MATLAB

When MATLAB quits, it runs the script finish.m, if finish.m exists in the current directory or anywhere on the MATLAB search path. You create the file finish.m. It contains functions to run when MATLAB terminates, such as saving the workspace or displaying a confirmation dialog box. There are two sample files in \$matlabroot $\backslash$ toolbox $\backslash$ local that you can use as the basis for your own finish.m file:

- finishsav.m-Includes a save function so the workspace is saved to a MAT-file when MATLAB quits.
- finishdlg.m - Displays a confirmation dialog box that allows you to cancel quitting.

1 Starting and $Q$ uitting MATLAB

## Using the Desktop

Desktop Tools ..... 2-4
Launch Pad ..... 2-5
Configuring the Desktop ..... 2-7
Opening and Closing Desktop Tools ..... 2-7
Resizing Windows ..... 2-9
Moving Windows ..... 2-10
Using Predefined Desktop Configurations ..... 2-16
Common Desktop Features ..... 2-17
Desktop Toolbar ..... 2-17
Context Menus ..... 2-17
Keyboard Shortcuts and Accelerators ..... 2-18
Selecting Multiple Items ..... 2-19
Using the Clipboard ..... 2-20
Accessing The MathWorks on the Web ..... 2-20
Setting Preferences ..... 2-21
General Preferences for MATLAB ..... 2-23

When you start MATLAB, the MATLAB desktop appears, containing tools (graphical user interfaces) for managing files, variables, and applications associated with MATLAB. Think of the desktop as your instrument panel for MATLAB. The main things you need to know about the desktop are:

- "Desktop Tools" on page 2-4 - All of the tools managed by the desktop.
- "Configuring the Desktop" on page 2-7 - Arranging the tools in the desktop.
- "Common Desktop Features" on page 2-17 - Features you can use in the tools, such as context menus.

The first time MATLAB starts, the desktop appears as shown in the following illustration, although your Launch Pad may contain different entries.

## Desktop Tools

The following tools are managed by the MATLAB desktop, although not all of them appear by default when you first start. If you prefer a command line interface, you can use functions to perform most of the features found in the MATLAB desktop tools. Instructions for using these function equivalents are provided with the documentation for each tool.

- Command Window - Run MATLAB functions.
- Command History - View a log of thefunctions you entered in the Command Window, copy them, and execute them.
- Launch Pad - Run tools and access documentation for all of your MathWorks products.
- Current Directory Browser - View MATLAB files and related files, and perform file operations such as open, and find content.
- Help Browser - View and search the documentation for the full family of MATLAB products.
- Workspace Browser - View and make changes to the contents of the workspace.
- Array Editor - View array contents in a table format and edit the values.
- Editor/Debugger - Create, edit, and debug M-files (files containing MATLAB functions).

Other MATLAB tools and windows, such as figure windows, are not managed by the desktop.

## Launch Pad

MATLAB's Launch Pad provides easy access to tools, demos, and documentation for all of your MathWorks products. To open it, select Launch Pad from the View menu in the MATLAB desktop. All the products installed on your system are listed.

Sample of listings in Launch Pad - you'll see listings for all products installed on your system.

To display the listings for a product, click the + to the left of the product. To collapse the listings, click the - to the left of the product.

To open one of the listings, doubleclick it, or right-click and select Open from the context menu. The action depends on the listing you selected, as described in the following table.

| Icon | Description of Action When Opened |
| :--- | :--- |
|  | Documentation roadmap page for that product opens in the <br> Help browser. |
|  | Demo launcher opens, with the demo for that product selected. |
|  | Selected tool opens. |
| $\boldsymbol{l}$ | Product Page, which contains the latest product information <br> on the MathWorks Web site, opens in your Web browser. |

## Refreshing the Launch Pad

The Launch Pad includes entries for all products found on the MATLAB search path when the MATLAB session was started. If you change the search path after the start of a session, such as by adding a tool box directory, the Launch Pad is not automatically updated. Right-click in the Launch Pad and select Refresh from the context menu to update the Launch Pad so it reflects all products on the current search path.

## Adding Your Own Entries to the Launch Pad

You can add your own entries to the Launch Pad by creating an info.xml file. To see an example, select one of the existing entries in the Launch Pad, right-click, and select Edit Source from the context menu. The info.xml file for that product appears. The line for thetool you selected appears highlighted.

Create a similar info.xml file for your own application and put it in a folder that is on the search path. Right-click in the Launch Pad and select Refresh from the context menu to update the Launch Pad so it includes your entries.

## Configuring the Desktop

You can modify the desktop configuration to best meet your needs. Close tools you don't use, open those you do, resize, and reposition them. Configure the MATLAB desktop by:

- "Opening and Closing Desktop Tools" on page 2-7
- "Resizing Windows" on page 2-9
- "Moving Windows" on page 2-10
- "Using Predefined Desktop Configurations" on page 2-16

When you end a session, MATLAB saves its desktop configuration. The next time you start MATLAB, the desktop is restored the way you left it.

## Opening and Closing Desktop Tools

As part of configuring the MATLAB desktop so that it best meets your needs, you can use the following features:

- "Opening Desktop Tools" on page 2-7 - Open only those tools you use.
- "Going to Documents in Desktop Tools" on page 2-8 - Go directly to opened M-files, figures, and more.
- "Closing Desktop Tools" on page 2-9 - Close those tools you don't use.

## Opening Desktop Tools

To open a tool from the desktop, select the tool from the View menu or double-click it in thelist of tools displayed in the Launch Pad for MATLAB. The tool opens in the location it occupied the last time it was open.

There are a few tools controlled by the desktop that you don't open from the View menu or Launch Pad:

- Array Editor - Open it by double-clicking a variable in the Workspace Browser.
- Editor/Debugger - Open it by creating a new M-file or opening an existing M-file. For instructions, see "Starting the Editor/Debugger" on page 7-3.

Another way to open a tool is using a function. F or example, helpbrowser opens the Help browser. These functions are documented with each tool.

The following example shows how the MATLAB desktop might look with the Command Window, Command History, and Help browser open.

## Going to Documents in Desktop Tools

The Window menu displays all open Editor/Debugger documents, variables in the Array E ditor, and figure windows. Select an entry in the Window menu to go directly to that window or tabbed document. Select Close All to close all items listed in the Window menu.

For example, the Window menu in the following illustration shows three documents open in the Array Editor and two documents open in the Editor/

Debugger. Selecting variance.m, for example, makes the Editor/Debugger window with the file variance.m become the active window.

## Closing Desktop Tools

To close a desktop tool, do one of the following:

- Select the item in the View menu (the item becomes unchecked).
- Click the close box $\boldsymbol{\otimes}$ in the window's title bar.
- Select Close from the File menu to close the current window.

The window closes.

## Resizing Windows

Toresize windows in the MATLAB desktop, use the separator bar, which is the bar between two windows:

1 Move the cursor onto the separator bar.
The cursor assumes a different shape. On Windows platforms, it is a double-headed arrow $\leftrightarrow$. On UNIX, it is an arrow with a bar.

2 Drag the separator bar to change the sizes of the windows.

To resize the MATLAB desktop itself or windows for MATLAB tools outside of the desktop, drag any edge or corner of the window.

## Moving Windows

There are three basic ways to move MATLAB desktop windows:

- "Moving Windows Within the MATLAB Desktop" on page 2-10
- "Moving Windows Out of the MATLAB Desktop" on page 2-12 and "Moving Windows Into the MATLAB Desktop" on page 2-13
- "Grouping (Tabbing) Windows Together" on page 2-13

## Moving Windows Within the MATLAB Desktop

To move a window to another location in the MATLAB desktop:
1 Drag the title bar of the window towards where you want the window to be located.

As you drag the window, an outline of it appears. When the outline nears a position where you can dock (keep) it, the outline snaps to that location. The
status bar displays instructions about moving the window while you drag the outline.

In the following example, the Command History window is originally to the left of the Command Window and is being dragged above the Command Window. When the top of Command History window touches the bottom of the tool bar, the outline appears.

2 Release the mouse to dock the window at the new location.
Other windows in the desktop resize to accommodate the new configuration. The following example shows how the desktop looks after having moved the Command History window above the Command Window.

## Moving Windows 0 ut of the MATLAB Desktop

To move a window outside of the MATLAB desktop, do one of the following:

- Click the arrow $₫$ 긔 thetitlebar of the window you want to move outside of the desktop.
- Select Undock for that tool from the View menu; the window must be the currently active window.
- Drag the title bar of the window outside of the desktop. As you drag, an outline of the window appears. When the cursor is outside of the MATLAB desktop, release the mouse.

The window appears outside of the MATLAB desktop. In the following example, the Command History window has been moved outside of the desktop.

## Moving W indows Into the MATLAB Desktop

To move a window that is outside of the MATLAB desktop into the desktop, select Dock for that tool from the window's View menu.

## Grouping (Tabbing) W indows Together

You can group windows so that they occupy the same space in the MATLAB desktop, with access to the individual windows via tabs. These are the main features in working with tabbed windows:

- "Grouping Windows" on page 2-14
- "Viewing Tabbed Windows" on page 2-15
- "Moving Tabbed Windows" on page 2-15
- "Closing Tabbed Windows" on page 2-15

Grouping Windows. To group (also called "to tab") windows together:
1 Drag the title bar of one window in the desktop on top of the title bar of another window in the desktop.

The outline of the window you're dragging overlays the target window, and the bottom of the outline includes a tab. In the following example, the Command History window is originally to the left of the Command Window and its title bar is being dragged on top of the title bar of the Command Window.

2 Release the mouse.
B oth windows occupy the same space and labeled tabs appear at the bottom of that space. In the following example, the Command History and Command Window are tabbed together, with the Command History tab currently selected.

Viewing Tabbed Windows. To view a tabbed window, click the window's tab. The window moves to the foreground and becomes the currently active window. If there are more tabs in a window than are currently visible, use the arrows to the left of the tabs to see additional tabs.

Moving Tabbed Windows. To move a tabbed window to another location, drag the title bar or the tab to the new location. You can move it inside or outside of the MATLAB desktop.

Closing Tabbed Windows. When you click the close box $\begin{aligned} & \text { for a window that is }\end{aligned}$ part of a group of windows tabbed together, that window closes. You cannot close all of the tabbed windows at one time; instead close each window individually.

## Using Predefined Desktop Configurations

There are six predefined MATLAB desktop configurations, which you can select from the View -> Desktop Layout menu:

- Default - Contains the Command Window, the Command History and Current Directory browser tabbed together, and the Launch Pad and Workspace browser tabbed together.
- Command Window Only - Contains only the Command Window. This makes MATLAB appear similar to how it looked in previous versions.
- Simple - Contains the Command History and Command Window, side-by-side.
- Short History - Contains the Current Directory browser and Workspace browser tabbed together above the Command Window and a small Command History.
- Tall History - Contains the Command History along the left, and the Current Directory browser and Workspace browser tabbed together above the Command Window.
- Five Panel - Contains the Launch Pad above the Command History along the left, the Workspace browser above the Current Directory browser in the center, and the Command Window on the right.

After selecting a predefined configuration, you can move, resize, and open and close windows.

## Common Desktop Features

These common features are available for the desktop tools:

- "Desktop Toolbar" on page 2-17
- "Context Menus" on page 2-17
- "Keyboard Shortcuts and Accelerators" on page 2-18
- "Selecting Multiple Items" on page 2-19
- "Using the Clipboard" on page 2-20
- "Accessing The MathWorks on the Web" on page 2-20

## Desktop Toolbar

The tool bar in the MATLAB desktop provides easy access to popular operations. Hold the cursor over a button and a tooltip appears describing the item. Note that some of the tools also have a toolbar within their window.

## Current Directory Field

The Current Directory field in the tool bar shows MATLAB's current working directory. Y ou can change the current directory using this field and perform other fileoperations using the Current Directory browser - for instructions, see "File Operations" on page 5-20.

## Context Menus

Many of the features of the MATLAB desktop tools are available from context menus, also known as pop-up menus. To access a context menu, right-click on
a selection and the context menu for it appears, presenting the available actions. For example, following is the context menu for a selection in the Command History window.

| Command History | त $\times$ |  |
| :---: | :---: | :---: |
| $\begin{aligned} & \text { theta= -pi:0.01:pi } \\ & \text { rho }(1,)^{*}=2^{*} \sin \left(5^{*}\right. \end{aligned}$ | heta). ${ }^{n} 2$ |  |
| $\begin{aligned} & \text { rho }(2, \text {; })=\cos (10 \\ & \text { rho }(3,)=\sin (\text { the } \\ & \text { rho }(4,)=5^{*} \cos ( \\ & \text { for } i=1: 4 \\ & \text { polar(theta,rho(i } \\ & \text { pause } \end{aligned}$ | Copy <br> Evaluate Selection Create M-File | Access context (pop-up) menus by right-clicking on a selection. |
|  | Delete Selection |  |
|  | Delete to Selection |  |
|  | Delete Entire History |  |

## Keyboard Shortcuts and Accelerators

You can access many of the menu items using keyboard shortcuts or accel erators for your platform, such as using Ctrl+X to perform a Cut on Windows platforms, or Alt+F to open the File menu. Many of the shortcuts and accelerators are listed with the menu item. F or example, on Windows platforms, the Edit menu shows Cut CtrI+X, and the File menu shows the $\mathbf{F}$ in File underlined, which indicates that Alt+X opens it. Many standard shortcuts for your platform will work but are not listed with the menu items.

Following are some additional shortcuts that are not listed on menu items.

| Keys | Result |
| :--- | :--- |
| Enter | The equivalent of double-clicking, it performs the <br> default action for a selection. For example, pressing <br> Enter while a line in the Command History window <br> is selected runs that line in the Command Window. |
| Escape | Cancels the current action. |
| CtrI+Tab | Moves to the next tab in the desktop, where the tab is <br> for a tool, or for a file in the Editor/Debugger. When <br> used in the Editor/Debugger in tabbed mode outside <br> of the desktop, moves to the next open file. |
| CtrI+F6 |  |

| Keys | Result (Continued) |
| :--- | :--- |
| CtrI+Shift+Tab | Moves to the previous tab in the desktop, where the <br> tab is for a tool, or for a file in the Editor/Debugger. <br> When used in the Editor/Debugger in tabbed mode <br> outside of the desktop, moves to the previous open <br> file. |
| CtrI+Page Up | Moves to the next tab within a group of tools or files <br> tabbed together. |
| CtrI+Page Down | Moves to the previous tab within a window. |
| Alt+F4 | Closes desktop or window outside of desktop. |
| Alt+Space | Displays the system menu. |

On theAlpha platform, even though shortcuts are not listed on the menu items, most standard Alpha shortcuts will work.

## Selecting Multiple Items

In many of the desktop tools, you can select multiple items and then select an action to perform on all of the selected items. Select multiple items using the standard practices for your platform.
For example, if your platform is Windows, do the following to select multiple items:

1 Click on the first item you want to select.
2 Hold the Ctrl key and then click on the next item you want to select. Repeat this step until you've selected all the items you want.

If you hold the Shift key instead of the Ctrl key while dicking on an item, you'll select all the items between and including that item and the last item you clicked on.

Now you can perform an action, such as delete, on the selected items.

## Using the Clipboard

You can cut and copy a selection from a desktop tool to the clipboard and then paste it from the clipboard into another desktop tool. Use the Edit menu, context menus, or standard keyboard shortcuts. F or example, you can copy a selection of commands from theCommand History window and paste them into the desktop.

The Paste Special item in the Edit menu opens the selection on the clipboard in the Import Wizard. Y ou can use this to copy data from another application, such as Excel, into MATLAB. For details, see Chapter 6, "Importing and Exporting Data."

To undo the most recent cut, copy, or paste command, select Undo from the Edit menu. Use Redo to reverse the Undo.

You can also copy by dragging a selection. For example, make a selection in the Command History window and drag it to the Command Window, which pastes it there. Edit the lines in the Command Window, if needed and then press the Enter key to run the lines from the Command Window.

## Accessing The MathWorks on the Web

You can access popular MathWorks Web pages from the MATLAB desktop. Select one of the following items from the Web menu - the Web page opens in your default Web browser:

- The MathWorks Web Site - Links you to the home page of the M athWorks Web site (http: / /www. mathworks.com).
- Technical Support Knowledge Base - Links you to the MathWorks Support page (http: / /www. mathworks.com/support), whereyou can look for solutions for problems you are having or report new problems.
- Products - Links you to the MathWorks Products page (http: / / www.mathworks.com/products/), where you can get information about the full family of products.
- Membership - Links you to the MATLAB Access page (http: // www.mathworks.com/mla/index. shtml) for Access members. If you are not a member, you can join online to help you keep up-to-date on the latest MATLAB developments.

## Setting Preferences

Set preferences to modify the default behavior of some aspects of MATLAB such as the font used in the Command Window. Preferences remain persistent across MATLAB sessions. N ote that some tools allow you to control these aspects from within the tool without setting a preference - use that method if you only want the change to apply to the current session.

To set preferences:
1 Select Preferences from the File menu.
The Preferences dialog box opens. The page it opens to reflects the currently active window.

2 In the left pane, select the type of preferences you want to specify. In the above example, General preferences are selected.

If a + appears to the left of an item, click the + to display more items, and then select the item you want to set preferences for.

The right pane reflects the type of preference you selected.
3 In the right pane, specify the preference values and click OK.
The preferences take effect immediately.

## Type of Preference and Where Described

"General Preferences for MATLAB" on page 2-23
"Preferences for the Command Window" on page 3-13
"Preferences for the Editor/Debugger" on page 7-35
"Printing
Documentation" on
page 4-26
"Preferences for the
Current Directory
Browser" on page 5-30
"Preferences for the Workspace Browser" on page 5-9
"Preferences for the Array Editor" on page 5-12

Items You Can Set Preferences For

For desktop display, caching, printing, fonts, colors, and source control system

Numeric format and display, echo, font, and colors

Startup options, font, colors, display, keyboard shortcuts, indenting, and printing

Documentation location, products, PDF reader location, synchronization, and fonts

Number of entries in history and file display options

Font and confirm deletion of variables

Font and numeric format

| Type of Preference and <br> Where Described | Items You Can Set Preferences For (Continued) |
| :--- | :--- |
| GUIDE | Display options |
| Figure Copy Template | Application, text, line, uicontrols, axis, format, <br> background col or, and size |
| Simulink | Display, fonts, and simulation. |

The preferences file is matlab. prf. Type prefdir in the Command Window to see the location of the file. The matlab. prf file is loaded when MATLAB starts and overwritten when you close MATLAB.

## General Preferences for MATLAB

These preferences apply to all relevant tools in the MATLAB desktop.

## Display

To show tooltips when you hold the cursor over a tool bar button, check the Show tooltips check box.

## Toolbox caching

See "Reducing Startup Time with Toolbox Path Caching" on page 1-10.

## Figure window printing

Specify how colored lines and text are sent to the printer. See the Printing documentation for more information.

## Font \& Colors

Desktop font. Desktop font preferences specify the characteristics of the font used in tools under the control of the MATLAB desktop. The font characteristics are:

- Type, for example, SansSerif
- Style, for example, bold
- Size in points, for example, 12 points

After you make a selection, the Sample area shows how the font will look. Lucida Console approximates the fixedsys font available in previous versions of MATLAB.

You can specify a different font for the Command Window, Editor/Debugger, Help browser, Workspace browser, and Array Editor using preferences for those tools.

Syntax highlighting colors. Select the colors to use to highlight syntax. For more information, see "Syntax Highlighting" on page 3-5.

- Keywords - Flow control and other functions such as for and if are colored.
- Comments - All lines beginning with a \% are colored.
- Strings - Single quotes and whatever is between them are col ored.
- Unterminated strings - A single quote without a matching single quote, and whatever follows or precedes the quote are col ored.
- System commands - Commands such as the! (shell escape) are colored.
- Errors - The error text is colored.

Click Restore Default Colors to return to the default settings. The following example uses the default values for col or preferences.

## Source Control

Specify the source control system you want to interface MATLAB to. F or more information, see Chapter 9, "Interfacing with Source Control Systems."

## Running MATLAB Functions

The Command Window ..... 3-2
Opening the Command Window ..... 3-2
Running Functions and Entering Variables ..... 3-2
Controlling Input and Output ..... 3-4
Running Programs ..... 3-11
Keeping a Session Log ..... 3-12
Preferences for the Command Window ..... 3-13
Command History ..... 3-17
Viewing Functions in the Command History Window ..... 3-17
Running Functions from the Command History Window ..... 3-18
Copying Functions from the Command History Window ..... 3-19

## The Command Window

The Command Window is the main way you communicate with MATLAB. It appears in the desktop when you first start MATLAB. Use the Command Window torun MATLAB functions (also referred to as commands) and perform MATLAB operations. The main features of the Command Window are:

- "Opening the Command Window" on page 3-2
- "Running Functions and Entering Variables" on page 3-2
- "Controlling Input and Output" on page 3-4, such as suppressing output and command line editing
- "Running Programs" on page 3-11, including M-files and external programs
- "Keeping a Session Log" on page 3-12
- "Preferences for the Command Window" on page 3-13

## Opening the Command Window

To show the Command Window in the MATLAB Desktop, select Command Window from the View menu - see "Opening and Closing Desktop Tools" on page 2-7 for details.

## Running Functions and Entering Variables

The prompt (>>) in the Command Window indicates that MATLAB is ready to accept input from you. When you see the >> prompt, you can enter a variable or run a function. For example, to create A, a 3-by-3 matrix, type

$$
A=[123 ; 456 ; 7810]
$$

When you press the Enter or Return key after typing the line, MATLAB responds with
$\mathrm{A}=$

| 1 | 2 | 3 |
| :--- | :--- | ---: |
| 4 | 5 | 6 |
| 7 | 8 | 10 |

Torun a function, type the function including all arguments and press Return or Enter. MATLAB displays the result. For example, type

```
magic(2)
```

and MATLAB returns
ans =
13
42
If you want to enter multiple lines before running, use Shift+E nter or Shift+Return after each line until the last. Then press Enter or Return to run all of the lines.

The K>> prompt in the Command Window indicates that MATLAB is in debug mode. F or more information, see Chapter 7, "Editing and Debugging M-Files."

## Evaluating a Selection

To run a selection in the Command Window, make the selection, and then right-click and select E valuate Selection from the context menu. You cannot evaluate a selection while MATLAB is busy, for example, running an M-file.

## 0 pening a Selection

To open theM-file for a function, select that function in theCommand Window, and then right-click and select Open Selection from the context window. The M -file for that function opens in the Editor/Debugger.

## Running One Process

You can only run one process at a time. If MATLAB is busy running one function, any commands you issue will be stacked. The next command will run when the previous one finishes. F or example, you cannot set breakpoints from
the Editor/Debugger while MATLAB is running a function in the Command Window.

## Controlling Input and Output

You can control and interpret input and output in the Command Window in these ways:

- "Case and Space Sensitivity" on page 3-4
- "Entering Multiple Functions in a Line" on page 3-4
- "Entering Long Lines" on page 3-5
- "Syntax Highlighting" on page 3-5
- "Font Used in the Command Window" on page 3-6
- "Command Line Editing" on page 3-6
- "Clearing the Command Window" on page 3-9
- "Suppressing Output" on page 3-9
- "Paging of Output in the Command Window" on page 3-10
- "Controlling the F ormat and Spacing of Numeric Output" on page 3-10
- "Printing Command Window Contents" on page 3-11

## Case and Space Sensitivity

MATLAB is case sensitive. F or example, you cannot run the function Plot but must instead use plot. Similarly, the variable a is not the same as the variable A. Note that if you use the help function, function names are shown in all uppercase, for example, PLOT, solely to distinguish them. Do not use uppercase when running the functions. Some functions for interfacing to J ava actually used mixed case and the M-file help accurately reflects that.
Blank spaces around operators such as -, :, and ( ), are optional, but they improve readability.

## Entering Multiple Functions in a Line

To enter multiple functions on a single line, separate the functions with a comma ( , ) or semicolon (; ). Using the semicol on instead of the comma will suppress the output for the command preceding it. For example, put three functions on one line to build a table of logarithms by typing

```
format short; x = (1:10)'; logs = [x log10(x)]
```

and then press Enter or Return to run the functions in left-to-right order.

## Entering Long Lines

If a statement does not fit on one line, use an ellipsis (three periods, ...) to indicate that the statement continues on the next line, press Enter or Return to advance to the next line, and then continue entering the statement. For example,

```
s=1-1/2 + 1/3-1/4 + 1/5-1/6 + 1/7 \ldots
    - 1/8 + 1/9 - 1/10 + 1/11 - 1/12;
```

For items in single quotes, such as strings, put the quotes in each line. For example, entering the following long string

```
headers = ['Author Last Name, Author First Name, , ...
'Author Middle Initial']
results in
headers =
Author Last Name, Author First Name, Author Middle Initial
```

The maximum number of characters allowed on a single line is 4096.

## Syntax Highlighting

Some entries appear in different col ors to help you better find elements, such as matching if/else statements:

- Type a string and it is col ored purple. When you close the string, it becomes maroon.
- Type a keyword, such as the flow control function for, or a continuation (ellipsis ...), and it is col ored blue. Lines you enter between the opening and closing flow control functions are indented.
- Double-click an opening or closing token, a parenthesis ( ), bracket [ ], or brace \{\}. This selects the characters between the token and its mate.
- Type a closing (or opening) token and the matching opening (or closing) token is highlighted briefly.
- Type a mismatched closing (or opening) token and a strikethrough character appears on the token. For example

```
>CC=C{:+
```

- Use an arrow key to move over an opening or closing token. That token and its matching closing or opening token briefly appear underlined.
- Type a comment symbol, \%, and what follows on the line appears in green. That information is treated by MATLAB as a comment.
- Type a system command, such as the! (shell escape), and the line appears in gold.
- Errors appear in red.

Default colors are shown here - to change them, use Preferences.

To change the col ors used for syntax highlighting, see "F ont \& Col ors Preferences for the Command Window" on page 3-15.

## Font Used in the Command Window

You can specify the font type, style, and size used in the Command Window. For instructions, see "F ont \& Colors Preferences for the Command Window" on page 3-15.

## Command Line Editing

These are time-saving features you can use in the Command Window:

- Clipboard features
- Recalling previous lines
- Tab completion

Clipboard Features. Use the Cut, Copy, Paste, Undo, and Redo features from the Edit menu when working in theCommand Window. Some of these features are also available in the context menu for the Command Window.

Recalling Previous Lines. Use the arrow, tab, and control keys on your keyboard to recall, edit, and reuse functions you typed earlier. F or example, suppose you mistakenly enter

$$
\text { rho }=(1+\operatorname{sqt}(5)) / 2
$$

MATLAB responds with

```
Undefined function or variable 'sqt'.
```

because you misspelled sqrt. Instead of retyping the entire line, press the $\uparrow$ key. The previously typed line is redisplayed. Use the left arrow key to move the cursor and add the missing r. Repeated use of the up arrow key recalls earlier lines.

The functions you enter arestored in a buffer. You can usesmart recall to recall a previous function whose first few characters you specify. For example, typing the letters plo and pressing the up arrow key recalls the last function that started with plo, as in the most recent plot function. This feature is case sensitive.

Following is the complete list of arrow and control keys you can use in the Command Window. Many of these keys should be familiar to users of the Emacs editor.
$\left.\begin{array}{l|l|}\hline \text { Key } & \begin{array}{l}\text { Control } \\ \text { Key }\end{array} \\ \hline \uparrow & \text { CtrI+P }\end{array} \begin{array}{l}\text { Operation } \\ \text { Recall previous line. See also "Command } \\ \text { History" on page 3-17, which is a log of } \\ \text { previously used functions, and "Keeping a } \\ \text { Session Log" on page 3-12. }\end{array}\right]$

Tab Completion. MATLAB completes the name of a function, variable, filename, or handle graphics property if you type the first few letters and then press the Tab key. If there is a unique name, the name is automatically completed. F or example, if you created a variable costs_march, type
and press Tab. MATLAB completes the name, displaying

```
costs_march
```

Press Return or Enter to run the statement. In this example, MATLAB displays the contents of costs_march.

If there is more than one name that starts with the letters you typed, press the Tab key again to see a list of the possibilities. For example, type

```
cos
```

and press Tab. MATLAB does not display anything, indicating there are multiple names beginning with cos. Press Tab again and MATLAB displays

| cos | cosh | costfun |
| :--- | :--- | :--- |
| cos_tr | cosint | costs_march |

The resulting list of possibilities includes the variable name you created, costs_march, but also includes functions that begin with cos.

Note that the list might include files which are not valid commands, including private functions.

## Clearing the Command Window

Select Clear Command Window from the Edit menu to clear it. This does not clear the workspace, but only clears the view. Afterwards, you still can use the up arrow key to recall previous functions.

Function Equivalent. Use clc to clear the Command Window. Similar to clc, the home function moves the prompt to the top of the Command Window.

## Suppressing Output

If you end a line with a semicol on (; ), MATLAB runs the statement but does not display any output when you press the Enter or Return key. This is particularly useful when you generate large matrices. For example, typing
A = magic(100) ;
and then pressing Enter or Return creates A but does not display the resulting matrix.

## Paging of Output in the Command Window

If output in the Command Window is lengthy, it might not fit within the screen and will display too quickly for you to see it. Use the more function to control the paging of output in the Command Window. By default, more is off. When you type more on, MATLAB displays only a page (a screen full) of output at a time. After the first screen displays, press one of the following keys.

| Key | Action |
| :--- | :--- |
| Enter or Return | To advance to the next line |
| Space Bar | To advance to the next page |
| $\mathbf{q}$ | To stop displaying the output |

## Controlling the Format and Spacing of Numeric Output

By default, numeric output in the Command Windows is displayed as 5-digit scaled, fixed-point values. Use the text display preference to change the numeric format of output. The text display format affects only how numbers are shown, not how MATLAB computes or saves them.

Function Equivalent. Use the format function to control the output format of the numeric values displayed in the Command Window. The format you specify applies only to the current session. M oreadvanced alternatives arelisted in the "See Also" section of the format reference page.

Examples of Formats. Here are a few examples of the various formats and the output produced from the following two-element vector $x$, with components of different magnitudes.

```
x = [4/3 1.2345e-6]
format short e
    1.3333e+000 1.2345e-006
format short
    1.3333 0.0000
format +
++
```

F or a complete list and description of available formats, see the reference page for format. If you want more control over the output format, use the sprintf and fprintf functions.

Controlling Spacing. Use thetext display preference or format function to control spacing in the output. Use

```
format compact
```

to suppress blank lines, allowing you to view more information in the Command Window. To include the blank lines, which can help make output more readable, use
format loose

## Printing Command Window Contents

To print the complete contents of the Command Window, select Print from the File menu. To print only a selection, first make the selection in the Command Window and then choose Print Selection from the File menu.

## Running Programs

## Running M -Files

Run M-files, files that contain code in the MATLAB Ianguage, the same way that you would run any other MATLAB function. Type the name of the M-file in the Command Window and press Enter or Return.

Todisplay each function in theM-file as it executes, usethe Display preference and check Echo on, or use the echo function set to on.

## Interrupting a Running Program

You can interrupt a running program by pressing Ctrl+C or Ctrl+Break at any time.

On Windows platforms, you may have to wait until an executing built-in function or MEX-file has finished its operation. On UNIX systems, program execution will terminate immediately.

## Running External Programs

The exclamation point character, ! , is a shell escapeand indicates that the rest of the input line is a command tothe operating system. Useit to invoke utilities or run other programs without quitting from MATLAB. On UNIX, for example,

```
!vi darwin.m
```

invokes the vi editor for a filenamed darwin.m. After the program completes or you quit the program, the operating system returns control to MATLAB. See the functions unix and dos to run external programs that return results and status.

## Opening M-Files

To open an M-file, select the file or function name in the Command Window, and then right-click and select Open Selection from the context window. The $M$-file opens in the Editor/Debugger.

## Examining Errors

If an error message appears when running an $M$-file, click on the underlined portion of the error message, or press CtrI+E nter. The offending M-file opens in the Editor, scrolled to the line containing the error.

## Keeping a Session Log

## The diary Function

The diary function creates a copy of your MATLAB session in a disk file, including keyboard input and system responses, but excluding graphics. You can view and edit the resulting text file using any word processor. To create a file on your disk called sept23. out that contains all the functions you enter, as well as MATLAB's output, enter

```
diary('sept23.out')
```

To stop recording the session, use

```
diary('off')
```

## Other Session Logs

There are two other means of seeing session information:

- The Command History, which contains a log of all functions executed in the current and previous sessions
- F or Windows platforms, the logfile startup option - see "Adding Startup Options for Windows Platforms" on page 1-5

## Preferences for the Command Window

Using preferences, you can specify the format for how numeric values are displayed, set echoing on automatically for each session, specify the font type, style, and size, and set the colors used for syntax highlighting for contents of the Command Window.

To set preferences for the Command Window, select Preferences from the File menu in the Command Window. The Preferences dialog box opens showing Command Window Preferences.

## Text Display and Display Preferences for the Command W indow

Text display. Specify how output appears in the Command Window:

- Numeric format - Output format of numeric values displayed in the Command Window. This affects only how numbers are displayed, not how MATLAB computes or saves them. The format reference page includes the list of available formats.
- Numeric display - Spacing of output in the Command Window. To suppress blank lines, use compact. To display blank lines, use loose. For more information, see the reference page for format.
- Spaces per tab - Number of spaces assigned to a tab stop when displaying output. The default is 4 .

Display. Specify echoing option and buffer size:

- Echo on - Check thebox if you want commands running in M-files to display in the Command Window during the M-file execution. For moreinformation, see the reference page for echo.
- Wrap lines - Input and output in the Command Window uses multiple lines to fit within the current width of the Command Window. Note that the horizontal scroll bar does not appear in this mode because it is not needed.
- Limit matrix display width to eighty columns-Check the box if you want MATLAB to display only 80 columns of matrix output, regardless of the width of the Command Window. Uncheck the box if you make the Command Window wider than 80 columns and want matrix output to fill the width of the Command Window. See also the display reference page.
- Enable up to $\boldsymbol{n}$ tab completions - Check the box if you want to use tab completion when typing functions in the Command Window. Then enter a limit in the edit box. F or example, if you enter 10, when you use the tab completion feature, MATLAB displays the list of possible completions if there are 10 or less. If there are more than 10, MATLAB displays a message stating there are more than 10 completions.
Uncheck the box if you do not want to use the tab completion feature. MATLAB moves the cursor to the next tab stop when you press the Tab key, rather than completing a function.
- Command session scroll buffer size - Set the size of the buffer that maintains a list of previously run commands to be used for command recall. See "Recalling Previous Lines" on page 3-7 for more information.

## Font \& Colors Preferences for the Command W indow

Font. Command Window font preferences specify the characteristics of the font used in the Command Window. Select Use desktop font if you want the font in the Command Window to be the same as that specified for General Font \& Colors preferences.

If you want the Command Window font to be different, select Use custom font and specify the font characteristics for the Command Window:

- Type, for example, SansSerif
- Style, for example, bold
- Size in points, for example, 12 points

After you make a selection, the Sample area shows how the font will look.
Colors. Specify the colors used in the Command Window:

- Text color - The col or of nonspecial text; special text uses col ors specified for Syntax highlighting
- Background color - The color of background in the window
- Syntax highlighting- The col ors to use to highlight syntax. If checked, click Set Colors to specify them. For a description of syntax highlighting, see "Syntax Highlighting" on page 3-5.

## Command History

The Command History window appears when you first start MATLAB. The Command History window displays a log of the functions most recently run in the Command Window. Toshow or hide the Command History window, use the View menu - see "Opening and Closing Desktop Tools" on page 2-7 for details.

Use the Command History window for:

- "Viewing Functions in the Command History Window" on page 3-17
- "Running Functions from the Command History Window" on page 3-18
- "Copying F unctions from the Command History Window" on page 3-19

| Timestamp marks the start of each session. | - Command History | - a] $^{\text {a }}$ |
| :---: | :---: | :---: |
|  | File Edit View Web Window | Help |
|  |  |  |
| Select one or more lines and right-click to copy, evaluate, or create an M-file from the |  |  |
|  | ```rho(4,:)=5*}\operatorname{cos(3.5*theta)./33; for n=1:4``` |  |
|  | ```polar(theta, rho(n,:)) pause end``` |  |
|  | ```%-- 1:12 PM 8/7/00 --% type collatz collatz(3) collatzplot(3) type collatz``` |  |
|  | 4\| | - |
|  | Ready |  |

## View ing Functions in the Command History Window

The log in the Command History window includes functions from the current session, as well as from previous sessions. The time and date for each session appear at the top of the history of functions for that session. Use the scroll bar or the up and down arrow keys to move through the Command History window.

The Command History file is history.m. Type prefdir in the Command Window to see the location of the file. The history.m file is loaded when MATLAB starts and overwritten when you close MATLAB.

## Deleting Entries in the Command History Window

Del ete entries in the Command History window when you feel there are too many and it's inconvenient finding the ones you want. All entries remain until you del ete them.

To delete entries in the Command History window, select an entry, or Shift+click or CtrI+click to select multiple entries, or use Ctrl+A to select all entries. Then right-click and select one of the delete options from the context menu:

- Delete Selection - Deletes the selection
- Delete to Selection - Deletes all functions previous to (above) the selected function
- Delete Entire History - Deletes all functions in the Command History window

Another way to clear the entire history is by selecting Clear Command History from the Edit menu.

## Running Functions from the Command History Window

Double-click on any function entry (entries) in the Command History window to execute that function(s). For example, double-click edit myfile to open myfile.m in the Editor. You can also run a function entry by right-clicking on it and selecting Evaluate Selection from the context menu, or by copying the function entry to the Command Window, as described in the next section.

## Copying Functions from the Command History Window

Select a function entry, or Shift+click or CtrI+click to select multiple entries, or use Ctrl+A to select all entries. Then you can do any of the following.

| Action | How to Perform the Action |
| :--- | :--- |
| Run the functions in the <br> command window | Copy the selection to the clipboard by <br> right-clicking and selecting Copy from <br> the context menu. Paste the selection into <br> the Command Window. (Alternatively, <br> drag the selection to the Command <br> Window.) In the Command Window, edit <br> the functions if desired, and press Enter <br> or Return to execute the functions. |
| Copy thefunctions to another | Copy the selection to the clipboard by <br> right-clicking and selecting Copy from <br> the context menu. Paste the selection into <br> an open M-file in the E ditor or any |
| application. |  |

## Getting Help

Types of Information ..... 4-3
Using the Help Browser ..... 4-4
Using the Help Navigator ..... 4-7
Viewing Documentation in the Display Pane ..... 4-17
Preferences for the Help Browser ..... 4-21
Printing Documentation ..... 4-26
Using Help Functions ..... 4-28
Other Methods for Getting Help ..... 4-31

The M athWorks provides onlinehelp for all products. Printed versions for some of the online documentation are also provided. The online material sometimes has information not included with the printed material and may be more current than the printed material.

The primary ways to access the online help are:

- "Using the Help Browser" on page 4-4 - Use the Help browser to find and view information about your MathWorks products. It includes a contents listing, global index, and search feature.
- "Using Help Functions" on page 4-28- Typehelp functionname to get M-file help, which provides a brief description of the function and its syntax in the Command Window. Other help functions are available as well.
- "Other Methods for Getting Help" on page 4-31 - You can use product-specific help features, run demos, contact Technical Support, search documentation for other MathWorks products, view a list of other books, and participate in a MATLAB newsgroup.

In addition to using online help, you can print documentation - see "Printing Documentation" on page 4-26.

## Types of Information

The Help browser and help functions provide access to the following types of documentation. Use the type of documentation most suited to your needs.

- Release Notes - An overview of new products and features in this release, it also includes upgrade information and any known problems and limitations. Review the Release Notes for all your products when you first start using the new release.
- Getting Started with ... - Primarily aimed at novice users, this documentation contains instructions for a product's main features. Review Getting Started documentation before you begin using a product or feature for the first time. Then, to learn more, go to the "Using..." collections or reference pages.
- Using ... collections - This material contains overviews and complete instructions for using a product. Consult it after reviewing Getting Started material.
- Reference Pages - Every function has a reference page that provides the syntax, description, examples, and other information for that function. It includes links to related functions and additional information. Reference pages are also provided for blocks. Use reference pages to learn about a function or to see its syntax.
- M-File Help - Get M-file help in the Command Window to quickly access basic information for a function. It provides a brief description of a function and its syntax. It is called M -file help because the text of the help is a series of comments at the start of the M-file for a function.
- Product Page - Available on MathWorks Web site, a product page contains the latest product information, such as system requirements.
- Online Knowledge Base - This is the MathWorks Technical Support online knowledge base. It provides solutions to questions posed by users.

## Using the Help Browser

UsetheHelp browser tosearch and view documentation for MATLAB and your other MathWorks products. The Help browser is a Web browser integrated into the MATLAB desktop that displays HTML documents.

To open the Help browser, click the help button ? in the tool bar, or type helpbrowser in the Command Window. You can also access the Help browser by selecting Help from the View menu or by using the Help menu in any tool. The Help browser opens.

The Help browser consists of two panes:

- TheH elp Navigator on the left, which you use to find information. It includes a Product Filter and Contents, Index, Search, and Favorites tabs. F or more information, see "Using the Help Navigator" on page 4-7.
- The display pane on the right, which is for viewing documentation.

## Changing the Size of the Help Browser

To adjust the relative width of the two panes, drag the separator bar between them. You can also change the font in either of the panes - use "Help Fonts Preferences - Specifying Font Name, Style, and Size" on page 4-24.

Once you've found the documentation you want, you can close the Help Navigator pane so there is more screen space to view the documentation itself. This is shown in the following figure. To close the Help Navigator pane, click the close box $\begin{aligned} & \text { in the pane's upper right corner or select View -> Help View }\end{aligned}$ Options ->Show Help Navigator from the menu, which unchecks it. To open the Help Navigator pane from the display pane, click the Help Navigator
button ? ${ }^{-\frac{1}{-1} \text { in the upper left corner of the Help browser, or select View ->Help }}$ View Options -> Show Help Navigator, which checks it.

## Using the Help Navigator

Use the Help Navigator, the left pane in the Help browser, to find information in the online help. These sections describe the main features:

- "Using the Product Filter" on page 4-7 - Show documentation only for specified products.
- "Viewing the Contents Listing in the Help Browser" on page 4-9 - View an expandable table of contents for documentation.
- "Finding Documentation Using the Index" on page 4-11 - Use keywords to find information.
- "Searching Documentation" on page 4-13 - Find documentation using full-text and other forms of search.
- "Bookmarking Favorite Pages" on page 4-15 - Designate favorite pages for later use.

## Using the Product Filter

Use the Product filter in the Help Navigator to show documentation only for the products you specify.

```
Product filter: }\odot\mathrm{ All }\odot\mathrm{ Selected
```

$\square$
To show documentation for all MathWorks products installed on your system, select AII.

To show only a subset of the documentation for MathWorks products installed on your system, set the Product filter to Selected, which results in the following:

- The Contents listing shows only the subset of products you specify.
- The Index shows only index terms for the subset of products you specify.
- The Search feature only looks through the subset of products you specify.

To specify the subset of products, click the Select button. The Help Product Filter dialog box opens.

A checkmark appears for all products whose documentation is used in the Help Navigator. Makechanges tothe selected products and click OK. Then, with the Product filter set to Selected, the Help Navigator only shows documentation for those products you specified.

For example, if you're doing a search and know the information you're seeking is in MATLAB or the Communications Toolbox, in the Help Product Filter, click Clear All and then select MATLAB and Communications Toolbox. In the Help Navigator, set the Product filter to Selected. Then, the Contents would only show MATLAB and the Communications Tool box documentation, the Index would only show entries for MATLAB and theCommunications Tool box, and the Search feature would only look in and show results for MATLAB and the Communications Tool box.

The product filter settings are remembered for your next MATLAB session.

## View ing the Contents Listing in the Help Browser

To list the titles and table of contents for all product documentation, click the Contents tab in the Help Navigator pane.

Ready
In the Contents listing, you can:

- Click the + to the left of an item to expand the listing for the item.
- Click the - to the left of an item, or double-click the item to collapse the listings for that item.
- Select an item to show the first page of that document or section in the display pane.
- Double-dick an item to expand the listing for that item and show the first page of that document or section in the display pane.
- Use the down and up arrow keys to move through the list of items.

The Contents listing shows documentation for all products installed on your system, or only shows documentation for specified products if you have the Product filter set to Selected.

## Product Roadmap

When you select a product in the Contents pane (any entry with a book icon *), such as MATLAB or the Communications Tool box, a roadmap of the documentation for that product appears in the display pane. The roadmap points to the key documentation for that product and provides links to:

- An index of documentation examples for that product
- The PDF version of the documentation, which is suitable for printing

## Product Pages

After expanding the listing for a product in the Contents pane, the last entry is Product Page (Web). This allows you to link to the MathWorks Web site for latest information about that product.

## Contents Pane Is Synchronized with Display Pane

By default, the topic highlighted in the Contents panealways matches thetitle of the page appearing in the display pane. The Contents listing is said to be synchronized with the displayed document. This feature is useful if you access documentation with a method other than the Contents pane, for example, using a link in a page in the display pane. With synchronization, you always know what book and section the displayed page is part of.

You can turn off synchronization. To do so, use preferences - see "General Synchronizing the Contents Pane with the Displayed Page" on page 4-23.
Note that synchronization only applies to the Contents pane. The page shown in the display pane does not necessarily correspond to the selection in the Search, Index, or Favorites tabs.

## Finding Documentation Using the Index

To find specific index entries (selected keywords) in the MathWorks documentation for your products, use the Index tab in the Help Navigator pane.

## 1 Set the Product filter to All or Selected.

## 2 Click the Index tab.

3 Type a word or words in the Search index for field. As you type, the index displays matching entries and their subentries (indented). It might take a few moments for the display to appear.

The product and title of the document that includes the matching index entry are listed next to the index entry, which is useful when there are multiple matching index entries. Y ou might have to make the Help Navigator pane wider to see the product and document.

4 Select the index entry from the list to display that page.
The page appears in the display pane, scrolled to the location where the index entry appears.

5 To see more matching entries, scroll through the results.
Tips for Using the Index. If you're not satisfied with the resulting index entries, try one of the following:

- If the Product filter is set to Selected, change it to All to see more results. If it's set to AII, change it to Selected to see fewer results.
- Type a different term or reverse the order of the words you type. For example, if you're looking for writing M-files, instead typeM-files and look for the subentry creating.
- Search for the term in the displayed page using the Find in page field.
- Make the Help Navigator pane wider to see the name of the product and document to which the index entry pertains.
- Try the Search tab - for instructions, see "Searching Documentation" on page 4-13.

## Searching Documentation

To look for a specific phrase in the documentation, use the Search tab in the Help Navigator pane.

1 Set the Product filter to All or Selected.
2 Click the Search tab.
3 Select a Search type:

- Full Text searches through all the text in the documentation. This can result in a very large number of results, so it's best to use this after using the Document Titles or Function Name search types.
- Document Titles searches through the headings in the documentation. This is the best way to start most searches.
- Function Name searches through thefunction reference pages. This is the equivalent of the doc function.
- Online Knowledge Base connects to the MATLAB Web site and searches through the Technical Support information.

4 Typethe word or words you want tolook for in the Search for field, and click Go (or press Enter or Return). The search automatically performs a bool ean AND for multiple words. Do not explicitly type AND or similar boolean expressions between words and do not place quotes around terms.

The documents containing the search term are listed, grouped by product. The number of pages containing the search term is displayed in the status bar. F or each result, the Title and Section of the document containing the search phrase are displayed. You might have to make the Help Navigator pane wider to see the Section name.

5 Select an entry from the list of results.
The page containing the search term appears in the display pane and all occurrences of the search term are highlighted in the page. For example, if the search term is font preferences, all occurrences of font and all occurrences of preference arehighlighted in the page. Toseevariants of the term in the page, use the $F$ ind in page field.

6 To see more matching search results, scroll through the list.

## Tips for Using Search

Try "Narrowing Search Results" or "M ore Search Results and Information".
Narrowing Search Results. If you see many results that are not relevant, try the following.

- Change the Search type. For example, for a general topic, use the type Document Titles, or to go to the reference page for a function use the Function name search type.
- Scroll through the list of results. Results are grouped by product, with a labeled banner separating each group.
- If the Product filter is set to AlI, change it to Selected to see fewer results.
- Type more than one word in the Search for field. F or example, type font preferences. The search performs a Boolean AND between the search words. In the example font preferences, it finds all pages that have both the word font and the word preferences, although the pagemay not necessarily have the exact term "font preferences". At the top of the results list are any pages that contain both words in the page title.
- Try the Index. For operators and special characters, you must use the Index, because Search won't find them. Index results might return fewer but more relevant entries because the specified term is a keyword, whereas search results include pages with any mention of the specified term.

More Search Results and Information. To see more information about the search results or to get more results, try the following suggestions.

- Search for variants of the term or other terms on the displayed page using the $F$ ind in page field.
- If the Product filter is set to Selected, change it to All to see more results.
- Make the Help Navigator pane wider so you can see the second column, which displays the documentation section that the result appears in.
- To get more search results, try variations of the search word(s) since the search looks for an exact match. For example, search for preferences. If you don't find what you want, try preference. If you are searching for information about an option, try including the - before the option, for example, save -append.

## Bookmarking Favorite Pages

Click the Favorites tab in the Help Navigator to view a list of documents you previously designated as favorites. From the list of favorites you can:

- Select an entry - That document appears in the display pane.
- Remove an entry - Right-click the item in the favorites list and select Remove from the context menu, or press the Delete key.
- Rename an entry - Right-click the item in the favorites list and select Rename from the context menu. Type over the existing name to replace it with a new name.

## Adding Favorites

To designate a document page as a favorite, do one of the following:

- While a page is open in the display pane, click the Add to Favorites button in the display pane tool bar.
- In the Contents listing, right-click an item and select Add to Favorites from the context menu.
- In the Help browser index or search results list, right-dick an entry and select Add to Favorites from the context menu.

The bookmarks file is matlab_help.hst. Type prefdir in the Command Window to see the location of the file. The matlab_help.hst fileis loaded when MATLAB starts, and is overwritten when you close MATLAB.

## Viewing Documentation in the Display Pane

After finding documentation with the Help Navigator, view the documentation in the display pane. The features available to you while viewing the documentation are:

- "Browsing to Other Pages" on page 4-18
- "Bookmarking Pages" on page 4-18
- "Revisiting Pages" on page 4-19
- "Printing Pages" on page 4-19
- "Finding Terms in Displayed Pages" on page 4-19
- "Copying Information" on page 4-19
- "Evaluating a Selection" on page 4-19
- "Viewing the Page Source (HTML)" on page 4-20
- "Viewing Web Pages" on page 4-20

## Browsing to Other Pages

Use the arrow buttons in the page and the tool bar to go to other pages.

View the next page in the document by clicking the right arrow $\Delta$ at the top or bottom of the page. View the previous page in the document by clicking the left arrow at the top or bottom of the page. The arrows at the bottom of the page are labeled with the title of the page they go to.
View the page previously shown by clicking the back button in the display pane tool bar. After using the back button, view thenext pageshown by clicking the forward button in the display pane tool bar. Y ou can also go back or forward by right-clicking on the page and selecting Back or Forward from the context menu, or by selecting Back or Forward from the Go menu.

## Bookmarking Pages

Add the currently displayed page to your list of favorite documents by clicking Add to Favorites in the display pane tool bar.

## Revisiting Pages

To display a page that you previously viewed in the current MATLAB session, select the page title from the drop-down list in the display pane tool bar.

## Printing Pages

For instructions to print the currently displayed page, see "Printing a Page from the Help Browser" on page 4-26.

## Finding Terms in Displayed Pages

To find a phrase in the currently displayed page:
1 In the Find in page field in the display pane tool bar, type the phrase you're looking for. Then press Enter or Return, or click Go. Y ou can type a partial word, for example, preference to find all occurrences of preference and preferences.

The page scrolls to the location containing the phrase, and highlights it.
2 Press Enter or Return again to find the next occurrence in that page.
See "Searching Documentation" on page 4-13 for instructions to look through all of the documentation instead of just on one page.

## Copying Information

To copy information from the display pane, first select the information. Then either right-click and select Copy from the context menu, or select Copy from the E dit menu. Y ou can then paste the information into another tool, such as the Command Window, or into another application, such as a word processor.

## Evaluating a Selection

To run code examples that appear in the documentation, select the code in the display pane. Then right-click and select Evaluate Selection from the context menu, or select Evaluate Selection from the Go menu. The functions execute in the Command Window.

## View ing the Page Source (HTML)

To view theHTML sourcefor thecurrently displayed page, select View ->Help View Options -> Page Source. The HTML version of the page appears in the Editor/Debugger. Y ou can modify or copy the HTML source. To view a modified page, use the reload button - in the display pane tool bar, or select Reload from the Go menu.

## Viewing Web Pages

You can use the Help browser to view any Web page, although the Help browser might not support all the features you are used to in your usual Web browser. In the display pane pagetitle field, type the URL and press the Enter key. For example, type www. mathworks.com. The MathWorks Web page appears in the Help browser.

## Preferences for the Help Browser

Using preferences, you can specify the location of your help files, fonts used in the Help browser, and the products whose documentation you want to include in your Help browser.

To set preferences for the Help browser, select Preferences from the File menu. The Preferences dialog box opens showing Help Preferences.

Set the preferences and then click OK. Help browser preferences include:

- "Documentation Location - Specifying the help Directory" on page 4-22
- "Product Filter - Limiting the Product Documentation" on page 4-23
- "PDF Reader - Specifying Its Location" on page 4-23
- "General - Synchronizing the Contents Pane with the Displayed Page" on page 4-23
- "Help Fonts Preferences - Specifying Font Name, Style, and Size" on page 4-24

## Documentation Location - Specifying the help Directory

Use the Documentation location preference to specify where the MATLAB help directory resides for your system. The help directory contains the online help files used by the Help browser:

- If you elected to install the help files when you installed MATLAB, the documentation location should already be set to point to the help files. If the help files location changes or you want to access different help files, change the Documentation location for Local or network directory. On Windows, use the ... button to browse your file system to sel ect the new location.
- On Windows platforms, if you did not install the help files during MATLAB installation, the Help browser attempts to find the files on the documentation CD. Y ou need to specify the Documentation location to be CD-ROM drive. Use the ... button to browse your file system to select the drive's location and select the help directory, as shown in the following example.

For UNIX platforms that do not support J ava GUIs, use the docopt function to specify the location of your help directory.

## Product Filter - Limiting the Product Documentation

If you have MathWorks products in addition to MATLAB, such as Simulink and tool boxes, you can use the Product filter to limit the product documentation used.

In Help Preferences, under Product filter, click Select products. The Help Product Filter dialog box opens. Select the products whose documentation you want to appear in the Help Navigator. Then, to use only those products you specified, in the Help browser set the Product filter to Selected. When you want to use all product documentation, in the Help browser set the Product filter to All. Note that you can also access the Help Product Filter dialog box by clicking the Select button in the Help browser.

## PDF Reader - Specifying Its Location

If you want to access the PDF versions of the documentation, the Help system needs to know the location of your PDF reader (Adobe Acrobat).

For Windows systems, MATLAB reads the location from the registry so you cannot specify its location in the preferences.

For UNIX systems, when you installed MATLAB, it looked for your system's PDF reader. If found, MATLAB automatically supplied the PDF reader location in the preferences PDF reader field. If MATLAB could not locate your PDF reader or if you moved your PDF reader since installation, change the location in the PDF reader field. Use the ... button to browse your file system to select the location.

## General - Synchronizing the Contents Pane with the Displayed Page

To turn synchronization off, uncheck the item Keep contents tree synchronized with displayed document, which is in Help Preferences, General. Check theitem toturn synchronization on. F or moreinformation, see "Contents Pane Is Synchronized with Display Pane" on page 4-10.

## Help Fonts Preferences - Specifying Font Name, Style, and Size

You can specify the font name, style, and size used in the Help Navigator, and the font used in the display pane. Expand the Help listing in the left pane of the Preferences dialog box and select the Fonts item. The Help Fonts Preferences panel appears.

## Help Navigator Font

Use Help Navigator font preferences to specify the characteristics of the font in the Help Navigator. For example, specify a smaller font size for the Help Navigator to see more information without scrolling.

Select Use desktop font if you want the font in the Help Navigator to be the same as that specified under General - Font \& Colors. If you want the Help

Navigator font to be different, select Use custom font and specify the font characteristics for the Help Navigator:

- Type, for example, SansSerif
- Style, for example, bold
- Size in points, for example, 12 points

After you make a selection, the Sample area shows how the font will look.

## HTML Brow ser Font

Specify the font type and size used in the display pane for Fixed width and Proportional width fonts. In MathWorks documentation, most of the text uses proportional-width fonts. A fixed-width font is used for code examples, function names, and system input and output, as shown in this example.

```
t = 0:pi/20:2*pi;
y = exp(sin(t));
plotyy(t,y,t,y,'plot','stem')
```

To easily distinguish code, function names, and system input and output from surrounding text in the documentation, specify a different font for fixed width than for proportional width.

## Printing Documentation

You can print the current page displayed in the Help browser, or can print a page to an entire book from the PDF version of the documentation. If you wish to purchase printed documentation, see the online store at the MathWorks Web site at http://www.mathworks.com.

## Printing a Page from the Help Browser

To print the page currently shown in the Help browser, select the print button湲 from the display panetool bar, or select Print from the File menu. The Print dialog box appears. Complete the dialog box and press OK to print the page.

## Printing the PDF Version of Documentation

If you need to print only a few pages and if the quality does not need to be equivalent to pages in a printed book, you can print directly from the MATLAB Help browser - see "Printing Pages" on page 4-19.

If you need to print more than a few pages of documentation, or if you need the pages to appear as if they came from a printed book, print the PDF version of the documentation. PDF documentation is shown and printed using your PDF reader, Adobe Acrobat Reader. The PDF documentation reproduces the look and feel of the printed book, complete with fonts, graphics, formatting, and images. In the PDF document, use links from the table of contents, index, or within the document to go directly to the page of interest.

To print a PDF version of documentation:
1 F or Windows systems only, insert the documentation CD provided with MATLAB into your CD-ROM drive. PDF files are on the CD and are not installed on your system. (F or UNIX systems, the PDF files are installed).If you have problems, check the Help preferences - see "Documentation Location - Specifying the help Directory" on page 4-22.

2 In the Help browser, go to the Contents tab and select the title (first entry) for a product.

The Roadmap page opens for that product, providing links to key documentation for that product.

3 On the bottom of the Roadmap page, listed under Printing the Documentation, is a link for printing. Click that link.

If there is only one manual for the product, Acrobat Reader opens, displaying the table of contents and first page of the manual.

If there is more than one item you can print for the product, a page listing the choices appears. Select the item you want to print. Acrobat Reader opens, displaying the documentation.

If you have problems, check the Help preferences - see "PDF Reader Specifying Its Location" on page 4-23.

4 To print the documentation, select Print from the File menu in Acrobat.

## Using Help Functions

There are several help functions that provide different forms of help than the Help browser, or provide alternative ways to access help.

| Function | Description |
| :--- | :--- |
| doc | Displays the reference page for the specified function in <br> the Help browser, providing syntax, a description, <br> examples, and links to related functions. |
| docopt | For UNIX platforms that do not support J ava GUIs, use <br> docopt to specify the location of help files. |
| help | Displays M-file help (a description and syntax) in the <br> Command Window for the specified function. |
| helpdesk | Opens the Help browser, the MATLAB interface for <br> accessing documentation. |
| Opens the Help browser. In previous releases, helpdesk <br> displayed the Help Desk, which was the precursor to the <br> Help browser. In a future release, the helpdesk function <br> will be phased out. |  |
| helpwin | Displays in the Help browser a list of all functions, <br> providing access to M-file help for the functions. |
| lookfor | Displays in the Command Window a list and brief <br> description for all functions whose brief description <br> includes the specified keyword. |
| web | Opens the specified URL in the specified Web browser, <br> with the default being theMATLAB Help browser. You can <br> use the web function in your own M-files to display <br> documentation. |

## View ing Function Reference Pages - the doc Function

To view the reference page for a function in the Help browser, use doc. This is like using the Help browser search feature, with Search type set to F unction name. F or example, type
doc format
to view the reference page for the format function.

## Overloaded Functions

When a function name is used in multiple products, it is said to be an overloaded function. The doc function displays the reference page for the first function with that name found on the path, and lists the overloaded functions in the Command Window. To get help for an overloaded function, specify the name of the directory containing the function you want the reference page for, followed by the function name. For example, to display the reference page for the set function in the Database Toolbox, type

```
doc database/set
```

## Getting Help in the Command Window - the help Function

To quickly view a brief description and syntax for a function in the Command Window, use the help function. For example, typing
help bar
displays a description and syntax for the bar function in the Command Window. This is called the M-filehelp. For other arguments you can supply, see the reference page for help.

If you need more information than the help function provides, use the doc function, which displays the reference page in the Help browser. It can include color, images, links, and more extensive examples than the M-file help. For example, typing
doc bar
displays the reference page for the bar function in the Help browser.

#### Abstract

Note M-file help displayed in the Command Window uses all uppercase characters for the function and variable names to make them stand out from the rest of the text. When typing function names, however, use lowercase characters. Some functions for interfacing to J ava do use mixed case; the $M$-file help accurately reflects that and you should use mixed case when typing them.

## Overloaded Functions

When a function name is used in multiple products, it is said to be an overloaded function. The help function displays $M$-file help for the first function with that name found on the path, and lists the overloaded functions at the end. To get help for an overloaded function, specify the name of the directory containing the function you want help for, followed by the function name. F or example, to get help for the set function in the Database Toolbox, type
help database/set

## Creating M-File Help for Your Own M-Files

You can create $M$-file help for your own $M$-files and access it using the help command. See the help reference page for details.

## Other Methods for Getting Help

In addition to using the Help browser and help functions, these are the other ways to get help for MathWorks products:

- "Product-Specific Help Features" on page 4-31
- "Running Demos" on page 4-31
- "Contacting Technical Support" on page 4-32
- "Providing Feedback" on page 4-32
- "Getting Version and License Information" on page 4-32
- "Accessing Documentation for Other Products" on page 4-33
- "Participating in the Newsgroup for MathWorks Products" on page 4-33

## Product-Specific Help Features

In addition to the Help browser and help functions, some products and tools allow other methods for getting help. You will encounter some methods in the course of using a product, such as entries in the Help menu, Help buttons in dialog boxes, and selecting Help from a context menu. These methods all display context-sensitive help in the Help browser. Other methods for getting help, such as pressing the F1 key, are described in the documentation for the product or tool that uses the method.

## Running Demos

Many products include demos that show the key features. It's often hel pful to run demos when you first use a product. To see a list of the demos available for a product, use the L aunch Pad, and then select a demo to run it. Some products also provide access to their demos on the Help menu.

## Contacting Technical Support

If your computer is connected to the Internet, you can contact MathWorks Technical Support for help with product problems.

- Find specific Technical Support information using the Help browser Search feature, with the Search type set to Online Knowledge Base. The knowledge base provides the most up-to-date solutions for questions users pose.
- Select Technical Support Knowledge Base from the Web menu to go the Technical Support Web page. The page displays in your system's default Web browser. You can find out about other types of information including third-party books, ask questions, make suggestions, and report possible bugs.

## Providing Feedback

To report any problems or provide any comments or suggestions to The MathWorks about the documentation and help features, send e-mail to doc@mathworks.com.

Alternatively, you can fill out a form on the Web. To access the form, go to the Contents pane in the Help browser. Open the last entry, Support and Web Services, and select Feedback on Help.

To suggest enhancements for or provide feedback about MathWorks products, send e-mail to suggest@mathworks.com. To report problems, send e-mail to bugs@mathworks.com or contact Technical Support.

## Getting Version and License Information

If you need the product version or license information, select About from the Help menu for that product. The version is displayed in an About dialog box. Click Show License in the dialog box to view license information. Notethat the information displayed does not cover your specific license agreement. If the product does not have a Help menu, use the ver function. To see the license number for MATLAB, type license in theCommand Window. See also the ver and version functions.

## Accessing Documentation for Other Products

The Help browser provides access to documentation for all products installed on your system. If you want to look through documentation for MathWorks products you don't have, you can:

- View any product's online documentation at the MathWorks Web site, http: / /www.mathworks. com. Use Access login. If you are not an Access member, select Membership from the Web menu and follow the instructions to join.
- You can access documentation for all products from the documentation CD provided with MATLAB. It contains PDF files for all products. Use preferences for the Help browser to set the documentation location to the CD-ROM drive and use the product filter to specify those products whose documentation you want to see. For instructions, see "Preferences for the Help Browser" on page 4-21.

## Participating in the Newsgroup for MathWorks Products

The USENET newsgroup for MATLAB and related products, comp.soft-sys.matlab, is read by thousands of users worldwide. Access the newsgroup to ask or provide help or advice, and to share code or examples. Y ou can view and search through a sizable archive of postings from the comp.soft-sys.matlab link on the Technical Support Web page. Select Technical Support Knowledge Base from the Web menu.

## Workspace, Search Path, and File Operations

MATLAB Workspace ..... 5-3
Workspace Browser ..... 5-3
Viewing and Editing Workspace Variables Using the Array Editor ..... 5-10
Search Path ..... 5-14
How the Search Path Works ..... 5-14
Viewing and Setting the Search Path ..... 5-15
File Operations ..... 5-20
Current Directory Field ..... 5-20
Current Directory Browser ..... 5-20
Viewing and Making Changes to Directories ..... 5-22
Creating, Renaming, Copying, and Removing Directories and Files ..... 5-23
Opening, Running, and Viewing the Content of Files ..... 5-26
Finding and Replacing Content Within Files ..... 5-28
Preferences for the Current Directory Browser ..... 5-30

When you work with MATLAB, you'll need to understand these important aspects:

- Workspace - The workspace is the set of variables maintained in memory during a MATLAB session. Use the Workspace browser or equivalent functions to view the workspace.
- Search path - MATLAB uses a search path to find M-files and other MATLAB related files. Use the Set Path dialog box or equivalent functions to view and change the path.
- File operations - To search for, view, open, and make changes to MATLAB related directories and files, use the MATLAB Current Directory browser or equivalent functions.

## MATLAB Workspace

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M -files, and loading saved workspaces. For example, if you type

```
t = 0:pi/4:2*pi;
y = sin(t);
```

the workspace includes two variables, $y$ and $t$, each having nine values.

## Workspace Browser

Use the Workspace browser to perform operations on the MATLAB workspace. Equivalent functions are available and are documented for each feature of the Workspace browser.

To open the Workspace browser, do one of the following:

- From the View menu in the MATLAB desktop, select Workspace.
- In the Launch Pad, under MATLAB, double-click Workspace.
- Type workspace at the Command Window prompt.

The Workspace browser opens.

Workspace operations you can perform from the Workspace browser or with functions are:

- "Viewing the Current Workspace" on page 5-4
- "Saving the Current Workspace" on page 5-5
- "Loading a Saved Workspace" on page 5-7
- "Clearing Workspace Variables" on page 5-8
- "Viewing Base and Function Workspaces Using the Stack" on page 5-8
- "Creating Graphics from the Workspace Browser" on page 5-9
- "Viewing and Editing Workspace Variables Using the Array Editor" on page 5-10

You can also set preferences - see "Preferences for the Workspace Browser" on page 5-9.

## Viewing the Current W orkspace

The Workspace browser shows the name of each variable, its array size, its size in bytes, and the class. The icon for each variable denotes its class.

To resize the columns of information, drag the column header borders. To show or hide any of the columns, or to specify the sort order, select Workspace View Options from the View menu.
You can select the column on which to sort in the Workspace browser as well as reverse the sort order of any column. Click on a column heading to sort on that column. Click on the column heading again to reverse the sort order in that column. F or example, to sort on Size, click the column heading once. To change from ascending to descending, click on the heading again.

Function Alternative. Use who to list the current workspace variables. Use whos to list the variables and information about their size and class. For example:
who
Your variables are:
A
M
whos
Name
A
M

Use the exist function to see if the specified variable is in the workspace.

## Saving the Current Workspace

The workspace is not maintained across MATLAB sessions. When you quit MATLAB, the workspace is cleared. You can save any or all of the variables in the current workspace to a MAT-file, which is a MATLAB specific binary file. You can then load the MAT-file at a later time during the current or another session to reuse the workspace variables. MAT-files usea . mat extension. Note that the .mat extension is also used by Microsoft Access.

Saving All Variables. To save all of the workspace variables using the Workspace browser:

1 From the File or context menu, select Save Workspace As, or click the save button in the Workspace browser tool bar.

The Save dialog box opens.
2 Specify the location and File name. MATLAB automatically supplies the .mat extension.

## 3 Click Save.

The workspace variables are saved under the MAT-file name you specified.
You can also save the workspace variables from the Command Window by selecting Save Workspace As from the File menu.

Saving Selected Variables. To save some but not all of the current workspace variables:

1 Select the variable in the Workspace browser. To select multiple variables, Shift+click or Ctrl+click.

2 Right-click and from the context menu, select Save Selection As.
The Save to MAT-File dialog box opens.
3 Specify the location and File name. MATLAB automatically supplies the .mat extension.

4 Click Save.

The workspace variables are saved under the MAT-file name you specified.
Function Alternative. To save workspace variables, use the save function followed by the filename you want to save to. For example,

```
save('june10')
```

saves all current workspace variables to the file june10.mat.
If you don't specify a filename, the workspace is saved to matlab. mat in the current working directory. You can specify which variables to save, as well as control theformat in which the data is stored, such as ascii. For these and other
forms of the function, see the reference page for save. MATLAB provides additional functions for saving information - see Chapter 6, "Importing and Exporting Data."

## Loading a Saved Workspace

To load a workspace that you previously saved:
1 Click the load data button on the toolbar in the Workspace browser, or right-click in the Workspace browser and select Import Data from the context menu.

The Open dialog box opens.
2 Select the MAT-file you want to load and click Open.
The variables and their values, as stored in the MAT-file, are loaded intothe workspace.

You can also load a saved workspace using the I mport Wizard. Select Import Data from the File menu and then select a file from the I mport dialog box. The I mport Wizard opens. Use the I mport Wizard to open the saved workspace. F or instructions, see "Using the I mport Wizard with Binary Data Files" on page 6-20.

Function Alternative. Use load to open a saved workspace. For example,
load('june10')
loads all workspace variables from the file june10.mat.

#### Abstract

Note If the saved MAT-file june10 contains the variables A, B, and C, then loading june10 places the variables A, B, and C back into the workspace. If the variables already exist in the workspace, they are overwritten with the variables from june10. For more information, see the reference page for load. MATLAB provides other functions for loading information - see Chapter 6, "I mporting and Exporting Data."

## Clearing Workspace Variables

You can delete a variable, which removes it from the workspace.
To clear a variable using the Workspace browser:
1 In theWorkspace browser, select the variable, or Shift+click or CtrI+click to select multiple variables. To select all variables, choose Select All from the Edit or context menus.

2 Do one of the following to clear the selected variables:

- Press the Delete key.
- From the Edit menu, select Delete.
- Click the delete button 眝 on the toolbar.
- Right-click and select Delete Selection from the context menu.

3 A confirmation dialog box may appear. If it does, click Yes to clear the variables.

The confirmation dialog box appears if you specify it as a preference. See "Preferences for the Workspace Browser" on page 5-9 to change the preference.
To del ete all variables at once, select Clear Workspace from the Edit menu, or from the context menu in the Workspace browser.

Function Alternative. Use the clear function. For example,
clear A M
clears the variables $A$ and $M$ from the workspace.

## Viewing Base and Function Workspaces Using the Stack

When you run M-files, MATLAB assigns each function its own workspace, called the function workspace, which is separate from MATLAB's base workspace. You can access the base and function workspaces when debugging M-files by using the Stack field in the Workspace browser. The Stack field is only available in debug mode; otherwise it is grayed out. The Stack field is also accessiblefrom the Editor/Debugger. See "Debugging M-Files" on page 7-17 for more information.

## Creating Graphics from the Workspace Browser

From the Workspace browser, you can generate a graph of a variable. Right-click on the variable you want to graph. From the context menu, select Graph Selection and then choose the type of graph you want to create. The graph appears in a figure window. F or more information about creating graphs in MATLAB, see MATLAB graphics documentation.

## Preferences for the Workspace Browser

You can specify as a preference the fonts to use in the Workspace browser and whether or not you want a confirmation dialog box to appear when you clear variables using the Workspace browser.

From the Workspace browser File menu, select Preferences. The Preferences dialog box opens to the Workspace Preferences panel.

Font. Workspace browser font preferences specify the characteristics of thefont used in the Workspace browser. Select Use desktop font if you want the font in the Workspace browser to be the same as that specified for General Font \& Colors preferences.

If you want the Workspace browser font to be different, select Use custom font and specify the font characteristics for the Workspace browser:

- Type, for example, SansSerif
- Style, for example, bold
- Size in points, for example, 12 points

After you make a selection, the Sample area shows how the font will look.
Confirm Deletion of Variables. Check the box for Confirm deletion of variables if you want a confirmation dialog box to appear when you delete a variable.

## View ing and Editing Workspace Variables Using the Array Editor

Use the Array Editor to view and edit a visual representation of one or two-dimensional numeric arrays, strings, and cell arrays of strings. The Array Editor features are:

- "Opening the Array Editor" on page 5-10
- "Changing Values of Elements in the Array Editor" on page 5-12
- "Controlling the Display of Values in the Array Editor" on page 5-12

In addition, you can set preferences. See "Preferences for the Array Editor" on page 5-12.

## Opening the Array Editor

You can open the Array Editor from the Workspace browser:
1 In the Workspace browser, select the variable you want to open. Shift+click or CtrI+click to select multiple

2 variables to open.
3 Click the open selection button on the tool bar, or right-click and select Open Selection from the context menu.

Alternatively, for one variable, you can double-click it to open it.
The Array Editor opens, displaying the values for the selected variable.
You cannot open an array with 10,000 or more elements.

Repeat the steps to open additional variables in the Array Editor. Access each variable via its tab at the bottom of the window, or use the Window menu.

Function Alternative. To see the contents of a variable in the workspace, just type the variable name at the Command Window prompt. F or example, type
m
and MATLAB returns

| $m=$ |  |  |  |
| :---: | :---: | :---: | :---: |
| 16 | 2 | 3 | 13 |
| 5 | 11 | 10 | 8 |
| 9 | 7 | 6 | 12 |
| 4 | 14 | 15 | 1 |

To open a variable in the Array Editor, use openvar with the name of the variable you want to open as the argument. For example, type

```
openvar('m')
```

MATLAB opens m in the Array Editor.

## Changing Values of Elements in the Array Editor

In the Array Editor, click in the cell whose value you want to change. Type a new value. Press E nter or Return, or click in another cell and the changetakes effect.

To change the dimensions of an array, type the new values for the rows and columns in the Size fields. If you increase the size, the new rows and columns are added to the end and are filled with zeros. If you decrease the size, you will lose data - MATLAB removes rows and columns from theend. Some data types do not allow you to change the dimension; for these variables, the Size field is not editable.

If you opened an existing MAT-file and made changes to it using the Array Editor, you'll have to save that MAT-file if you want the changes to be saved. For instructions, see "Saving the Current Workspace" on page 5-5.

## Controlling the Display of Values in the Array Editor

In the Array Editor, select an entry in the Numeric format list box to control how numeric values are displayed. For descriptions of the formats, see the reference page for format. The format applies only to the Array Editor display for that variable for the current session; it does not affect how MATLAB computes or saves the numeric value, nor does it affect the format used for display in the Command Window.

To specify a format for all variables in the Array Editor and keep it persistent across sessions, specify the format for the Array Editor using preferences as discussed in the next topic.

## Preferences for the Array Editor

Using preferences for the Array Editor, you can specify the format for how numeric values are displayed, as well as their font type, style, and size.

To set preferences for the Array Editor, select Preferences from the File menu. The Preferences dialog box opens showing Array Editor Preferences.

Specify the Font and Default format preferences.

Font. Array Editor font preferences specify the characteristics of the font used in the Array Editor. Select Use desktop font if you want the font in the Array Editor to be the same as that specified for General Font \& Colors preferences. If you want the Array Editor font to be different, select Use custom font and specify the font characteristics for the Array Editor:

- Type, for example, SansSerif
- Style, for example, bold
- Size in points, for example, 12 points

After you make a selection, the Sample area shows how the font will look.
Default Format. Specify the output format of numeric values displayed in the Array Editor. This affects only how numbers are displayed, not how MATLAB computes or saves them. F or more information, see "Controlling the Display of Values in the Array Editor" on page 5-12 or see the reference page for format.

## Search Path

MATLAB uses a search path to find M-files and other MATLAB related files, which are organized in directories on your file system. These files and directories are provided with MATLAB and associated tool boxes. Any file you want to run in MATLAB must reside in a directory that is on the search path or in the current directory. By default, the files supplied with MATLAB and MathWorks toolboxes are included in the search path.

If you create any MATLAB related files, add the directories containing the files to MATLAB's search path. When you create your own M-files or if you modify any MATLAB supplied M-files, save them in a directory that is not in \$matlabroot/toolbox/matlab. If you do keep any of your files in \$matlabroot/toolbox/matlab, they may be overwritten when you install a new version of MATLAB. In addition, you might need to restart MATLAB or use the rehash function before you use the new or updated file. This is because the locations of those files are loaded and cached in memory at the beginning of each MATLAB session to improve performance, and changes are not always recognized automatically.

For instructions to view and modify the search path, see "Viewing and Setting the Search Path" on page 5-15.

## How the Search Path Works

The search path is also referred to as the MATLAB path. Files included are considered to be on the path. When you include a directory on the search path, you add it to thepath. Subdirectories must be explicitly added to the path; they are not on the path just because their parent directories are. The search path is stored in the file pathdef.m.

The order of directories on the path is relevant. MATLAB looks for a named element, for example, foo, as described here. If you enter foo at the MATLAB prompt, MATLAB performs the following actions:

1 Looks for foo as a variable.
2 Checks for foo as a built-in function.
3 Looks in the current directory for a file named foo.m.
4 Searches the directories on the MATLAB search path, in order, for foo.m.

Although the actual search rules are more complicated because of the restricted scope of private functions, subfunctions, and object-oriented functions, this simplified perspective is accurate for the ordinary M-files you usually work with.

The order of the directories on the search path is important if there is more than one function with the same name. When MATLAB looks for that function, only the first one in the search path order is found; other functions with the same name are considered to be shadowed and cannot be executed. For more information, see "H ow MATLAB Determines Which Method to Call".

To see the pathname used, use which for a specified function. For more information, see the reference page for which.

## View ing and Setting the Search Path

Use the Set Path dialog box to view and modify MATLAB's search path and see files in directories that are on the path. Equivalent functions are documented for each feature of the Set Path dialog box.

Select Set Path from the File menu, or type pathtool at the Command Window prompt. The Set Path dialog box opens.

Use the Set Path dialog box for the following:

- "Viewing the Search Path" on page 5-17
- "Adding Directories to the Search Path" on page 5-17
- "Moving Directories within the Search Path" on page 5-17
- "Removing Directories from the Search Path" on page 5-18
- "Restoring the Default Search Path" on page 5-18
- "Reverting to the Previous Path" on page 5-18
- "Saving Settings to the Path" on page 5-18

## Viewing the Search Path

The MATLAB search path field in the Set Path dialog box lists all of the directories on the search path.

Function Alternative. Use the path function to view the search path.

## Adding Directories to the Search Path

To add directories to the MATLAB search path using the Set Path dialog box:
1 Click the Add Folder or the Add with Subfolders button.

- If you want to add only the selected directory but do not want to add all of its subdirectories, click Add Folder.
- If you want to add the selected directory and all of its subdirectories, click Add with Subfolders.

The Browse for Folder dialog box opens.
2 In the Browse for Folder dialog box, use the view of your file system to select the directory to add, and then click OK.

The selected directory, and subdirectories if specified, are added to the front (top) of the search path. They remain on the search path until you end the current MATLAB session. To use the newly modified search path in subsequent sessions, you need to save the path - see "Saving Settings to the Path" on page 5-18.

You cannot add method directories (directories that start with @) or private directories directly to the search path. Instead, add their parent directories.

Function Equivalent. To add directories to the search path, use addpath. The addpath function offers an option to get the path as a string and to concatenate multiple strings to form a new path.
You can include addpath in your startup M-file to automatically modify the path when MATLAB starts.

## Moving Directories within the Search Path

The order of files on the search path is relevant - for more information, see "How the Search Path Works" on page 5-14.

To modify the order of directories within the search path, first select the directory you want to move. Then select one of the Move buttons, such as Move to Top. The top of the list corresponds to the front of the search path and the bottom of the list corresponds to the end of the search path.

The new order of files on the search path remains in effect until you end the current MATLAB session. To use the newly modified search path in subsequent sessions, you need to save the path - see "Saving Settings to the Path" on page 5-18.

## Removing Directories from the Search Path

Toremove directories from the MATLAB search path usingthe Set Path dialog box:

1 Select the directory to remove.

## 2 Click Remove.

The directory is removed from the search path for the remainder of the current MATLAB session. To use the newly modified search path in subsequent sessions, you need to save the path - see "Saving Settings to the Path" on page 5-18.

Function Equivalent. To remove directories from the search path, use rmpath.
You can include rmpath functions in your startup M-file to automatically modify the path when MATLAB starts.

## Restoring the Default Search Path

To restore the default search path, click Default in the Set Path dialog box. This changes the search path so that it uses the factory settings.

## Reverting to the Previous Path

To restore the previous path, click Revert in the Set Path dialog box. This cancels any unsaved changes you've made in the Set Path dialog box.

## Saving Settings to the Path

When you make changes to the search path, they remain in effect during the current MATLAB session. To keep the changes in effect for subsequent
sessions, save the changes. Tosave changes using the Set Path dialog box, click Save.

The search path is stored in the pathdef.m file. By default, pathdef.m is stored in \$matlabroot \toolbox\local. On Windows platforms, you can use a different pathdef.m if you store it in your startup directory - see "Startup Directory for MATLAB" on page 1-3.
You can directly edit pathdef.m with a text editor to change the path.
On UNIX workstations you may not have file system permission to edit pathdef.m. In this case, put path and addpath functions in your startup M-file to change your path defaults.

## File Operations

MATLAB fileoperations use the current directory as a reference point. Any file you want to run must either be in the current directory or on the search path. Also, when you open a file in MATLAB, the starting point for the file open dialog box is the current directory. The keys tools for performing file operations are:

- Current directory field
- Current directory browser

## Current Directory Field

A quick way to view or change the current directory is by using the Current Directory field in the desktop tool bar.

```
Current Directony: D:Imymfiles
\nabla
```

To change the current directory from this field, do one of the following:

- In the field, type the path for the new current directory.
- Click the down arrow to view a list of previous working directories, and select an item from the list to make that directory become MATLAB's current working directory. The directories are listed in order, with the most recently used at the top of the list. Y ou can clear the list and set the number of directories saved in the list - see "Preferences for the Current Directory Browser" on page 5-30.
- Click the browse button (...) to set a new current directory.

## Current Directory Browser

To search for, view, open, and make changes to MATLAB related directories and files, use the MATLAB Current Directory browser. Equivalent functions are documented for each feature of the Current Directory browser.
To open the Current Directory browser, select Current Directory from the View menu in the MATLAB desktop, or type filebrowser at the Command

Window prompt. You can also open it from the Launch Pad, under MATLAB.

The Current Directory browser opens.

The main file operations you can perform using the Current Directory browser are:

- "Viewing and Making Changes to Directories" on page 5-22
- "Creating, Renaming, Copying, and Removing Directories and Files" on page 5-23
- "Opening, Running, and Viewing the Content of Files" on page 5-26
- "Finding and Replacing Content Within Files" on page 5-28

You can also set preferences - see "Preferences for the Current Directory Browser" on page 5-30.

## Viewing and Making Changes to Directories

The ways to view and make changes to directories are:

- "Changing the Current Working Directory and Viewing Its Contents" on page 5-22
- "Adding Directories to the MATLAB Search Path" on page 5-23
- "Changing the Display" on page 5-23

## Changing the Current Working Directory and Viewing Its Contents

To change the current directory, type the directory name in the pathname edit box in the Current Directory browser, and press the Enter or Return key. That directory becomes the current working directory and the files and subdirectories in it are listed.

To view a directory that has recently been displayed, click the down arrow at the right side of the pathname edit box in the Current Directory browser. The previously displayed directories are listed, sorted by most recent to least recent. Select an entry to view the contents of that directory. Y ou can clear the list and set the number of directories saved in thelist - see "Preferences for the Current Directory Browser" on page 5-30.

To view the contents of a subdirectory within the directory being displayed, double-click the subdirectory in the Current Directory browser, or select the subdirectory and press the Enter or Return key. You can also right-click on that subdirectory and select Open from the context menu.

To move up one level in the directory structure, click the up button in the Current Directory browser tool bar, or press the Back Space key.

Function Alternative. Use dir to view the contents of the current working directory or another specified directory.

Use what to see only the MATLAB related files in a directory. With no arguments, what displays the MATLAB related files in the current working directory. Use which to display the pathname for the specified function. Use exist to see if a directory or file exists.

## Adding Directories to the MATLAB Search Path

From the Current Directory browser, you can add directories to the MATLAB search path. Right-click and from the context menu, select Add to Path. Then select one of the options:

- Current Directory - Adds the current directory to the path.
- Selected Folders - Adds the directory selected in the Current Directory browser to the path.
- Selected Folder and Subfolders - Adds the directory selected in the Current Directory browser to the path, and adds all of its subdirectories to the path.

## Changing the Display

To specify the types of files shown in the Current Directory browser, use
View ->Current Directory Filter. For example, you can show only M-files.
You can sort the information shown in the Current Directory browser by column. Click the title of column on which you want to sort. The display is sorted, with the information in the that column shown in ascending order. Click a second time on the column title to sort the information in descending order.

If you make changes to the current directory from your filesystem, the Current Directory browser display won't immediately reflect those changes. Select
Refresh from the context menu to update the Current Directory browser display.

## Creating, Renaming, Copying, and Removing Directories and Files

If you have write permission, you can create, copy, remove, and rename MATLAB related files and directories for the directory shown in the Current Directory browser. If you do not have write permission, you can still copy files and directories to another directory.

## Creating New Files

To create a new file in the current directory:
1 Select New from the context menu or File menu and then select the type of file to create.

An icon for that file type, for example, an M-file icon 葍, with the default name Untitled appears at the end of the list of files shown in the Current Directory browser.

2 Type over Untitled with the name you want to give to the new file.
3 Press the Enter or Return key.
The file is added.
4 To enter the contents of the new M-file, open the file - see "Opening, Running, and Viewing the Content of Files" on page 5-26. If you created the file using the context menu, the new file opens with a template for writing an M-file function.

## Create New Directories

To create a new directory in the current directory:
1 Click the new folder button in the Current Directory browser tool bar, or select New ->F older from context menu.

An icon, with the default name NewFolder appears at the end of the list of files shown in the Current Directory browser.

2 Type over NewFolder with the name you want to give to the new directory.

## 3 Press the Enter or Return key.

The directory is added.
Function Equivalent. To create a directory, use the mkdir function. For example, mkdir .. \testdata newdir
creates the directory newdir within the directory testdata.

## Renaming Files and Directories

To rename a file or directory, select the item, right-click, and select Rename from the context menu. Type over the existing name with the new name for the file or directory, and press the Enter or Return key. The file or directory is renamed.

## Cutting or Deleting Files and Directories

To cut or delete files and directories:
1 Select the files and directories to remove. Use Shift+click or CtrI+click to select multiple items.

2 Right-click and select Cut or Delete from the context menu. Cut is also available from the E dit menu.

The files and directories are removed.
Function Equivalent. To delete a file, use the delete function. For example, delete('d:\mymfiles\testfun.m')
deletes the file testfun.m.

## Copying and Pasting Files

You can copy and paste files, but not directories. To copy and paste files:
1 Select the files. Use Shift+click or Ctrl+click to select multiple items.
2 Right-click and select Copy from the context menu, or select Copy from the Edit menu.

3 Move tothe directory where you want to paste the files you just copied or cut.
4 Paste the files by right-clicking and selecting Paste from the context menu, or by selecting Paste from the Edit menu.

## Opening, Running, and Viewing the Content of Files

## Opening Files

You can open a file using the open feature of the Current Directory browser. The file opens in the tool associated with that file type.

To open a file, select one or more files and perform one of the following actions:

- Press the Enter or Return key.
- Right-click and select Open from the context menu.
- Double-click on the file(s).

The files open in the appropriate tools. For example, the Editor/Debugger opens for M-files, and Simulink opens for model (mdl) files.

To open any file in the Editor, no matter what type it is, select Open as Text from the context menu.

You can also import data from a file. Select the file, right-click, and select Import Data from the context menu. The Import Wizard opens. See Chapter 6, "Importing and Exporting Data" for instructions to import the data.

Function Alternative. Use the open function to open a file into the tool appropriate for the file, given its file extension. Default behavior is provided for standard MATLAB filetypes. Y ou can extend the interface to include other filetypes and to override the default behavior for the standard files.

| File Type | Extension | Action |
| :--- | :--- | :--- |
| Figure file | fig | Open figure in a figure window. |
| HTML file | html | Open HTML file name in the Help browser. |
| M-file | m | Open M-file name in the Editor. |
| MAT-file | mat | Open MAT-file name in the Import Wizard. |
| Model | mdl | Open model name in Simulink. <br> P-file p |
| Open the corresponding M-file, name.m, if it <br> exists, in the Editor. |  |  |

| File Type | Extension | Action (Continued) |
| :--- | :--- | :--- |
| Variable | not <br> applicable | Open the numeric or string array name in the <br> Array Editor; open calls openvar. |
| Other | custom | Open name.custom by calling the helper <br> function opencustom, where opencustom is a <br> user-defined function. |

To view the content of an ASCII file, such as an M-file, use the type function. For example

```
type('startup')
```

displays the contents of the file startup.m in the Command Window.

## Running M-Files

To run an M-file from the Current Directory browser, select it, right-click, and select Run from the context menu. The results appear in the Command Window.

## Viewing Help for an M-File

You can view help for the M-file selected in the Current Directory browser. From the context menu, select View Help. The reference page for that function appears in the Help browser, or if a reference page does not exist, the M-file help appears.

You can view the M-file help in the Current Directory browser - for instructions, see "Preferences for the Current Directory Browser" on page 5-30.

## Finding and Replacing Content Within Files

From the Current Directory browser, you can search for a specified string within files. If the file is open in the Editor, you can replace the specified string in a file.

## Finding a Specified String Within a File

To search for a specified string in files:
1 Click the find button in the Current Directory browser tool bar.
The Find \& Replace dialog box appears. This provides the same features as the Find \& Replace dialog box accessible from the Editor/Debugger.

2 Completethe Find \& Replace dialog box to find all occurrences of the string you specify.

- Type the string in the Find what field.
- Select the directories to search through from the Look in listbox, or type a directory name directly in this field.
- Constrain the search by checking Match case or Whole word.
- Check the box for Subdirectories if you want the search to also look through the subdirectories.

## 3 Click Find.

Results appear in the lower part of the Find \& Replace dialog box and include the filename, M -file line number, and content of that line.

4 Open any M -file(s) in the results list by doing one of the following:

- Double-clicking the file(s)
- Selecting the file(s) and pressing the Enter or Return key
- Right-clicking the file(s) and selecting Open from the context menu

The M-file(s) opens in the Editor, scrolled to the line number shown in the results section of the Find \& Replace dialog box.

5 If you perform another search, the results of each search are accessible via tabs just bel ow the current results list. Click a tab to see that results list as well as the search criteria.

Function Equivalent. Use lookfor to search for the specified string in the first line of help in all M-files on the search path.

## Replacing a Specified String Within Files

After searching for a string within a file, you can replace the string.
1 Open the file in MATLAB Editor. You can open the file from the Current Directory browser Find \& Replace dialog box results list - see step 4 in "Finding a Specified String Within a File" on page 5-28. Be sure that the file in which you want to replace the string is the current file in the Editor.

2 In the Look in field in the Find \& Replace dialog box, select the name of the file in which you want to replace the string.

The Replace button in the Find \& Replace dialog box becomes selectable.
3 In the Replace with field, type the text that is to replace the specified string.
4 Click Replace to replace the string in the selected line, or click Replace All to replace all instances in the currently open file.

The text is replaced.
5 To save the changes, select Save from the File menu in the Editor.

## Preferences for the Current Directory Brow ser

You can specify the number of recently used current directories to maintain in the history list as well as the type of information to display in the Current Directory browser using preferences.

From the Current Directory browser File menu, select Preferences. The Current Directory Preferences panel appears in the Preferences dialog box.

Preferences

- 回 x

| T-General <br> ©-Command Window <br> 也-Editor/'Debugger <br> ( - Help <br> - Current Directory <br> - Workspace <br> -Array Editor <br> - GUIDE <br> ©-Figure Copy Template <br> +-Simulink |
| :---: |

## History

The drop down list in the Current Directory browser tool bar, as well as in the MATLAB desktop Current Directory field, show the most recently used current directories. The list contains all of the current directories used in the current MATLAB session.

Removing Directories. To remove the entries in the list, select Clear History. The list is cleared immediately.

Saving Directories. When the MATLAB session ends, the list of directories will be maintained. Use the Save most recent directories field to specify how many directories will appear on the list in at the start of the next MATLAB session.

## Browser display options

In theCurrent Directory browser, you can view thefiletype, last modified date, $M$-file descriptions, and M-file comments and MAT-file contents by checking the appropriate Browser display options.
Importing and Exporting Data
Importing Text Data ..... 6-4
Exporting ASCII Data ..... 6-16

Exporting Binary Data ..... 6-25
Working with HDF Data ..... 6-29
Using Low-Level File I/O Functions ..... 6-51

MATLAB provides many ways toload data from disk files or the clipboard into the workspace, a process called importing data, and to save workspace variables to a disk file, a process called exporting data. Your choice of which mechanism to use depends on which operation you are performing, importing or exporting, and the format of the data, text or binary.

> Note The easiest way to import data into MATLAB is to use the Import Wizard. When you use the Import Wizard, you do not need to know the format of the data. You simply specify the file that contains the data and the Import Wizard processes the file contents automatically. For more information, see "Using the Import Wizard with Text Data" on page 6-4 and "Using the Import Wizard with Binary Data Files" on page 6-20.

## Text Data

In text formats, the data values are American Standard Code for Information Interchange (ASCII) codes that represent alphabetic and numeric characters. ASCII text data can be viewed in a text editor. For more information about working with text data, see:

- "Importing Text Data" on page 6-4
- "Exporting ASCII Data" on page 6-16

## Binary Data

In binary format, the values are not ASCII codes and cannot be viewed in a text editor. Binary files contain data that represents images, sounds, and other formats. For more information about working with binary data, see:

- "Importing Binary Data" on page 6-20
- "Exporting Binary Data" on page 6-25

## Other Formats

MATLAB also supports the importing of scientific data that uses the Hierarchical Data F ormat (HDF). See "Working with HDF Data" on page 6-29 for more information.

## Low-Level File I/ 0

MATLAB also supports C-style, Iow-level I/O functions that you can use with any data format. For more information, see "Using Low-Level File I/O Functions" on page 6-51.

## Importing Text Data

The easiest way to import text data into the workspace is to use the MATLAB Import Wizard. Y ou simply start the Import Wizard and specify the file that contains the data you want to import. The I mport Wizard can process most numeric data files automatically, even if they contain text headers. See "Using the I mport Wizard with Text Data" below for more detailed information.

If you need to work from the MATLAB command line or perform import operations as part of an M-file, you must use one of the MATLAB import functions. Your choice of which function to use depends on the type of data in the file and how the data is formatted. MATLAB has functions that work with numeric data and other functions that can handle both alphabetic and numeric data. See "Using Import F unctions with Text Data" on page 6-9 for more information about choosing the function that is right for your data.

Caution When you import data into the MATLAB workspace, you overwrite any existing variable in the workspace with the same name.

## Using the Import Wizard with Text Data

To import text data using the Import Wizard, perform these steps:
1 Start the Import Wizard, by selecting the Import Data option on the MATLAB File menu. MATLAB displays a file selection dialog box. You can also use the uiimport function to start the Import Wizard.

Touse the Import Wizard to import data from the clipboard, select the Paste Special option on the MATLAB Edit menu. You can also right-click in the MATLAB command window and choose Paste Special from the context menu. Skip to step 3 to continue importing from the clipboard.

2 Specify the file you want to import in the file selection dialog box and click Open. The Import Wizard opens the file and attempts to process its contents.

3 Specify the character used to separate the individual data items. This character is called the delimiter or column-separator. The Import Wizard
can determine the delimiter used in many cases. However, you may need to specify the character used in your text file. See "Specifying theDelimiter" on page 6-5 for more information. Once the Import Wizard has correctly processed the data, click Next.

4 Select the variables that you want to import. By default, the Import Wizard puts all the numeric data in one variable and all the text data in other variables but you can choose other options. See "Selecting the Variables to Import" on page 6-7 for more information.

5 Click Finish to import the data into the workspace.

## Specifying the Delimiter

When the Import Wizard opens a text file, or copies data from the clipboard, it displays a portion of the raw data in the Preview pane of the dialog box. Y ou can use this display to verify that the file contains the data you expected.
The I mport Wizard also attempts to process the data, identifying the delimiter used in the data. The I mport Wizard displays the variables it has created based on its interpretation of the delimiter, using tabbed panels to display multiple variables.

F or example, in the following figure, thel mport Wizard has opened this sample file, grades.txt.

| John | 85 | 90 | 95 |
| :--- | ---: | ---: | ---: |
| Ann | 90 | 92 | 98 |
| Martin | 100 | 95 | 97 |
| Rob | 77 | 86 | 93 |

In the figure, note how the Import Wizard has correctly identified the tab character as the delimiter used in the file and has created three variables from the data:

- data -- containing all the numeric data in the file
- textdata -- containing all the text found in the file
- rowheaders -- containing the names in the left-most column of data.

Handling Alphabetic Data. The Import Wizard recognize data files that use row or column headers and extract these headers into separate variables. It can also ignore any text header lines that may precede the data in a file.

Specifying 0 ther Delimiters. If the Import Wizard cannot determine the delimiter used in the data, it displays a preview of the raw data, as before, but the variables it displays will not be correct. If your data uses a character other than a comma, space, tab, or semicol on as a delimiter, you must specify it by clicking the Other button and entering the character in the text box. The Import Wizard immediately reprocesses the data, displaying the new variables it creates.

List of variables to be imported.

Import Wizard displays content of the variable highlighted in the list.

## Selecting the Variables to Import

The I mport Wizard displays a list of the variables it has created from your data. You can select which variables you want to import by clicking in the check box next to its name. By default, all variables are selected.

The Import Wizard displays the contents of the variable that is highlighted in the list in the right pane of the dialog box. To view the contents of one of the other variables, click on it. Choose the variables you want to import and click Next.

Changing the Variable Selection. By default, the I mport Wizard puts all the numeric data in the file into one variable. If the file contains text data, the Import Wizard puts it in a separate variable. If the file contains row- or column-headers, the Import Wizard puts them in a separate variables, called rowheaders or colheaders, respectively.
In some cases, it might be more convenient to create variables out of each row or column of data and use the row headers or column header text as the name of each variable. To do this, click the appropriate button from the list of buttons at the top of the dialog box.

```
¢ Create variables matching preview.
C- Create vectors from each column using row names.
```

For example, it would ease calculations of the student averages it we created separate variables for each student that contained that student's grades. To create these variables, click the Create variables from each column using row names button. When you click this option, the I mport Wizard reprocesses the file creating these new variables.

When you are satisfied with the list of variables to be imported, click Next to bring the data into the MATLAB workspace. This button also dismisses the Import Wizard. The Import Wizard displays a message in the MATLAB command window, reporting that it created variables in the workspace. In the following example, note how the numeric text data in each variable is imported as an array of doubles.

```
Import Wizard created variables in the current workspace.
>> whos
    Name Size Bytes Class
```

| Ann | $1 \times 3$ | 24 double array |
| :--- | :--- | :--- | :--- |
| John | $1 \times 3$ | 24 double array |
| Martin | $1 \times 3$ | 24 double array |
| Rob | $1 \times 3$ | 24 double array |

Grand total is 12 elements using 96 bytes

## Using Import Functions with Text Data

To import text data from the command line or in an M-file, you must use one of the MATLAB import functions. Your choice of function depends on how the data in the text file is formatted.

The text data must be formatted in a uniform pattern of rows and columns, using a text character, called a delimiter or column separator, to separate each data item. The delimiter can be space, comma, semicol on, tab, or any other character. The individual data items can be alphabetic or numeric characters or a mix of both.

The text file may also contain one or more lines of text, called header lines, or may use text headers to label each column or row. The following example illustrates a tab-delimited text file with header text and row and column headers.

To find out how your data is formatted, view it in a text editor. After you determine the format, scan the data format samples in Table 6-1 and look for the sample that most closely resembles the format of your data. Read the topic referred to in the table for more information.

Table 6-1: ASCII Data File Formats and MATLAB Import Commands

| Data Format Sample | File Extension | Description |
| :---: | :---: | :---: |
| $\begin{array}{lllll} 1 & 2 & 3 & 4 & 5 \\ 6 & 7 & 8 & 9 & 10 \end{array}$ | $\begin{aligned} & \text {.txt } \\ & \text {.dat } \\ & \text { or other } \end{aligned}$ | See "I mporting Numeric Text Data" on page 6-11 for more information. You can also use the Import Wizard for this data format. See "Using the I mport Wizard with Text Data" on page 6-4 for more information. |
| $\begin{aligned} & 1 ; 2 ; 3 ; 4 ; 5 \\ & 6 ; 7 ; 8 ; 9 ; 10 \\ & \text { or } \\ & 1,2,3,4,5 \\ & 6,7,8,9,10 \end{aligned}$ | .txt <br> .dat <br> .csv <br> or other | See "Importing Delimited ASCII Data Files" on page 6-12 for more information. You can also use the Import Wizard for this data format. See "Using the Import Wizard with Text Data" on page 6-4 for more information. |
| Ann Type1 12.3445 Yes Joe Type2 45.6767 No | $\begin{aligned} & . \text { txt } \\ & \text {.dat } \\ & \text { or other } \end{aligned}$ | See "Importing Numeric Data with Text Headers" on page 6-13 for more information. |
| Grade1 Grade2 Grade3 <br> 91.5 89.2 77.3 <br> 88.0 67.8 91.0 <br> 67.3 78.1 92.5 | .txt <br> .dat <br> or other | See "Importing Numeric Data with Text Headers" on page 6-13 for more information. You can also use the Import Wizard for this data format. See "Using the Import Wizard with Text Data" on page 6-4 for more information. |

If you are familiar with MATLAB import functions but not sure when to use them, view Table 6-2 which compares the features of each function.

Table 6-2: ASCII Data Import Function Feature Comparison

| Function | Data Type | Delimiters | Number of <br> Return <br> Values | Notes |
| :--- | :--- | :--- | :--- | :--- |
| csvread | Numeric data | Only <br> commas | One | Primarily used with <br> spreadsheet data. See <br> also the binary format <br> spreadsheet import <br> functions. |
| dlmread | Numeric data | Any <br> character | One | Flexible and easy to use. |
| fscanf | Alphabetic and <br> numeric; <br> however, both <br> types returned <br> in a single <br> return variable | Any <br> character | One | Part of low-level file I/O <br> routines. Requires use of <br> fopen to obtain file <br> identifier and fclose <br> after read. |
| Numeric data | Only spaces | One | E asy to use. Use the <br> functional form of load <br> to specify the name of |  |
| load |  | Ane output variable. |  |  |

## Importing Numeric Text Data

If your data file contains only numeric data, you can use many of the MATLAB import functions (listed in Table 6-2), depending on how the data is delimited. If the data is rectangular, that is, each row has the same number of elements, the simplest command to use is the load command. (The load command can also be used to import MAT-files, MATLAB's binary format for saving the workspace.)

For example, the file named my_data.txt contains two rows of numbers delimited by space characters.

12345
678910
When you use load as a command, it imports the data and creates a variable in the workspace with the same name as the filename, minus the fileextension.

```
load my_data.txt;
whos
    Name Size Bytes Class
    my_data 2x5 80 double array
my_data
my_data =
    1
    6
```

If you want to name the workspace variable something other than the file name, use the functional form of load. In the following example, the data from my_data.txt is loaded into the workspace variable A.

```
A = load('my_data.txt');
```

## Importing Delimited ASCII Data Files

If your data file uses a character other than a space as a delimiter, you have a choice of several import functions you can use. (See Table 6-4 for a complete list.) The simplest to use is the dlmread function.

For example, consider a file named ph. dat whose contents are separated by semicolons.

$$
\begin{aligned}
& 7.2 ; 8.5 ; 6.2 ; 6.6 \\
& 5.4 ; 9.2 ; 8.1 ; 7.2
\end{aligned}
$$

To read the entire contents of this file into an array named $A$, enter
A = dlmread('ph.dat', ';');

You specify the delimiter used in the data file as the second argument to dlmread. Note that, even though the last items in each row are not followed by a delimiter, dlmread can still process the file correctly. dlmread ignores space characters between data elements. So, the preceding dlmread command works even if the contents of ph. dat are

| $7.2 ;$ | $8.5 ;$ | $6.2 ; 6.6$ |
| :--- | :--- | :--- |
| $5.4 ;$ | 9.2 | $; 8.1 ; 7.2$ |

## Importing Numeric Data with Text Headers

To import an ASCII data file that contains text headers, use the textread function, specifying the headerlines parameter. textread accepts a set of predefined parameters that control various aspects of the conversion. (For a complete list of these parameters, see the textread reference page.) The headerlines parameter lets you specify the number of lines at the head of the file that textread should ignore.

For example, the file, grades.dat, contains formatted numeric data with a one-line text header.

| Grade1 | Grade2 | Grade3 |
| :--- | ---: | ---: |
| 78.8 | 55.9 | 45.9 |
| 99.5 | 66.8 | 78.0 |
| 89.5 | 77.0 | 56.7 |

To import this data, use this command:

```
[grade1 grade2 grade3] = textread('grades.dat','%f %f %f',...
```

'headerlines',1)
grade1 =
78.8000
99.5000
89.5000
grade2 =
55.9000
66.8000
77.0000

```
grade3 =
    45.9000
    78.0000
    56.7000
```

## Importing Mixed Alphabetic and Numeric Data

If your data file contains a mix of alphabetic and numeric ASCII data, use the textread function to import the data. textread can return multiple output variables and you can specify the data type of each variable.

For example, the file mydata.dat contains a mix of alphabetic and numeric data.

| Sally | Type1 | 12.34 | 45 | Yes |
| :--- | :--- | :--- | :--- | :--- |
| Larry | Type2 | 34.56 | 54 | Yes |
| Tommy | Type1 | 67.89 | 23 | No |

Note To read an ASCII data file that contains primarily numeric data but with text column headers, see "I mporting Numeric Data with Text Headers" on page 6-13.

To read the entire contents of the file mydata. dat into the workspace, specify the name of the data file and the format string as arguments to textread. In the format string, you include conversion specifiers that define how you want each data item to be interpreted. F or example, specify \%s for strings data, \%f for floating point data, and so on. (F or a complete list of format specifiers, see the textread reference page.)

F or each conversion specifier in your format string, you must specify a separate output variable. textread processes each data item in the file as specified in the format string and puts the value in the output variable. The number of output variables must match the number of conversion specifiers in the format string.

In this example, textread reads the file mydata. dat, applying the format string to each line in the file until the end of the file.

```
[names,types,x,y,answer] = textread('mydata.dat','%s %s %f ...
    %d %s',1)
```

```
names =
    'Sally'
    'Larry'
    'Tommy'
types =
    'Type1'
    'Type2'
    'Type1'
x =
    12.3400
    34.5600
    67.8900
y =
    4 5
54
    23
answer =
    'Yes'
    'Yes'
    'No'
```

If your data uses a character other than a space as a delimiter, you must use the textread parameter 'delimiter' to specify the delimiter. F or example, if the file mydata. dat used a semicol on as a delimiter, you would use this command.

```
[names, types, \(x, y\), answer]=textread('mydata.dat', \(\%\) \% \%s \%f...
    \%d \%s', 'delimiter',';')
```

See the textread reference page for more information about these optional parameters.

## Exporting ASCII Data

MATLAB supports several ways to export data in many different ASCII formats. For example, you may want to export a MATLAB matrix as text file where the rows and columns are represented as space-separated, numeric values.

This section describes how to use MATLAB functions to export data in several common ASCII formats, including:

- "Exporting Delimited ASCII Data Files" on page 6-17
- "Using the diary Command to Export Data" on page 6-18

Thefunction you use depends on the amount of data you want to export and its format.

If you are not sure which section describes your data, scan the data format samples in Table 6-3 and look for the samplethat most nearly matches the data format you want to create. Then, read the section referred to in the table.
If you are familiar with MATLAB export function but not sure when to use them, view Table 6-4, which compares the features of each function.

Note If C or Fortran routines for writing data files in the form needed by other applications exist, create a MEX file to write the data. See the External Interfaces Guide for more information.

Table 6-3: ASCII Data File Formats and MATLAB Export Commands

| Data Format Sample | MATLAB Export Function |
| :---: | :---: |
| 12345 | See "Exporting Delimited ASCII Data Files" on page 6-17 and |
| 678910 | "Using the diary Command to Export Data" on page 6-18 for information about these options. |
| $\begin{aligned} & 1 ; 2 ; 3 ; 4 ; 5 ; \\ & 6 ; 7 ; 8 ; 9 ; 10 ; \end{aligned}$ | See "Exporting Delimited ASCII Data Files" on page 6-17 for more information. The example shows a semicolon-delimited file but you can specify other characters as the delimiter. |

Table 6-4: ASCII Data Export Function Feature Comparison

| Function | Use With | Delimiters | Notes |
| :--- | :--- | :--- | :--- |
| csvwrite | Numeric data | Only <br> commas | Primarily used with spreadsheet data. <br> See also the binary format spreadsheet <br> export functions |
| diary | Numeric data or <br> cell array | Only spaces | Can be used for small arrays. Requires <br> editing of data file to remove extraneous <br> text. |
| dlmwrite | Numeric data | Any <br> character | Easy to use, flexible. |
| fprintf | Alphabetic and <br> numeric data | Any <br> character | Part of low-level file I/O routines. M ost <br> flexible command but most difficult to <br> use. Requires use of fopen to obtain file <br> identifier and fclose after write. |
| save | Numeric data | Tabs or <br> spaces | Easy to use; output values are high <br> precision. |

## Exporting Delimited ASCII Data Files

To export an array as a delimited ASCII data file, you can use either the save command, specifying the -ASCII qualifier, or the dlmwrite function. The save command is easy to use; however, the dlmwrite function provides more flexibility, allowing you to specify any character as a delimiter and to export subsets of an array by specifying a range of values.

## Using the save Command

To export the array A,

$$
A=[1234 ; 5678] ;
$$

use the save command, as follows.
save my_data.out A -ASCII
If you view the created file in a text editor, it looks like this.
$1.0000000 \mathrm{e}+000$
$2.0000000 \mathrm{e}+000$
$3.0000000 \mathrm{e}+000$
$4.0000000 \mathrm{e}+000$
$5.0000000 \mathrm{e}+000$
$6.0000000 \mathrm{e}+000$
$7.0000000 \mathrm{e}+000$
$8.0000000 \mathrm{e}+000$

By default, save uses spaces as delimiters but you can use tabs instead of spaces by specifying the -tabs qualifier.

When you use save to write a character array to an ASCII file, it writes the ASCII equivalent of the characters to the file. If you write the character string 'hello' to a file, save writes the values

104101108108111

## Using the dlmw rite Function

To export an array in ASCII format and specify the delimiter used in the file, use the dlmwrite function.

For example, to export the array A,
$A=\left[\begin{array}{lllllllll} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8\end{array}\right] ;$
as an ASCII data file that uses semicolons as a delimiter, use this command

```
dlmwrite('my_data.out',A, ';')
```

If you view the created file in a text editor, it looks like this

$$
1 ; 2 ; 3 ; 4 \text { 5;6;7;8 }
$$

Note that dlmwrite does not insert delimiters at the end of rows.
By default, if you do not specify a delimiter, dlmwrite uses commas as a delimiter. Y ou can specify a space (' ') as a delimiter or, if you specify empty quotes ("), no delimiter.

## Using the diary Command to Export Data

To export small numeric arrays or cell arrays, you can usethe diary command. diary creates a verbatim copy of your MATLAB session in a disk file (excluding graphics).

For example, if you have the array, $A$, in your workspace

$$
A=\left[\begin{array}{cccccccc}
1 & 2 & 3 & 4 & 6 & 7 & 8
\end{array}\right]
$$

execute these commands at the MATLAB prompt to export this array using diary:

1 Turn on the diary function. You can optionally name the output file diary creates.
diary my_data.out
2 Display the contents of the array you want to export. This example displays the array A. Y ou could also display a cell array or other MATLAB data type.

A =

| 1 | 2 | 3 | 4 |
| :--- | :--- | :--- | :--- |
| 5 | 6 | 7 | 8 |

3 Turn off the diary function.
diary off
diary creates the file, my_data. out, and records all the commands executed in the MATLAB session until it is turned off.

A =

| 1 | 2 | 3 | 4 |
| :--- | :--- | :--- | :--- |
| 5 | 6 | 7 | 8 |

diary off
4 Open the diary file, my_data.out, in a text editor and remove all the extraneous text.

## Importing Binary Data

The easiest way to import binary data is by using the Import Wizard. Y ou simply start the Import Wizard and specify the file that contains the data you want to import. For more information, see "Using the I mport Wizard with Binary Data Files" on page 6-20.

If you need to work from the MATLAB command line or perform import operations as part of an M-file, you must use one of the MATLAB import functions. MATLAB supports many functions to import data in different binary formats, such as image files or spreadsheet data files. Your choice of which function to use depends on the type of data in the file and how the data is formatted.

Caution When you import data into the MATLAB workspace, it overwrites any existing variables in the workspace with the same name.

## Using the Import Wizard with Binary Data Files

To import text data using the Import Wizard, perform these steps:
1 Start the I mport Wizard, by selecting the Import Data option on the MATLAB File menu. MATLAB displays a file selection dialog box. You can also use the uiimport function to start the Import Wizard.

Touse the Import Wizard to import data from the clipboard, select the Paste Special option on the MATLAB Edit menu. You can also right-dick in the MATLAB command window and choose Paste Special from the context menu. Skip to step 3 to continue importing from the clipboard.

2 Specify the file you want to import in the file selection dialog box and click Open. The Import Wizard opens the file and attempts to process its contents. See Viewing the variables for more information.

3 Select the variables that you want to import. By default, the Import Wizard creates variables depending on the type of data in the file.

4 Click Finish to import the data into the workspace.

## Viewing the Variables

When the Import Wizard opens a binary data file, it attempts to process the data in the file, creating variables from the data it finds in the file.
For example, if you use the Import Wizard to import this sample MAT-file, my_data.mat,

A $=$
12345
678910
$B=$
a test string
it creates two variables, listed in the Preview pane. You can select the variables you want to import by clicking in the check box next to its name. All variables are preselected by default.

For other binary data types, such as images and sound files, the I mport Wizard displays information about the data in the left pane and provides a Preview button in the right pane of the dialog box. Click the preview button to view (or listen to) the data.

For example, when used to import a movie in Audio Video Interleaved (AVI) format, the Import Wizard displays this dialog box..

## Using Import Functions with Binary Data

To import binary data from the command line or in an M-file, you must use one of the MATLAB import functions. Your choice of function depends on how the data in the text file is formatted.

To find the function designed to work with a particular binary data format, scan the data formats listed in Table 6-5. The tablelists the binary formats and the MATLAB high-level functions you use to import them, al ong with pointers to additional information.

Table 6-5: Binary Data Formats and MATLAB Import Functions

| Data Format | File <br> Extension | Description |
| :--- | :--- | :--- |
| Audio files | .au <br> .wav | Use the auread function to import audio files on Sun <br> Microsystems platforms and the wavread function to <br> import audio files on M icrosoft Windows systems. |
| Audio-video <br> Interleaved (AVI) | .avi | Use the aviread function to import Audio-video <br> Interleaved (AVI) files. |
| Hierarchical Data <br> Format (HDF) | .hdf | For HDF image files, use imread. For all other HDF files, <br> see "Working with HDF Data" on page 6-29 for complete <br> information. |
| Image files | .jpeg <br> .tiff | Use the imread function to import image data in many <br> different formats. See Reading, Writing, and Querying <br> Graphics Image Files for more information. |
| .bmp |  |  |
| .gif |  |  |
| .png |  |  |
| .hdf |  |  |$\quad$| .pcx |
| :--- |

To view the alphabetical list of MATLAB binary data export functions, see Table 6-6.

If MATLAB does not support a high-level function that works with a data format, you can use the MATLAB low-level file I/O functions, if you know how the binary data is formatted in the file. See "Using Low-Level File I/O Functions" on page 6-51 for more information.

Table 6-6: Binary Data Import Functions

| Function | File Extension | Data Format |
| :--- | :--- | :--- |
| auread | .au | Import sound data in Sun Microsystems format. |
| aviread | .avi | Import audio-visual data in AVI format. |
| hdf | .hdf | Import data in Hierarchical Data Format (HDF). For <br> HDF image file formats, use imread. For all other <br> HDF files, see "Working with HDF Data" on page <br> 6-29 for complete information. |
| imread | .jpeg, .tiff, .bmp, <br> .png, .hdf, .pcx, | Import images in many formats. |
| load | .mat, .gif | Import MATLAB workspace variables in MAT-files <br> format. |
| wavread | . wav | Import sound data in Microsoft Windows format. |
| wk1read | .wk1 | Import data in Lotus 123 spreadsheet format. |
| xlsread | .$x l s$ | Import data in Microsoft Excel spreadsheet format. |

## Exporting Binary Data

To export binary data in one of the standard binary formats, you can use the MATLAB high-level function designed to work with that format.

To find the function designed to work with a particular binary data format, scan the data formats listed in Table 6-7. Thetablelists thebinary formats and the MATLAB high-level functions you use to import them, with pointers to sources of additional information.

Table 6-7: Binary Data Formats and MATLAB Export Functions

| Data Format | File <br> Extension | Description |
| :--- | :--- | :--- |
| Audio files | .au <br> .wav | Use the auwrite function to export audio files on Sun <br> Microsystems platforms and the wavwrite function to <br> export audio files in Microsoft Windows format. |
| Audio Video <br> Interleaved (AVI) | .avi | You must use the avifile, addframe, and the close <br> function overloaded for AVI data to export a sequence of <br> MATLAB figures in AVI format. See "Exporting MATLAB <br> Graphs in AVI Format" on page 6-27 for more information. |
| Hierarchical Data <br> Format (HDF) | .hdf | To export image data in HDF format, use imwrite. For all <br> other HDF formats, see "Working with HDF Data" on <br> page 6-29 for complete information. |
| Image files | .jpeg <br> .tiff <br> .bmp <br> .png <br> .hdf <br> .$p c x$ <br> .$x w d ~$ | Use the imwrite function to export image data in many <br> different formats. See Reading, Writing, and Querying <br> Graphics Image Files for more information. |

| Data Format | File <br> Extension | Description |
| :--- | :--- | :--- |
| MATLAB <br> proprietary format <br> (MAT-files) .mat | Use the save command to export data in MATLAB <br> proprietary format. See "Saving the Current Workspace" <br> on page 5-5 for more information. |  |
| Spreadsheets | .xls <br> .$w k 1$ | Use the wk1write function to export data in Lotus 123 <br> format. |

To view the alphabetical list of MATLAB binary data export functions, see Table 6-6.

If MATLAB does not support a high-level function that works with a data format, you can use the MATLAB low-level fileI/O functions, if you know how the binary data is formatted in the file. See "Using Low-Level File I/O Functions" on page 6-51 for more information.

Table 6-8: Binary Data Export Functions

| Function | File Extension | Data Format |
| :--- | :--- | :--- |
| addframe | .au | Capture snapshots of the current axes and put them <br> in an AVI file object. See also avifile. |
| auwrite | .au | Export sound data in Sun Microsystems format. |
| avifile | .au | Export audio-visual data in AVI format. Creates an <br> AVI file object. See also addframe. |
| hdf | .hdf | Export data in Hierarchical Data Format (HDF). For <br> HDF image file formats, use imwrite. For all other <br> HDF files, see "Working with HDF Data" on page <br> 6-29 for complete information. |
| imwrite | .jpeg, .tiff, <br> .bmp,. <br> .hdf, .pcx, .xwd <br> .mat | Export image files in many formats. |
| save |  | Export MATLAB variables in MAT-files format. |

| Function | File Extension | Data Format |
| :--- | :--- | :--- |
| wavwrite | .wav | Export sound data on Microsoft Windows platforms. |
| wk1write | .wk1 | Export data in Lotus 123 spreadsheet format. |

## Exporting MATLAB Graphs in AVI Format

In MATLAB, you can save a sequence of graphs as a movie that can then be played back using the movie function. You can export a MATLAB movie by saving it in MAT-file format, like any other MATLAB workspace variable. However, anyone who wants to view your movie must have MATLAB. (F or more information about MATLAB movies, seethe "Animation" section in Using MATLAB Graphics.)

To export a sequence of MATLAB graphs in a format that does not require MATLAB for viewing, save the figures in Audio Video I nterleaved (AVI) format. AVI is a file format that allows animation and video clips to be played on a PC running Windows or on UNIX systems.

## Creating an AVI Format Movie

To export a sequence of MATLAB graphs as an AVI format movie, perform these steps:

1 Create an AVI file, using the avifile function.
2 Capture the sequence of graphs and put them into the AVI file, using the addframe function.

3 Close the AVI file, using the close function, overloaded for AVI files.

Note To convert an existing MATLAB movie into an AVI file, use the movie2avi function.

For example, this code example exports a sequence of MATLAB graphs as the AVI file mymovie. avi. The numbers in comments correspond to notes following the code example.

```
aviobj = avifile('mymovie.avi','fps',5);
for k=1:25
    h = plot(fft(eye(k+16)));
    set(h,'EraseMode', 'xor');
    axis equal;
    frame = getframe(gca);
    aviobj = addframe(aviobj,frame);
end
aviobj = close(aviobj);
```

Note the following items in this code example:

- The avifile function creates an AVI file and returns a handleto an AVI file object. AVI file objects support properties that let you control various characteristics of theAVI movie, such as col ormap, compression, and quality. (See the avifile reference page for a complete list.) avifile uses default values for all properties, unless you specify a value. In the example, the call to avifile explicitly sets the value of one frames per second (fps) property.
- The example uses a for loop to capture the series of graphs to be included in the movie. Y ou typically use addframe to capture a sequence of graphs for AVI movies. However, because this particular MATLAB animation uses XOR graphics, you must call getframe to capture the graphs and then call addframe to add the captured frameto the movie. See the addframe reference page for more information.
- The example calls the close function to finish writing the frames to the file and to close the file.

## Working with HDF Data

Hierarchical Data Format (HDF ) is a general-purpose, machine-independent standard for storing scientific data in files. The National Center for Supercomputing Applications (NCSA), the original developer of HDF, distributes libraries of C and F ortran routines that scientists use to read and write data in HDF format.

This section describes how to call these NCSA routines from within MATLAB. Topics include:

- An overview of MATLAB HDF support
- MATLAB HDF function calling conventions
- I mporting HDF data into the MATLAB workspace
- Exporting MATLAB data in an HDF file
- Including metadata in an HDF file
- Using MATLAB specific HDF functions

## Additional Information Sources

This section does not attempt to describeall HDF features and routines. To use the MATLAB HDF interface effectively, you must use this documentation in conjunction with the official HDF documentation, available in many formats at the NCSA Web site (http: / / hdf.ncsa. uiuc.edu/). In particular, consult the following documentation:

- TheHDF User's Guide, which describes key HDF concepts and programming models and provides tutorial information about using the library routines
- The HDF Reference Manual, which provides detailed reference information about the hundreds of HDF routines, their arguments, and return values

The National Aeronautics and Space Administration (NASA) has created an extension of HDF as one of the data standards for the E arth Observing System (EOS). F or information about this extension to HDF , consult the official HDF-EOS documentation at the EOS Web site (http://hdfeos.gsfc.nasa.gov/hdfeos/workshop.html).
Finally, for details about the syntax of the MATLAB HDF functions, consult the MATLAB online Function Reference. For most HDF routines, the

MATLAB syntax is essentially the same as the HDF version; however, for certain routines, the MATLAB version has a different syntax.

## Overview of MATLAB HDF Support

The NCSA organizes the routines in the HDF library into collections, called External Interfaces (APIs). Each API works with particular type of data. For example, the HDF Scientific Data (SD) API works with multidimensional arrays of numeric data. Table , , lists all the HDF APIs supported by MATLAB (listed al phabetically by acronym). The table includes a MATLAB specific API made up of utility functions.

In addition to these standard HDF APIs, MATLAB also supports the EOS extension to HDF. HDF-EOS provides functions to store, manage, and retrieve multidimensional arrays of numeric data, point data, and swath data. See the HDF-EOS documentation for more information.

Note MATLAB supports the version $4.1 r 3$ of the NCSA multifile APIs to HDF data. The multifile API s replace the original NCSA APIs. MATLAB does not support HDF version 5.0, which is a completely new format and is not compatible with version 4.1r3.

Table 6-9: Supported HDF Application Programming Interfaces (APIs)

| Application <br> Programming <br> Interface | Acronym | Description |
| :--- | :--- | :--- |
| Annotations | AN | Stores, manages, and retrieves text used to describe <br> an HDF file or any of the data structures contained in <br> the file. |
| General Raster <br> Images | DF24 | DFR8 | | Stores, manages, and retrieves raster images, their |
| :--- |
| dimensions and palettes. It can also manipulate |
| unattached palettes. |
| Note: Use the MATLAB high-level functions imread |
| and imwrite with HDF raster image formats. |

Table 6-9: Supported HDF Application Programming Interfaces (APIs)

| Application | Acronym | Description |
| :--- | :--- | :--- |
| Programming <br> Interface |  |  |

| HDF Utilities | H, HD, and HE | Provides functions to open and close HDF files and <br> handle errors. |
| :--- | :--- | :--- |
| MATLAB HDF <br> Utilities | ML | Provides utility functions that help you work with <br> HDF files in the MATLAB environment. |
| Scientific Data | SD | Stores, manages, and retrieves multidimensional <br> arrays of character or numeric data, along with their <br> dimensions and attributes. |
| V Groups | V | Creates and retrieves groups of other HDF data <br> objects, such as raster images or V data. |
| V Data | VS <br> VF <br> VH | Stores, manages, and retrieves multivariate data <br> stored as records in a table. |

## MATLAB HDF Function Calling Conventions

E ach HDF API includes many individual routines to read data from files, write data to files, and perform other related functions. F or example, the HDF SD API includes separate $C$ routines to open (SDopen), close(SDend), and read data (SDreaddata).

MATLAB, instead of supporting a corresponding function for each individual HDF API routine, supports a single function for each HDF API. You use this singlefunction to access all the individual routines in the HDF API, specifying the name of the individual HDF routine as the first argument.

For example, to call the HDF SD API routine to terminate access to an HDF file in a C program, you use

```
status = SDend(sd_id);
```

To call this routine from MATLAB, use the MATLAB function associated with the API. By convention, the name of the MATLAB function associated with an HDF API includes the API acronym in the function name. For example, the MATLAB function used to access routines in the HDF SD API is called hdfsd.

As the first argument to this function, specify the name of the API routine, minus the acronym, and pass theremaining arguments expected by the routine in the order they are required. Thus, to call the sDend routine from MATLAB, use this syntax.

```
status = hdfsd('end',sd_id);
```

Note For some HDF API routines, particularly those that use output arguments to return data, the MATLAB calling sequence is different. (See "Handling HDF Routines with Output Arguments" on page 6-32 for more information.) Refer to the MATLAB online Function Reference to make sure you have the correct syntax.

## Handling HDF Routines with Output Arguments

When calling HDF API routines that use output arguments to return data, you must specify all output arguments as return values. For example, in C syntax, the SDfileinfo routine returns data about an HDF file in two output arguments, ndatasets and nglobal_atts.

```
status = SDfileinfo(sd_id, ndatasets, nglobal_atts);
```

To call this routine from MATLAB, change the output arguments into return values.

```
[ndatasets, nglobal_atts, status] = hdfsd('fileinfo',sd_id);
```

Specify the return values in the same order as they appear as output arguments. The function status return value is always specified last.

## Handling HDF Library Symbolic Constants

TheC versions of the HDF APIs use symbolic constants, defined in header files, to specify modes and data types. For example, the SDstart routine uses a symbolic constant to specify the mode in which to open an HDF file.

```
sd_id = SDstart("my_file.hdf",DFACC_RDONLY);
```

When calling this routine from MATLAB, specify these constants as text strings.

```
sd_id = hdfsd('start','my_file.hdf','DFACC_RDONLY')
```

In MATLAB, you can specify the entire constant or leave off the prefix. F or example, in this call to SDstart, you can use any of these variations as the constant text string: 'DFACC_RDONLY', 'dfacc_rdonly ', or 'rdonly'. Notethat you can use any combination of upper- and lower-case characters.

## Importing HDF Data into the MATLAB Workspace

To import HDF data into MATLAB, you must use the routines in the HDF API associated with the particular HDF data type. Each API has a particular programming model, that is, a prescribed way to use the routines to open the HDF file, access data sets in the file, and read data from the data sets. (In HDF terminology, the numeric arrays stored in HDF files are called data sets.)
To illustrate this concept, this section details the programming model of one particular HDF API: the Scientific Data (SD) API. For information about working with other HDF APIs, see the official NCSA documentation.

Note The following sections, when referring to specific routines in the HDF SD API, use the C library name rather than the MATLAB function name. The MATLAB syntax is used in all examples.

## The HDF SD Import Programming Model

To import data in HDF SD format, you must useAPI routines to perform these steps:

1 Open the file containing HDF SD data sets.
2 Select the data set in the file that you want to import.
3 Read the data from the data set.
4 Close access to the data set and HDF file.

There are several additional steps that you may also need to perform, such as retrieving information about the contents of the HDF fileor the data sets in the file. The following sections provide more detail about the basic steps as well as optional steps.

## Opening HDF Files

To import an HDF SD data set, you must first open the file containing the data set. In the HDF SD API, you use the SDstart routine to open the file and initialize the HDF interface. In MATLAB, you use the hdfsd function with start specified as the first argument.

SDstart accepts these arguments:

- A text string specifying the name of the file you want to open
- A text string specifying the mode in which you want to open it

For example, this code opens the file mydata. hdf for read access.

```
sd_id = hdfsd('start','mydata.hdf','read');
```

If SDstart can find and open the file specified, it returns an HDF SD file identifier, named sd_id in the example. Otherwise, it returns-1.

The HDF SD API supports several file access modes. You use a symbolic constant, defined by the HDF SD API, to specify each mode. In MATLAB, you specify these constants as text strings. You can specify the full HDF constant or one of the abbreviated forms listed in table.

HDF File Creation Mode
Create a new file
Read access

Read and write access

HDF Symbolic Constant
'DFACC_CREATE'
'DFACC_RDONLY' 'read' or
'DFACC_RDWR' 'rdwr' or 'write'

## Retrieving Information About an HDF File

After opening a file, you can get information about what the file contains using the SDfileinfo routine. In MATLAB, you use the hdfsd function with fileinfo specified as the first argument. This function returns the number of data sets in the file and whether the file includes any global attributes. (F or more information about global attributes, see "Retrieving Attributes from an HDF File" on page 6-35.)

As an argument, SDfileinfo accepts the SD file identifier, sd_id, returned by SDstart. In this example, the HDF file contains three data sets and one global attribute.

```
[ndatasets, nglobal_atts, stat] = hdfsd('fileinfo',sd_id)
ndatasets =
    3
nglobal_atts =
    1
status =
    0
```

## Retrieving Attributes from an HDF File

HDF files are self-documenting, that is, they can optionally include information, called attributes, that describes the data the file contains. Attributes associated with an HDF file are called global attributes. (Y ou can also associate attributes with data sets or dimensions. For more information about these attributes, see "I ncluding M etadata in an HDF File" on page 6-47.)
In the HDF SD API, you use the SDreadattr routine to retrieve global attributes from an HDF file. In MATLAB, you use the hdfsd function, specifying readattr as the first argument. As other arguments, you specify:

- The HDF SD file identifier (sd_id) returned by the SDstart routine
- The index value specifying the attribute you want to view. HDF uses zero-based indexing so the first global attribute has an index value zero, the second has an index value one, and so on.

F or example, this code returns the contents of the first global attribute, which is simply the character string 'my global attribute'.

```
attr_idx = 0;
[attr, status] = hdfsd('readattr', sd_id, attr_idx)
attr =
    my global attribute
stat =
    0
```

MATLAB automatically sizes the return value, attr, to fit the data in the attribute.

Retrieving Attributes by Name. Attributes have names as well as values. If you know the name of an attribute, you can use the SDfindattr function to determine its index value so you can retrieveit. In MATLAB, you use the hdfsd function, specifying findattr as the first argument.
As other arguments, you specify:

- The HDF SD file identifier, when searching for global attributes
- A text string specifying the name of the attribute

SDfindattr searches all theglobal attributes associated with the file. If it finds an attribute with this name, SDfindattr returns the index of theattribute. You can then use this index value to retrieve the attribute using SDreadattr.

This example uses SDfindattr to obtain the index for the attribute named my_att and then passes this index as an argument to SDreadattr.

```
attr_idx = hdfsd('findattr',sd_id,'my_att');
[attr, status] = hdfsd('readattr', sd_id, attr_idx);
```

## Selecting Data Sets in HDF Files

After opening an HDF file, you must specify the data set in the file that you want to read. An HDF file can contain multiple data sets. In the HDF SD API, you use the SDselect routine to select a data set. In MATLAB, you use the hdfsd function, specifying select as the first argument.

As arguments, this function accepts:

- The HDF SD file identifier (sd_id) returned by SDstart
- The index value specifying the attribute you want to view. HDF uses zero-based indexing so the first global attribute has an index value zero, the second has an index value one, and so on.

F or example, this code selects the third data set in the HDF file identified by sd_id. If SDselect finds the specified data set in the file, it returns an HDF SD data set identifier, called sds_id in the example. If it cannot find the data set, it returns -1 .

Note Do not confuse HDF SD fileidentifiers, named sd_id in the examples, with HDF SD data set identifiers, named sds_id in the examples.

```
sds_idx = 2; % HDF uses zero-based indexing.
sds_id = hdfsd('select',sd_id,sds_idx)
```

## Retrieving Data Sets by Name

Data sets in HDF files can be named. If you know the name of the data set you are interested in, but not its index value, you can determine its index by using the SDnametoindex routine. In MATLAB, use the hdfsd function, specifying nametoindex as the first argument.

## Getting Information About a Data Set

After you select a data set in an HDF file, you can obtain information about the data set, such as the number and size of the array dimensions. You need this information to read the data set using the SDreaddata function. (See "Reading Data from an HDF File" on page 6-39 for more information.)

In the HDF SD API, you use the SDgetinfo routine to gather this information. In MATLAB, use the hdfsd function, specifying getinfo as the first argument. In addition, you must specify the HDF SD data set identifier returned by SDselect (sds_id).

This table lists the information returned by SDgetinfo.

| Data Set Information Returned | MATLAB Data Type |
| :--- | :--- |
| Name | Character array |
| Number of dimensions | Scalar |
| Size of each dimension | Vector |
| Data type of the data stored in <br> the array | Character array |
| Number of attributes associated <br> with the data set | Scalar |

```
F or example, this code retrieves information about the data set identified by
sds_id.
    [dsname, dsndims, dsdims, dstype, dsatts, stat] =
            hdfsd('getinfo',sds_id)
    dsname =
            A
    dsndims =
        2
    dsdims =
            5 3
    dstype =
            double
    dsatts =
        O
    stat =
        0
```

## Retrieving Data Set Attributes

Like HDF files, HDF SD data sets are self-documenting, that is, they can optionally include information, called attributes, that describes the data in the data set. Attributes associated with a data set are called local attributes. (Y ou can also associate attributes with files or dimensions. For more information about these attributes, see "I ncluding M etadata in an HDF File" on page 6-47.)
In the HDF SD API, you use the SDreadattr routine to retrieve local attributes. In MATLAB, use the hdfsd function, specifying readattr as the first argument. As other arguments, specify

- The HDF SD data set identifier (sds_id) returned by SDselect
- The index of the attribute you want to view. HDF uses zero-based indexing so the first attribute has the index valuezero, the second has an index value one, and so on.

This code example returns the contents of the first attribute associated with a data set identified by sds_id. In this case, the value of the attribute is the
character string 'my local attribute'. MATLAB automatically sizes the return value, ds_attr, to fit the value of the attribute.

```
attr_idx = 0;
[ds_attr, status] = hdfsd('readattr', sds_id, attr_idx)
ds_attr =
    my local attribute
stat =
    0
```

## Reading Data from an HDF File

After you open an HDF file and select a data set in the file, you can read the entire data set, or part of the data set. In the HDF SD API, you use the SDreaddata routine to read a data set. In MATLAB, use the hdfsd function, specifying readdata as the first argument. As other arguments, specify:

- The HDF SD data set identifier (sds_id) returned by SDselect
- The location in the data set where you want to start reading data, specified as a vector of index values, called the start vector in HDF terminology
- The number of elements along each dimension to skip between each read operation, specified as a vector scalar values, called thestridevector in HDF terminology
- The total number of elements to read along each dimension, specified as a vector of scalar values, called the edges vector in HDF terminology

For example, to read the entire contents of a data set containing this 3-by-5 matrix of numeric values

12345
678910
$\begin{array}{lllll}11 & 12 & 13 & 14 & 15\end{array}$
you could use this code.

```
[ds_name, ds_ndims, ds_dims, ds_type, ds_atts, stat] =
    hdfsd('getinfo',sds_id);
ds_start = zeros(1,ds_ndims); % Creates the vector [0 0]
ds_stride = [];
```

```
ds_edges = ds_dims;
[ds_data, status] =
    hdfsd('readdata',sds_id,ds_start,ds_stride,ds_edges);
disp(ds_data)
\begin{tabular}{rrrrl}
1 & 2 & 3 & 4 & 5 \\
6 & 7 & 8 & 9 & 10 \\
11 & 12 & 13 & 14 & 15
\end{tabular}
```

In this example, note the following:

- The return values of SDgetinfo are used to specify the dimensions of the return values and as arguments to SDreaddata.
- To read from the beginning of a data set, specify zero for each element of the start vector (ds_start). N ote how the example uses SDgetinfo to determine the length of the start vector.
- To read every element of a data set, specify one for each element of the stride vector or specify an empty array ([ ]).
- To read every element of a data set, set each element of the edges vector to the size of each dimension of the data set.

Note Use the dimensions vector returned by SDgetinfo, dsdims, to set the value of the edges vector because SDgetinfo returns these values in row-major order, the ordering used by HDF. MATLAB stores data in column-major order. An array referred to as a 3-by-5 array in MATLAB is described as a 5-by-3 array in HDF.

## Reading a Portion of a Data Set

To read less than the entire data set, use the start, stride, and edges vectors to specify where you want to start reading data and how much data you want to read.

For example, this codefragment uses SDreaddata to read theentire second row of the sample data set.

```
12345
6 7 8 9 10
11}1213141
```

Note that in the start, stride, and edges arguments, you must specify the dimensions in column-major order, that is, [columns, rows]. In addition, note that you must use zero-based indexing in these arguments.

```
ds_start = [0 1] % Start reading at the first column, second row
ds_stride = []; % Read each element
ds_edges = [5 1]; % Read a 1-by-5 vector of data
[ds_data, status] =
    hdfsd('readdata',sds_id,ds_start,ds_stride,ds_edges);
disp(ds_data)
    6 % 7 8 9 10
```

For more information about specifying ranges in data sets, see "Writing MATLAB Data to an HDF File" on page 6-44.

## Closing HDF Files and HDF Data sets

After reading data from a data set in an HDF file, you must close access to the data set and the file. The HDF SD API includes functions to perform these tasks. See "Closing HDF Data Sets" on page 6-46 for more information.

## Exporting MATLAB Data in an HDF File

To export data from MATLAB in an HDF file, you must use the functions in the HDF API associated with the HDF data type. Each API has a particular programming model, that is, a prescribed way to use the routines to open the HDF file, access data sets in the file, and write data to the data sets. (In HDF terminology, the numeric arrays stored in HDF files are called data sets.)

To illustrate this concept, this section details the programming model of one particular HDF API: the Scientific Data (SD) API. For information about working with other HDF APIs, see the official NCSA documentation.

## The HDF SD Export Programming Model

The programming model for exporting HDF SD data involves these steps:
1 Create the HDF file, or open an existing one.
2 Create a data set in the file, or select an existing one.
3 Write data to the data set.
4 Close access to the data set and the HDF file.
You can optionally include information in the HDF file that describes your data. See "Including Metadata in an HDF File" on page 6-47 for more information.

## Creating an HDF File

To export MATLAB data in HDF format, you must first create an HDF file, or open an existing one. In the HDF SD API, you use the SDstart routine. In MATLAB, use the hdfsd function, specifying start as the first argument. As other arguments, specify:

- A text string specifying the name you want to assign to the HDF file (or the name of an existing HDF file)
- A text string specifying the HDF SD interface file access mode

For example, this code creates an HDF file named mydata.hdf.

```
sd_id = hdfsd('start','mydata.hdf','DFACC_CREATE');
```

If it can create (or open) the file, SDstart returns an HDF SD file identifier, named sd_id in the example. Otherwise, it returns -1.

When you specify the DFACC_CREATE access mode, SDstart creates the file and initializes the HDF SD multifile interface. If you specify DFACC_CREATE mode and the file already exists, sDstart fails, returning -1. To open an existing HDF file, you must use HDF read or write modes. F or information about using sDstart in these modes, see "Opening HDF Files" on page 6-34.

## Creating an HDF Data Set

After creating the HDF file, or opening an existing one, you must create a data set in the file for each MATLAB array you want to export. In the HDF SD API, you use the SDcreate routine to create data sets. In MATLAB, you use the hdfsd function, specifying create as the first argument. To write data to an existing data set, you must obtain the HDF SD data set identifier. See "Selecting Data Sets in HDF Files" on page 6-36 for more information.

This table lists the other arguments to SDcreate.

| Argument | MATLAB Data Type |
| :--- | :--- |
| Valid HDF SD file identifier | Returned from SDstart |
| Name you want assigned to the <br> data set | Text string |
| Data type of the data set | Text string. For information about <br> specifying data types, see "I mporting <br> HDF Data into the MATLAB <br> Workspace" on page 6-33 |
| Number of dimensions in the <br> data set. This is called the rank of <br> the data set in HDF terminology | Scalar numeric value |
| Size of each dimension | Vector |

The values you assign to these arguments depend on the MATLAB array you want to export. F or example, to export this MATLAB 3-by-5 array of doubles,

$$
A=\left[\begin{array}{llllllllllllllll} 
& 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 ; 11 & 12 & 13 & 14 & 15
\end{array}\right] ;
$$

you could set the values of these arguments as in this code fragment.

```
ds_name = 'A';
ds_type = 'double';
ds_rank = ndims(A);
ds_dims = fliplr(size(A));
sds_id = hdfsd('create',sd_id,ds_name,ds_type,ds_rank,ds_dims);
```

If SDcreate can successfully create the data set, it returns an HDF SD data set identifier (sds_id). Otherwise, SDcreate returns -1.

Note In this example, note how the code fragment reverses the order of the values in the dimensions argument (ds_dims). This processing is necessary because the MATLAB size function returns the dimensions in column-major order and HDF expects to receive dimensions in row-major order.

Once you create a data set, you cannot change its characteristics. You can, however, modify the data it contains. To do this, initiate access to the data set, using sDselect, and write to the data set as described in "Writing MATLAB Data to an HDF File" on page 6-44.

## Writing MATLAB Data to an HDF File

After creating an HDF file and creating a data set in thefile, you can write data to the entire data set or just a portion of the data set. In the HDF SD API, you use the SDwritedata routine. In MATLAB, use the hdfsd function, specifying writedata as the first argument.
This table lists the other arguments to SDwritedata.

| Argument | MATLAB Data Type |
| :--- | :--- |
| Valid data set identifier (sds_id) | Returned by SDcreate |
| Location in the data set where you want to <br> start writing data, called the start vector in <br> HDF terminology | Vector of index values |
| Number of elements along each dimension to <br> skip between each write operation, called the <br> stride vector in HDF terminology | Vector of scalar values |
| Total number of elements to write along each <br> dimension, called the edges vector in HDF <br> terminology | Vector of scalar values |
| MATLAB array to be written | Array of doubles |

Note You must specify the values of the start, stride, and edges arguments in row-major order, rather than the column-major order used in MATLAB. Note how the example uses fliplr to reverse the order of the dimensions in the vector returned by the size function before assigning it as the value of the edges argument.

The values you assign to these arguments depend on the MATLAB array you want to export. For example, this code fragment writes this MATLAB 3-by-5 array of doubles,

```
A = [ 1 2 3 4 5; 6 7 8 9 10; 11 12 13 14 15 ];
into an HDF file.
ds_start = zeros(1:ndims(A)); % Start at the beginning
ds_stride = []; % Write every element.
ds_edges = fliplr(size(A)); % Reverse the dimensions.
stat = hdfsd('writedata',sds_id,
    ds_start, ds_stride, ds_edges, A)
```

If it can write the data to the data set, SDwritedata returns 0; otherwise, it returns - 1 .

Note SDwritedata queues write operations. To ensure that these queued write operations are executed, you must close the file, using the sDend routine. See "Closing an HDF File" on page 6-46 for more information. As a convenience, MATLAB provides a function, MLcloseall, that you can use to close all open data sets and file identifiers with a single call. See "Using the MATLAB HDF Utility API" on page 6-49 for more information.

## Writing Data to Portions of Data Sets

To write less than the entire data set, use the start, stride, and edges vectors to specify where you want to start writing data and how much data you want to write.

For example, this codefragment uses SDwritedata to replace the values of the entire second row of the sample data set

12345
678910
$\begin{array}{llll}11 & 12 & 13 & 14 \\ 15\end{array}$
with the vector, B .

```
B = [ [ 9 9 9 9 9]
```

In the example, the start vector specifies that you want to start the write operation in the first column of the second row. Note how HDF uses zero-based indexing and specifies the column dimension first. In MATLAB, you would specify this location as $(2,1)$. The edges argument specifies the dimensions of the data to be written. N ote that the size of the array of data to be written must match the edge specification.

```
ds_start = [0 1] % Start writing at the first column, second row.
ds_stride = []; % Write every element.
ds_edges = [5 1]; % Each row is a 1-by-5 vector.
stat = hdfsd('writedata',sds_id,ds_start,ds_stride,ds_edges,B);
```

## Closing HDF Data Sets

After writing data to a data set in an HDF file, you must closeaccess to the data set. In the HDF SD API, you use the SDendaccess routine to close a data set.
In MATLAB, use the hdfsd function, specifying endaccess as the first argument. As the only other argument, specify a valid HDF SD data set identifier, sds_id in this example.

```
stat = hdfsd('endaccess',sds_id);
```

## Closing an HDF File

After writing data to a data set and closing the data set, you must al so close the HDF file. In the HDF SD API, you use the SDend routine. In MATLAB, use the hdfsd function, specifying end as the first argument. As the only other argument, specify a valid HDF SD file identifier, sd_id in this example.

```
stat = hdfsd('end',sd_id);
```

You must close access to all the data sets in an HDF file before closing it.

#### Abstract

Note Closing an HDF file executes all the write operations that have been queued using SDwritedata. As a convenience, the MATLAB HDF Utility API provides a function, MLcloseall, that can close all open data set and file identifiers with a single call. See "Using the MATLAB HDF Utility API" on page 6-49 for more information.

## Including Metadata in an HDF File

You can optionally include information in an HDF filethat describes your data. HDF defines an separate annotation API, however, the HDF SD API includes an annotation capability. This section only describes the annotation capabilities of theHDF SD API. F or information about theAnnotation API, see the official NCSA documentation.

## Types of Attributes

Using HDF SD API, you can associate attributes with three types of HDF objects:

- An entire HDF file - File attributes, also called global attributes, generally contain information pertinent to all the data sets in the file.
- A data set in and HDF file - Data set attributes, al so called local attributes, describe individual data sets.
- A dimension of a data set - Dimension attributes provide information applicable to an individual data set dimension.

## Multiple Attributes

You can associate multiple attributes with a single HDF object. HDF maintains an attribute index for each object. The attribute index is zero-based. The first value has the index value zero, the second has the value one, and so on. You access an attribute by its index value.

Each attribute has the format name=value, where name (called label in HDF terminology) is a text string up to 256 characters in length and value contains one or more entries of the same data type. A single attribute can have multiple values.

## Associating Attributes with HDF SD $\mathbf{O}$ bjects

In the HDF SD API, you use the SDsetattr routine to associate an attribute with a file, data set or dimension. In MATLAB, use the hdfsd function, specifying setattr as the first argument. As other arguments, specify

- A valid HDF SD identifier associated with the object. This value could be a fileidentifier (sd_id), a data set identifier (sds_id), or a dimension identifier (dim_id).
- A text string that defines the name of the attribute. The SD interface supports predefined attributes that havereserved names and, in some cases, data types. F or information about these attributes, see "Creating Predefined Attributes" on page 6-48.
- The attribute value

For example, this code creates a global attribute, named my_global_attr, and associates it with the HDF file identified by sd_id.

```
status = hdfsd('setattr',sd_id,'my_global_attr','my_attr_val');
```

#### Abstract

Note In the NCSA documentation, the SDsetattr routine has two additional arguments: data type and the number of values in the attribute. When calling this routine from MATLAB, you do not have to include these arguments. The MATLAB HDF function can determine the data type and size of the attribute from the value you specify.

## Creating Predefined Attributes

Predefined attributes are identical to user-defined attributes except that the the HDF SD API has already defined their names and data types. For example, the HDF SD API defines an attribute, named cordsys, in which you can specify the coordinate system used by the data set. Possible values of this attribute include the text strings 'cartesian', 'polar', and 'spherical'.

Predefined attributes can be useful because they establish conventions that applications can depend on. The HDF SD API supports predefined attributes for data sets and dimensions only; there are no predefined attributes for files. For a complete list of the predefined attributes, see the NCSA documentation.

In the HDF SD API, you create predefined attributes the same way you create user-defined attributes, using the SDsetattr routine. In MATLAB, use the hdfsd function, specifying setattr as the first argument.

```
attr_name = 'cordsys';
attr_value = 'polar';
status = hdfsd('setattr',sds_id,attr_name,attr_value);
```

The HDF SD API also includes specialized functions for writing and reading the predefined attributes. These specialized functions, such as SDsetdatastrs, are sometimes easier to use, especially when reading or writing multiple related predefined attributes. You must use specialized functions to read or write the predefined dimension attributes.

## Using the MATLAB HDF Utility API

In addition to the standard HDF APIs, listed in Table , , on page 6-30, MATLAB supports an API of utility functions that are designed to make using HDF in the MATLAB environment easier.

For example, the MATLAB utility API includes a function, MLlistinfo, which you can use to view all types of open HDF identifiers, such as HDF SD file identifiers. MATLAB updates theselists whenever HDF identifiers are created or closed.

This code obtains a list of all open HDF file and data set identifiers, using the MLlistinfo function. In this example, only two identifiers are open.

```
hdfml('listinfo')
No open RI identifiers
No open GR identifiers
No open grid identifiers
No open grid file identifiers
No open annotation identifiers
No open AN identifiers
Open scientific dataset identifiers:
    262144
Open scientific data file identifiers:
    393216
No open Vdata identifiers
No open Vgroup identifiers
```

```
No open Vfile identifiers
No open point identifiers
No open point file identifiers
No open swath identifiers
No open swath file identifiers
No open access identifiers
No open file identifiers
```

## Closing All 0 pen HDF Identifiers

To close all open HDF identifiers in a single call, use the MLcloseall function. This call closes all open HDF identifiers.

```
hdfml('closeall')
```

## Using Low-Level File I/ O Functions

MATLAB includes a set of low-level filel/O functions that arebased on the I/O functions of the ANSI Standard C Library. If you know C, therefore, you are probably familiar with these routines.

For example, the MATLAB fileI/O functions use the same programming model as the C language routines. To read or write data, you perform these steps:

1 Open the file, using fopen. fopen returns a file identifier which you use with all the other low-level file I/O routines.

2 Operate on the file.
a Read binary data using fread.
b Write binary data using fwrite.
c Read text strings from a file line-by-line using fgets/fgetl.
d Read formatted ASCII data using fscanf.
e Write formatted ASCII data using fprintf.
3 Close the file, using fclose.
This section also describes how these functions affect the current position in the file where read or write operations happen and how you can change the position in the file.

#### Abstract

Note While the MATLAB fileI/O commands are modeled on the C language I/O routines, in some ways their behavior is different. For example, the fread function is "vectorized," that is, it continues reading until it encounters a text string or the end of file. These sections, and the MATLAB reference pages for these functions, highlight any differences in behavior.

## Opening Files

Before reading or writing a text or binary file, you must open it with the fopen command.

```
fid = fopen('filename','permission')
```

## Specifying the Permissions String

The permission string specifies the kind of access to the file you require. Possible permission strings include:

- $r$ for reading only
- w for writing only
- a for appending only
- $r+$ for both reading and writing

Note Systems such as Microsoft Windows that distinguish between text and binary files may require additional characters in the permission string, such as 'rb' to open a binary file for reading.

## Using the Returned File Identifier (fid)

If successful, fopen returns a a nonnegative integer, called a fileidentifier (fid). You pass this value as an argument to the other I/O functions to access the open file. For example, this fopen statement opens the data file named penny. dat for reading.

```
fid = fopen('penny.dat','r')
```

If fopen fails, for example if you try to open a file that does not exist, fopen:

- Assigns - 1 to the file identifier.
- Assigns an error message to an optional second output argument. Note that the error messages are system dependent and are not provided for all errors on all systems. The function ferror may also provide information about errors.

It's good practice to test the file identifier each time you open a file in your code. For example, this code loops a readable filename is entered.

```
fid=0;
while fid < 1
    filename=input('Open file: ', 's');
    [fid,message] = fopen(filename, 'r');
    if fid == -1
        disp(message)
    end
end
```

Now assume that nofile.mat does not exist but that goodfile.mat does exist. On one system, the results are

```
Open file: nofile.mat
```

Cannot open file. Existence? Permissions? Memory? . . .

Open file: goodfile.mat

## 0 pening Temporary Files and Directories

The tempdir and tempname commands assist in locating temporary data on your system.

| Function | Purpose |
| :--- | :--- |
| tempdir | Get temporary directory name. |
| tempname | Get temporary filename. |

You can create temporary files. Some systems deletetemporary files every time you reboot the system. On other systems, designating a file as temporary may mean only that the file is not backed up.

A function named tempdir returns the name of the directory or folder that has been designated to hold temporary files on your system. For example, issuing tempdir on a UNIX system returns the / tmp directory.

MATLAB also provides a tempname function that returns a filename in the temporary directory. The returned filename is a suitable destination for temporary data. F or example, if you need to store some data in a temporary file, then you might issue the following command first.

```
fid = fopen(tempname, 'w');
```

Note The filename that tempname generates is not guaranteed to be unique; however, it is likely to be so.

## Reading Binary Data

The fread function reads all or part of a binary file (as specified by a file identifier) and stores it in a matrix. In its simplest form, it reads an entire file and interprets each byte of input as the next element of the matrix. For example, the following code reads the data from a file named nickel. dat into matrix $A$.

```
fid = fopen('nickel.dat','r');
A = fread(fid);
```

To echo the data to the screen after reading it, use char to display the contents of A as characters, transposing the data so it displays horizontally.

```
disp(char(A'))
```

The char function causes MATLAB to interpret the contents of A as characters instead of as numbers. Transposing A displays it in its more natural horizontal format.

## Controlling the Number of Values Read

fread accepts an optional second argument that controls the number of values read (if unspecified, the default is the entire file). F or example, this statement reads the first 100 data values of the file specified by fid into the column vector $A$.

$$
A=\operatorname{fread}(f i d, 100) ;
$$

Replacing the number 100 with the matrix dimensions [ 10 10] reads the same 100 elements into a 10-by-10 array.

## Controlling the Data Type of Each Value

An optional third argument to fread controls the data type of the input. The data type argument controls both the number of bits read for each value and the interpretation of those bits as character, integer, or floating-point values.

MATLAB supports a wide range of precisions, which you can specify with MATLAB specific strings or their $C$ or Fortran equivalents.

Some common precisions include:

- 'char' and 'uchar' for signed and unsigned characters (usually 8 bits)
- 'short' and 'long' for short and long integers (usually 16 and 32 bits, respectively)
- 'float' and 'double' for single and double precision floating-point values (usually 32 and 64 bits, respectively)

Note The meaning of a given precision can vary across different hardware platforms. For example, a 'uchar' is not always 8 bits. fread also provides a number of more specific precisions, such as 'int8' and 'float32'. If in doubt, use these precisions, which are not platform dependent. Look up fread in online help for a complete list of precisions.

For example, if fid refers to an open file containing single-precision floating-point values, then the following command reads the next 10 floating-point values into a column vector A.

```
A = fread(fid,10,'float');
```

## Writing Binary Data

The fwrite function writes the elements of a matrix to a file in a specified numeric precision, returning the number of values written. F or instance, these lines create a 100-byte binary file containing the 25 elements of the 5-by-5 magic square, each stored as 4-byte integers.

```
fwriteid = fopen('magic5.bin','w');
count = fwrite(fwriteid,magic(5),'int32');
status = fclose(fwriteid);
```

In this case, fwrite sets the count variable to 25 unless an error occurs, in which case the value is less.

## Controlling Position in a File

Once you open a file with fopen, MATLAB maintains a file position indicator that specifies a particular location within a file. MATLAB uses the file position indicator to determine where in the file the next read or write operation will begin. The following sections describe how to:

- Determine if the file position indicator is at the end of the file
- Move to specific location in the file
- Retrieve the current location of the file position indicator
- Reset the file position indicator to the beginning of the file

## Determining End-of-file

The fseek and ftell functions let you set and query the position in the file at which the next input or output operation takes place:

- The fseek function repositions the file position indicator, letting you skip over data or back up to an earlier part of the file.
- The ftell function gives the offset in bytes of the file position indicator for a specified file.

The syntax for fseek is

```
status = fseek(fid,offset,origin)
```

fid is the file identifier for the file. offset is a positive or negative offset value, specified in bytes. origin is an origin from which to calculate the move, specified as a string.

```
'bof' Beginning of file
'cof' Current position in file
'eof' End of file
```

## Understanding File Position

To see how fseek and ftell work, consider this short M-file.

```
A = 1:5;
fid = fopen('five.bin','w');
fwrite(fid, A,'short');
status = fclose(fid);
```

This code writes out the numbers 1 through 5 to a binary file named five. bin. The call to fwrite specifies that each numerical element be stored as a short. Consequently, each number uses two storage bytes.

Now reopen five.bin for reading.

```
fid = fopen('five.bin','r');
```

This call to fseek moves the file position indicator forward 6 bytes from the beginning of the file.

```
status = fseek(fid,6,'bof');
```

| File Position | bof | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | eof |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | :--- | :--- | :--- |
| File Contents |  | 0 | 1 | 0 | 2 | 0 | 3 | $\uparrow^{0}$ | 4 | 0 | 5 |  |
| File Position Indicator |  |  |  |  |  |  |  |  |  |  |  |  |

This call to fread reads whatever is at file positions 7 and 8 and stores it in variable four.

```
four = fread(fid,1,'short');
```

The act of reading advances the file position indicator. To determine the current file position indicator, call ftell.

```
position = ftell(fid)
position =
```

8

| File Position | bof | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | eof |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| File Contents | 0 | 1 | 0 | 2 | 0 | 3 | 0 | 4 | 0 | 5 |  |  |
| File Position Indicator |  |  |  |  |  |  |  |  |  |  |  |  |

This call to fseek moves the file position indicator back 4 bytes.

```
status = fseek(fid,-4,'cof');
```

| File Position | bof | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | eof |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| File Contents | 0 | 1 | 0 | 2 | 0 | 3 | 0 | 4 | 0 | 5 |  |  |
| File Position Indicator |  |  |  |  |  |  |  |  |  |  |  |  |

Calling fread again reads in the next value (3).

```
three = fread(fid,1,'short');
```

## Reading Strings Line-By-Line from Text Files

MATLAB provides two functions, fgetl and fgets, that read lines from formatted text files and store them in string vectors. The two functions are almost identical; the only difference is that fgets copies the newline character to the string vector but fgetl does not.

The following M-file function demonstrates a possible use of fgetl. This function uses fgetl to read an entire file one line at a time. For each line, the function determines whether an input literal string (literal) appears in the line.

If it does, the function prints the entire line preceded by the number of times the literal string appears on the line.

```
function y = litcount(filename, literal)
% Search for number of string matches per line.
fid = fopen(filename, 'rt');
y = 0;
while feof(fid) == 0
    tline = fgetl(fid);
    matches = findstr(tline, literal);
    num = length(matches);
    if num > O
        y = y + num;
        fprintf(1, '%d:%s\n',num,tline);
        end
end
fclose(fid);
```

For example, consider the following input data file called badpoem.

```
Oranges and lemons,
Pineapples and tea.
Orangutans and monkeys,
Dragonflys or fleas.
```

To find out how many times the string ' an 'appears in this file, use litcount.
litcount('badpoem', 'an')
2: Oranges and lemons,
1: Pineapples and tea.
3: Orangutans and monkeys,

## Reading Formatted ASCII Data

The fscanf function is like the fscanf function in standard $C$. Both functions operate in a similar manner, reading data from a file and assigning it to one or more variables. Both functions use the same set of conversion specifiers to control the interpretation of the input data.
The conversion specifiers for fscanf begin with a \% character; common conversion specifiers include:

- \%s to match a string
- \%d to match an integer in base 10 format
- \%g to match a double-precision floating-point value

You can also specify that fscanf skip a value by specifying an asterisk in a conversion specifier. For example, $\%$ *f means skip the floating point value in the input data; \%*d means skip the integer value in the input data.

## Differences Between the MATLAB fscanf and the C fscanf

Despite all the similarities between the MATLAB and $C$ versions of fscanf, there are some significant differences. For example, consider a file named moon. dat for which the contents are as follows.
3.654234533
2.71343142314
5.34134135678

The following code reads all three elements of this file into a matrix named MyData.

```
fid = fopen('moon.dat','r');
MyData = fscanf(fid,'%g');
status = fclose(fid);
```

Notice that this code does not use any loops. Instead, the fscanf function continues to read in text as long as the input format is compatible with the format specifier.
An optional size argument controls the number of matrix elements read. For example, if fid refers to an open file containing strings of integers, then this line reads 100 integer values into the column vector $A$.

$$
A=f s c a n f(f i d, ' \% 5 d ', 100) ;
$$

This line reads 100 integer values into the 10-by-10 matrix A.

```
A = fscanf(fid,'%5d',[10 10]);
```

A related function, sscanf, takes its input from a string instead of a file. F or example, this line returns a column vector containing 2 and its square root.

```
root2 = num2str([2, sqrt(2)]);
rootvalues = sscanf(root2,'%f');
```

## Writing Formatted Text Files

The fprintf function converts data to character strings and outputs them to the screen or a file. A format control string containing conversion specifiers and any optional text specify the output format. The conversion specifiers control the output of array elements; fprintf copies text directly.
Common conversion specifiers include:

- \%e for exponential notation
- \%f for fixed point notation
- $\% g$ to automatically select the shorter of $\% e$ and $\% f$

Optional fields in the format specifier control the minimum field width and precision. For example, this code creates a text file containing a short table of the exponential function.

```
x = 0:0.1:1;
y = [x; exp(x)];
```

The code below writes $x$ and $y$ into a newly created file named exptable.txt.

```
fid = fopen('exptable.txt','w');
fprintf(fid,'Exponential Function\n\n');
fprintf(fid,'%6.2f %12.8f\n',y);
status = fclose(fid);
```

The first call to fprintf outputs a title, followed by two carriage returns. The second call to fprintf outputs the table of numbers. The format control string specifies the format for each line of the table:

- A fixed-point value of six characters with two decimal places
- Two spaces
- A fixed-point value of twelve characters with eight decimal places
fprintf converts the elements of array y in column order. The function uses the format string repeatedly until it converts all the array elements.

Now use fscanf to read the exponential data file.

```
fid = fopen('exptable.txt','r');
title = fgetl(fid);
[table,count] = fscanf(fid,'%f %f',[2 11]);
```

```
table = table';
status = fclose(fid);
```

The second line reads the filetitle. The third line reads the table of values, two floating-point values on each line until it reaches end of file. count returns the number of values matched.

A function related to fprintf, sprintf, outputs its results to a string instead of a file or the screen. F or example,

```
root2 = sprintf('The square root of %f is %10.8e.\n',2, sqrt(2));
```

## Closing a File

When you finish reading or writing, use fclose to close the file. For example, this line closes the file associated with file identifier fid.

```
status = fclose(fid);
```

This line closes all open files.

```
status = fclose('all');
```

Both forms return 0 if the file or files were successfully closed or -1 if the attempt was unsuccessful.

MATLAB automatically closes all open files when you exit from MATLAB. It is still good practice, however, to close a file explicitly with fclose when you are finished using it. Not doing so can unnecessarily drain system resources.

Note Closing a file does not clear the file identifier variable fid. However, subsequent attempts to access a file through this file identifier variable will not work.

## Editing and Debugging M-Files

There are several methods for creating, editing, and debugging M-files, which are files containing MATLAB code.

| Task | Option | Instructions |
| :--- | :--- | :--- |
| Creating <br> and Editing <br> M-files | MATLAB Editor | "Starting the Editor/Debugger" <br> on page 7-3 |
|  | MATLAB Editor in <br> stand-alone mode <br> (without running <br> MATLAB) | "Opening the Editor Without <br> Starting MATLAB" on page 7-6 |
|  | Any text editor, such as <br> Emacs or vi | Specify the other editor as the <br> default using preferences - see <br> "E ditor" on page 7-36 |
| Debugging | General debugging tips | "Types of Errors" and "Finding <br> Errors" on page 7-17 |
| M-files | MATLAB Debugger | "Using Debugging Features" on <br> page 7-22 |
|  | MATLAB debugging <br> functions | "Using Debugging Features" on <br> page 7-22 |

Use preferences to set up the editing and debugging environment to best meet your needs.
To learn more about writing M-files, see "Programming and Data Types".

## Starting the Editor/ Debugger

The MATLAB Editor/Debugger provides a graphical user interface for basic text editing features for any file type, as well as for M -file debugging. The Editor/Debugger is a single tool that you can use for editing, debugging, or both. There are various ways to start the Editor/Debugger - see the sections:

- "Creating a New M-File in the Editor/Debugger" on page 7-4
- "Opening Existing M-Files in the Editor/Debugger" on page 7-5
- "Opening the Editor Without Starting MATLAB" on page 7-6 (no Debugger)

After starting the Editor/Debugger, follow the instructions for:

- "Creating and Editing M-Files with the Editor/Debugger" on page 7-8
- "Debugging M-Files" on page 7-17
- "Closing the Editor/Debugger" on page 7-6

Following is an illustration of the Editor/Debugger opened to an existing M-file.

If the Editor/Debugger window is not wide enough, the tool bar buttons on the right will be not be shown. The menu will wrap, and all tool bar functions are
available from equivalent menu items. To see all toolbar buttons, make the Editor/Debugger window wider.

To dock the Editor/Debugger inside the MATLAB desktop, select Dock M-File from the View menu.

To change the default appearance and behavior of the Editor/Debugger, follow the instructions in "Preferences for the Editor/Debugger" on page 7-35.

## Creating a New M-File in the Editor/ Debugger

To create a new M -file in the Editor/Debugger, either click the new file button [] on the MATLAB tool bar, or select File -> New -> M-file from the MATLAB desktop. You can also create a new $M$-file using the context menu in the Current Directory browser - see "Creating New Files" on page 5-24. The Editor/Debugger opens, if it is not already open, with a blank file in which you can create an M -file.

If the Editor/Debugger is open, create more new files by using the new file button $\square$ on the tool bar, or select File -> New $\boldsymbol{-}$ M-file.

## Function Equivalent

Type edit in the Command Window to create a new M-file in the Editor/ Debugger.

If you type edit filename.m and filename.m does not yet exist, a prompt appears asking if you want to create a new file titled filename.m.

- If you click Yes, the Editor/Debugger creates a blank file titled filename.m. If you do not want the dialog to appear in this situation, either check that box in the dialog or specify it in preferences for "Prompt" on page 7-40. In that case, the next time you type edit filename.m, the file will be created without first prompting you.
- If you click No, the E ditor/Debugger does not create a new file. If you do not want the dialog to appear in this situation, either check that box in the dialog or specify it in preferences for "Prompt" on page 7-40. In that case, the next time you type edit filename.m, a "file not found" error will appear.

## Opening Existing M-Files in the Editor/ Debugger

To open an existing M-file in the Editor/Debugger, click the open button $\mathrm{z}_{\text {zin }}$ on the MATLAB or Editor/Debugger tool bar, or select File -> Open. Then, from the Open dialog box, select the M-file and click Open. You can also open files from the Current Directory browser - see "Opening Files" on page 5-26.

You can select a file to open from the most recently used files, which are listed at the bottom of the File menu in the desktop as well as in theE ditor/Debugger. You can change the number of files appearing on the list - see "Preferences for the Editor/Debugger" on page 7-35.

If the Editor/Debugger is not already open, it opens with the file displayed. If it is already open, the file appears either in its own window or as a tab in the current window as specified in "Opening files in editor" on page 7-38. To make a document in the E ditor/Debugger becomethe current document, click on it or use the Window menu or tabs.

You can set a preference that instructs MATLAB on startup to automatically open the files that were open when the previous MATLAB session ended. For instructions, see the On restart preference in "General Preferences for the Editor/Debugger" on page 7-36.

## Function Equivalent

Use the edit or open function to open an existing M-file in the Editor/ Debugger. For example, type

```
edit collatz.m
```

to open the file collatz.m in the Editor/Debugger.

## 0 pening a Selection

Within a file in the Editor/Debugger, select a function, right-click, and select Open Selection from the context menu. The file opens in the Editor/Debugger.

## Getting Help for a Function

Within a file in the Editor/Debugger, select a function, right-click, and select Help on Selection from the context menu. The reference pagefor that function opens in the Editor/Debugger, or if the reference page does not exist, the M-file help is shown instead.

## Accessing Your Source Control System

If you use a source control system for M-files, you can access it from within the Editor/Debugger to check out files. See Chapter 9, "Interfacing with Source Control Systems."

## Opening the Editor Without Starting MATLAB

On Windows platforms, you can use the MATLAB Editor without starting MATLAB. To do so, double-click an M-file in Windows Explorer. The M-file opens in the MATLAB Editor. To open the Editor without a file, open \$matlabroot/bin/win32/meditor.exe. Regardless of the type of MATLAB license you have, you can open multiple instances of meditor because it is not considered an instance of MATLAB.

When you open the MATLAB Editor without starting MATLAB, the Editor is a stand-alone application. Y ou cannot debug $M$-files from it, evaluate a selection, access source control features, dock the Editor in the MATLAB desktop, nor access help from it. It remains a stand-al one application, even if you subsequently open MATLAB. Other than theselimitations, you can use the editing features as described in "Creating and Editing M-Files with the Editor/ Debugger" on page 7-8.

For Windows platforms, when MATLAB is installed, the stand-alone Editor is automatically associated with files having a .m extension. If you double-click on an $M$-file, the stand-alone Editor opens. You can change the association using Windows Explorer so that files with a .m extension will open in the Editor/Debugger in MATLAB.

## Closing the Editor/ Debugger

To close the Editor/Debugger, click the close box in the title bar of the Editor/ Debugger. This is different from the close box in the tool bar of the Editor/

Debugger, which closes the current file when multiple files are open in a single window.

When you close the current file and it is the only file open, then the Editor/ Debugger closes as well.

If multiple files are open with each in a separate Editor/Debugger window, close each window separately or close all of the files at once using the Close All item in the Window menu.

When you close the Editor/Debugger and any of the open files have unsaved changes, you will be prompted to save the files.

## Creating and Editing M-Files with the Editor/ Debugger

After opening an existing file or creating a new file, enter text in the Editor/ Debugger. Follow the same rules you would use for entering text in the Command Window as described in these sections:

- "Case and Space Sensitivity" on page 3-4
- "Entering Multiple Functions in a Line" on page 3-4
- "Entering Long Lines" on page 3-5
- "Suppressing Output" on page 3-9
- "Controlling the F ormat and Spacing of Numeric Output" on page 3-10

Use the editing features described in these sections:

- "Appearance of an M-File" on page 7-8, including syntax highlighting
- "Navigating in an M-File" on page 7-11, including go to and find features
- "Saving M-Files" on page 7-15
- "Running M-Files from the Editor/Debugger" on page 7-15
- "Printing an M-File" on page 7-16
- "Closing M-Files" on page 7-16

## Appearance of an M-File

The following features make $M$-files more readable:

- "Syntax Highlighting" on page 7-8
- "Indenting" on page 7-9
- "Commenting" on page 7-9
- "Showing Balanced Delimiters" on page 7-10

You can specify the default behavior for many of them - see "Preferences for the E ditor/Debugger" on page 7-35.

## Syntax Highlighting

Some entries appear in different colors to help you better find matching elements, such as if/else statements. For more information, see "Syntax Highlighting" on page 3-5.

## Indenting

Flow control entries are automatically indented to aid in reading the loops, such as while/end statements.

To move the current or selected lines further to the left, select Decrease I ndent from the Text menu. To move the current or selected lines further to the right, select Increase Indent from the Text menu. If after using these features you want to apply automatic indenting to selected lines, select Smart Indent from the Text menu, or right-click and select it from the context menu. For more information about smart indenting, see the preference for smart indent.

## Commenting

You can comment the current line or a selection of lines. To select a line, click just to the left of the line - theline becomes highlighted. Drag or Shift+click to select multiple lines. Then select Comment from the Text menu, or right-dick and sel ect it from the context menu. A comment symbol, \%, is added at the start of the line, and the color of the text becomes green.

You can make any line a comment by typing a \% at the beginning of it. To put a comment within a line, type \% followed by the comment text; MATLAB treats all the information after the $\%$ on that line as a comment.

You can also uncomment a selected group of lines - select Uncomment from the Text menu, or right-click and select it from the context menu.

Click in the area to the left of a line to select that line.

## Showing Balanced Delimiters

When you position the cursor inside a pair of delimiters, that is, inside ( ), [ ], or $\}$, and select Balance Delimiters from the Text menu, the string inside the pair of delimiters is highlighted. In this example, when the cursor is positioned before / norm, as indicated here

$$
\text { alfa }=a \sin \left(T^{*} v^{\prime} \cdot / \operatorname{sqrt}\left(\operatorname{diag}\left(T^{*} T^{\prime}\right)\right)\right. \text { /norm(v)); }
$$

selecting Balance Delimiters highlights the selection as shown here.

```
alfa = asin(T*V'./sqrt(diag(T*T'))/norm(vD);
```

## Navigating in an M-File

There are several options for navigating in M-files:

- "Going to a Line Number"
- "Going to a Bookmark"
- "Going to a Function"
- "Finding a Selection"
- "Finding and Replacing a String"

## Going to a Line Number

Line numbers are displayed along the left side of the Editor/Debugger window. Select Go to Line from the Edit menu. Enter the line number in the edit box and click OK. The cursor moves to that line number in the current M-file.

## Going to a Bookmark

You can set a bookmark at a line in an M-file so you can quickly go to the bookmarked line. This is particularly useful in long $M$-files. For example, if you're working on a line but need to look at another part of the file, set a bookmark at the current line, go to the other part of the file, and then go back to the bookmark.

To set a bookmark, position the cursor anywhere in the line and select Set Bookmark from the Edit menu. A bookmark icon appears to the left of theline.

```
11|- \hile next_value > 1
```

To go to a bookmark, select Next Bookmark or Previous Bookmark from the Edit menu.

To clear a bookmark, position the cursor anywhere in the line and select Clear Bookmark from the Edit menu.

Bookmarks are not saved when you close a file.

## Going to a Function

To go to a function in an M-file(referred to as a subfunction), click the function button $f$ b on the tool bar. Select the function you want to go to from the list of all functions in that M -file. The list does not include functions that are called from the $M$-file, but only lists lines in the current $M$-file that begin with a function statement.

## Finding a Selection

Within the current M-file, select a string. From the Edit menu, select Find
Selection. The next occurrence of that string becomes highlighted. Use Find
Selection from the Edit menu to continue finding the next occurrences of the string.

To find the previous occurrence of the selected string (find backwards), press Ctrl+Shift+F 3.

## Finding and Replacing a String

You can search for a specified string within multiple files, and replace the string within a file.

Finding a String. To search for a string in files:
1 Click the find button in the Editor/Debugger tool bar, or select Find and Replace from the Edit menu.

The Find \& Replace dialog box appears. This provides the samefeatures as the Find \& Replace dialog box accessible from the Current Directory browser.

2 Complete the Find \& Replace dialog box to find all occurrences of the string you specify.
a Type the string in the Find what field.
b Select the files to search through from the Look in listbox.
c Limit the search using Match case, Whole word, or Wrap around. These settings are remembered for your next MATLAB session.

## 3 Click Find.

- If you search for the current file, the next occurrence of the string is highlighted in the file.
- If the search is through multiple files, results appear in the lower part of the Find \& Replace dialog box and include the filename, M-file line number, and content of that line.

4 Open any M-file(s) in the results list by doing one of the following:

- Doubleclickingit.
- Selecting it and pressing the Enter or Return key.
- Right-clicking it and selecting Open from the context menu.

The M-file opens, scrolled to the line number shown in the results section of the Find \& Replace dialog box.

5 If you perform another search, the results of each search are accessible via tabs just bel ow the results list. Click a tab to see that results list as well as the search criteria.

Finding the Next or Previous $\mathbf{O}$ ccurrence of the String. To find the next occurrence of the string you entered in theFind \& Replace dialog box, select Find Next from the Edit menu. To find the previous occurrence of that string (find backwards), press Shift+F3.

Function Equivalent. Use lookfor to search for the specified string in the first line of help in all $M$-files on the search path.

Replacing a String. After searching for a string within files, you can replace the specified content i
n the current file.
1 Open the file in the E ditor if it's not already open. You can open it from the Find \& Replace dialog box - see step 4 in "Finding a String" on page 7-12. Be sure that the file in which you want to replace the string is the current file in the Editor.

2 Be sure the Look in field in the Find \& Replace dialog box shows the name of the file in which you want to replace the string. The Replace button in the Find \& Replace dialog box becomes selectable.

3 In the Replace with field, typethetext that is to replace the specified string.
4 Click Replace to replace the string in the selected line, or click Replace All to replace all instances in the currently open file.

The text is replaced.

5 To save the changes, select Save from the File menu.
You can repeat this for multiple files.

## Saving M-Files

After making changes to an M-file, you will see an asterisk (*) next to the file name in the title bar of the Editor/Debugger. This indicates there are unsaved changes to the file.

To save the changes, use one of the Save commands in the File menu:

- Save - Saves the file to its existing name. If the file was newly created, the Save file as dialog box opens, where you assign a name to the file and save it. Another way to save is by using the save button on the tool bar.
- Save As - The Save file as dialog box opens, where you assign a name to the file and save it. You do not need to type the .m extension because MATLAB automatically assigns the .m extension to the filename. If you do not want an extension, type a . (period) after the filename.
- Save All - Saves all named files to their existing filenames. For all newly created files, the Save file as dialog box opens, where you assign a name to each file and save it.

## Running M-Files from the Editor/ Debugger

You can run a script, that is, an M-file that doesn't require an input argument, directory from the Editor/Debugger by clicking the run button on the tool bar, or by selecting R un from the Debug menu.
If the file is not in a directory on the search path or in the current directory, a dialog box appears presenting you with options that allow you to run the file. You can either change the current directory to the directory containing the file, or you can add to the search path the directory containing the file.

Note that if thefile has unsaved changes, running it from the Editor/Debugger automatically saves the changes before running. In that event, the menu item becomes Save and Run.

See "Running an M-File with Breakpoints" on page 7-24 for additional information about running $M$-files while debugging.

## Accessing Your Source Control System

If you use a source control system for $M$-files, you can access it from within the Editor/Debugger to check in files. See Chapter 9, "Interfacing with Source Control Systems."

## Printing an M-File

To print an entire M-file, select Print from the File menu, or click the print button 量 on the tool bar. To print the current selection, select Print Selection from the File menu. Complete the standard print dialog box that appears.

See also "Printing Preferences for the Editor/Debugger" on page 7-42 to specify a different font for printing, color or black and white printing, and other options.

## Closing M-Files

To cl ose the current M-file, select Close filename from the File menu. If there are multiple files open in a single Editor/Debugger window, click the close box in the Editor tool bar to close the current M -file. This is different from the close box in the titlebar of the Editor/Debugger, which closes the Editor/Debugger, including all open files.

If each file is open in a separate Editor/Debugger window, close all of the files at once using the Close All item in the Window menu.

When you close the current file and it is the only file open, then the Editor/ Debugger closes as well.

When you close a file which has unsaved changes, you are prompted to save the file.

## Debugging M-Files

This section introduces general techniques for finding errors, and then illustrates MATLAB debugger features found in the Editor/Debugger and debugging functions using a simple example. It includes these topics:

- "Types of Errors" on page 7-17
- "Finding Errors" on page 7-17
- "Debugging Example - The Collatz Problem" on page 7-18
- "Trial Run for Example" on page 7-20
- "Using Debugging Features" on page 7-22

## Types of Errors

Debugging is the process by which you isolate and fix problems with your code.
Debugging helps to correct two kinds of errors:

- Syntax errors - For example, misspelling a function name or omitting a parenthesis. "Syntax Highlighting" on page 7-8 helps you identify these problems. MATLAB detects most syntax errors and displays an error message in the Command Window describing the error and showing its line number in the M -file. Position the cursor over the error message and press CtrI+E nter to open the M-file at that line. Use the pcode function to check for syntax errors in your M-file without running the M-file.
- Run-time errors - These errors are usually algorithmic in nature. For example, you might modify the wrong variable or perform a calculation incorrectly. Run-time errors are apparent when an M-file produces unexpected results.

## Finding Errors

Usually, it's easy to find syntax errors based on MATLAB's error messages. Run-time errors are more difficult to track down because the function's local workspace is lost when the error forces a return to the MATLAB base workspace. Use the following techniques to isolate the cause of run-time errors:

- Remove selected semicol ons from the statements in your M-file. Semicolons suppress the display of intermediate calculations in the M-file. By removing
the semicol ons, you instruct MATLAB to display these results on your screen as the M-file executes.
- Add keyboard statements to the M-file. Keyboard statements stop M-file execution at the point where they appear and allow you to examine and change the function's local workspace. This mode is indicated by a special prompt, "K>>." Resumefunction execution by typing return and pressing the Return key.
- Comment out the leading function declaration and run the M-file as a script. This makes the intermediate results accessible in the base workspace.
- Use the depfun function to see the dependent functions.
- Use the MATLAB Editor/Debugger or debugging functions. They are useful for correcting run-time errors because you can access function workspaces and examine or change the values they contain. Y ou can set and clear breakpoints, lines in an M-file at which execution halts. Y ou can change workspace contexts, view the function call stack, and execute the lines in an M -file one by one.
The remainder of this section on debugging $M$-files describes the use of the Editor/Debugger and debugging function using an example.

## Debugging Example - The Collatz Problem

The example debugging session requires you to create two M-files, collatz.m and collatzplot.m, that produce data for the Collatz problem. For any given positive integer, $n$, the Collatz function produces a sequence of numbers that al ways resolves to 1 . If $n$ is even, divide it by 2 to get the next integer in the sequence. If n is odd, multiply it by 3 and add 1 to get the next integer in the sequence. Repeat the steps for the next integer in the sequence until the next integer is 1 . The number of integers in the sequence varies, depending on the starting value, $n$.

The Collatz problem is to prove that the Collatz function will resolveto 1 for all positive integers. The $M$-files for this example are useful for studying the problem. The file collatz.m generates the sequence of integers for any given n . Thefile collatzplot.m calculates the number of integers in the sequence for any given n and plots the results. The plot shows patterns that can be further studied.

Following are the results when $n$ is 1,2 , or 3 .

| $\mathbf{n}$ | Sequence |  | Number of Integers in the Sequence |  |
| :--- | :--- | :--- | :--- | :--- |
| 1 | 1 |  | 1 |  |
| 2 | 2 | 1 |  |  |
|  | 3 | 10 | 5 | 16 |

## M-Files for the Collat Problem

Following are the two M-files you use for the debugging example. To create these files on your system, open two new M-files. Select and copy the following code from the Help browser and paste it into the M-files. Save and name the files collatz.m and collatzplot.m. Be sure to save them to your current directory or add to the search path the directory where you save them. One of the files has an embedded error for purposes of illustrating the debugging features.

```
Codefor collatz.m.
    function sequence=collatz(n)
% Collatz problem. Generate a sequence of integers resolving to 1
% For any positive integer, n:
% Divide n by 2 if n is even
% Multiply n by 3 and add 1 if n is odd
% Repeat for the result
% Continue until the result is 1%
sequence = n;
next_value = n;
while next_value > 1
    if rem(next_value,2)==0
        next_value = next_value/2;
    else
        next_value = 3*next_value+1;
    end
    sequence = [sequence, next_value];
end
```

```
Codefor collatzplot.m.
    function collatzplot(n)
    % Plot length of sequence for Collatz problem
    % Prepare figure
    clf
    set(gcf,'DoubleBuffer','on')
    set(gca,'XScale','linear')
%
% Determine and plot sequence and seqeuence length
for m = 1:n
    plot_seq = collatz(m);
    seq_length(m) = length(plot_seq);
    line(m,plot_seq,'Marker','.','MarkerSize',9,'Color','blue')
    drawnow
end
```

## Trial Run for Example

Try out collatzplot to see if it works correctly. Use a simple input value, for example, 3 , and compare the results to those shown in the preceding table. Typing

```
collatzplot(3)
```

produces the plot shown in the following figure.

The plot for 1 appears to be correct - when $n=1$, the Collatz series is 1 , and contains one integer. But for $n=2$ and $n=3$ it is wrong because there should be only one value plotted for each integer, the length of the sequences, which the preceding table shows to be 2 and 8 respectively. I nstead, multiple values are plotted. Use MATLAB debugging features to isolate the problem.

## Using Debugging Features

Y ou can debug theM-files using the Editor/Debugger and debugging functions. You can use both methods interchangeably. The example describes both methods.

The debugging process consists of:

- "Preparing for Debugging" on page 7-22
- "Setting Breakpoints" on page 7-22
- "Running an M-File with Breakpoints" on page 7-24
- "Stepping Through an M-File" on page 7-25
- "Examining Values" on page 7-26
- "Correcting Problems and Ending Debugging" on page 7-29

## Preparing for Debugging

Do the following to prepare for debugging:

- Open the file - To use the Editor/Debugger for debugging, open it with the file you will run, in this example, collatzplot.m.
- Save changes - If you are editing the file, save the changes before you begin debugging. If you try to run and debug a file with unsaved changes, the file is automatically saved before it runs.
- Add the file(s) to a directory on the search path or be sure it is in the current directory - Besurethefileyou run and any files it calls are in directories that are on the search path. If all files to be used are in the same directory, you can instead make that directory be the current directory.

## Setting Breakpoints

Set breakpoints to pause execution of the function so you can examine values where you think the problem might be. You can only set breakpoints at executable lines in saved files that are in the current directory or in directories on the search path. When you create a new M-file, save it before setting breakpoints. Y ou cannot set breakpoints while MATLAB is busy, for example, running an M -file.

Breakpoints for the Example. It is unclear whether the problem in the example is in collatzplot or collatz. Tostart, set breakpoints in collatzplot.mat lines 10,11 , and 12. The breakpoint at line 10 allows you to step into collatz to see
if the problem might be there. The breakpoints at lines 11 and 12 stop the program where you can examine the interim results.

Setting Breakpoints Using the Editor/ Debugger. To set a breakpoint using the Editor/ Debugger, click in the breakpoint alley at the line where you want to set the breakpoint. The breakpoint alley is the column to the right of the line number. You can set breakpoints only at lines that are preceded by a - (dash). Lines not preceded by a dash, such as comments, are not executable. Other ways to set a breakpoint are to position the cursor in the line and then click the set/clear breakpoint button ${ }^{6}$ 曾 on the tool bar, or select Set/Clear Breakpoint from the Breakpoints menu or the context menu.

A breakpoint icon appears, as in the following illustration for line 10.

```
10|| plot_seq = collatz(m);
```

Function Equivalent. To set a breakpoint using the debugging functions, use dbstop. For the example, type

```
dbstop in collatzplot at 10
dbstop in collatzplot at 11
dbstop in collatzplot at 12
```

Some useful related functions are:

- dbtype - Lists the M-file with line numbers in the Command Window.
- dbstatus - Lists breakpoints.

Setting Stops for Conditions. Use the items on the Breakpoints menu or the dbstop function equivalents to instruct the program to stop when it encounters a problem. For details, see dbstop.

- Stop If Error, or dbstop if error
- Stop If Warning, or dbstop if warning
- Stop If NaN Or Inf (for not-a-number or infinitevalue), or dbstop if naninf or dbstop if infnan
- Stop If All Error, or dbstop if all error

If the File Is Not on the Search Path or In the Current Directory. When you add a breakpoint to a filethat is not in a directory on the search path or in thecurrent directory, a dialog box appears presenting you with options that allow you to
add the breakpoint. Y ou can either change the current directory to the directory containing the file, or you can add to the search path the directory containing the file.

## Running an M-File with Breakpoints

After setting breakpoints, run the M-file from the Command Window or the Editor/Debugger.
For the example, run collatzplot for the simple input value, 3, by typing in the Command Window

```
collatzplot(3)
```

The example, collatzplot, requires an input argument and therefore runs only from the Command Window and not from the Editor/Debugger.

Results of Running an M-File Containing Breakpoints. Running the M-file results in the following:

- The prompt in the Command Window changes to $\mathrm{K} \gg$, indicating that MATLAB is in debug mode.
- The program is paused at the first breakpoint, which in the example is line 10. This means that line 10 will be executed when you continue. The pause is indicated in the Editor/Debugger by the green arrow just tothe right of the breakpoint as shown here.

```
10|@l=> plot_seq = collatz(m);
```

If you use debugging functions and have the Debugger options preference for Command Window debugging checked, the line at which you are paused is displayed in the Command Window. For the example, it would show

```
10 plot_seq = collatz(m);
```

- Thefunction displayed in the Stack field on thetoolbar changes to reflect the current function. If you use debugging functions, use dbstack to view the current call stack. The call stack includes subfunctions as well as called functions.
- If the file you're running is not in the current directory or in a directory on the search path, you're prompted to either add the directory to the path or change the current directory.

## Stepping Through an M－File

While in debug mode，you can step through an M－file，pausing at points where you want examine values．

Use the step buttons or the step items in the Debug menu of the E ditor／ Debugger，or use the equivalent functions．

| Toolbar Button | Debug Menu Item | Description | Function Equivalent |
| :---: | :---: | :---: | :---: |
| 相 | Continue | Continue execution of M －file until completion or until another breakpoint is encountered．The menu item says Run or Save and Run if the file is not running． | dbcont |
| None | Go Until Cursor | Continue execution of M－file until the line where the cursor is positioned．Also available on the context menu． | None |
| 同 | Step | Execute the current line of the M－file． | dbstep |
| 雨 | Step In | Execute the current line of the M－file and，if the line is a call to another function，step into that function． | dbstep in |
| 國 | Step Out | After stepping in，runs the rest of the called function or subfunction，leaves the called function，and pauses． | dbstep out |

Stepping In．In the example，collatzplot is paused at line 10．Use the step－in button or type dbstep in in the Command Window to step into collatz and walk through that M－file．Stepping in takes you to line 9 of collatz．

The pause indicator at line 10 of collatzplot changes to a hollow arrow $\Rightarrow$, indicating that MATLAB control is now in a function called from the main program, which in the example is collatz.

In the called function, you can do the same things you can do in the main (calling) function - set breakpoints, run, step through, and examine values.

Stepping Out In the example, the program is paused at step 9 in collatz. Because the problem results are correct for $n=1$, continue running the program since there is no need to examine values until $n=2$. The fastest way to run through collatz is to step out, which runs the rest of collatz and returns to the next line in collatzplot, line 11. To step out, use the step-out button or type dbstep out in the Command Window.

## Examining Values

While the program is paused, you can view the value of any variable currently in the workspace. Use the following methods to examine values:

- "Where to Examine Values" on page 7-26
- "Selecting the Workspace" on page 7-27
- "Viewing Datatips in the Editor/Debugger" on page 7-27
- "Viewing Values in the Command Window" on page 7-28
- "Viewing Values in the Array Editor" on page 7-28
- "Evaluating a Selection" on page 7-28

Many of these methods are used in "Examining Values in the Example" on page 7-28.

Where to Examine Values. When the program is paused, either at a breakpoint or at a line you have stepped to, you can examine values. Examine values when you want to see if a line of code has produced the expected result or not. If the result is as expected, continue running or step to the next line. If the result is not as expected, that line, or a previous line, contains an error.

In the example, because the results for $n=1$ are correct, there is no need to examine values until $n=2$. Therefore, continue or step through the first iteration of the loop in collatzplot when $m=1$. When collatzplot stops at line 10 the next time (when $m=2$ ), step in to the collatz function so you can examine values there.

Selecting the Workspace. Variables assigned through the Command Window are considered to be the base workspace. Variables created in each function have their own workspace. To examine a variable, you must first select its workspace. When you run a program, the current workspace is shown in the Stack field. To examine values that are part of another function workspace currently running or the base workspace, first select that workspace from the list in the Stack field.

Viewing Datatips in the Editor/ Debugger. In the Editor/Debugger, position the cursor to the left of a variable. Its current value appears and stays in view until you move the cursor - this is called a datatip. In the example, position the cursor over n in collatz - the datatip shows that $\mathrm{n}=2$, as expected. Note that the Stack shows collatz as the current function.

Hold the cursor over a variable to view its current value.

Viewing Values in the Command Window. Type a variable name in the Command Window and MATLAB displays its current value. To see the variables currently in the workspace, use who. To see the value of $n$ for the example, type
n
and MATLAB returns the expected result

$$
n=
$$

Viewing Values in the Array Editor. You can view the value of any variable in the Array Editor. To view the current variables, open the Workspace browser. In the Workspace browser, double-click a variable - the Array Editor opens, displaying the value for that variable. Y ou can also open the Array Editor for a variable using openvar.

To see the value of $n$ in the Array Editor for the example, type
openvar $n$
and the Array Editor opens, showing that $\mathrm{n}=2$ as expected.

Evaluating a Selection. Select a variable or equation in an M-file in the Editor/ Debugger. Right-click and select Evaluate Selection from the context menu. MATLAB displays the value of the variable or equation in the Command Window. Y ou cannot evaluate a selection while MATLAB is busy, for example, running an M -file.

Examining Values in the Example. In collatz, use the step button or the function dbstep. The program advances to line 10, where there is no need to examine values. Continue stepping until line 13.

When you step again, the pause indi cator jumps to line 17, just after the if loop, as expected, given the code in line 13 for next_value $=2$. When you step
again, you can check the value of sequence in line 17 and see that it is 21 as expected for $n=2$. Stepping again takes you from line 17 to line 10. Because next_value is 1, the while loop ends. The pause indicator is at line 10 and appears as a green down arrow $\sqrt{ }$. This indicates that processing in the called function is complete and program control will return to the calling program, in this case, collatzplot line 10.

In collatzplot, step again to advance to line 11, then line 12. The variable sequence_length in line 11 is a vector with the elements 12 , which is correct.

Finally, step again to advance to line 13. Examining the values in line 12, $\mathrm{m}=2$ as expected, but the second variable, plot_seq, has two values, where only one value is expected. While plot_seq has the value expected, 21 , it is the incorrect variable for plotting. Instead, the variable seq_length should be plotted.

## Correcting Problems and Ending Debugging

These are some of the ways to correct problems and end the debugging session:

- "Changing Values and Checking Results" on page 7-29
- "Ending Debugging" on page 7-30
- "Clearing Breakpoints" on page 7-30
- "Correcting an M-File" on page 7-31

Many of these features are used in "Completing the Example" on page 7-31.
Changing Values and Checking Results. While debugging, you can change the value of a variable in the current workspace to see if the new value produces expected results. While the program is paused, assign a new value to the variable in the Command Window or in the Array Editor. Then continue running or stepping through the program. If the new value does not produce the expected results, the program has a different or another problem.

Ending Debugging. After identifying a problem, end the debugging session. Y ou must end a debugging session if you want to change an M -file to correct a problem or if you want to run other functions in MATLAB.

Note Always quit debug mode before editing an M-file. If you edit an M-file while in debug mode, you can get unexpected results when you run the file.

To end debugging, click the exit debug mode icon Mode from the Debug menu.
You can instead use the function dbquit to end debugging.
After quitting debugging, the pause indicators in the Editor/Debugger display no longer appear, and the normal prompt >> now appears in the Command Window instead of the debugging prompt, k>>. You can nolonger access the call stack.

Clearing Breakpoints. Breakpoints remain in a file until you clear them. Clear the breakpoints if you want the program to run uninterrupted, such as after identifying and correcting a problem.

To clear a breakpoint in the Editor/Debugger, click on the breakpoint icon for a line, or select Set/Clear Breakpoint from the Breakpoints or context menu. The breakpoint for that line is cleared.
To clear all breakpoints in all files, select Clear All Breakpoints from the Breakpoints menu, or click the 精 equivalent button on the toolbar.
The function that clears breakpoints is dbclear. To clear all breakpoints, use dbclear all. F or the example, clear all of the breakpoints in collatzplot by typing

```
dbclear all in collatzplot
```

Breakpoints are automatically cleared when you:

- End the MATLAB session
- Clear the M-file using clear name or clear all
- Edit the file if the changes impact line numbering
- Edit the file while in debug mode (although this does not always clear breakpoints)

Correcting an M-File. To correct a problem in an M-file:
1 Quit debugging.
Do not make changes to an M-file while MATLAB is in debug mode. It could produce unexpected debugging results when you run the $M$-file.

2 Clear all the breakpoints in the file.
The breakpoints become unreliable once the $M$-file is edited. The breakpoints will produce unexpected debugging results when you run the file.

3 Make changes to the M-file.
4 Save the M-file.
5 Set breakpoints, if desired.
6 Run the M-file again to be sure it produces the expected results.
Completing the Example. To correct the problem in the example, do the following:
1 End the debugging session. One way to do this is to select Exit Debug Mode from the Debug menu.

2 Clear the breakpoints in collatzplot.m. One way to do this is by typing dbclear all in collatzplot
in the Command Window.

3 Incollatzplot.mline12, changethestringplot_seq to seq_length(m) and save the file.

4 Run collatzplot for $\mathrm{n}=3$ by typing
collatzplot(3)
in the Command Window.
5 Verify the result. The figure shows that the length of the Collatz series is 1 when $\mathrm{n}=1$, 2 when $\mathrm{n}=2$, and 8 when $\mathrm{n}=3$, as expected.

6 Test the function for a slightly larger value of $n$, such as 6 , to be sure the results are still accurate. To make it easier to verify collatzplot for $n=6$ as well as the results for collatz, add this line at the end of collatz.m sequence
which displays the series in the Command Window.
Then run collatzplot for $\mathrm{n}=6$ by typing
collatzplot(6)

7 To make debugging easier, you ran collatzplot for a small value of n. Now that you know it works correctly, run collatzplot for a larger value to produce more interesting results. Before doing so, you might want to suppress output for the line you just added in step 6, line 18 of collatz.m, by adding a semicolon to the end of the line so it appears as

```
sequence;
```

## Then run

```
collatzplot(500)
```

The following figure shows the lengths of the Collatz series for $n=1$ through $\mathrm{n}=500$.

```
4 Figure No. }
    -|\square|
Eile Edit View Insert Iools Window Help
```

## Preferences for the Editor/ Debugger

Using preferences, you can specify the default behavior for various aspects of the Editor/Debugger.

To set preferences for the Editor/Debugger, select Preferences from the File menu in the Editor/Debugger. The Preferences dialog box opens showing Editor/Debugger Preferences.

| -) Preferences |  |  |  | X |
| :---: | :---: | :---: | :---: | :---: |
| General <br> Command Window <br> EditoriDebugger <br> -Font \& Colors <br> - Display <br> - Keyboard \& Indenting <br> -Printing | Editor/Debugger Preferences |  |  |  |
|  | Editor |  |  |  |
|  | ¢ Built-in editor |  |  |  |
|  | Debugger options |  |  |  |
| - Workspace | Most recently used file list |  |  |  |
| ©-Figure Copy Template <br> +-Simulink | On restart $\qquad$Reopen files from previous MATLAB session |  |  |  |
|  |  |  |  |  |
| $4 \mid \square$ |  |  |  |  |
|  | OK | Cancel | Help |  |

You can specify the following Editor/Debugger preferences:

- "General Preferences for the Editor/Debugger" on page 7-36 (on the first panel, including the Editor preference)
- "F ont \& Col ors Preferences for the Editor/Debugger" on page 7-37
- "Display Preferences for the Editor/Debugger" on page 7-38
- "Keyboard and Indenting Preferences for the Editor/Debugger" on page 7-40
- "Printing Preferences for the Editor/Debugger" on page 7-42

## General Preferences for the Editor/ Debugger

When you first access preferences for the Editor/Debugger, you can specify the general preferences described here.

## Editor

By default, the Built-in editor option is selected, meaning that MATLAB uses its own Editor/Debugger.

To specify a text editor other than MATLAB's Editor, such as Emacs or vi, to be used when you open an M-file from within MATLAB, select Other. In the Other field, type the path to the editor application you want to use.
For example, specify C: \Applications \Emacs. exe in the Other field, and then open a file using Open from the File menu the MATLAB desktop. The file opens in Emacs instead of in the MATLAB Editor/Debugger.

## Debugger options

By default, the item Automatically open files when debugging is checked. The result is that when you run an M -file containing breakpoints, the MATLAB Editor/Debugger opens when it encounters a breakpoint.

If you use debugging functions, you might want to uncheck the item so that the Editor/Debugger does not open when a breakpoint is encountered.

## Most recently used file list

Use this preference to specify the number of files that appear in the list of most recently used files in the File menu.

## On restart

To start MATLAB and automatically open the files that were open when you last shut down MATLAB, check the item Reopen files from previous
MATLAB session. If theitem is unchecked and you close MATLAB when there are files open in the Editor/Debugger, the next time you start MATLAB, the Editor/Debugger is not opened upon startup.

## Font \& Colors Preferences for the Editor/ Debugger

Use Font \& Colors preferences to specify thefont and colors used in files in the Editor/Debugger.

## Font

E ditor/Debugger font preferences specify the characteristics of the font used in files in the Editor/Debugger. Select Use desktop font if you want the font in the files to be the same as that specified under General - Font \& Colors. If you want the font for Editor/Debugger files to be different, select Use custom font and specify the font characteristics:

- Type, for example, Lucida Console
- Style, for example, Plain
- Size in points, for example, 12 points

After you make a selection, the Sample area shows how the font will look.
You can specify different font characteristics for printing files from the Editor

- see "Printing Preferences for the Editor/Debugger" on page 7-42.

## Colors

Specify the col ors used in files in the Editor/Debugger:

- Text color - The col or of nonspecial text; special text uses col ors specified for Syntax highlighting.
- Background color - The color of background in the window.
- Syntax highlighting - The col ors to use to highlight syntax. If checked, click Set Colors to specify them. For a description of syntax highlighting, see "Syntax Highlighting" on page 3-5.

## Display Preferences for the Editor/ Debugger

Use Display preferences to specify how the Editor/Debugger window should look.

## 0 pening files in editor

This preference controls how files are arranged when you open them in the Editor/Debugger. When you change this preference, it applies to files you open after making the change. Currently opened files are not rearranged to match the preference.

Check Single window contains all files (tabbed style) to have a singleEditor/ Debugger window for all open files, as shown in thefollowing illustration. Click the tab for a file to make it the current file.

Files are tabbed within one window.

Check Each file is displayed in its own window to have a separate Editor/ Debugger window for each open file, as shown in the following illustration.

Each file is in its own window.

## Display

Use display options to specify what is shown and what is hidden in the Editor/ Debugger.

Show toolbar. Check this item to display the tool bar. Uncheck it to hide the tool bar.

Show line numbers. Check this item to show line numbers. They appear al ong the left side of the window. When you uncheck this item, line numbers aren't shown.

Enable datatips in edit mode. Check this item to see datatips while in edit mode. Datatips are always enabled in debug mode.

## Prompt

When you type edit filename and filename does not exist, MATLAB displays a prompt asking if you want to create a new file named filename. m. If you do not want to see this prompt, uncheck the preference Show dialog prompt when editing files that do not exist. Then, the next time you type edit filename, the file will be created without first prompting you.
If you do not generally use the edit command to create new files, then you might want to check the box to show the prompt. This alerts you to the possibility that you mistyped the filename you want to open.

## Keyboard and Indenting Preferences for the Editor/ Debugger

Use keyboard preferences to specify the key binding conventions MATLAB should follow. Use indenting preferences to specify how the Editor/Debugger indents lines.

## Key bindings

Select Windows or Emacs depending on which convention you want the Editor/Debugger to follow for accelerators and shortcuts. The accelerators seen on the menus change after you change this option.

For example, when you select Windows key bindings, the shortcut to paste a selection is $\mathbf{C t r I + V}$. When you select E macs key bindings, the shortcut to paste a selection is CtrI+Y. You can see the accelerator on the Edit menu for the Paste item.

## M-file indenting for Enter key

Select the style of indenting you want the Editor/Debugger to use when you press the Enter key. Examples follow, illustrating the different styles.

- No indent - Nolines are indented. Use this is you want lines to be aligned on the left or want to insert line indents manually.
- Block indent - Indents a line the same amount as the line above it.
- Smart indent - Automatically indents lines that start with keyword functions or that follow certain keyword functions. Smart indenting can help you to follow the code sequence.

The indenting style only applies to lines you enter after changing the preference; it does not affect the indenting of existing lines. To change the indenting for existing lines, use the Text menu entries for "I ndenting" on page 7-9.
For any indenting style, you can manually insert tabs at the start of a line.

## Example of No Indent W ithout Tabs.

```
sequence = n
next_value = n;
while next_value > 1
if rem(next_value,2)==0 Created using No indent preference.
next_value = next_value/2; Did not manually insert any tabs.
next_value = 3*next_value+1;
kend
sequence = [sequence, next_value]
end
```

## Example of No Indent with Tabs.

```
sequence = n
next_value = n;
    else
    next_value = 3*next_value+1;
    end
    sequence = [sequence, next_value]
end
```

while next_value $>1 \quad$ Created using No indent preference.
$\begin{array}{ll}\text { if rem(next_value, } 2 \text { ) }==0 \\ \text { next_value }= & \text { next_value/2; }\end{array} \quad$ Created indentation by manually inserting a tab

## Example of Block Indent.

```
sequence = n
next_value = n;
    if rem(next_value, 2)==0
    next_value = next_value/2;
    else
    next_value = 3*next_value+1;
    end
    sequence = [sequence, next_value]
    end
```

while next_value >1 $\quad$ Created using Block indent preference.
Inserted a tab before the if statement.
Subsequent lines automatically indented one tab.

## Example of Smart Indent.

```
sequence = n
next_value = n;
        next_value = next_value/2;
    else
        next_value = 3*next_value+1;
    end
    sequence = [sequence, next_value]
end
```

while next_value $>1 \quad$ Created using Smart indent preference.

Created using Smart indent preference.
Did not manually insert any tabs.
Indented lines were automatically indented.

## Indent

Indent size. Specify the indent size for smart indenting.
Emacs-style tab key smart indenting. This indenting convention is based on the style used by the Emacs editor. When you select the style, lines are not automatically indented. To indent a line(s) according to smart indenting practices, you can position the cursor in that line or select a group of lines and then press the Tab key.

## Tab

Tab size. Specify the amount of space inserted when you press the Tab key. When you change the Tab size, it changes the tab space for existing lines in that file.

Tab key inserts spaces. Check this item if you want a series of spaces to be inserted when you press the Tab key. If the item is unchecked, a tab acts as one space whose length is determined by Tab size.

## Printing Preferences for the Editor/ Debugger

Use printing preferences to specify how printed M-files will look.

## Syntax higlighting

This preference specifies how highlighted syntax is printed. The options are:

## - Print as black and white text

- Print as colored text
- Print as styled text - Prints in black and white. Comments are italicized and keywords are bold.

## Print options

- Check Print header to include a header on the printed page that lists the full pathname for the file, page numbers, and the date and time it is printed.
- Check Print line numbers to include line numbers when printing files.

## Font

Use this preference to specify font characteristics for printed M-files. This is especially useful on Windows platforms because a given font size is displayed slightly smaller than the actual size, but is printed at the actual size. Therefore the font in the printed output might look larger than you expected.

To print documents using the same font characteristics as specified for the Editor/Debugger (see "F ont \& Colors Preferences for the Editor/Debugger" on page 7-37), select Use editor font.
To print documents with different font characteristics than those specified for the Editor/Debugger, select Use custom font. After selecting this option, specify the font characteristics:

- Type, for example, Lucida Console
- Style, for example, Plain
- Size in points, for example, 12 points

## Improving M-File Performance - the Profiler

What Is Profiling? ..... 8-3
Using the Profiler ..... 8-4
The profile Function ..... 8-4
An Example Using the Profiler ..... 8-6
Viewing Profiler Results ..... 8-7
Viewing Profile Reports ..... 8-7
Profile Plot ..... 8-12
Saving Profile Reports ..... 8-13

One way to improve the performance of your M-files is to profile them. MATLAB provides an M-file profiler that lets you see how much computation time each line of an M-file uses.

This section on profiling covers the following topics:

- "What Is Profiling?" on page 8-3
- "Using the Profiler" on page 8-4, including "The profile F unction" and "An Example Using the Profiler"
- "Viewing Profiler Results" on page 8-7

There are numerous other techniques for improving the performance of your $M$-files. For a list of these types of functions, see Performance Tools and Techniques.

## What Is Profiling?

Profiling is a way to measure where a program spends its time. M easuring is a much better method than guessing where the most execution time is spent. You probably deal with obvious speed issues at design time and can then discover unanticipated effects through measurement. One key to effective coding is to create an original implementation that is as simple as possible and then use a profiler to identify bottlenecks if speed is an issue. Premature optimization often increases code complexity unnecessarily without providing a real gain in performance.

Use the profiler to identify functions that are consuming the most time, then determine why you are calling them and look for ways to minimize their use. It is often hel pful to decide whether the number of times a particular function is called is reasonable. Because programs often have several layers, your code may not explicitly call the most expensive functions. Rather, functions within your code may be calling other time-consuming functions that can be several layers down in the code. In this case it's important to determine which of your functions are responsible for such calls.

The profiler often helps to uncover problems that you can solve by:

- Avoiding unnecessary computation, which can arise from oversight.
- Changing your algorithm to avoid costly functions.
- Avoiding recomputation by storing results for future use.

When you reach the point where most of the time is spent on calls to a small number of built-in functions, you have probably optimized the code as much as you can expect.

## Using the Profiler

Use the profile function to generate and view statistics.
1 Start the profiler by typing profile on in the Command Window. Specify any options you want to use.

2 Execute your M-file.
The profiler counts how many seconds each line in the M-files use. The profiler works cumulatively, that is, adding to the count for each M-file you execute until you clear the statistics.

3 Use profile report to display the statistics gathered in an HTML-formatted report in your system's default Web browser.

## The profile Function

Here is a summary of the main forms of profile. For details about these and other options, type doc profile.

| Syntax | Option | Description |
| :--- | :--- | :--- |
| profile on |  | Starts the profiler, clearing previously recorded <br> statistics. |
|  | -detail level | Specifies the level of function to be profiled. |
| -history | Specifies that the exact sequence of function <br> calls is to be recorded. |  |
| profile off |  | Suspends the profiler. |
| profile report | basename | Suspends the profiler, generates a profile report <br> in HTML format, and displays the report in <br> your system's default Web browser. |
|  | Saves the report in the file basename in the <br> current directory. |  |

| Syntax | Option | Description (Continued) |
| :--- | :--- | :--- |
| profile plot |  | Suspends the profiler and displays in a figure <br> window a bar graph of the functions using the <br> most execution time. |
| profile resume | Restarts the profiler without clearing <br> previously recorded statistics. |  |
| profile clear | Clears the statistics recorded by the profiler. |  |
| s = profile('status' ) | Displays a structure containing the current <br> profiler status. |  |
| stats = profile('info' ) | Suspends the profiler and displays a structure <br> containing profiler results. |  |

Some people use profile simply to see the child functions; see also depfun for that purpose.

## An Example Using the Profiler

This example demonstrates how to run the profiler.
1 To start the profiler, type in the Command Window
profile on -detail builtin -history
The -detail builtin option instructs the profiler to gather statistics for built-in functions, in addition to the default M -functions, M -subfunctions, and MEX-functions.

The -history option instructs the profiler to track the exact sequence of entry and exit calls.

2 Execute an M-file. This example runs the Lotka-Volterra predator-prey population model. For more information about this model, type lotkademo to run a demonstration.
[t,y] = ode23('lotka',[0 2],[20;20]);
3 Generate the profile report and save the results to the file lotkaprof. profile report lotkaprof

This suspends the profiler, displays the profile report in your system's default Web browser, and saves the results. See "Viewing Profiler Results" on page 8-7 for more information.

4 Restart the profiler, without clearing the existing statistics.
profile resume
The profiler is now ready to continue gathering statistics for any more $M$-files you run. It will add these new statistics to those generated in the previous steps.

5 Stop the profiler when you are finished gathering statistics.
profile off

## Viewing Profiler Results

There are two main ways to view the profiler results:

- "Viewing Profile Reports" on page 8-7
- "Profile Plot" on page 8-12

To save results, see "Saving Profile Reports" on page 8-13.

## Viewing Profile Reports

To display profiler results, type
profile report
This suspends the profiler and produces three reports:

- "Summary Profile Report" on page 8-7
- "F unction Details Profile Report" on page 8-10
- "Function Call History Profile Report" on page 8-11

The summary report appears in your system's default Web browser. Use the links at the top of the report page to see the other reports.

## Summary Profile Report

The summary report presents statistics about the overall execution and provides summary statistics for each function called. Values reported include:

- Number of functions - The numbers of built-in functions, M-functions, and M-subfunctions are reported.
- Clock precision - The precision of the profiler's time measurement. When Time for a function is 0 , it is actually a positive value, but smaller than the profiler can detect given the clock precision.
- Time columns - The total time spent in a function, including all child functions called. Because the time for a function includes time spent on child functions, the times do not add up to the Total recorded time and the percentages add up to more than 100\%.
- Self time columns - The total time spent in a function, not including time for any child functions called. Adding the Self time values for all functions listed
equals the Total recorded time. The Self time percentages for all functions add up to approximately $100 \%$.

Note that the profiler itself uses some time, which is included in the profiler results.

Following is the summary report for theLotka-Volterra model described in "An Example Using the Profiler" on page 8-6.

## Function Details Profile Report

The function details report provides statistics for the parent and child functions of a function, and reports the line numbers on which the most time was spent. F ollowing is detail report for the lotka function, which is one of the functions called in "An Example Using the Profiler" on page 8-6.

## Function Call History Profile Report

The function call history displays the exact sequence of functions called. To view this report, you must have started the profiler using the - history option.

```
profile on -history
```

The profiler records up to 10,000 function entry and exit events. For more than 10,000 events, the profiler continues to record other profile statistics, but not the sequence of calls. Following is the history report generated from "An Example Using the Profiler" on page 8-6.

| \section*{就 MATLAB Profiler Report - Netscape <br> Eile Edit View Go Communicator Help <br> Summary \| Function Details \| Function Call History <br> MATLAB Profile Report: Function Call History} |
| :-- |

display

horzcat
horzcat
horzeat
vertcat
ode23 (D: \matlabr12\toolbox\matlab funfun \ode23
struct
nargin

## Profile Plot

To view a bar graph for the functions using the most execution time, type

```
profile plot
```

This suspends the profiler. The bar graph appears in a figure window. Following is the bar graph generated from "An Example Using the Profiler" on page 8-6.

## Saving Profile Reports

When you generate the profile report, use the option to save it. F or example, profile report basename
saves the profile report to the file basename in the current directory. Later you can view the saved results using a Web browser.

Another way to save results is with the info = profile function, which displays a structure containing the profiler results. Save this structure so that later you can generate and view the profile report using profreport (info).

## Example Using Structure of Profiler Results

The profiler results are stored in a structure that you can view or access. This example illustrates how you can view the results.

1 Run the profiler for code that computes the Lotka-Volterra predator-prey population model.

```
profile on -detail builtin -history
[t,y] = ode23('lotka',[0 2],[20;20]);
```

2 To view the structure containing profiler results, type
stats $=$ profile('info')
MATLAB returns
stats $=$
FunctionTable: [41x1 struct]
FunctionHistory: [2x826 double]
ClockPrecision: 0.0100
Name: 'MATLAB'
3 You can view and access the contents of the structure. For example, type stats.FunctionTable

```
MATLAB displays the FunctionTable structure.
ans =
41x1 struct array with fields:
    FunctionName
    FileName
    Type
    NumCalls
    TotalTime
    TotalRecursiveTime
    Children
    Parents
    ExecutedLines
```

4 Toview the contents of an element in the FunctionTable structure, type, for example,
stats.FunctionTable(2)

MATLAB returns the second element in the structure.
ans $=$
FunctionName: 'horzcat'
FileName:
Type: 'Builtin-function'
NumCalls: 43
TotalTime: 0.0100
TotalRecursiveTime: 0.0100
Children: [0x1 struct]
Parents: [2x1 struct]
ExecutedLines: [0x3 double]
5 Save the results.
save profstats

6 In a later session, to generate the profiler report using the saved results, type
load profstats
profreport(stats)
MATLAB displays the profile report.

## Interfacing with Source Control Systems

Process of Interfacing to an SCS ..... 9-3
Viewing or Selecting the Source Control System ..... 9-4
Function Alternative for Viewing the SCS ..... 9-5
Setting Up the Source Control System ..... 9-6
For SourceSafe Only - Mirroring MATLAB Hierarchy ..... 9-6
For ClearCase on UNIX Only - Set a View and
Check Out a Directory ..... 9-6
Checking Files into the Source Control System ..... 9-7
Function Alternative for Checking In Files ..... 9-8
Checking Files Out of the SCS ..... 9-9
Function Alternative for Checking Out Files ..... 9-10
Undoing the Check-Out ..... 9-10

If you use a source control system (SCS) to manage your files, you can check M-files and Simulink and Stateflow files into and out of the source control system from within MATLAB, Simulink, and Stateflow.

MATLAB, Simulink, and Stateflow do not perform source control functions, but only provide an interface to your own source control system. This means, for example, that you can open a file in the MATLAB Editor and modify it without checking it out. However, the file will remain read-only so that you cannot accidentally overwrite the source control version of the file.

Four popular source control systems are supported, as well as a custom option:

- ClearCase from Rational Software
- PVCS from Merant
- RCS
- Visual SourceSafe from Microsoft
- Custom option - Allows you to build your own interface if you use a different source control system

## Process of Interfacing to an SCS

You can interface to your source control system by using menus if you prefer a graphical user interface, or by using functions if you prefer to use the Command Window. There are some options you can perform using the functions that are not available with the menus - these are noted in the instructions.

Create M-files, Simulink files, or Stateflow files as you normally would and save the files. Then follow these steps to use MATLAB, Simulink, or Stateflow to interface with your source control system.

| Steps | Instructions |
| :--- | :--- |
| 1 <br> Select the source control system to <br> use. | See "Viewing or Selecting the <br> Source Control System" on <br> page 9-4. |
| 2Set up your source control system <br> to correctly include the files. This <br> is only required for some source <br> control systems. | "For SourceSafe Only - Mirroring <br> MATLAB Hierarchy" on page 9-6 |
| "For ClearCase on UNIX Only - <br> Check the files into the source <br> control system. Note that for some <br> source control systems, you must <br> check out the files before you can <br> check them in. | "Checking Files into the Source <br> Control System" on page 9-7 |
| 4Next time you want to modify the <br> files, open them in the MATLAB <br> Editor, Simulink, or Stateflow, and <br> check them out. | "Checking Files Out of the SCS" <br> on page 9-9 |
| 5Undo a check-out if you want the <br> files to remain checked in, without <br> any of the changes you made since <br> you checked them out. | "Undoing the Check-Out" on <br> page 9-10 |

## Viewing or Selecting the Source Control System

Specify the source control system for MATLAB to interface with:
1 From the MATLAB desktop, select Preferences from the File menu. Y ou can also select this from the Simulink or Stateflow model or library windows.

The Preferences dialog box opens.
2 Click the + for General and then select Source Control.
The currently selected system is shown. The default selection is None.

3 Select the system you want to use from the Source control system list.

4 For Visual SourceSafe only, supply your Username, Password, and the Database.

- Password is not required if SourceSafe does not require it.
- Database is the full path for the srcsafe.ini file associated with the SourceSafe database you want to use. F or example, D: \Applications $\backslash$ Microsoft SourceSafe $\backslash$ srcsafe.ini.

## 5 Click OK.

## Function Alternative for View ing the SCS

To view the currently selected system, type cmopts in the Command Window. MATLAB displays the current source control system.

## Setting Up the Source Control System

For ClearCase on UNIX and for SourceSafe, set up your source control system as described here.

## For SourceSafe Only - Mirroring MATLAB Hierarchy

If you use Visual SourceSafe, you must set up a project hierarchy in SourceSafe that mirrors the hierarchy of your MATLAB, Simulink, and Stateflow files. F or example, if you want to use the MATLAB Editor to interface to SourceSafe for the files in D: \matlabr12\mymfiles, configure a SourceSafe project as \$: \matlabr12\mymfiles.

In addition to setting up the hierarchy, you must supply your user name, password, and database in MATLAB general preferences. See "Viewing or Selecting the Source Control System" on page 9-4 for instructions.

## For ClearCase on UNIX Only - Set a View and Check Out a Directory

If you use ClearCase on a UNIX platform, do the following using ClearCase:
1 Set a view.
2 Check out the directory in which you want to save files, check files into, or check files out of.

You can now use the MATLAB, Simulink, or Stateflow interfaces to ClearCase to check files into and out of the directory you checked out in step 2.

## Checking Files into the Source Control System

After creating or editing a file in the MATLAB Editor, Simulink, or Stateflow, save it, and then check in the file by following these steps:

1 From the MATLAB Editor, select File ->Source Control ->Check In. Y ou can also select this from the Simulink or Stateflow model or library windows.

The Check in dialog box opens.

2 If you want to check in the file but keep it checked out so you can continue making changes, select Keep checked out.

3 If you have comments, type them in the Comments area.
Your comments will be submitted whether or not you select Keep checked out, y .

4 Click OK.

The file is checked into the source control system. If you did not save the file before checking it in, it is automatically saved when it is checked in.

If you did not keep the file checked out and you keep the file open, note that it is a read-only version.

## Function Alternative for Checking In Files

Use checkin to check files into the source control system. The files can be open or closed when you use checkin. The checkin function has this form.

```
checkin({'file1',...'filen'},'comments','string','option',...
'value')
```

For file, use the complete path. You must supply the comments argument and a comments string with checkin.

Use the option argument to:

- Check in a file and keep it checked out - set the lock option to on.
- Check in a file even though it has not changed since the previous check in set the force option to on.

The comments argument, and the lock and force options apply to all files checked in.

After checking in the file, if you did not keep it checked out and have it open, note that it is a read-only version.

## Example - Check in a File with Comments

To check in the file clock.m with a comment Adjustment for Y2K, type checkin('\matlabr12\mymfiles \clock.m', 'comments', 'Adjustment ... for Y2K')

For other examples, see the reference page for checkin.

## Checking Files Out of the SCS

To check files out of the source control system using MATLAB, follow these steps:

1 Open the M-file, Simulink file, or Stateflow file you want to check out. The file opens and the title bar indicates it is read-only.

2 From theMATLAB Editor, select File->Source Control ->Check Out. Y ou can also select this from the Simulink or Stateflow model or library windows.

The Check-Out dialog box opens.

3 Tocheck out the version that was most recently checked in, select Latest. To check out a specific version of the file, select Specific and type the version number in the field

When you check out the latest version, you can use the Lock option. To prevent others from checking out the file while you have it checked out, select Lock. To check out a read-only version of the file, uncheck Lock.

4 Click OK.
The file is checked out from the source control system and is available to you for editing.

## Function Alternative for Checking Out Files

Use checkout to check a file out of the source control system. You can check out multiplefiles at once and specify check-out options. The checkout function has this form.

```
checkout({'file1',...'filen'},'option','value')
```

For file, use the complete path.
Use the option argument to:

- Check out a read-only version of the file - set the lock option to off.
- Check out the file even if you already have it checked out - set the force option to on.
- Check out a specific revision of thefile - use the revision option, and assign the revision number to the value argument.

The options apply to all files checked out. The file can be open or closed when you use checkout.

Example - Check out a Specific Revision of a File
To check out the 1.1 revision of the file clock.m, type

```
checkout('\matlab\mymfiles\clock.m', 'revision', '1.1')
```

For other examples, see the reference page for checkout.

## Undoing the Check-Out

Y ou can undo the check-out for a file. The files remain checked in, without any of the changes you made since you checked them out. If you want to keep a local copy of your changes, use the Save As item from the File menu.

From the MATLAB Editor, select File ->Source Control ->Undo Check Out. You can also select this from the Simulink or Stateflow model or library windows.

## Function Alternative for Undoing a Check-Out

The undocheckout function has this form.
undocheckout(\{'file1',...'filen'\})
Use the complete path for file.
Example - Undo the Check-Out for Two Files. To undo the check-out for the files clock.m and calendar.m, type
undocheckout(\{'\matlab\mymfiles\clock.m',
'\matlab\mymfiles\calendar.m'\})

Notebook allows you to access MATLAB's numeric computation and visualization software from within a word processing environment (Microsoft Word). Using Notebook, you can create a document, called an M-book, that contains text, MATLAB commands, and the output from MATLAB commands.

You can think of an M-book as a record of an interactive MATLAB session annotated with text or as a document embedded with live MATLAB commands and output. Notebook is useful for creating electronic or printed records of MATLAB sessions, class notes, textbooks or technical reports.

This section provides information about:

- "Notebook Basics" on page 10-3
- "Defining MATLAB Commands as Input Cells" on page 10-8
- "Evaluating MATLAB Commands" on page 10-12
- "Printing and Formatting an M-Book" on page 10-18
- "Configuring Notebook" on page 10-24
- "Notebook Command Reference" on page 10-26.

## Notebook Basics

This section introduces basic Notebook capabilities, including:

- "Creating an M-Book" on page 10-3
- "Entering MATLAB Commands in an M-Book" on page 10-6
- "Protecting the Integrity of Y our Workspace" on page 10-6
- "Ensuring Data Consistency" on page 10-7

## Creating an M-Book

This section describes how to:

- Create an M-book from MATLAB
- Create an M-book while running Notebook
- Open an existing M-book
- Convert a Word document into an M-book

## Creating an M-Book from MATLAB

To create a new M-book from within MATLAB, type
notebook
at the prompt. If you are running Notebook for the first time, you may need to configure it. See "Configuring Notebook" on page 10-24 for more information.

Notebook starts Microsoft Word on your system and creates a new M-book, called Document1. Notebook adds the Notebook menu to the Word menu bar. Y ou use this menu, illustrated below, to access Notebook commands.

Note Notebook defines Microsoft Word macros that enable MATLAB to interpret the different types of cells that hold MATLAB commands and their output.

## Creating an M-Book While Running Notebook

With Notebook running, you can also create a new M-book by selecting New M-book from the Word File menu.

## 0 pening an Existing M-Book

You can also use the notebook command to open an existing M-book
notebook filename
where filename is the $M$-book you want to open, or you can simply double-click on an M-book file.

When you double-dick on an M-book, Microsoft Word opens the M-book and starts MATLAB, if it is not already running. Notebook adds the Notebook menu to the Word menu bar.

## Converting a Word Document to an M-Book

To convert a Word document to an M-book, follow these steps:
1 Create a new M-book.
2 From the Insert menu, select the File command.

3 Select the file you want to convert.
4 Click on the OK button.

## Entering MATLAB Commands in an M-Book

#### Abstract

Note A good way to learn how to use Notebook is to open the sample M-book, Readme. doc, and try out the various techniques described in this section. You can find this file in the \$MATLAB notebook $\backslash p c$ directory, where $\$$ MATLAB represents your installation directory.

You enter MATLAB commands in an M-book the same way you enter text in any other Word document. F or example, you can enter the following text in a Word document. The example uses text in Courier Font but you can use any font.

```
Here is a sample M-book.
```

```
a = magic(3)
```

To execute the MATLAB magic command in this document, you must:

- Define the command as an input cell
- Evaluate the input cell.

MATLAB displays the output of the command in the Word document in an output cell.

## Protecting the Integrity of Your Workspace

When you work on more than one $M$-book in a single word processing session, note that:

- E ach M-book uses the same "copy" of MATLAB.
- All M-books share the same workspace.

If you use the same variable names in more than one M-book, data used in one $M$-book can be affected by another $M$-book. Y ou can protect theintegrity of your
workspace by specifying the clear command as the first autoinit cell in the M-book.

## Ensuring Data Consistency

An M-book can be thought of as a sequential record of a MATLAB session. When executed in order, from the first MATLAB command to the last, the M -book accurately reflects the relationships among these commands.

If, however, you change an input cell or output cell as you refine your M-book, N otebook does not automatically recalculate input cells that depend on either the contents or the results of the changed cells. As a result, the M-book may contain inconsistent data.

When working on an M-book, you might find it useful to select the Evaluate M-book command periodically to ensure that your M-book data is consistent. You could also use calc zones to isolate related commands in a section of the M-book. Y ou can then use the Evaluate Calc Zone command to execute only those input cells contained in the calc zone.

## Defining MatLab Commands as Input Cells

To define a MATLAB command in a Word document as an input cell:
1 Type the command into the M-book as text. For example,
This is a sample M-book.
$\mathrm{a}=\operatorname{magic}(3)$
2 Position the cursor anywhere in the command and choose the Define Input Cell command from the Notebook menu or press Alt+D. If the command is embedded in a line of text, use the mouse to select it. Notebook defines the MATLAB command as an input cell.
This is a sample M-book.
[a = magic(3)]
Note how Notebook changes the character font of the text in the input cell to a bold, dark green color and encloses it within cell markers. Cell markers are bold, gray brackets. They differ from the brackets used to enclose matrices by their size and weight. For information about changing these default formats, see "M odifying Styles in the M-Book Template" on page 10-18.

For information about defining other types of input cells, see:

- "Defining Cell Groups" on page 10-8
- "Defining Autoinit Input Cells" on page 10-10
- "Defining Calc Zones" on page 10-10
- "Converting an Input Cell to Text" on page 10-11

For information about evaluating the input cells you define, see "Evaluating MATLAB Commands" on page 10-12.

## Defining Cell Groups

You can collect several input cells into a single input cell. This is called a cell group. Because all the output from a cell group appears in a single output cell that Notebook places immediately after the group, cell groups are useful when several MATLAB commands are needed to fully define a graphic.

F or example, if you define all the MATLAB commands that produce a graphic as a cell group and then evaluate the cell, Notebook generates a single graphic that includes all the graphic components defined in the commands. If instead you define all the MATLAB commands that generate the graphic as separate input cells, evaluating the cells generates multiple graphic output cells.
See "Evaluating Cell Groups" on page 10-13 for information about evaluating a cell group. F or information about undefining a cell group, see "U ngroup Cells Command" on page 10-32.

## Creating a Cell Group

To create a cell group:
1 Use the mouse to select the input cells that are to make up the group.
2 Select the Group Cells command from the Notebook menu or press Alt+G.
Notebook converts the selected cells into a cell group and replaces cell markers with a single pair that surrounds the group.

```
This is a sample cell group.
```

## [date

a $=$ magic(3) ]
Note the following:

- A cell group cannot contain text or output cells. If the selection includes output cells, Notebook deletes them.
- If the selection includes text, N otebook places the text after the cell group. However, if the text precedes the first input cell in the selection, Notebook leaves it where it is.
- If you select part or all of an output cell but not its input cell, Notebook includes the input cell in the cell group.

When you create a cell group, Notebook defines it as an input cell unless its first line is an autoinit cell, in which case Notebook defines the group as an autoinit cell.

## Defining Autoinit Input Cells

You can use autoi nit cells to specify MATLAB commands to be automatically evaluated each time an $M$-book is opened. This is a quick and easy way to initialize the workspace. Autoi nit cells aresimply input cells with the following additional characteristics:

- Notebook evaluates the autoinit cells when it opens the M-book.
- Notebook displays the commands in autoinit cells using dark blue characters.

Autoinit cells are otherwise identical to input cells.

## Creating an Autoinit Cell

You can create an autoinit cell in two ways:

- Enter the MATLAB command as text, then convert the command to an autoinit cell by selecting the Define Autol nit Cell command from the Notebook menu.
- If you already entered the MATLAB command as an input cell, you can convert the input cell to an autoinit cell. Either select the input cell or position the cursor in the cell, then select the Define Autolnit Cell command from the Notebook menu.

See "E valuating MATLAB Commands" on page 10-12 for information about evaluating autoinit cells.

## Defining Calc Zones

You can partition an M-book into self-contained sections, called calc zones. A calc zone is a contiguous block of text, input cells, and output cells. Notebook inserts Microsoft Word section breaks before and after the section to define the calc zone. The section break indicators include bold, gray brackets to distinguish them from standard Word section breaks.
You can use calc zones to prepare problem sets, making each problem a separate calc zone that can be created and tested on its own. An M-book can contain any number of calc zones.

Note Using calc zones does not affect the scope of the variables in an M-book. Variables used in one calc zone are accessible to all calc zones.

## Creating a Calc Zone

After you create the text and cells you want to include in the calc zone, you define the calc zone by following these steps:

1 Select the input cells and text to be included in the calc zone.
2 Choose the Define Calc Zone command from the Notebook menu.

Note You must select an input cell and its output cell in their entirety to include them in the calc zone.

See "E valuating a Calc Zone" on page 10-14 for information about evaluating a calc zone.

## Converting an Input Cell to Text

To convert an input cell (or an autoinit cell or a cell group) to text:
1 Select the input cell with the mouse or position the cursor in the input cell.
2 Select the Undefine Cells command from the Notebook menu or press Alt+U.

When Notebook converts the cell to text, it reformats the cell contents according to the Microsoft Word Normal style. For more information about M-book styles, see "M odifying Styles in the M-Book Template" on page 10-18. When you convert an input cell to text, N otebook al so converts the corresponding output cell to text.

## Evaluating MATLAB Commands

After you define a MATLAB command as an input cell, or as an autoinit cell, you can evaluate it in your M-book. Use the following steps to define and evaluate a MATLAB command:

1 Type the command into the M-book as text. For example,
This is a sample M-book
a = magic(3)
2 Position the cursor anywhere in the command and choose the Define Input Cell command from the Notebook menu or press Alt+D. If the command is embedded in a line of text, use the mouse to select it. Notebook defines the MATLAB command as an input cell. For example,

This is a sample M-book
[a = magic(3)]
3 Choose the Evaluate Cell command from the Notebook menu or press Ctrl+Enter. Y ou can specify the input cell to be evaluated by selecting it with the mouse, or placing the cursor in it.

Notebook evaluates the input cell and displays the results in a output cell immediately following the input cell. If there is already an output cell, Notebook replaces its contents, wherever it is in the M-book. For example,

This is a sample M-book.
[a = magic(3) ]
[a =

| 8 | 1 | 6 |
| :--- | :--- | :--- |
| 3 | 5 | 7 |
| 4 | 9 | 2 |

The text in the output cell is blue and is enclosed within cell markers. Cell markers are bold, gray brackets. They differ from the brackets used to enclose matrices by their size and weight. Error messages appear in red. For
information about changing these default formats, see "M odifying Styles in the M-Book Template" on page 10-18.

For more information about evaluating MATLAB commands in an M-book, see:

- "Evaluating Cell Groups" on page 10-13
- "Evaluating a Range of Input Cells" on page 10-14
- "Evaluating a Calc Zone" on page 10-14
- "Evaluating an Entire M-Book" on page 10-15
- "Using a Loop to Evaluate I nput Cells Repeatedly" on page 10-15.
- "Converting Output Cells to Text" on page 10-16
- "Deleting Output Cells" on page 10-17

## Evaluating Cell Groups

You evaluate a cell group the same way you evaluate an input cell (because a cell group is an input cell):

1 Position the cursor anywhere in the cell or in its output cell.
2 Choose the E valuate Cell command from the Notebook menu or press
Ctrl+E nter.

For information about creating a cell group, see "Defining Cell Groups" on page 10-8.

When MATLAB evaluates a cell group, the output for all commands in the group appears in a single output cell. By default, N otebook places the output cell immediately after the cell group the first time the cell group is evaluated. If you evaluate a cell group with an existing output cell, Notebook places the results in the output cell wherever it is located in the M-book.

## Note Text or numeric output always comes first, regardless of the order of the commands in the group.

The illustration shows a cell group and the figure created when you evaluate the cell group.

```
This is a sample M-book with a cell group.
t = 0:pi/100:2*pi;
y = sin(t);
plot(t,y) ]
```

## Evaluating a Range of Input Cells

To evaluate more than one MATLAB command contained in different but contiguous input cells:

1 Select the range of cells that includes the input cells you want to evaluate. Y ou can include text that surrounds input cells in your selection.

2 Choose the Evaluate Cell command from the Notebook menu or press Ctrl+Enter.

Notebook evaluates each input cell in the selection, inserting new output cells or replacing existing ones.

## Evaluating a Calc Zone

To evaluate a calc zone:
1 Position the cursor anywhere in the calc zone.

## 2 Select the E valuate Calc Zone command from the Notebook menu or press Alt+Enter.

For information about creating a calc zone, see "Defining Calc Zones" on page 10-10.

By default, N otebook places the output cell immediately after the calc zone the first time the calczone is evaluated. If you evaluatea calc zone with an existing output cell, N otebook places the results in the output cell wherever it is located in the M-book.

## Evaluating an Entire M-Book

To evaluate the entireM-book, either select the E valuate M-book command or press Alt+R.
Notebook begins at the top of the $M$-book regardless of the cursor position and evaluates each input cell in the M-book. As it evaluates the M-book, N otebook inserts new output cells or replaces existing output cells.

## Controlling Execution of Multiple Commands

When you evaluate an entire M-book, and an error occurs, evaluation continues. If you want to stop evaluation if an error occurs, follow this procedure:

1 Choose Notebook Options from the N otebook menu.
2 Click the Stop evaluating on error check box.

## Using a Loop to Evaluate Input Cells Repeatedly

To evaluate a sequence of MATLAB commands repeatedly:
1 Use the mouse to select the input cells, including any text or output cells located between them.

2 Choose the Evaluate Loop command or press Alt+L. Notebook displays the Evaluate Loop dialog box.

3 E nter the number of times you want MATLAB to evaluate the selected commands in the Stop After field, then click on the Start button. The label on the button changes to Stop. N otebook begins evaluating the commands and indicates the number of completed iterations in the Loop Count field.

You can increase or decrease the delay at the end of each iteration by clicking on the Slower or Faster button. Slower increases the delay. Faster decreases the delay.

To suspend evaluation of the commands, click on the Pause button. The label on the button changes to Resume. Click on the Resume button to continue evaluation.

To stop processing the commands, click on the Stop button. To close the Evaluate Loop dialog box, click on the Close button.

## Converting Output Cells to Text

You can convert an output cell to text using the Undefine Cells command. If the output is numeric or textual, Notebook removes the cell markers and converts the cell contents to text according to the Microsoft Word Normal style. If the output is graphical, Notebook removes the cell markers and dissociates the graphic from its input cell, but does not alter its contents.

Note Undefining an output cell does not affect the associated input cell.

To undefine an output cell:
1 Select the output cell you want to undefine.

2 Choose the Undefine Cells command from the Notebook menu or press Alt+U.

## Deleting Output Cells

To delete output cells:
1 Select an output cell, using the mouse, or place the cursor in the output cell.
2 Choosethe Purge Output Cells command from the N otebook menu or press Alt+P.

If you select a range of input cells, each with output cells, Notebook deletes all the associated output cells.

## Printing and Formatting an M-Book

This section describes:

- "Printing an M-Book" on page 10-18
- "Modifying Styles in the M-Book Template" on page 10-18
- "Choosing Loose or Compact Format" on page 10-19
- "Controlling Numeric Output F ormat" on page 10-20
- "Controlling Graphic Output" on page 10-20

## Printing an M-Book

You can print all or part of an M-book by selecting the Print command from the File menu. Word follows these rules when printing M-book cells and graphics:

- Cell markers are not printed.
- Input cells, autoinit cells, and output cells (including error messages) are printed according to their defined styles. If you prefer to print these cells using black typeinstead of col ors or shades of gray, you can modify thestyles.

## Modifying Styles in the M-Book Template

You can control the appearance of the text in your M-book by modifying the predefined styles stored in the M-book template. These styles control the appearance of text and cells. By default, M-books use the Word Normal style for all other text.

For example, if you print an M-book on a col or printer, input cells appear dark green, output and autoinit cells appear dark blue, and error messages appear red. If you print the M-book on a grayscale printer, these cells appear as shades of gray. To print these cells using black type, you need to modify the col or of the Input, Output, Autol nit, and Error styles in the M-book template.
The table below describes the default styles used by Notebook. If you modify styles, you can use the information in the tables bel ow to help you return the styles to their original settings. For general information about using styles in Word documents, see the Word documentation.

| Style | Font | Size | Weight | Color |
| :--- | :--- | :--- | :--- | :--- |
| Normal | Times New Roman | 10 points |  | Black |
| Autol nit | Courier New | 10 points | Bold | Dark Blue |
| Error | Courier New | 10 points | Bold | Red |
| Input | Courier New | 10 points | Bold | Dark Green |
| Output | Courier New | 10 points |  | Blue |

When you change a style, Word applies the change to all characters in the M-book that use that style and gives you the option to change the template. Be cautious about making changes to the template. If you choose to apply the changes to the template, you will affect all new M-books you create using the template. See the Word documentation for more information.

## Choosing Loose or Compact Format

You can specify whether a blank line appears between the input and output cells by selecting Loose or Compact format.

1 Click on the Notebook menu and select Notebook Options.
2 In the Notebook Options dialog box, select either the Loose or Compact check box. Loose format adds an empty line. Compact format does not.

```
C Loose
C Compact
```

## 3 Click OK.

Note Changes you make using the Notebook Options dialog box take effect for output generated after you click on the OK button. To affect existing input or output cells, you must re-evaluate the cells.

## Controlling Numeric Output Format

To change how Notebook displays numeric output:
1 Click on the Notebook menu and select Notebook Options.
2 In the Notebook Options dialog box, click on the Numeric Format menu to view a list of available formats. These settings correspond to the choices available with the MATLAB format command. The figure below shows the available numeric formats.

3 Click OK.

Note Changes you make using the Notebook Options dialog box take effect for output generated after you click on the OK button. To affect existing input or output cells, you must re-evaluate the cells.

## Controlling Graphic Output

This section describes how to control several aspects of the graphic output produced by MATLAB commands in an M-book, including:

- "Embedding Graphic Output in the M-Book" on page 10-21
- "Suppressing Graphic Output for Individual Input Cells" on page 10-21
- "Sizing Graphic Output" on page 10-22
- "Cropping Graphic Output" on page 10-22
- "Adding White Space Around Graphic Output" on page 10-22
- "Specifying Color Mode" on page 10-23

## Embedding Graphic Output in the M-Book

By default, graphic output is embedded in an $M$-book. To display graphic output in a separate figure window:

1 Click on the Notebook menu and choose Notebook Options.
2 In the Notebook Options dialog box, deselect the Embed Figures in M-book check box.

```
Figure Options
/V}\mathrm{ Embed Figures in M-book
```

## 3 Click OK.

Note Embedded figures do not include Handle Graphics ${ }^{\circledR}$ objects generated by the uicontrol and uimenu functions.

Notebook determines whether to embed a figure in the M-book by examining the value of the figure object's Visible property. If the value of the property is off, N otebook embeds the figure. If the value of this property is on, all graphic output is directed to the current figure window.

## Suppressing Graphic Output for Individual Input Cells

If an input or autoinit cell generates figure output that you want to suppress:
1 Place the cursor in the input cell.
2 Click on the Notebook menu and choose the Toggle Graph Output for Cell command.

Notebook suppresses graphic output from the cell, inserting the string (no graph) after the input cell.

To allow graphic output for a cell, repeat the same procedure. Notebook allows graphic output from the cell and removes the (no graph) marker.

Note The Toggle Graph Output for Cell command overrides the Embed Figures in M-book option, if that option is set.

## Sizing Graphic Output

To set the default size of embedded graphics in an M-book:
1 Click on the Notebook menu and choose Notebook Options.
2 In the Notebook Options dialog box, use the Height and Width fields to set the size of graphics generated by the M-book.

3 Click OK.

Note Changes you make using the Notebook Options dialog box take effect for graphic output generated after you click on the OK button. To affect existing input or output cells, you must re-evaluate the cells.

You change the size of an existing embedded figure by selecting the figure, clicking the left mouse button anywhere in the figure, and dragging the resize handles of the figure. If you resize an embedded figure using its handles and then regenerate the figure, its size reverts to its original size.

## Cropping Graphic Output

To crop an embedded figure to cut off areas you do not want to show:
1 Select the graphic, by clicking the left mouse button anywhere in the figure.
2 Hold down the Shift key.
3 Drag a sizing handle toward the center of the graphic.

## Adding White Space Around Graphic 0 utput

You can add whitespace around an embedded figure by moving the boundaries of a graphic outward. Select the graphic, then hold down the Shift key and drag a sizing handle away from the graphic.

## Specifying Color Mode

If you print graphic output that includes surfaces or patches, the output uses 16 -col or mode by default. To use 256 -col or mode:

1 Click on the Notebook menu and choose Notebook Options.
2 Deselect the Use 16-Color Figures check box in the Notebook Options dialog box.

## Figure Options

V Embed Figures in M-book
■ Use 16-Color Figures

## 3 Click OK.

Note Changes you make using the Notebook Options dialog box take effect for graphic output generated after you click on the OK button. To affect existing input or output cells, you must re-evaluate the cells.

## Configuring Notebook

After you install Notebook, you must configure it. (N otebook is installed as part of the MATLAB installation process. See the MATLAB Installation Guidefor PC for more information.)

To configure Notebook, type

```
notebook -setup
```

in the MATLAB command window. N otebook prompts you to specify which version of Microsoft Word you are using.

Choose your version of Microsoft Word:
[1] Microsoft Word for Windows 95 (Version 7.0)
[2] Microsoft Word 97
[3] Microsoft Word 2000
[4] Exit, making no changes
Microsoft Word Version: 2
Next Notebook prompts you to specify the location of the Microsoft Word executable (winword.exe) on your system.

You will be presented with a dialog box. Please use it to select your copy of the Microsoft Word 97 executable (winword.exe). Press any key to continue...

Use this dialog box to specify the location of your Microsoft Word program.

When you click Open, N otebook prompts you to specify the name of a Microsoft Word template file.

You will be presented with a dialog box. Please use it to select a Microsoft Word template (.dot) file in one of your Microsoft Word template directories. We suggest that you specify your normal.dot file.
Press any key to continue...
Use this dialog box to specify the name of your Microsoft Word template file.

When configuration is completed, Notebook outputs this message.
Notebook setup is complete.

## Notebook Command Reference

This section provides reference information about each of the N otebook commands, listed al phabetically. To use these commands, select them from the Notebook menu.

- "Bring MATLAB to Front Command" on page 10-26
- "Define Autoinit Cell Command" on page 10-26
- "Define Calc Zone Command" on page 10-27
- "Define Input Cell Command" on page 10-27
- "Evaluate Calc Zone Command" on page 10-28
- "Evaluate Cell Command" on page 10-28
- "Evaluate Loop Command" on page 10-29
- "Evaluate M-Book Command" on page 10-30
- "Group Cells Command" on page 10-30
- "Hide Cell Markers Command" on page 10-31
- "Notebook Options Command" on page 10-31
- "Purge Output Cells Command" on page 10-31
- "Toggle Graph Output for Cell Command" on page 10-31
- "Undefine Cells Command" on page 10-32
- "Ungroup Cells Command" on page 10-32

## Bring MATLAB to Front Command

The Bring MATLAB to Front command brings the MATLAB command window to the foreground.

## Define Autoinit Cell Command

The Define Autolnit Cell command creates an autoinit cell by converting the current paragraph, selected text, or input cell. An autoinit cell is an input cell that is automatically evaluated whenever you open an M-book.

## Action

If you select this command while the cursor is in a paragraph of text, N otebook converts the entire paragraph to an autoinit cell. If you select this command
while text is selected, Notebook converts the text to an autoinit cell. If you select this command while the cursor is in an input cell, Notebook converts the input cell to an autoinit cell.

## Format

Notebook formats the autoinit cell using the Autol nit style, defined as bold, dark blue, 10-point Courier New.

## See Also

For more information about autoinit cells, see "Defining Autoinit Input Cells" on page 10-10.

## Define Calc Zone Command

The Define Calc Zone command defines the selected text, input cells, and output cells as a calc zone. A calc zone is a contiguous block of related text, input cells, and output cells that describes a specific operation or problem.

## Action

Notebook defines a calc zone as a Word document section, placing section breaks before and after the calc zone. However, Word does not display section breaks at the beginning or end of a document.

## See Also

For information about evaluating calc zones, see "Evaluating a Calc Zone" on page 10-14. F or more information about document sections, see the Microsoft Word documentation.

## Define Input Cell Command

The Define Input Cell command creates an input cell by converting the current paragraph, selected text, or autoinit cell. An input cell contains a MATLAB command.

## Action

If you select this command while the cursor is in a paragraph of text, Notebook converts the entire paragraph to an input cell. I f you select this command while text is selected, Notebook converts the text to an input cell.

If you select this command while the cursor is in an autoinit cell, Notebook converts the autoinit cell to an input cell.

## Format

Notebook encl oses the text in cell markers and formats the cell using the Input style, defined as bold, dark green, 10-point Courier New.

## See Also

For more information about creating input cells, see "Defining MATLAB Commands as Input Cells" on page 10-8. For information about evaluating input cells, see "Evaluating MATLAB Commands" on page 10-12.

## Evaluate Calc Zone Command

The Evaluate Calc Zone command sends the input cells in the current calc zone to MATLAB to be evaluated. A calc zone is a contiguous block of related text, input cells, and output cells that describes a specific operation or problem.

The current calc zone is the Word section that contains the cursor.

## Action

As Notebook evaluates each input cell, it generates an output cell. When you evaluate an input cell for which there is no output cell, Notebook places the output cell immediately after the input cell that generated it. If you evaluate an input cell for which there is an output cell, Notebook replaces the results in the output cell wherever it is in the M-book.

## See Also

For more information, see "Evaluating a Calc Zone" on page 10-14.

## Evaluate Cell Command

The Evaluate Cell command sends the current input cell or cell group to MATLAB to be evaluated. An input cell contains a MATLAB command. A cell group is a single, multiline input cell that contains more than one MATLAB command. Notebook displays the output or an error message in an output cell.

## Action

If you evaluate an input cell for which there is no output cell, N otebook places the output cell immediately after the input cell that generated it. If you evaluate an input cell for which there is an output cell, Notebook replaces the results in the output cell wherever it is in the M-book. If you evaluate a cell group, all output for the cell appears in a single output cell.

An input cell or cell group is the current input cell or cell group if:

- The cursor is in the input cell or cell group.
- The cursor is at the end of the line that contains the closing cell marker for the input cell or cell group.
- The cursor is in the output cell for the input cell or cell group.
- The input cell or cell group is selected.

Note Evaluating a cell that involves a lengthy operation may cause a time-out. If this happens, Word displays a time-out message and asks whether you want to continue waiting for a response or terminate the request. If you choose to continue, Word resets the time-out value and continues waiting for a response. Word sets the time-out value; you cannot change it.

## See Also

For more information, see "Evaluating MATLAB Commands" on page 10-12. For information about evaluating the entire M-book, see "Evaluating an Entire M-Book" on page 10-15.

## Evaluate Loop Command

The Evaluate Loop command evaluates the selected input cells repeatedly.
For more information, see "Using a Loop to Evaluate Input Cells Repeatedly" on page 10-15.

## Evaluate M-Book Command

The Evaluate M-book command evaluates the entire M-book, sending all input cells to MATLAB to be evaluated. N otebook begins at the top of the M -book regardless of the cursor position.

## Action

As Notebook evaluates each input cell, it generates an output cell. When you evaluate an input cell for which there is no output cell, Notebook places the output cell immediately after the input cell that generated it. If you evaluate an input cell for which there is an output cell, N otebook replaces the results in the output cell wherever it is in the M-book.

## See Also

For more information, see "Evaluating an Entire M-Book" on page 10-15.

## Group Cells Command

The Group Cells command converts the input cells in the selection into a single multiline input cell called a cell group. You evaluate a cell group using the Evaluate Cell command. When you evaluate a cell group, all of its output follows the group and appears in a single output cell.

## Action

If you include text in the selection, N otebook moves it after the cell group. However, if text precedes the first input cell in the group, the text will remain before the group.
If you include output cells in the selection, N otebook deletes them. If you select all or part of an output cell before selecting this command, Notebook includes its input cell in the cell group.

If the first line in the cell group is an autoinit cell, the entire group acts as a sequence of autoinit cells. Otherwise, the group acts as a sequence of input cells.Y ou can convert an entire cell group to an autoinit cell with the Define Autolnit Cell command.

## See Also

For more information, see "Defining Cell Groups" on page 10-8. For information about converting a cell group to individual input cells, see the description of the "Ungroup Cells Command" on page 10-32.

## Hide Cell Markers Command

The Hide Cell Markers command hides cell markers in the M-book.
When you select this command, it changes to Show Cell Markers.

Note Notebook does not print cell markers whether you choose to hide them or show on the screen.

## Notebook Options Command

The Notebook Options command allows you to examine and modify display options for numeric and graphic output.

## See Also

See "Printing and Formatting an M-Book" on page 10-18 for more information.

## Purge Output Cells Command

The Purge Output Cells command deletes all output cells from the current selection.

## See Also

For more information, see "Deleting Output Cells" on page 10-17.

## Toggle Graph Output for Cell Command

The Toggle Graph Output for Cell command suppresses or allows graphic output from an input cell.

If an input or autoinit cell generates figure output that you want to suppress, place the cursor in the input cell and choose this command. The string (no
graph) will be placed after the input cell to indicate that graph output for that cell will be suppressed.

To allow graphic output for that cell, place the cursor inside the input cell and choose Toggle Graph Output for Cell again. The (no graph) marker will be removed. This command overrides the Embed Graphic Output in the M-Book option, if that option is set in the Notebook Options dialog.

## See Also

See "E mbedding Graphic Output in the M-Book" on page 10-21 and "Suppressing Graphic Output for Individual Input Cells" on page 10-21 for more information.

## Undefine Cells Command

The Undefine Cells command converts the selected cells totext. If no cells are selected but the cursor is in a cell, Notebook undefines that cell. Notebook removes the cell markers and reformats the cell according to the Normal style.

If you undefine an input cell, N otebook automatically undefines its output cell. However, if you undefine an output cell, Notebook does not undefine its input cell. If you undefine an output cell containing an embedded graphic, the graphic remains in the $M$-book but is no longer associated with an input cell.

## See Also

For information about the Normal style, see "M odifying Styles in the M-Book Template" on page 10-18. F or information about deleting output cells, see the description of the "Purge Output Cells Command" on page 10-31.

## Ungroup Cells Command

The Ungroup Cells command converts the current cell group into a sequence of individual input cells or autoinit cells. If the cell group is an input cell, Notebook converts the cell group to input cells. If the cell group is an autoinit cell, Notebook converts the cell group to autoinit cells. Notebook deletes the output cell for the cell group.

A cell group is the current cell group if:

- The cursor is in the cell group.
- The cursor is at the end of a line that contains the closing cell marker for the cell group.
- The cursor is in the output cell for the cell group.
- The cell group is selected.

## See Also

For information about creating cell groups, see the description of the "Defining Cell Groups" on page 10-8.

10 Using N otebook

## Mathematics

MATLAB provides many functions for performing mathematical operations and analyzing data. The following list summarizes the contents of this collection:

- Matrices and Linear Algebra - describes matrix creation and matrix operations that are directly supported by MATLAB. Topics covered include matrix arithmetic, linear equations, eigenvalues, singular values, and matrix factorizations.
- Polynomials and Interpolation - describes functions for standard polynomial operations such as polynomial roots, evaluation, and differentiation. Additional topics covered include curve fitting and partial fraction expansion.
- Data Analysis and Statistics - describes how to organize arrays for data analysis, how to use simple descriptive statistics functions, and how to perform data pre-processing tasks in MATLAB. Additional topics covered include regression, curve fitting, data filtering, and fast Fourier transforms (FFTs).
- Function Functions - describes MATLAB functions that work with mathematical functions instead of numeric arrays. These function functions include plotting, optimization, zero finding, and numerical integration (quadrature).
- Differential Equations - describes the solution, in MATLAB, of initial value problems for ordinary differential equations (ODEs) and differential-algebraic equations (DAEs), and the solution of boundary value problems for ODEs. It also describes the solution of initial-boundary value problems for systems of parabolic and elliptic partial differential equations (PDEs). Topics covered include representing problems in MATLAB, solver syntax, and using integration parameters.
- Sparse Matrices - describes how to createsparse matrices in MATLAB, and how to use them in both specialized and general mathematical operations.

MATLAB supports many matrix operations that are commonly used in linear algebra, including matrix arithmetic, linear equations, eigenvalues, singular values, and matrix factorizations. MATLAB enables you to work with entire matrices quickly and easily.

This chapter describes basic matrix operations in MATLAB and explains their use in solving problems. It includes:

## Function Summary

Summarizes the MATLAB linear algebra functions

## Matrices in MATLAB

Explains the use of matrices and basic matrix operations in MATLAB

## Solving Linear Systems of Equations

Discusses the solution of simultaneous linear equations in MATLAB, including square systems, overdetermined systems, and underdetermined systems

## Inverses and Determinants

Explains the usein MATLAB of inverses, determinants, and pseudoinverses in the solution of systems of linear equations

## Cholesky, LU, and QR Factorizations

Discusses the solution in MATLAB of systems of linear equations that involve triangular matrices, using Cholesky factorization, Gaussian elimination, and orthogonalization

## Matrix Powers and Exponentials

Explains the use of MATLAB notation to obtain various matrix powers and exponentials

## Eigenvalues

Explains eigenvalues and describes eigenvalue decomposition in MATLAB

## Singular Value Decomposition

Describes singular value decomposition of a rectangular matrix in MATLAB

## Function Summary

The linear algebra functions are located in the MATLAB matfun directory.

| Category | Function | Description |
| :---: | :---: | :---: |
| Matrix analysis | norm | Matrix or vector norm. |
|  | normest | Estimate the matrix 2-norm. |
|  | rank | Matrix rank. |
|  | det | Determinant. |
|  | trace | Sum of diagonal elements. |
|  | null | Null space. |
|  | orth | Orthogonalization. |
|  | rref | Reduced row echelon form. |
|  | subspace | Angle between two subspaces. |
| Linear equations | / and / | Linear equation solution. |
|  | inv | Matrix inverse. |
|  | cond | Condition number for inversion. |
|  | condest | 1-norm condition number estimate. |
|  | chol | Cholesky factorization. |
|  | cholinc | Incomplete Cholesky factorization. |
|  | lu | LU factorization. |
|  | luinc | Incomplete LU factorization. |
|  | qr | Orthogonal-triangular decomposition. |
|  | lsqnonneg | Nonnegative least-squares. |

| Function Summary | (Continued) |  |
| :--- | :--- | :--- |
| Category | Function | Description |
|  | pinv | Pseudoinverse. |
| Eigenvalues and <br> singular values | lscov | Least squares with known covariance. |
|  | svd | Eigenvalues and eigenvectors. |
|  | eigs | A few eigenvalues. |
|  | svds | A few singular values. |
|  | poly | Characteristic polynomial. |
|  | polyeig | Polynomial eigenvalue problem. |
|  | condeig | Condition number for eigenvalues. |
|  | hess | Hessenberg form. |
|  | qz | QZ factorization. |
| Matrix functions | schur | Schur decomposition. |
|  | logm | Matrix exponential. |
|  | sqrtm | Matrix logarithm. |
|  | funm | Evaluate general matrix function. |

## Matrices in MATLAB

A matrix is a two-dimensional array of real or complex numbers. Linear algebra defines many matrix operations that are directly supported by MATLAB. Linear algebra includes matrix arithmetic, linear equations, eigenvalues, singular values, and matrix factorizations.

This section describes these matrix operations:

- Creation
- Addition and subtraction
- Vector products
- Matrix multiplication

It also describes the MATLAB functions you use to produce:

- An identity matrix
- The Knonecker Tensor product of two matrices
- Vector and matrix norms

## Creation

Informally, the terms matrix and array are often used interchangeably. More precisely, a matrix is a two-dimensional rectangular array of real or complex numbers that represents a linear transformation. The linear al gebraic operations defined on matrices have found applications in a wide variety of technical fields. (The optional Symbolic Math Tool box extends MATLAB's capabilities to operations on various types of nonnumeric matrices.)
MATLAB has dozens of functions that create different kinds of matrices. Two of them can be used to create a pair of 3-by-3 example matrices for use throughout this chapter. The first example is symmetric.

```
A = pascal(3)
A =
\begin{tabular}{lll}
1 & 1 & 1 \\
1 & 2 & 3 \\
1 & 3 & 6
\end{tabular}
```

The second example is not symmetric.

```
\(B=\operatorname{magic}(3)\)
\(B=\)
```

816
$\begin{array}{lll}3 & 5 & 7\end{array}$
$4 \quad 9 \quad 2$

Another example is a 3-by-2 rectangular matrix of random integers.

```
C = fix(10*rand(3,2))
C =
            9 4
            2
            6
```

A column vector is an m-by-1 matrix, a row vector is a 1-by-n matrix and a scalar is a 1-by-1 matrix. The statements

```
u = [3; 1; 4]
    v = [2 0 -1]
    s = 7
```

produce a column vector, a row vector, and a scalar.
u =
3
1
4
v =
$2 \quad 0 \quad-1$
s =
7

## Addition and Subtraction

Addition and subtraction of matrices is defined just as it is for arrays, element-by-element. Adding A to B and then subtracting A from the result recovers $B$.

```
X = A + B
X =
        9 2 7
        4 7 10
        5 12 8
Y = X -A
Y =
    8 1 6
    3 5
    4 9 2
```

Addition and subtraction require both matrices to have the same dimension, or one of them be a scalar. If the dimensions are incompatible, an error results.

```
X = A + C
Error using ==> +
Matrix dimensions must agree.
w = v + s
w =
    9 7 7 6
```

## Vector Productsand Transpose

A row vector and a column vector of the same length can be multiplied in either order. The result is either a scalar, the inner product, or a matrix, the outer product.

$$
\begin{aligned}
& x=v * u \\
& x= \\
& 2
\end{aligned}
$$

$$
\begin{array}{lll}
X=u * v \\
X= & \\
& & \\
& & \\
2 & 0 & -3 \\
8 & 0 & -1 \\
8 & 0 & -4
\end{array}
$$

For real matrices, the transposeoperation interchanges $\mathrm{a}_{\mathrm{ij}}$ and $\mathrm{a}_{\mathrm{j} i}$. MATLAB uses the apostrophe (or single quote) to denote transpose. Our example matrix $A$ is symmetric, so $A^{\prime}$ is equal to $A$. But $B$ is not symmetric.

```
\(X=B^{\prime}\)
X =
    \(8 \quad 3 \quad 4\)
    \(1 \quad 5 \quad 9\)
    \(\begin{array}{lll}6 & 7 & 2\end{array}\)
```

Transposition turns a row vector into a column vector.

```
x = v'
x =
```

    2
    0
    -1

If $x$ and $y$ are both real column vectors, the product $x * y$ is not defined, but the two products

```
x'*y
```

and

$$
y^{\prime *} x
$$

are the same scalar. This quantity is used so frequently, it has three different names: inner product, scalar product, or dot product.

For a complex vector or matrix, z, the quantity z ' denotes the complex conjugate transpose, where the sign of the complex part of each element is reversed. The unconjugated complex transpose, where the complex part of each element retains its sign, is denoted by z. '. So if

```
    z = [1+2i 3+4i]
then z' is
    1-2i
    3-4i
while z.' is
    1+2i
    3+4i
```

For complex vectors, the two scalar products $x^{\prime}$ *y and $y^{\prime}$ *x are complex conjugates of each other and the scalar product $x^{\prime}{ }^{*} x$ of a complex vector with itself is real.

## Matrix Multiplication

Multiplication of matrices is defined in a way that reflects composition of the underlying linear transformations and allows compact representation of systems of simultaneous linear equations. The matrix product $C=A B$ is defined when the column dimension of $A$ is equal to the row dimension of $B$, or when one of them is a scalar. If $A$ is $m-b y-p$ and $B$ is $p-b y-n$, their product $C$ is $m$-by-n. The product can actually be defined using MATLAB for loops, colon notation, and vector dot products.

```
for i = 1:m
    for j = 1:n
        C(i,j) = A(i,:)*B(:,j);
    end
end
```

MATLAB uses a single asterisk to denote matrix multiplication. The next two examples illustrate the fact that matrix multiplication is not commutative; $A B$ is usually not equal to $B A$.

```
X = A*B
X =
    15 15 15
    26 38 26
    41 70 39
```

$$
\begin{aligned}
& Y=B * A \\
& Y= \\
& \\
& Y
\end{aligned} \begin{array}{lll} 
\\
15 & 28 & 47 \\
15 & 34 & 60 \\
15 & 28 & 43
\end{array}
$$

A matrix can be multiplied on the right by a column vector and on the left by a row vector.

$$
\begin{aligned}
& x=A^{*} u \\
& x=
\end{aligned}
$$

8
17
$\mathrm{y}=\mathrm{v} * \mathrm{~B}$
$y=$
$\begin{array}{lll}12 & -7 & 10\end{array}$
Rectangular matrix multiplications must satisfy the dimension compatibility conditions.

$$
X=A * C
$$

$\mathrm{X}=$
$17 \quad 19$
$31 \quad 41$
$51 \quad 70$
$Y=C * A$

Error using ==> *
Inner matrix dimensions must agree.
Anything can be multiplied by a scalar.

```
w = s*v
```

## The Identity Matrix

Generally accepted mathematical notation uses the capital letter I to denote identity matrices, matrices of various sizes with ones on the main diagonal and zeros elsewhere. These matrices have the property that AI = A and IA = A whenever the dimensions are compatible. The original version of MATLAB could not use I for this purpose because it did not distinguish between upper and lowercase letters and i already served double duty as a subscript and as the complex unit. So an E nglish Ianguage pun was introduced. The function

```
eye(m,n)
```

returns an m-by-n rectangular identity matrix and eye ( n ) returns an $n$-by- n square identity matrix.

## The Kronecker Tensor Product

The K ronecker product, kron ( $\mathrm{X}, \mathrm{Y}$ ), of two matrices is the larger matrix formed from all possible products of the elements of $X$ with those of $Y$. If $X$ is $m$-by-n and $Y$ is $p-b y-q$, then $\operatorname{kron}(X, Y)$ is $m p-b y-n q$. The elements are arranged in the order

```
[X(1,1)*Y X(1,2)*Y . . . X(1,n)*Y
X(m,1)*Y X(m,2)*Y . . . X(m,n)*Y]
```

The Kronecker product is often used with matrices of zeros and ones to build up repeated copies of small matrices. For example, if $x$ is the 2 -by- 2 matrix

```
X =
    1 2
    3 4
```

and $I=$ eye $(2,2)$ is the 2-by-2 identity matrix, then the two matrices

```
kron(X, I)
```

and

```
kron(I,X)
```

are

| 1 | 0 | 2 | 0 |
| :--- | :--- | :--- | :--- |
| 0 | 1 | 0 | 2 |
| 3 | 0 | 4 | 0 |
| 0 | 3 | 0 | 4 |

and

| 1 | 2 | 0 | 0 |
| :--- | :--- | :--- | :--- |
| 3 | 4 | 0 | 0 |
| 0 | 0 | 1 | 2 |
| 0 | 0 | 3 | 4 |

## Vector and Matrix Norms

The $p$-norm of a vector $x$

$$
\|x\|_{p}=\left(\sum\left|x_{i}\right|^{p}\right)^{1 / p}
$$

is computed by norm ( $x, p$ ). This is defined by any value of $p>1$, but the most common values of $p$ are 1,2 , and $\infty$. The default value is $p=2$, which corresponds to E uclidean length.

```
[norm(v,1) norm(v) norm(v,inf)]
ans =
    3.0000 2.2361 2.0000
```

The p-norm of a matrix $A$,

$$
\|A\|_{p}=\max _{x} \frac{\|A x\|_{p}}{\|x\|_{p}}
$$

can be computed for $p=1,2$, and $\infty$ by norm $(A, p)$. Again, the default value is $p=2$.

```
    [norm(C,1) norm(C) norm(C,inf)]
```

    ans =
        \(19.0000 \quad 14.8015 \quad 13.0000\)
    
## Solving Linear Systems of Equations

This section describes:

- The general solution of systems of linear equations
- The solution of square systems
- The solution of overdetermined systems
- The solution of underdetermined systems

## Overview

One of the most important problems in technical computing is the solution of simultaneous linear equations. In matrix notation, this problem can be stated as follows.

Given two matrices $A$ and $B$, does there exist a unique matrix $X$ so that $A X=B$ or $\mathrm{XA}=\mathrm{B}$ ?

It is instructive to consider a 1-by-1 example.
Does the equation

$$
7 x=21
$$

have a unique solution?
The answer, of course, is yes. The equation has the unique solution $x=3$. The solution is easily obtained by division.

$$
x=21 / 7=3
$$

The solution is not ordinarily obtained by computing the inverse of 7 , that is $7^{-1}=0.142857 \ldots$, and then multiplying $7^{-1}$ by 21 . This would be more work and, if $7^{-1}$ is represented to a finite number of digits, less accurate. Similar considerations apply to sets of linear equations with more than one unknown; MATLAB solves such equations without computing the inverse of the matrix.

Although it is not standard mathematical notation, MATLAB uses the division terminology familiar in the scalar case to describe the solution of a general system of simultaneous equations. The two division symbols, slash, /, and
backslash, <br>, are used for the two situations where the unknown matrix appears on the left or right of the coefficient matrix.
$X=A \backslash B \quad$ Denotes the solution to the matrix equation $A X=B$.
$X=B / A \quad$ Denotes the solution to the matrix equation $X A=B$.
You can think of "dividing" both sides of the equation $A X=B$ or $X A=B$ by $A$. The coefficient matrix A is always in the "denominator."

The dimension compatibility conditions for $\mathrm{X}=\mathrm{A} \backslash \mathrm{B}$ require the two matrices A and $B$ to have the same number of rows. The solution $X$ then has the same number of columns as $B$ and its row dimension is equal to the column dimension of $A$. For $X=B / A$, the roles of rows and columns are interchanged.

In practice, linear equations of the form $A X=B$ occur more frequently than those of the form $\mathrm{XA}=\mathrm{B}$. Consequently, backslash is used far more frequently than slash. The remainder of this section concentrates on the backslash operator; the corresponding properties of the slash operator can be inferred from the identity
$(B / A)^{\prime}=\left(A^{\prime} \backslash B^{\prime}\right)$
The coefficient matrix A need not be square. If A is m-by-n, there are three cases.
$m=n \quad$ Square system. Seek an exact solution.
$m>n \quad$ Overdetermined system. Find a least squares solution.
$\mathrm{m}<\mathrm{n} \quad$ Underdetermined system. Find a basic solution with at most $m$ nonzero components.

The backslash operator employs different algorithms to handle different kinds of coefficient matrices. The various cases, which are diagnosed automatically by examining the coefficient matrix, include:

- Permutations of triangular matrices
- Symmetric, positive definite matrices
- Square, nonsingular matrices
- Rectangular, overdetermined systems
- Rectangular, underdetermined systems

## Square Systems

The most common situation involves a square coefficient matrix a and a single right-hand side column vector $b$. The solution, $x=A \backslash b$, is then the same size as b. For example,
$x=A \backslash u$
x =
10
-12
5
It can be confirmed that $A * x$ is exactly equal to $u$.
If $A$ and $B$ are square and the same size, then $X=A \backslash B$ is also that size.
$X=A \backslash B$
$X=$

-19

It can be confirmed that A*X is exactly equal to B.
Both of these examples have exact, integer solutions. This is because the coefficient matrix was chosen to be pascal (3), which has a determinant equal to one. A later section considers the effects of roundoff error inherent in more realistic computation.

A square matrix $A$ is singular if it does not have linearly independent columns. If $A$ is singular, the solution to $A X=B$ either does not exist, or is not unique. The backslash operator, $A \backslash B$, issues a warning if $A$ is nearly singular and raises an error condition if exact singularity is detected.

## Overdetermined Systems

Overdetermined systems of simultaneous linear equations are often encountered in various kinds of curve fitting to experimental data. Here is a hypothetical example. A quantity y is measured at several different values of time, $t$, to produce the following observations.

| t | y |
| :--- | :--- |
| 0.0 | 0.82 |
| 0.3 | 0.72 |
| 0.8 | 0.63 |
| 1.1 | 0.60 |
| 1.6 | 0.55 |
| 2.3 | 0.50 |

This data can be entered into MATLAB with the statements

```
t = [0 .3 .8 1.1 1.6 2.3]';
y = [. . 82 .72 . 63 .60 .55 .50]';
```

The data can be modeled with a decaying exponential function.

$$
\mathrm{y}(\mathrm{t}) \approx \mathrm{c}_{1}+\mathrm{c}_{2} \mathrm{e}^{-\mathrm{t}}
$$

This equation says that the vector y should be approximated by a linear combination of two other vectors, one the constant vector containing all ones and the other the vector with components $\mathrm{e}^{-\mathrm{t}}$. The unknown coefficients, $\mathrm{c}_{1}$ and $c_{2}$, can be computed by doing a least squares fit, which minimizes the sum of the squares of the deviations of the data from the model. There are six equations in two unknowns, represented by the 6-by-2 matrix.

```
E = [ones(size(t)) exp(-t)]
E =
    1.0000 1.0000
    1.0000 0.7408
    1.0000 0.4493
    1.0000 0.3329
    1.0000 0.2019
    1.0000 0.1003
```

The least squares solution is found with the backslash operator.

$$
\begin{aligned}
& c=E \backslash y \\
& c= \\
& \\
& \\
& \\
& \\
& 0.4760 \\
& 0.3413
\end{aligned}
$$

In other words, the least squares fit to the data is

$$
y(t) \approx 0.4760+0.3413 \mathrm{e}^{-t}
$$

The following statements evaluate the model at regularly spaced increments in t , and then plot the result, together with the original data.

```
T = (0:0.1:2.5)';
Y = [ones(size(T)) exp(-T)]*c;
plot(T,Y,'-',t,y,'o')
```

You can see that E*c is not exactly equal to $y$, but that the differencemight well be less than measurement errors in the original data.

A rectangular matrix $A$ is rank deficient if it does not havelinearly independent columns. If $A$ is rank deficient, the least squares solution to $A X=B$ is not unique. The backslash operator, $A \backslash B$, issues a warning if $A$ is rank deficient and produces a basic solution that has as few nonzero elements as possible.

## Underdetermined Systems

Underdetermined linear systems involve more unknowns than equations. When they are accompanied by additional constraints, they are the purview of linear programming. By itself, the backslash operator deals only with the unconstrained system. The solution is never unique. MATLAB finds a basic solution, which has at most $m$ nonzero components, but even this may not be unique. The particular solution actually computed is determined by the QR factorization with column pivoting (see a later section on the QR factorization).

Here is a small, random example.

```
R = fix(10*rand(2,4))
R =
    6
    3 5
```

$b=\operatorname{fix}(10 * r a n d(2,1))$
b =
1
2

The linear system $R x=b$ involves two equations in four unknowns. Since the coefficient matrix contains small integers, it is appropriate to use the format command to display the solution in rational format. The particular solution is obtained with

```
format rat
p = R\b
p =
            0
        5/7
        0
    -11/7
```

One of the nonzero components is $p(2)$ because $R(:, 2)$ is the column of $R$ with largest norm. The other nonzero component is $p(4)$ because $R(:, 4)$ dominates after $\mathrm{R}(:, 2)$ is eliminated.

The complete solution to the overdetermined (overdetermi ned?) system can be characterized by adding an arbitrary vector from the null space, which can be found using the null function with an option requesting a "rational" basis.

```
Z = null(R,'r')
Z =
\begin{tabular}{lr}
\(-1 / 2\) & \(-7 / 6\) \\
\(-1 / 2\) & \(1 / 2\)
\end{tabular}
```

# 1 <br> 0 <br> 0 1 <br> It can be confirmed that $\mathrm{R} * \mathrm{Z}$ is zero and that any vector x where $x=p+Z *$ 

for an arbitrary vector $q$ satisfies $\mathrm{R} * \mathrm{x}=\mathrm{b}$.

## Inverses and Determinants

This section provides:

- An overview of the use of inverses and determinants for solving square nonsingular systems of linear equations
- A discussion of the Moore-Penrose pseudoinverse for solving rectangular systems of linear equations

## Overview

If $A$ is square and nonsingular, the equations $A X=I$ and $X A=I$ have the same solution, $X$. This solution is called the inverse of $A$, is denoted by $A^{-1}$, and is computed by the function inv. The determinant of a matrix is useful in theoretical considerations and some types of symbolic computation, but its scaling and roundoff error properties make it far less satisfactory for numeric computation. Nevertheless, the function det computes the determinant of a square matrix.

Again, because A is symmetric, has integer elements, and has determinant equal to one, so does its inverse. On the other hand,

$$
B=\operatorname{magic}(3)
$$

```
B =
            8 1 6
            3 5 7
            4 9
d = det(B)
X = inv(B)
d =
            -360
X =
\begin{tabular}{rrr}
0.1472 & -0.1444 & 0.0639 \\
-0.0611 & 0.0222 & 0.1056 \\
-0.0194 & 0.1889 & -0.1028
\end{tabular}
```

Closer examination of the elements of $x$, or use of format rat, would reveal that they are integers divided by 360.

If $A$ is square and nonsingular, then without roundoff error, $X=\operatorname{inv}(A) * B$ would theoretically be the same as $X=A \backslash B$ and $Y=B * i n v(A)$ would theoretically be the same as $Y=B / A$. But the computations involving the backslash and slash operators are preferable because they require less computer time, less memory, and have better error detection properties.

## Pseudoinverses

Rectangular matrices do not have inverses or determinants. At least one of the equations $A X=I$ and $X A=I$ does not have a solution. A partial replacement for the inverse is provided by the M oore-Penrose pseudoinverse, which is computed by the pinv function.

```
X = pinv(C)
X =
\begin{tabular}{rrr}
0.1159 & -0.0729 & 0.0171 \\
-0.0534 & 0.1152 & 0.0418
\end{tabular}
```

The matrix

$$
Q=X * C
$$

```
Q =
        1.0000 0.0000
        0.0000 1.0000
```

is the 2-by-2 identity, but the matrix

```
P = C*X
P =
\begin{tabular}{rrr}
0.8293 & -0.1958 & 0.3213 \\
-0.1958 & 0.7754 & 0.3685 \\
0.3213 & 0.3685 & 0.3952
\end{tabular}
```

is not the 3-by-3 identity. However, P acts like an identity on a portion of the space in the sense that $P$ is symmetric, $P * C$ is equal to $C$ and $X * P$ is equal to $X$.

If $A$ is $m$-by- $n$ with $m>n$ and full rank $n$, then each of the three statements

```
x = A\b
x = pinv(A)*b
x = inv(A'*A)*A'*b
```

theoretically computes the same least squares solution $x$, although the backslash operator does it faster.

However, if A does not have full rank, the solution to the least squares problem is not unique. There are many vectors $x$ that minimize

```
norm(A*x -b)
```

The solution computed by $x=A \backslash b$ is a basic solution; it has at most $r$ nonzero components, wherer is therank of $A$. The solution computed by $x=\operatorname{pinv}(A) * b$ is the minimal norm solution because it minimizes norm ( $x$ ). An attempt to compute a solution with $x=\operatorname{inv}\left(A^{\prime} * A\right) * A^{\prime} * b$ fails because $A^{\prime} * A$ is singular.

Here is an example to illustrates the various solutions.
A =

| $[$ | 1 | 2 | 3 |
| ---: | ---: | ---: | ---: |
| 4 | 5 | 6 |  |
| 7 | 8 | 9 |  |
| 10 | 11 | 12 | ] |

does not have full rank. Its second column is the average of the first and third columns. If

$$
b=A(:, 2)
$$

is the second column, then an obvious solution to A* $x=b$ is $x=\left[\begin{array}{lll}0 & 1 & 0\end{array}\right]$ '. But none of the approaches computes that $x$. The backslash operator gives

```
x = A\b
Warning: Rank deficient, rank = 2.
x =
    0.5000
    0
    0.5000
```

This solution has two nonzero components. The pseudoinverse approach gives

```
y = pinv(A)*b
y =
    0.3333
    0.3333
    0.3333
```

There is no warning about rank deficiency. But norm $(y)=0.5774$ is less than norm $(x)=0.7071$. Finally $z=i n v\left(A^{\prime *} A\right) * A^{\prime *} b$
fails completely.

```
Warning: Matrix is singular to working precision.
```

Inf

## Cholesky, LU, and QR Factorizations

MATLAB's linear equation capabilities are based on three basic matrix factorizations:

- Cholesky factorization for symmetric, positive definite matrices
- LU factorization (Gaussian elimination) for general square matrices
- QR (orthogonal) for rectangular matrices

These three factorizations are availablethrough the chol, lu, and qr functions.
All three of these factorizations make use of triangular matrices where all the elements either above or below the diagonal are zero. Systems of linear equations involving triangular matrices are easily and quickly solved using either forward or back substitution.

## Cholesky Factorization

The Cholesky factorization expresses a symmetric matrix as the product of a triangular matrix and its transpose

$$
A=R^{\prime} R
$$

where $R$ is an upper triangular matrix.
N ot all symmetric matrices can be factored in this way; the matrices that have such a factorization are said to be positive definite. This implies that all the diagonal elements of A are positive and that the offdiagonal elements are "not too big." The Pascal matrices provide an interesting example. Throughout this chapter, our example matrix A has been the 3-by-3 Pascal matrix. Let's temporarily switch to the 6-by-6.

| $\mathrm{A}=\operatorname{pascal}(6)$ |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $A=$ |  |  |  |  |  |
| 1 | 1 | 1 | 1 | 1 | 1 |
| 1 | 2 | 3 | 4 | 5 | 6 |
| 1 | 3 | 6 | 10 | 15 | 21 |
| 1 | 4 | 10 | 20 | 35 | 56 |
| 1 | 5 | 15 | 35 | 70 | 126 |
| 1 | 6 | 21 | 56 | 126 | 252 |

The elements of A are binomial coefficients. Each element is the sum of its north and west neighbors. The Cholesky factorization is

| $\mathrm{R}=\operatorname{chol}(\mathrm{A})$ |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | ---: |
| $\mathrm{R}=$ |  |  |  |  |  |
| 1 | 1 | 1 | 1 | 1 | 1 |
| 0 | 1 | 2 | 3 | 4 | 5 |
| 0 | 0 | 1 | 3 | 6 | 10 |
| 0 | 0 | 0 | 1 | 4 | 10 |
| 0 | 0 | 0 | 0 | 1 | 5 |
| 0 | 0 | 0 | 0 | 0 | 1 |

The elements are again binomial coefficients. The fact that $R^{\prime *} R$ is equal to $A$ demonstrates an identity involving sums of products of binomial coefficients.

Note The Cholesky factorization also applies to complex matrices. Any complex matrix which has a Cholesky factorization satisfies $A^{\prime}=A$ and is said to be Hermitian positive definite.

The Cholesky factorization allows the linear system

$$
A x=b
$$

to be replaced by

$$
R^{\prime} R x=b
$$

Because the backslash operator recognizes triangular systems, this can be solved in MATLAB quickly with

$$
x=R \backslash\left(R^{\prime} \backslash b\right)
$$

If $A$ is $n$-by-n, the computational complexity of $\operatorname{chol}(A)$ is $O\left(n^{3}\right)$, but the complexity of the subsequent backslash solutions is only $\mathrm{O}\left(\mathrm{n}^{2}\right)$.

## LU Factorization

LU factorization, or Gaussian elimination, expresses any square matrix $A$ as the product of a permutation of a lower triangular matrix and an upper triangular matrix

$$
A=L U
$$

where $L$ is a permutation of a lower triangular matrix with ones on its diagonal and $U$ is an upper triangular matrix.

The permutations are necessary for both theoretical and computational reasons. The matrix

$$
\left[\begin{array}{ll}
0 & 1 \\
1 & 0
\end{array}\right]
$$

cannot be expressed as the product of triangular matrices without interchanging its two rows. Although the matrix

$$
\left[\begin{array}{ll}
\varepsilon & 1 \\
1 & 0
\end{array}\right]
$$

can be expressed as the product of triangular matrices, when $\varepsilon$ is small the elements in the factors are large and magnify errors, so even though the permutations are not strictly necessary, they are desirable. Partial pivoting ensures that the elements of $L$ are bounded by one in magnitude and that the elements of $U$ are not much larger than those of $A$.

For example

```
[L,U] = lu(B)
L =
\begin{tabular}{rrr}
1.0000 & 0 & 0 \\
0.3750 & 0.5441 & 1.0000 \\
0.5000 & 1.0000 & 0
\end{tabular}
U =
    8.0000 1.0000 6.0000
        0 8.5000 -1.0000
        0 0 5.2941
```

The LU factorization of A allows the linear system

$$
A^{*} x=b
$$

to be solved quickly with

```
x = U\(L\b)
```

Determinants and inverses are computed from the LU factorization using

```
det(A) = det(L)*det(U)
```

and

```
inv(A) = inv(U)*inv(L)
```

You can also compute the determinants using $\operatorname{det}(A)=\operatorname{prod}(\operatorname{diag}(U))$, though the signs of the determinants may be reversed.

## QR Factorization

An orthogonal matrix, or a matrix with orthonormal columns, is a real matrix whose columns all have unit length and are perpendicular to each other. If Q is orthogonal, then

$$
Q^{\prime} \mathrm{Q}=1
$$

The simplest orthogonal matrices are two-dimensional coordinate rotations.

$$
\left[\begin{array}{cc}
\cos (\theta) & \sin (\theta) \\
-\sin (\theta) & \cos (\theta)
\end{array}\right]
$$

For complex matrices, the corresponding term is unitary. Orthogonal and unitary matrices are desirable for numerical computation because they preserve length, preserve angles, and do not magnify errors.
The orthogonal, or QR , factorization expresses any rectangular matrix as the product of an orthogonal or unitary matrix and an upper triangular matrix. A column permutation may also be involved.

$$
A=Q R
$$

or

$$
A P=Q R
$$

where Q is orthogonal or unitary, R is upper triangular, and P is a permutation.

There are four variants of the QR factorization- full or economy size, and with or without column permutation.

Overdetermined linear systems involve a rectangular matrix with more rows than columns, that is $m$-by-n with $m>n$. The full size QR factorization produces a square, m-by-m orthogonal Q and a rectangular m-by-n upper triangular R.

```
[Q,R] = qr(C)
Q =
    -0.8182 0.3999 -0.4131
    -0.1818 -0.8616 -0.4739
    -0.5455 -0.3126 0.7777
R =
    -11.0000 -8.5455
        0 -7.4817
        0 0
```

In many cases, the last $\mathrm{m}-\mathrm{n}$ columns of Q are not needed because they are multiplied by the zeros in the bottom portion of $R$. So the economy size QR factorization produces a rectangular, m-by-n Q with orthonormal columns and a square n-by-n upper triangular R. F or our 3-by-2 example, this is not much of a saving, but for larger, highly rectangular matrices, the savings in both time and memory can be quite important.

```
[Q,R] = qr(C,0)
Q =
    -0.8182 0.3999
    -0.1818 -0.8616
    -0.5455 -0.3126
R =
    -11.0000 -8.5455
        0 -7.4817
```

In contrast to the LU factorization, the QR factorization does not require any pivoting or permutations. But an optional column permutation, triggered by the presence of a third output argument, is useful for detecting singularity or rank deficiency. At each step of the factorization, the column of the remaining unfactored matrix with largest norm is used as the basis for that step. This ensures that the diagonal elements of R occur in decreasing order and that any linear dependence among the columns is almost certainly be revealed by examining these elements. For our small example, the second column of C has a larger norm than the first, so the two columns are exchanged.

```
[Q,R,P] = qr(C)
Q =
    -0.3522 0.8398 -0.4131
    -0.7044 -0.5285 -0.4739
    -0.6163 0.1241 0.7777
R =
    -11.3578 -8.2762
        0 7.2460
        0
P =
    0 1
    1 0
```

When the economy size and column permutations are combined, the third output argument is a permutation vector, rather than a permutation matrix.

```
[Q,R,p] = qr(C,0)
Q =
    -0.3522 0.8398
    -0.7044 -0.5285
    -0.6163 0.1241
R =
    -11.3578 -8.2762
        0 7.2460
```

## $p=$ <br> 2 <br> 1

The QR factorization transforms an overdetermined linear system into an equivalent triangular system. The expression

```
norm(A*x - b)
```

is equal to

```
norm(Q*R*x - b)
```

Multiplication by orthogonal matrices preserves the Euclidean norm, so this expression is also equal to

```
norm(R*x - y)
```

where $y=Q$ '*b. Since the last $m-n$ rows of $R$ are zero, this expression breaks into two pieces

```
norm(R(1:n,1:n)*x - y(1:n))
```

and

```
norm(y(n+1:m))
```

When A has full rank, it is possible to solve for $x$ so that the first of these expressions is zero. Then the second expression gives the norm of theresidual. When A does not have full rank, the triangular structure of R makes it possible to find a basic solution to the least squares problem.

## Matrix Powers and Exponentials

This section tells you how to obtain the following matrix powers and exponentials in MATLAB:

- Positive integer
- Inverse and fractional
- Element-by-element
- Exponentials

## Positive Integer Powers

If $A$ is a square matrix and p is a positiveinteger, then $A^{\wedge} p$ effectively multiplies $A$ by itself p-1 times.

```
X = A^2
X =
            3 6 10
            6 14 25
            10 25 46
```

## Inverse and Fractional Powers

If A is square and nonsingular, then $A^{\wedge}(-p)$ effectively multiplies inv (A) by itself p-1 times.

```
Y = B^(-3)
Y =
    0.0053 -0.0068 0.0018
    -0.0034 0.0001 0.0036
    -0.0016 0.0070 -0.0051
```

Fractional powers, like A^(2/3), are also permitted; the results depend upon the distribution of the eigenvalues of the matrix.

## Element-by-Element Pow ers

The .^ operator produces element-by-element powers. For example,

$$
X=A \cdot \wedge 2
$$

```
A =
\begin{tabular}{rrr}
1 & 1 & 1 \\
1 & 4 & 9 \\
1 & 9 & 36
\end{tabular}
```

## Exponentials

The function

```
sqrtm(A)
```

computes $A^{\wedge}(1 / 2)$ by a more accurate algorithm. Them in sqrtm distinguishes this function from sqrt (A) which, like A. ^(1/2), does its job element-by-element.
A system of linear, constant coefficient, ordinary differential equations can be written

$$
\mathrm{dx} / \mathrm{dt}=\mathrm{Ax}
$$

where $x=x(t)$ is a vector of functions of $t$ and $A$ is a matrix independent of $t$. The solution can be expressed in terms of the matrix exponential,

$$
x(t)=e^{t A} x(0)
$$

The function

```
expm(A)
```

computes the matrix exponential. An example is provided by the 3-by-3 coefficient matrix
$A=$

| 0 | -6 | -1 |
| ---: | ---: | ---: |
| 6 | 2 | -16 |
| -5 | 20 | -10 |

and the initial condition, $x(0)$

```
x0 =
```

1

The matrix exponential is used to compute the solution, $\mathrm{x}(\mathrm{t})$, to the differential equation at 101 points on the interval $0 \leq \mathrm{t} \leq 1$ with

```
X = [];
for t = 0:.01:1
    X = [x expm(t*A)*x0];
end
```

A three-dimensional phase plane plot obtained with

$$
\operatorname{plot} 3\left(X(1,:), X(2,:), X(3,:), '-0^{\prime}\right)
$$

shows the solution spiraling in towards the origin. This behavior is related to the eigenvalues of the coefficient matrix, which are discussed in the next section.

## Eigenvalues

An eigenvalue and eigenvector of a square matrix $A$ are a scalar $\lambda$ and a nonzero vector $v$ that satisfy

$$
A v=\lambda v
$$

This section explains:

- Eigenvalue decomposition
- Problems associated with defective (not diagonalizable) matrices
- The use of Schur decomposition to avoid problems associated with eigenvalue decomposition

## Eigenvalue Decomposition

With the eigenvalues on the diagonal of a diagonal matrix $\Lambda$ and the corresponding eigenvectors forming the columns of a matrix V , we have

$$
\mathrm{AV}=\mathrm{V} \Lambda
$$

If V is nonsingular, this becomes the eigenvalue decomposition

$$
\mathrm{A}=\mathrm{V} \Lambda \mathrm{~V}^{-1}
$$

A good example is provided by the coefficient matrix of the ordinary differential equation in the previous section.

```
A =
    0 -6 -1
    6 2 -16
    -5 20 -10
```

The statement
lambda = eig(A)
produces a column vector containing the eigenvalues. For this matrix, the eigenvalues are complex.
lambda =
$-3.0710$
-2.4645+17.6008i
-2.4645-17.6008i

The real part of each of the eigenvalues is negative, so $e^{\lambda t}$ approaches zero as $t$ increases. The nonzero imaginary part of two of the eigenvalues, $\pm \omega$, contributes the oscillatory component, $\sin (\omega \mathrm{t})$, to the solution of the differential equation.

With two output arguments, eig computes the eigenvectors and stores the eigenvalues in a diagonal matrix.

```
[V,D] = eig(A)
V =
    -0.8326 0.2003-0.1394i 0.2003 + 0.1394i
    -0.3553 -0.2110 - 0.6447i -0.2110 + 0.6447i
    -0.4248 -0.6930 -0.6930
D =
    -3.0710 0 0
    0 -2.4645+17.6008i 0
    0 0 -2.4645-17.6008i
```

The first eigenvector is real and the other two vectors are complex conjugates of each other. All three vectors are normalized to have Euclidean length, norm ( $\mathrm{v}, 2$ ), equal to one.

The matrix V *D*inv ( V ), which can be written more succinctly as V * $\mathrm{D} / \mathrm{V}$, is within roundoff error of $A$. And, inv $(V) * A * V$, or $V \backslash A * V$, is within roundoff error of $D$.

## Defective Matrices

Some matrices do not have an eigenvector decomposition. These matrices are defective, or not diagonalizable. F or example,
$A=$
$\begin{array}{lll}6 & 12 & 19\end{array}$
$\begin{array}{lll}-9 & -20 & -33\end{array}$
$4 \quad 9 \quad 15$
For this matrix

$$
[\mathrm{V}, \mathrm{D}]=\operatorname{eig}(\mathrm{A})
$$

produces

```
V =
    -0.4741 -0.4082 -0.4082
    0.8127 0.8165 0.8165
    -0.3386 -0.4082 -0.4082
D =
    -1.0000 0 0
        0 1.0000 0
```

There is a double eigenvalue at $\lambda=1$. The second and third columns of $v$ are the same. F or this matrix, a full set of linearly independent eigenvectors does not exist.

The optional Symbolic Math Tool box extends MATLAB's capabilities by connecting to Maple, a powerful computer algebra system. One of the functions provided by the toolbox computes the J ordan Canonical Form. This is appropriate for matrices like our example, which is 3-by-3 and has exactly known, integer elements.

```
[X,J] = jordan(A)
X =
    -1.7500 1.5000 2.7500
    3.0000 -3.0000 -3.0000
    -1.2500 1.5000 1.2500
J =
    -1 0}
    0 1 1
    0 0
```

TheJ ordan Canonical Form is an important theoretical concept, but it is not a reliable computational tool for larger matrices, or for matrices whose elements are subject to roundoff errors and other uncertainties.

## Schur Decomposition in MATLAB Matrix Computations

MATLAB's advanced matrix computations do not require eigenvalue decompositions. They are based, instead, on the Schur decomposition

$$
A=U S U^{\top}
$$

where $U$ is an orthogonal matrix and $S$ is a block upper triangular matrix with 1-by-1 and 2-by-2 blocks on the diagonal. The eigenvalues are revealed by the diagonal elements and blocks of $S$, while the columns of $U$ provide a basis with much better numerical properties than a set of eigenvectors. The Schur decomposition of our defective example is

```
[U,S] = schur(A)
U =
        0.4741 -0.6571 0.5861
    -0.8127 -0.0706 0.5783
    0.3386 0.7505 0.5675
S =
    -1.0000 21.3737 44.4161
        0 1.0081 0.6095
        0 -0.0001 0.9919
```

The double eigenvalue is contained in the lower 2-by-2 block of s .

Note If A is complex, schur returns the complex Schur form, which is upper triangular with the eigenvalues of $A$ on the diagonal.

## Singular Value Decomposition

A singular valueand corresponding singular vectors of a rectangular matrix A are a scalar $\sigma$ and a pair of vectors $u$ and $v$ that satisfy

$$
\begin{aligned}
& A v=\sigma u \\
& A^{\top} u=\sigma v
\end{aligned}
$$

With the singular values on the diagonal of a diagonal matrix $\Sigma$ and the corresponding singular vectors forming the columns of two orthogonal matrices U and V , we have

$$
\begin{aligned}
& \mathrm{A} V=U \Sigma \\
& \mathrm{~A}^{\top} \mathrm{U}=\mathrm{V} \Sigma
\end{aligned}
$$

Since $U$ and $V$ are orthogonal, this becomes the singular value decomposition

$$
A=U \Sigma V^{\top}
$$

The full singular value decomposition of an m-by-n matrix involves an m-by-m $U$, an m-by-n $\Sigma$, and an n-by-n V. In other words, $U$ and $V$ are both square and $\Sigma$ is the same size as A. If A has many more rows than columns, the resulting $U$ can be quite large, but most of its columns are multiplied by zeros in $\Sigma$. In this situation, the economy sized decomposition saves both time and storage by producing an m-by-n $U$, an n-by-n $\Sigma$ and the same V.

The eigenvalue decomposition is the appropriate tool for analyzing a matrix when it represents a mapping from a vector space into itself, as it does for an ordinary differential equation. On the other hand, the singular value decomposition is the appropriate tool for analyzing a mapping from one vector space into another vector space, possibly with a different dimension. M ost systems of simultaneous linear equations fall into this second category.

If $A$ is square, symmetric, and positive definite, then its eigenvalue and singular value decompositions are the same. But, as A departs from symmetry and positive definiteness, the difference between the two decompositions increases. In particular, the singular value decomposition of a real matrix is always real, but the eigenvalue decomposition of a real, nonsymmetric matrix might be complex.

For the example matrix
A =
$9 \quad 4$
$6 \quad 8$
27
the full singular value decomposition is

```
[U,S,V] = svd(A)
U =
        -0.6105 0.7174 0.3355
        -0.6646 -0.2336 -0.7098
        -0.4308 -0.6563 0.6194
```

S =
14.93590
$0 \quad 5.1883$
$0 \quad 0$
V =
-0.6925 0.7214
-0.7214 -0.6925

You can verify that $\mathrm{U} * \mathrm{~S} * \mathrm{~V}$ ' is equal to A to within roundoff error. F or this small problem, the economy size decomposition is only slightly smaller.

```
[U,S,V] = svd(A,0)
U =
            -0.6105 0.7174
            -0.6646 -0.2336
            -0.4308 -0.6563
```

S =
$14.9359 \quad 0$
$0 \quad 5.1883$
V =
-0.6925 0.7214
$-0.7214 \quad-0.6925$

Again, $U^{*} S^{*} V$ ' is equal to $A$ to within roundoff error.

This chapter introduces MATLAB functions that enable you to work with polynomials and interpolate one, two-, and multi-dimensional data. It includes:

## Polynomials

Functions for standard polynomial operations. Additional topics include curve fitting and partial fraction expansion.

## Interpolation

Two- and multi-dimensional interpolation techniques, taking into account speed, memory, and smoothness considerations.

## Polynomials

This section provides:

- A summary of the MATLAB polynomial functions
- Instructions for representing polynomials in MATLAB

It also describes the MATLAB polynomial functions that:

- Calculate the roots of a polynomial
- Calculate the coefficients of the characteristic polynomial of a matrix
- Evaluate a polynomial at a specified value
- Convolve (multiply) and deconvolve (divide) polynomials
- Compute the derivative of a polynomial
- Fit a polynomial to a set of data
- Convert between partial fraction expansion and polynomial coefficients

## Polynomial Function Summary

MATLAB provides functions for standard polynomial operations, such as polynomial roots, evaluation, and differentiation. In addition, there are functions for more advanced applications, such as curve fitting and partial fraction expansion.

The polynomial functions reside in the MATLAB polyfun directory.
Polynomial Function Summary

| Function | Description |
| :--- | :--- |
| conv | Multiply polynomials. |
| deconv | Divide polynomials. |
| poly | Polynomial with specified roots. |
| polyder | Polynomial derivative. |
| polyfit | Polynomial curve fitting. |
| polyval | Polynomial evaluation. |

| Polynomial Function Summary (Continued) |  |
| :--- | :--- |
| Function | Description |
| polyvalm | Matrix polynomial evaluation. |
| residue | Partial-fraction expansion (residues). |
| roots | Find polynomial roots. |

The Symbolic Math Tool box contains additional specialized support for polynomial operations.

## Representing Polynomials

MATLAB represents polynomials as row vectors containing coefficients ordered by descending powers. For example, consider the equation

$$
p(x)=x^{3}-2 x-5
$$

This is the cel ebrated example Wallis used when he first represented $N$ ewton's method to the French Academy. To enter this polynomial into MATLAB, use

$$
p=\left[\begin{array}{llll}
1 & 0 & -2 & -5
\end{array}\right] ;
$$

## Polynomial Roots

The roots function calculates the roots of a polynomial.

```
r = roots(p)
r =
    2.0946
    -1.0473 + 1.1359i
    -1.0473 - 1.1359i
```

By convention, MATLAB stores roots in column vectors. The function poly returns to the polynomial coefficients.

```
p2 = poly(r)
p2 =
    1 8.8818e-16 -2 -5
```

poly and roots are inverse functions, up to ordering, scaling, and roundoff error.

## Characteristic Polynomials

The poly function also computes the coefficients of the characteristic polynomial of a matrix.

```
A = [1.2 3 -0.9; 5 1.75 6; 9 0 1];
poly(A)
ans =
    1.0000 -3.9500 -1.8500 -163.2750
```

The roots of this polynomial, computed with roots, are the characteristic roots, or eigenvalues, of the matrix A. (Use eig to compute the eigenvalues of a matrix directly.)

## Polynomial Evaluation

The polyval function evaluates a polynomial at a specified value. To evaluate $p$ at $s=5$, use

```
polyval(p,5)
ans =
    1 1 0
```

It is also possible to evaluate a polynomial in a matrix sense. In this case $p(s)=x^{3}-2 x-5$ becomes $p(X)=X^{3}-2 X-5 I$, where $X$ is a square matrix and $I$ is the identity matrix. For example, create a square matrix $X$ and evaluate the polynomial $p$ at $x$.

```
X = [2 4 5; -1 0 3; 7 1 5];
Y = polyvalm(p,X)
Y =
    377 179 439
    111 81 136
    490 253 639
```

## Convolution and Deconvolution

Polynomial multiplication and division correspond to the operations convolution and deconvolution. The functions conv and deconv implement these operations.
Consider the polynomials $a(s)=s^{2}+2 s+3$ and $b(s)=4 s^{2}+5 s+6$. To compute their product,

```
a = [1 2 3]; b = [4 5 6];
c = conv(a,b)
C =
    4
```

Use deconvolution to divide a(s) back out of the product.

```
\([q, r]=\operatorname{deconv}(c, a)\)
\(q\) =
    \(4 \quad 5 \quad 6\)
\(r=\)
    \(\begin{array}{lllll}0 & 0 & 0 & 0 & 0\end{array}\)
```

## Polynomial Derivatives

The polyder function computes the derivative of any polynomial. To obtain the derivative of the polynomial $p=\left[\begin{array}{llll}1 & 0 & -2 & -5\end{array}\right]$,

```
q = polyder(p)
q =
    3 0 -2
```

polyder also computes the derivative of the product or quotient of two polynomials. For example, create two polynomials a and b.

```
a = [1 3 5];
b = [2 4 6];
```

Calculate the derivative of the product a*b by calling polyder with a single output argument.

```
c = polyder(a,b)
c =
    8 30 56 38
```

Calculate the derivative of the quotient $\mathrm{a} / \mathrm{b}$ by calling polyder with two output arguments.

```
[q,d] = polyder(a,b)
q =
    -2 -8 -2
d =
    4 16 40 48
        36
```

$q / d$ is the result of the operation.

## Polynomial Curve Fitting

polyfit finds the coefficients of a polynomial that fits a set of data in a least-squares sense.

$$
p=\operatorname{polyfit}(x, y, n)
$$

$x$ and $y$ are vectors containing the $x$ and $y$ data to be fitted, and $n$ is the order of the polynomial to return. For example, consider the $x-y$ test data.

```
x = [1 2 3 4 5]; y = [5.5 43.1 128 290.7 498.4];
```

A third order polynomial that approximately fits the data is

```
p = polyfit(x,y,3)
p =
    -0.1917 31.5821 -60.3262 35.3400
```

Compute the values of the polyfit estimate over a finer range, and plot the estimate over the real data values for comparison.

```
x2 = 1:.1:5;
y2 = polyval(p,x2);
plot(x,y,'o',x2,y2)
grid on
```

To use these functions in an application example, see the "Data Analysis and Statistics" chapter.

## Partial Fraction Expansion

residue finds the partial fraction expansion of the ratio of two polynomials. This is particularly useful for applications that represent systems in transfer function form. For polynomials b and a, if there are no multiple roots,

$$
\frac{b(s)}{a(s)}=\frac{r_{1}}{s-p_{1}}+\frac{r_{2}}{s-p_{2}}+\ldots+\frac{r_{n}}{s-p_{n}}+k_{s}
$$

where $r$ is a column vector of residues, $p$ is a column vector of pole locations, and k is a row vector of direct terms. Consider the transfer function

$$
\frac{-4 s+8}{s^{2}+6 s+8}
$$

```
b = [-4 8];
a = [1 6 8];
[r,p,k] = residue(b,a)
r=
    -12
        8
p =
        -4
        -2
k =
    []
```

Given threeinput arguments ( $r, p$, and $k$ ), residue converts back to polynomial form.

```
[b2,a2] = residue(r,p,k)
b2 =
    -4 8
a2 =
    1 6
8
```

## Interpolation

Interpolation is a process for estimating values that lie between known data points. It has important applications in areas such as signal and image processing.

This section:

- Provides a summary of the MATLAB interpolation functions
- Discusses one-dimensional interpolation
- Discusses two-dimensional interpolation
- Uses an example to compare nearest neighbor, bilinear, and bicubic interpolation methods
- Discusses interpolation of multidimensional data
- Discusses triangulation and interpolation of scattered data

## Interpolation Function Summary

MATLAB provides a number of interpolation techniques that let you balance the smoothness of the data fit with speed of execution and memory usage.
The interpolation functions reside in the MATLAB polyfun directory.
Interpolation Function Summary

| Function | Description |
| :--- | :--- |
| griddata | Data gridding and surface fitting. |
| griddata3 | Data gridding and hypersurface fitting for <br> three-dimensional data. |
| griddatan | Data gridding and hypersurface fitting (dimension $>=3$ ). |
| interp1 | One-dimensional interpolation (table lookup). |
| interp2 | Two-dimensional interpolation (table lookup). |
| interp3 | Three-dimensional interpolation (table lookup). |
| interpft | One-dimensional interpolation using FFT method. |

| Interpolation Function Summary (Continued) |  |
| :--- | :--- |
| Function | Description |
| interpn | N-D interpolation (table lookup). |
| mkpp | Make a piecewise polynomial |
| pchip | Piecewise Cubic Hermite Interpolating Polynomial <br> (PCHIP). |
| ppval | Piecewise polynomial evaluation |
| spline | Cubic spline data interpolation |
| unmkpp | Piecewise polynomial details |

## One-Dimensional Interpolation

There are two kinds of one-dimensional interpolation in MATLAB:

- Polynomial interpolation
- FFT-based interpolation

## Polynomial Interpolation

The function interp1 performs one-dimensional interpolation, an important operation for data analysis and curve fitting. This function uses polynomial techniques, fitting the supplied data with polynomial functions between data points and evaluating the appropriate function at the desired interpolation points. Its most general form is

```
yi = interp1(x,y,xi,method)
```

$y$ is a vector containing the values of a function, and $x$ is a vector of the same length containing the points for which the values in $y$ are given. $x i$ is a vector containing the points at which to interpolate. method is an optional string specifying an interpolation method:

- Nearest neighbor interpolation (method = 'nearest'). This method sets the value of an interpolated point to the value of the nearest existing data point.
- Linear interpol ation (method = 'linear'). This method fits a different linear function between each pair of existing data points, and returns the value of
the relevant function at the points specified by xi. This is the default method for the interp1 function.
- Cubic splineinterpolation (method = 'spline'). This method fits a different cubic function between each pair of existing data points, and uses the spline function to perform cubic spline interpolation at the data points.
- Cubicinterpolation (method = 'pchip' or 'cubic'). These methods are identical. They use the pchip function to perform piecewise cubic Hermite interpolation within the vectors $x$ and $y$. These methods preserve monotonicity and the shape of the data.

If any element of $x i$ is outside the interval spanned by $x$, the specified interpolation method is used for extrapolation. Alternatively, yi = interp1(x, $\mathrm{Y}, \mathrm{xi}$, method, extrapval) replaces extrapolated values with extrapval. NaN is often used for extrapval.
All methods work with nonuniformly spaced data.

## Speed, Memory, and Smoothness Considerations

When choosing an interpolation method, keep in mind that some require more memory or longer computation time than others. However, you may need to trade off these resources to achieve the desired smoothness in the result.

- Nearest neighbor interpolation is the fastest method. However, it provides the worst results in terms of smoothness.
- Linear interpolation uses more memory than the nearest neighbor method, and requires slightly more execution time. Unlike nearest neighbor interpolation its results are continuous, but the slope changes at the vertex points.
- Cubic spline interpolation has the longest relative execution time, although it requires less memory than cubic interpolation. It produces the smoothest results of all the interpolation methods. You may obtain unexpected results, however, if your input data is non-uniform and some points are much closer together than others.
- Cubic interpolation requires more memory and execution time than either the nearest neighbor or linear methods. However, both the interpolated data and its derivative are continuous.

The relative performance of each method holds true even for interpolation of two-dimensional or multidimensional data. For a graphical comparison of
interpolation methods, see the section "Comparing Interpolation M ethods" on page 12-14.

## FFT-Based Interpolation

The function interpft performs one-dimensional interpolation using an FFT-based method. This method calculates the Fourier transform of a vector that contains the values of a periodic function. It then calculates the inverse Fourier transform using more points. Its form is

```
y = interpft(x,n)
```

x is a vector containing the values of a periodic function, sampled at equally spaced points. $n$ is the number of equally spaced points to return.

## Tw o-Dimensional Interpolation

The function interp2 performs two-dimensional interpolation, an important operation for image processing and data visualization. Its most general form is

$$
Z I=\operatorname{interp2}(X, Y, Z, X I, Y I, \text { method })
$$

$Z$ is a rectangular array containing the values of a two-dimensional function, and $X$ and $Y$ are arrays of the same size containing the points for which the values in $Z$ are given. XI and YI are matrices containing the points at which to interpolate the data. method is an optional string specifying an interpolation method.

There are three different interpolation methods for two-dimensional data:

- Nearest neighbor interpolation (method = 'nearest'). This method fits a piecewise constant surface through the data values. The value of an interpolated point is the value of the nearest point.
- Bilinear interpolation (method = 'linear'). This method fits a bilinear surface through existing data points. The value of an interpolated point is a combination of the values of the four closest points. This method is piecewise bilinear, and is faster and less memory-intensive than bicubic interpolation.
- Bicubicinterpolation (method = 'cubic'). This method fits a bicubic surface through existing data points. The value of an interpolated point is a combination of the values of the sixteen closest points. This method is piecewise bicubic, and produces a much smoother surface than bilinear interpolation. This can be a key advantage for applications like image
processing. Use bicubic interpolation when the interpolated data and its derivative must be continuous.

All of these methods require that $X$ and $Y$ be monotonic, that is, either always increasing or always decreasing from point to point. You should prepare these matrices using the meshgrid function, or else be sure that the "pattern" of the points emulates the output of meshgrid. In addition, each method automatically maps the input to an equally spaced domain before interpolating. If $X$ and $Y$ are already equally spaced, you can speed execution time by prepending an asterisk to the method string, for example, ' *cubic '.

## Comparing Interpolation Methods

This example compares two-dimensional interpolation methods on a 7-by-7 matrix of data.

1 Generate the peaks function at low resolution.

```
[x,y] = meshgrid(-3:1:3);
z = peaks(x,y);
surf(x,y,z)
```

2 Generate a finer mesh for interpolation.
[xi,yi] = meshgrid(-3:0.25:3);
3 Interpolate using nearest neighbor interpolation.
zi1 = interp2(x,y,z,xi,yi,'nearest');
4 Interpolate using bilinear interpolation:
zi2 = interp2(x,y,z,xi,yi,'bilinear');
5 Interpolate using bicubic interpolation.
zi3 = interp2(x,y,z,xi,yi,'bicubic');
6 Compare the surface plots for the different interpolation methods.

7 Compare the contour plots for the different interpolation methods.

Notice that the bicubic method, in particular, produces smoother contours. This is not always the primary concern, however. F or some applications, such as medical image processing, a method like nearest neighbor may be preferred because it doesn't generate any "new" data values.

## Interpolation and Multidimensional Arrays

Several interpolation functions operate specifically on multidimensional data.
Interpolation Functions for Multidimensional Data

| Function | Description |
| :--- | :--- |
| interp3 | Three-dimensional data interpolation. |
| interpn | Multidimensional data interpolation. |
| ndgrid | Multidimensional data gridding (ndfun directory). |

This section discusses:

- Interpolation of three-dimensional data
- Interpolation of higher dimensional data
- Multidimensional data gridding

## Interpolation of Three-Dimensional Data

The function interp3 performs three-dimensional interpolation, finding interpolated values between points of a three-dimensional set of samples $v$. You must specify a set of known data points:

- $X, Y$, and $Z$ matrices specify the points for which values of $V$ are given.
- A matrix $V$ contains values corresponding to the points in $X, Y$, and $Z$.

The most general form for interp3 is

```
VI = interp3(X,Y,Z,V,XI,YI,ZI,method)
```

XI, YI, and ZI are the points at which interp3 interpolates values of V. For out-of-range values, interp3 returns NaN.
There are three different interpolation methods for three-dimensional data:

- Nearest neighbor interpolation (method = 'nearest'). This method chooses the value of the nearest point.
- Trilinear interpolation (method = 'linear'). This method uses piecewise linear interpolation based on the values of the nearest eight points.
- Tricubicinterpol ation (method = ' cubic '). This method uses piecewisecubic interpolation based on the values of the nearest sixty-four points.

All of these methods requirethat $X, Y$, and $Z$ be monotonic, that is, either always increasing or always decreasing in a particular direction. In addition, you should prepare these matrices using the meshgrid function, or else be sure that the "pattern" of the points emulates the output of meshgrid.
E ach method automatically maps the input to an equally spaced domain before interpolating. If $x$ is already equally spaced, you can speed execution time by prepending an asterisk to the method string, for example, ' *cubic '.

## Interpolation of Higher Dimensional Data

The function interpn performs multidimensional interpolation, finding interpolated values between points of a multidimensional set of samples $v$. The most general form for interpn is

```
VI = interpn(X1,X2,X3...,V,Y1,Y2,Y3,...,method)
```

$1,2,3, \ldots$ are matrices that specify the points for which values of $V$ are given. $v$ is a matrix that contains the values corresponding to these points. $1,2,3, \ldots$
are the points for which interpn returns interpolated values of v . For out-of-range values, interpn returns NaN .

Y1, Y2, Y3, ... must be either arrays of the same size, or vectors. If they are vectors of different sizes, interpn passes them to ndgrid and then uses the resulting arrays.

There are three different interpolation methods for multidimensional data:

- $N$ earest neighbor interpolation (method $=$ 'nearest'). This method chooses the value of the nearest point.
- Linear interpolation (method = 'linear'). This method uses piecewise linear interpolation based on the values of the nearest two points in each dimension.
- Cubic interpolation (method = 'cubic'). This method uses piecewise cubic interpolation based on the values of the nearest four points in each dimension.

All of these methods require that $\mathrm{x} 1, \mathrm{x} 2, \mathrm{x} 3$ be monotonic. In addition, you should prepare these matrices using the ndgrid function, or else be sure that the "pattern" of the points emulates the output of ndgrid.

E ach method automatically maps the input to an equally spaced domain before interpolating. If X is already equally spaced, you can speed execution time by prepending an asterisk to the method string; for example, ' *cubic '.

## Multidimensional Data Gridding

The ndgrid function generates arrays of data for multidimensional function evaluation and interpolation. ndgrid transforms the domain specified by a series of input vectors into a series of output arrays. The ith dimension of these output arrays are copies of the elements of input vector $x_{i}$.

The syntax for ndgrid is

$$
[x 1, x 2, x 3, \ldots]=\operatorname{ndgrid}(x 1, x 2, x 3, \ldots)
$$

For example, assume that you want to evaluate a function of three variables over a given range. Consider the function

$$
z=x_{2} e^{\left(-x_{1}^{2}-x_{2}^{2}-x_{3}^{2}\right)}
$$

for $-2 \pi \leq x_{1} \leq 0,2 \pi \leq x_{2} \leq 4 \pi$, and $0 \leq x_{3} \leq 2 \pi$. To evaluate and plot this function:

```
x1 = -2:0.2:2;
x2 = -2:0.25:2;
x3 = -2:0.16:2;
[X1,X2,X3] = ndgrid(x1,x2,x3);
z = X2.*exp(-X1.^2 -X2.^2 - X3.^2);
slice(X2,X1,X3,z,[-1.2.8 2],2,[-2 0.2])
```

## Triangulation and Interpolation of Scattered Data

MATLAB provides routines that aid in the analysis of closest-point problems and geometric analysis.

Functions for Analysis of Closest-Point Problems and Geometric Analysis

| Function | Description |
| :--- | :--- |
| convhull | Convex hull. |
| delaunay | Delaunay triangulation. |

| Functions for Analysis of Closest-Point Problems and Geometric Analysis |  |
| :--- | :--- |
| Function | Description |
| delaunay3 | 3-D Delaunay tessellation. |
| dsearch | Nearest point search of Delaunay triangulation. |
| inpolygon | True for points inside polygonal region. |
| polyarea | Area of polygon. |
| rectint | Area of intersection for two or more rectangles. |
| tsearch | Closest triangle search. |
| voronoi | Voronoi diagram. |

This section applies the following techniques to the seamount data set supplied with MATLAB:

- Convex hulls
- Delaunay triangulation
- Voronoi diagrams

See also "Tessellation and Interpolation of Scattered Data in Higher Dimensions" on page 12-27.

Note Examples in this section use the MATLAB seamount data set. Seamounts are underwater mountains. They are valuable sources of information about marine geology. The seamount data set represents the surface, in 1984, of the seamount designated LR148.8W located at $48.2^{\circ} \mathrm{S}$, $148.8^{\circ} \mathrm{W}$ on the Louisville Ridge in the South Pacific. For more information about the data and its use, see Parker [2].

The seamount data set provides longitude (x), latitude (y) and depth-in-feet (z) data for 294 points on the seamount LR148.8W.

## Convex Hulls

The convhull function returns the indices of the points in a data set that comprise the convex hull for the set. Use the plot function to plot the output of convhull.

This example loads the seamount data and plots the longitudinal (x) and latitudinal (y) data as a scatter plot. It then generates the convex hull and uses plot to plot the convex hull.

```
load seamount
plot(x,y,'.','markersize',10)
k = convhull(x,y);
hold on, plot(x(k),y(k),'-r'), hold off
grid on
```

## Delaunay Triangulation

Given a set of coplanar data points, Delaunay triangulation is a set of lines connecting each point to its natural neighbors. The delaunay function returns a Delaunay triangulation as a set of triangles such that no data points are contained in any triangle's circumcircle.

You can use triplot to print the resulting triangles in two-dimensional space. Y ou can also add data for a third dimension to the output of delaunay and plot the result as a surface with trisurf, or as a mesh with trimesh.

Plotting a Delaunay Triangulation. To try delaunay, load the seamount data set and view the longitude ( $x$ ) and latitude ( y ) data as a scatter plot.

```
    load seamount
    plot(x,y,'.','markersize',12)
    xlabel('Longitude'), ylabel('Latitude')
    grid on
```

Apply Delaunay triangulation and use triplot to overplot the resulting triangles on the scatter plot.

```
tri = delaunay(x,y);
hold on, triplot(tri,x,y), hold off
```

Mesh and Surface Plots. Add the depth data (z) from seamount, to the Delaunay triangulation, and use trimesh to produce a mesh in three-dimensional space. Similarly, you can use trisurf to produce a surface.

```
figure
hidden on
trimesh(tri,x,y,z)
grid on
xlabel('Longitude'); ylabel('Latitude'); zlabel('Depth in Feet')
```

Contour Plots. This code uses meshgrid, griddata, and contour to produce a contour plot of the seamount data.

```
figure
[xi,yi] = meshgrid(210.8:.01:211.8,-48.5:.01:-47.9);
zi = griddata(x,y,z,xi,yi,'cubic');
[c,h] = contour(xi,yi,zi,'b-');
clabel(c,h)
xlabel('Longitude'), ylabel('Latitude')
```

The arguments for meshgrid encompass the largest and smallest x and y values in the original seamount data. To obtain these values, use min ( $x$ ), $\max (\mathrm{x}), \min (\mathrm{y})$, and $\max (\mathrm{y})$.

Closest-Point Searches. You can search through the Delaunay triangulation data with two functions:

- dsearch finds the indices of the ( $x, y$ ) points in a Delaunay triangulation closest to the points you specify. This code searches for the point closest to (211.32, -48.35) in the triangulation of the seamount data.

```
xi = 211.32; yi = -48.35;
p = dsearch(x,y,tri,xi,yi);
[x(p), y(p)]
    ans =
        211.3400 -48.3700
```

- tsearch, finds the indices into the delaunay output that specify the enclosing triangles of the points you specify. This example uses the index of the enclosing triangle for the point (211.32, -48.35) to obtain the coordinates of the vertices of the triangle.

```
xi = 211.32; yi = -48.35;
t = tsearch(x,y,tri,xi,yi);
r = tri(t,:);
A = [x(r) y(r)]
A =
    211.3000-48.3000
    211.3400 -48.3700
    211.2800 -48.3200
```

## Voronoi Diagrams

Voronoi diagrams are a closest-point plotting technique related to Delaunay triangulation.

F or each point in a set of coplanar points, you can draw a polygon that encloses all the intermediate points that are closer to that point than to any other point in the set. Such a polygon is called a Voronoi polygon, and the set of all Voronoi polygons for a given point set is called a Voronoi diagram.

The voronoi function can plot the cells of the Voronoi diagram, or return the vertices of the edges of the diagram. This example loads the seamount data, then uses the voronoi function to produce the Voronoi diagram for the longitudinal (x) and latitudinal (y) dimensions. Note that voronoi plots only the bounded cells of the Voronoi diagram.

```
load seamount
voronoi(x,y)
grid on
xlabel('Longitude'), ylabel('Latitude')
```

Note See the voronoi function for an example that uses the vertices of the edges to plot a Voronoi diagram.

## Tessellation and Interpolation of Scattered Data in Higher Dimensions

Many applications in science, engineering, statistics, and mathematics require structures like convex hulls, Voronoi diagrams, and Delaunay tessellations.

Using Qhull [1], MATLAB functions enable you to geometrically analyze data sets in any dimension.

Functions for Multidimensional Geometrical Analysis

| Function | Description |
| :--- | :--- |
| convhulln | n-D convex hull. |
| delaunayn | n-D Delaunay tessellation. |
| dsearchn | n-D nearest point search. |
| griddatan | n-D data gridding and hypersurface fitting. |
| tsearchn | n-D closest simplex search. |
| voronoin | n-D Voronoi diagrams. |

This section demonstrates these geometric analysis techniques:

- Convex hulls
- Delaunay triangulations
- Voronoi diagrams
- Interpolation of scattered multidimensional data

## Convex Hulls

The convex hull of a data set in n -dimensional space is defined as the smallest convex region that contains the data set.

Computing a Convex Hull. The convhulln function returns the indices of the points in a data set that comprise the facets of the convex hull for the set. For example, suppose $x$ is an 8 -by- 3 matrix that consists of the 8 vertices of a cube. The convex hull of $x$ then consists of 12 facets.

```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d);
X = [x(:),y(:),z(:)]; % corner points of a cube
C = convhulln(X)
C =
```

| 3 | 1 | 5 |
| :--- | :--- | :--- |
| 1 | 2 | 5 |
| 2 | 1 | 3 |
| 7 | 3 | 5 |
| 8 | 7 | 5 |
| 7 | 8 | 3 |
| 6 | 8 | 5 |
| 2 | 6 | 5 |
| 6 | 2 | 8 |
| 8 | 4 | 3 |
| 4 | 2 | 3 |
| 2 | 4 | 8 |

Because the data is three-dimensional, thefacets that make up the convex hull are triangles. The 12 rows of c represent 12 triangles. The elements of C are indices of points in x. F or example, the first row, 315 , means that the first triangle has $\mathrm{X}(3,:), \mathrm{X}(1,:)$, and $\mathrm{X}(5,:)$ as its vertices.

For three-dimensional convex hulls, you can use trisurf to plot the output. However, using patch to plot the output gives you more control over the color of the facets. Note that you cannot plot convhulln output for $n>3$.
This code plots the convex hull by drawing the triangles as three-dimensional patches.

```
figure, hold on
d = [1 1 2 3 1 % Index into C column.
for i = 1:size(C,1) % Draw each triangle.
    j= C(i,d); % Get the ith C to make a patch.
    h(i)=patch(X(j, 1),X(j, 2),X(j, 3),i,'FaceAlpha',0.9);
end % 'FaceAlpha' is used to make it transparent.
hold off
view(3), axis equal, axis off
camorbit(90,-5); % To view it from another angle
title('Convex hull of a cube')
```

## Delaunay Tessellations

A Delaunay tessellation is a set of simplices such that no data points are contained in any simplex's circumsphere. In two-dimensional space, a simplex is a triangle. In three-dimensional space, a simplex is a tetrahedron.

Computing a Delaunay Tessellation. The delaunayn function returns the indices of the points in a data set that comprise the simplices of an $n$-dimensional Delaunay tessellation of the data set.

This example uses the same $x$ as in the convex hull example, i.e. the 8 corner points of a cube, with the addition of a center point.

```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d);
X = [x(:),y(:),z(:)]; % 8 corner points of a cube
X(9,:) = [0 0 0]; % Add center to the vertex list.
T = delaunayn(X) %Generate Delaunay tessellation.
```

$\mathrm{T}=$|  |  |  |  |
| :--- | :--- | :--- | :--- |
| 9 | 1 | 5 | 6 |
| 3 | 9 | 1 | 5 |
| 2 | 9 | 1 | 6 |
| 2 | 3 | 9 | 4 |
| 2 | 3 | 9 | 1 |
| 7 | 9 | 5 | 6 |
| 7 | 3 | 9 | 5 |
| 8 | 7 | 9 | 6 |
| 8 | 2 | 9 | 6 |
| 8 | 2 | 9 | 4 |
| 8 | 3 | 9 | 4 |
| 8 | 7 | 3 | 9 |

The 12 rows of $T$ represent the 12 simplices, in this case irregular tetrahedrons, that partition the cube. Each row represents one tetrahedron, and the row elements are indices of points in $x$.

For three-dimensional tessellations, you can use tetramesh to plot the output. However, using patch to plot the output gives you more control over the color of the facets. Note that you cannot plot delaunayn output for $n>3$.
This code plots the tessellation $T$ by drawing the tetrahedrons using three-dimensional patches.

```
figure, hold on
d = [1 1 1 2; 2 2 3 3; 3 4 4 4]; % Index into T
for i = 1:size(T,1) % Draw each tetrahedron.
    y = T(i,d); % Get the ith T to make a patch.
    x1 = reshape(X(y,1),3,4);
    x2 = reshape(X(y,2),3,4);
    x3 = reshape(X(y,3),3,4);
    h(i)=patch(x1,x2,x3,(1:4)*i,'FaceAlpha',0.9);
end
hold off
view(3), axis equal
axis off
camorbit(65,120) % To view it from another angle
title('Delaunay tessellation of a cube with a center point')
```

You can use cameramenu to rotate the figure in any direction.

## Voronoi Diagrams

Given $m$ data points in n-dimensional space, a Voronoi diagram is the partition of $n$-dimensional space into $m$ polyhedral regions, one region for each data point. Such a region is called a Voronoi cell. A Voronoi cell satisfies the condition that it contains all points that are closer to its data point than any other data point in the set.

Computing a Voronoi Diagram. The voronoin function returns two outputs:

- $v$ is an $m$-by-n matrix of $m$ points in $n$-space. Each row of $v$ represents a Voronoi vertex.
- C is a cell array of vectors. Each vector in the cell array C represents a Voronoi cell. The vector contains indices of the points in $v$ that are the vertices of the Voronoi cell. Each Voronoi cell may have a different number of points.

Because a Voronoi cell can be unbounded, the first row of $v$ is a point at infinity. Then any unbounded Voronoi cell in c includes the point at infinity, i.e., the first point in $v$.

This example uses the same $x$ as in the Delaunay example, i.e., the 8 corner points of a cube and its center. Random noise is added to make the cube less regular. The resulting Voronoi diagram has 9 Voronoi cells.

```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d);
X = [x(:),y(:),z(:)]; % 8 corner points of a cube
X(9,:) = [0 0 0]; % Add center to the vertex list.
X = X+0.01*rand(size(X)); % Make the cube less regular.
[V,C] = voronoin(X);
V =
\begin{tabular}{rrr} 
Inf & Inf & Inf \\
0.0055 & 1.5054 & 0.0004 \\
0.0037 & 0.0101 & -1.4990 \\
0.0052 & 0.0087 & -1.4990 \\
0.0030 & 1.5054 & 0.0030 \\
0.0072 & 0.0072 & 1.4971 \\
-1.7912 & 0.0000 & 0.0044 \\
-1.4886 & 0.0011 & 0.0036 \\
-1.4886 & 0.0002 & 0.0045 \\
0.0101 & 0.0044 & 1.4971 \\
1.5115 & 0.0074 & 0.0033 \\
1.5115 & 0.0081 & 0.0040 \\
0.0104 & -1.4846 & -0.0007 \\
0.0026 & -1.4846 & 0.0071
\end{tabular}
C =
    [1x8 double]
    [1x6 double]
    [1x4 double]
        [1\times6 double]
        [1\times6 double]
        [1\times6 double]
        [1\times6 double]
        [1\times6 double]
        [1x12 double]
```

In this example, v is a 13-by-3 matrix, the 13 rows are the coordinates of the 13 Voronoi vertices. Thefirst row of $v$ is a point at infinity. $C$ is a 9 -by- 1 cell array,
where each cell in the array contains an index vector into V corresponding to one of the 9 Voronoi cells. For example, the 9th cell of the Voronoi diagram is

$$
C\{9\}=2345678910111213
$$

If any index in a cell of the cell array is 1, then the corresponding Voronoi cell contains the first point in V, a point at infinity. This means the Voronoi cell is unbounded.

To view a bounded Voronoi cell, i.e., one that does not contain a point at infinity, use the convhulln function to compute the vertices of the facets that make up the Voronoi cell. Then use patch and other plot functions to generate the figure. F or example, this code plots the Voronoi cell defined by the 9th cell in C.

```
X = V(C{9},:); % View 9th Voronoi cell.
K = convhulln(X);
figure
hold on
d = [1 2 3 1]; % Index into K
for i = 1:size(K,1)
    j = K(i,d);
    h(i)=patch(X(j,1),X(j, 2),X(j,3),i,'FaceAlpha',0.9);
end
hold off
view(3)
axis equal
title('One cell of a Voronoi diagram')
```

One cell of a Voronoi diagram

## Interpolating $\mathbf{N}$-Dimensional Data

Usethe griddatan function to interpolate multidimensional data, particularly scattered data. griddatan uses the delaunayn function to tessellate the data, and then interpolates based on the tessellation.

Suppose you want to visualize a function that you have evaluated at a set of $n$ scattered points. In this example, $x$ is an $n$-by- 3 matrix of points, each row containing the ( $x, y, z$ ) coordinates for one of the points. The vector v contains the $n$ function values at these points. The function for this example is the squared distance from the origin, $v=x .^{\wedge} 2+y . \wedge 2+z . \wedge 2$.
Start by generating $n=5000$ points at random in three-dimensional space, and computing the value of a function on those points.

```
n = 5000;
X = 2*rand(n,3)-1;
v = sum(X.^2,2);
```

The next step is to use interpolation to computefunction values over a grid. Use meshgrid to create the grid, and griddatan to do the interpolation.

```
delta = 0.05;
d = -1:delta:1;
[x0,y0,z0] = meshgrid(d,d,d);
XO = [xO(:), y0(:), zO(:)];
v0 = griddatan(X,v,XO);
v0 = reshape(v0, size(x0));
```

Then use isosurface and related functions to visualize the surface that consists of the ( $x, y, z$ ) values for which the function takes a constant value. You could pick any value, but the example uses the value 0.6 . Since the function is the squared distance from the origin, the surface at a constant value is a sphere.

```
p = patch(isosurface(x0,y0,z0,v0,0.6));
isonormals(x0,y0,z0,v0,p);
set(p,'FaceColor','red','EdgeColor','none');
view(3);
camlight;
lighting phong
axis equal
title('Interpolated sphere from scattered data')
```

Note A smaller delta produces a smoother sphere, but increases the compute time.

## Interpolated sphere from scattered data

This chapter introduces MATLAB's data analysis capabilities. It discusses how to organize arrays for data analysis, how to use simple descriptive statistics functions, and how to perform data preprocessing tasks in MATLAB. It also discusses other data analysis topics, including regression, curve fitting, data filtering, and fast Fourier transforms (FFTs). It includes:

## Column-O riented Data Sets

Organizing arrays for data analysis.

## Basic Data Analysis Functions

Basic data analysis functions and an example that uses some of the functions. This section also discusses functions for the computation of correlation coefficients and covariance, and for finite difference calculations.

## Data Preprocessing

Working with missing values, and outliers or misplaced data points in a data set.

## Regression and Curve Fitting

Investigates the use of different regression methods to find functions that describe the relationship among observed variables.

## Case Study: Curve Fitting

Uses a case study to look at some of MATLAB's basic data analysis capabilities. This section also provides information about the Basic Fitting interface.

## Difference Equations and Filtering

Discusses MATLAB functions for working with difference equations and filters.

## Fourier Analysis and the Fast Fourier Transform (FFT)

Discusses Fourier analysis in MATLAB

## Data Analysis and Statistics Functions

The data analysis and statistics functions are in the directory datafun in the MATLAB Tool box. Use online help to get a complete list of functions.

## Related Toolboxes

A number of related tool boxes provide advanced functionality for specialized data analysis applications.

| Toolbox | Data Analysis Application |
| :--- | :--- |
| Optimization | Nonlinear curve fitting and regression. |
| Signal Processing | Signal processing, filtering, and frequency <br> analysis. |
| Spline | Curve fitting and regression. |
| Statistics | Advanced statistical analysis, nonlinear curve <br> fitting, and regression. |
| System Identification | Parametric / ARMA modeling. |
| Wavelet | Wavelet analysis. |

## Column-Oriented Data Sets

Univariate statistical data is typically stored in individual vectors. The vectors can be either 1-by-n or n-by-1. F or multivariate data, a matrix is the natural representation but there are, in principle, two possibilities for orientation. By MATLAB convention, however, the different variables are put into columns, allowing observations to vary down through the rows. Therefore, a data set consisting of twenty four samples of three variables is stored in a matrix of size 24-by-3.

## Vehicle Traffic Sample Data Set

Consider a sample data set comprising vehicle traffic count observations at three locations over a 24 -hour period.

Vehicle Traffic Sample Data Set

| Time | Location 1 | Location 2 | Location 3 |
| :--- | :--- | :--- | :--- |
| 01 h 00 | 11 | 11 | 9 |
| 02 h 00 | 7 | 13 | 11 |
| 03 h 00 | 14 | 17 | 20 |
| 04 h 00 | 11 | 13 | 9 |
| 05 h 00 | 43 | 51 | 69 |
| 06 h 00 | 38 | 46 | 76 |
| 07 h 00 | 61 | 132 | 186 |
| $08 h 00$ | 75 | 135 | 180 |
| 09 h 00 | 38 | 88 | 115 |
| $10 h 00$ | 28 | 36 | 55 |
| $11 \mathrm{h00}$ | 12 | 12 | 14 |
| $12 h 00$ | 18 | 27 | 30 |
| $13 h 00$ | 18 | 19 | 29 |

Vehicle Traffic Sample Data Set (Continued)

| Time | Location 1 | Location 2 | Location 3 |
| :--- | :--- | :--- | :--- |
| 14 h 00 | 17 | 15 | 18 |
| 15 h 00 | 19 | 36 | 48 |
| 16 h 00 | 32 | 47 | 10 |
| 17 h 00 | 42 | 65 | 92 |
| 18 h 00 | 57 | 66 | 151 |
| 19 h 00 | 44 | 55 | 90 |
| 20 h 00 | 114 | 145 | 257 |
| 21 h 00 | 35 | 58 | 68 |
| 22 h 00 | 11 | 12 | 15 |
| 23 h 00 | 13 | 9 | 15 |
| 24 h 00 | 10 | 9 | 7 |

## Loading and Plotting the Data

The raw data is stored in the file, count. dat.

| 11 | 11 | 9 |
| ---: | ---: | ---: |
| 7 | 13 | 11 |
| 14 | 17 | 20 |
| 11 | 13 | 9 |
| 43 | 51 | 69 |
| 38 | 46 | 76 |
| 61 | 132 | 186 |
| 75 | 135 | 180 |
| 38 | 88 | 115 |
| 28 | 36 | 55 |
| 12 | 12 | 14 |
| 18 | 27 | 30 |
| 18 | 19 | 29 |
| 17 | 15 | 18 |
| 19 | 36 | 48 |

| 32 | 47 | 10 |
| ---: | ---: | ---: |
| 42 | 65 | 92 |
| 57 | 66 | 151 |
| 44 | 55 | 90 |
| 114 | 145 | 257 |
| 35 | 58 | 68 |
| 11 | 12 | 15 |
| 13 | 9 | 15 |
| 10 | 9 | 7 |

Use the load command to import the data.
load count.dat
This creates the matrix count in the workspace.
For this example, there are 24 observations of three variables. This is confirmed by

```
[n,p] = size(count)
n =
    24
p =
    3
```

Create a time vector, $t$, of integers from 1 to $n$.

```
t = 1:n;
```

Now plot the counts versus time and annotate the plot.

```
set(0,'defaultaxeslinestyleorder','-|--|-.')
set(0,'defaultaxescolororder',[0 0 0])
plot(t,count), legend('Location 1','Location 2','Location 3',2)
xlabel('Time'), ylabel('Vehicle Count'), grid on
```

The plot shows the vehicle counts at three locations over a 24-hour period.

## Basic Data Analysis Functions

This section introduces functions for:

- Basic column-oriented data analysis
- Computation of correlation coefficients and covariance
- Calculating finite differences

## Function Summary

A collection of functions provides basic column-oriented data analysis capabilities. These functions are located in the MATLAB datafun directory.
This section also gives you some hints about using row and column data, and provides some basic examples. This table lists the functions.

Basic Data Analysis Function Summary

| Function | Description |
| :--- | :--- |
| cumprod | Cumulative product of elements. |
| cumsum | Cumulative sum of elements. |
| cumtrapz | Cumulative trapezoidal numerical integration. |
| diff | Difference function and approximate derivative. |
| max | Largest component. |
| mean | Average or mean value. |
| median | Median value. |
| min | Smallest component. |
| prod | Product of elements. |
| sort | Sort in ascending order. |
| sortrows | Sort rows in ascending order. |
| std | Standard deviation. |

Basic Data Analysis Function Summary (Continued)

| Function | Description |
| :--- | :--- |
| sum | Sum of elements. |
| trapz | Trapezoidal numerical integration. |

For information about calculating the maximum, minimum, mean, median, range, and standard deviation on plotted data, and creating plots of these statistics, see "Adding Plots of Data Statistics to a Graph" in the MATLAB graphics documentation.

## Working with Row and Column Data

For vector input arguments to these functions, it does not matter whether the vectors are oriented in row or column direction. For array arguments, however, the functions operate column by column on the data in the array. This means, for example, that if you apply max to an array, the result is a row vector containing the maximum values over each column.

Note You can add more functions to this list using M-files, but when doing so, you must exercise care to handle the row-vector case. If you are writing your own column-oriented M -files, check other M-files; for example, mean.m and diff.m.

## Basic Examples

Continuing with the vehicle traffic count example, the statements

```
    mx = max(count)
    mu = mean(count)
    sigma = std(count)
result in
    mx =
        114 145 257
        mu =
            32.0000 46.5417 65.5833
```

```
sigma =
    25.3703 41.4057 68.0281
```

Tolocate the index at which the minimum or maximum occurs, a second output parameter can be specified. F or example,

```
[mx,indx] = min(count)
mx =
    7 9
        7
indx =
    2 23 24
```

shows that the lowest vehicle count is recorded at 02 h 00 for the first observation point (column one) and at 23 hOO and 24 h 00 for the other observation points.

Y ou can subtract the mean from each column of the data using an outer product involving a vector of $n$ ones.

```
[n,p] = size(count)
e = ones(n,1)
x = count - e*mu
```

Rearranging the data may help you evaluate a vector function over an entire data set. For example, to find the smallest value in the entire data set, use

```
min(count(:))
```

which produces
ans =
7
The syntax count ( : ) rearranges the 24-by-3 matrix into a 72 -by-1 column vector.

## Covariance and Correlation Coefficients

MATLAB's statistical capabilities includetwo functions for the computation of correlation coefficients and covariance.

Covariance and Correlation Coefficient Function Summary

| Function | Description |
| :--- | :--- |
| cov | Variance of vector - measure of spread or dispersion of <br> sample variable. |
| Covariance of matrix - measure of strength of linear <br> relationships between variables. |  |
| corrcoef | Correlation coefficient - normalized measure of linear <br> relationship strength between variables. |

## Covariance

cov returns the variance for a vector of data. The variance of the data in the first column of count is

```
cov(count(:,1))
ans =
    643.6522
```

For an array of data, cov calculates the covariance matrix. The variance values for the array columns are arranged al ong the diagonal of the covariance matrix. The remaining entries reflect the covariance between the columns of the original array. For an m-by-n matrix, the covariance matrix has size n-by-n. For example, the covariance matrix for count, cov (count), is arranged as

$$
\begin{gathered}
{\left[\begin{array}{ccc}
\sigma_{11}^{2} & \sigma_{12}^{2} & \sigma_{13}^{2} \\
\sigma_{21}^{2} & \sigma_{22}^{2} & \sigma_{23}^{2} \\
\sigma_{31}^{2} & \sigma_{32}^{2} & \sigma_{33}^{2}
\end{array}\right]} \\
\sigma_{\mathrm{ij}}^{2}=\sigma_{\mathrm{ji}}^{2}
\end{gathered}
$$

## Correlation Coefficients

corrcoef produces a matrix of correlation coefficients for an array of data where each row is an observation and each column is a variable. The correlation coefficient is a normalized measure of the strength of the linear relationship between two variables. Uncorrelated data results in a correlation coefficient of 0 ; equivalent data sets have a correlation coefficient of 1.

For an m-by-n matrix, the correlation coefficient matrix has size $n$-by-n. The arrangement of the elements in the correlation coefficient matrix corresponds to the location of the elements in the covariance matrix described above.

For our traffic count example

```
corrcoef(count)
```

results in
ans $=$

| 1.0000 | 0.9331 | 0.9599 |
| :--- | :--- | :--- |
| 0.9331 | 1.0000 | 0.9553 |
| 0.9599 | 0.9553 | 1.0000 |

Clearly there is a strong linear correlation between the three traffic counts observed at the three locations, as the results are close to 1.

## Finite Differences

MATLAB provides three functions for finite difference calculations.

| Function | Description |
| :--- | :--- |
| diff | Difference between successive elements of a vector. <br> Numerical partial derivatives of a vector. |
| gradient | Numerical partial derivatives a matrix. |
| del2 | Discrete Laplacian of a matrix. |

The diff function computes the difference between successive elements in a numeric vector. That is, $\operatorname{diff}(X)$ is $[X(2)-X(1) X(3)-X(2) \ldots$ $X(n)-X(n-1)]$. So, for a vector $A$,

$$
A=\left[\begin{array}{lllllll}
9 & -2 & 3 & 0 & 1 & 5 & 4
\end{array}\right] ;
$$

```
diff(A)
ans =
    -11 
```

Besides computing the first difference, diff is useful for determining certain characteristics of vectors. F or example, you can use diff to determine if a vector is monotonic (elements are always either increasing or decreasing), or if a vector has equally spaced elements. This table describes a few different ways to use diff with a vector $x$.

| Test | Description |
| :--- | :--- |
| $\operatorname{diff}(x)==0$ | Tests for repeated elements. |
| $\operatorname{all}(\operatorname{diff}(x)>0)$ | Tests for monotonicity. |
| $\operatorname{all}(\operatorname{diff}(\operatorname{diff}(x))==0)$ | Tests for equally spaced vector elements. |

## Data Preprocessing

This section tells you how to work with

- Missing values
- Outliers and misplaced data points

## Missing Values

The special value, NaN, stands for Not-a-N umber in MATLAB. IEEE floating-point arithmetic convention specifies NaN as the result of undefined expressions such as 0/0.

The correct handling of missing data is a difficult problem and often varies in different situations. For data analysis purposes, it is often convenient to use NaNs to represent missing values or data that are not available.

MATLAB treats NaNs in a uniform and rigorous way. They propagate naturally through to the final result in any calculation. Any mathematical calculation involving NaNs produces NaNs in the results.
For example, consider a matrix containing the 3-by-3 magic square with its center element set to NaN.

```
a = magic(3); a(2,2) = NaN
a =
\begin{tabular}{rrr}
8 & 1 & 6 \\
3 & NaN & 7 \\
4 & 9 & 2
\end{tabular}
```

Compute a sum for each column in the matrix.

```
sum(a)
ans =
    15 NaN 15
```

Any mathematical calculation involving NaNs propagates NaNs through to the final result as appropriate.

You should remove NaNs from the data before performing statistical computations. Here are some ways to use isnan to remove NaNs from data.

| Code | Description |
| :---: | :---: |
| $\begin{aligned} & \text { i }=\text { find }(\sim i s n a n(x)) ; \\ & x=x(i) \end{aligned}$ | Find indices of elements in vector that are not NaNs, then keep only the non-NaN elements. |
| $x=x(f i n d(\sim i s n a n(x)))$ | Remove NaNs from vector. |
|  | Remove NaNs from vector (faster). |
| $x(i s n a n(x))=$ [ ; | Remove NaNs from vector. |
| X(any(isnan (X)'), : ) = []; | Remove any rows of matrix $x$ containing NaNs. |

Note You must use the special function isnan to find NaNs because, by IEEE arithmetic convention, the logical comparison, $\mathrm{NaN}==\mathrm{NaN}$ always produces 0 . You cannot use $x(x==N a N)$ = [ ] to remove NaNs from your data.

If you frequently need to remove NaNs, write a short M-file function.
function $X=$ excise(X)
X(any(isnan(X)'),:) = [];
Now, typing
X = excise(X);
accomplishes the same thing.

## Removing Outliers

You can remove outliers or misplaced data points from a data set in much the same manner as NaNs. F or the vehicle traffic count data, the mean and standard deviations of each column of the data are

```
mu = mean(count)
```

```
sigma = std(count)
mu =
    32.0000 46.5417 65.5833
sigma =
    25.3703 41.4057
68.0281
```

The number of rows with outliers greater than three standard deviations is obtained with

```
[n,p] = size(count)
outliers = abs(count - mu(ones(n, 1),:)) > 3*sigma(ones(n, 1),:);
nout = sum(outliers)
nout =
    10
```

There is one outlier in the first column. Remove this entire observation with

```
count(any(outliers'),:) = [];
```

## Regression and Curve Fitting

It is often useful to find functions that describe the relationship between some variables you have observed. I dentification of the coefficients of the function often leads to the formulation of an overdetermined system of simultaneous linear equations. Y ou can find these coefficients efficiently by using the MATLAB backslash operator.

Suppose you measure a quantity y at several values of time $t$.

```
t = [llllllll}0.3.8 1.1 1.6 2.3]';
y = [lllllllllll}0.50.82 1.14 1.25 1.35 1.40]';'
plot(t,y,'o'), grid on
```

The following sections look at three ways of modeling the data:

- Polynomial regression
- Linear-in-the-parameters regression
- Multiple regression

## Polynomial Regression

Based on the plot, it is possible that the data can be modeled by a polynomial function

$$
y=a_{0}+a_{1} t+a_{2} t^{2}
$$

The unknown coefficients $a_{0}, a_{1}$, and $a_{2}$ can be computed by doing a least squares fit, which minimizes the sum of the squares of the deviations of the data from the model. There are six equations in three unknowns,

$$
\left[\begin{array}{l}
y_{1} \\
y_{2} \\
y_{3} \\
y_{4} \\
y_{5} \\
y_{6}
\end{array}\right]=\left[\begin{array}{lll}
1 & t_{1} & t_{1}^{2} \\
1 & t_{2} & t_{2}^{2} \\
1 & t_{3} & t_{3}^{2} \\
1 & t_{4} & t_{4}^{2} \\
1 & t_{5} & t_{5}^{2} \\
1 & t_{6} & t_{6}^{2}
\end{array}\right] \times\left[\begin{array}{l}
a_{0} \\
a_{1} \\
a_{2}
\end{array}\right]
$$

represented by the 6-by-3 matrix

| $x=$ [ones(size(t)) |  | t.^2] |
| :---: | :---: | :---: |
| $\mathrm{X}=$ |  |  |
| 1.0000 | 0 | 0 |
| 1.0000 | 0.3000 | 0.0900 |
| 1.0000 | 0.8000 | 0.6400 |
| 1.0000 | 1.1000 | 1.2100 |
| 1.0000 | 1.6000 | 2.5600 |
| 1.0000 | 2.3000 | 5.2900 |

The solution is found with the backslash operator.

$$
\begin{aligned}
& a= X \backslash y \\
& a= \\
& 0.5318 \\
& 0.9191 \\
&- 0.2387
\end{aligned}
$$

The second-order polynomial model of the data is therefore

$$
y=0.5318+0.919(1) t-0.2387 t^{2}
$$

Now evaluate the model at regularly spaced points and overlay the original data in a plot.

```
T = (0:0.1:2.5)';
Y = [ones(size(T)) T T.^2]*a;
plot(T,Y,'-',t,y,'o'), grid on
```

Clearly this fit does not perfectly approximate the data. We could either increase the order of the polynomial fit, or explore some other functional form to get a better approximation.

## Linear-in-the-Parameters Regression

Instead of a polynomial function, we could try using a function that is linear-in-the-parameters. In this case, consider the exponential function

$$
y=a_{0}+a_{1} e^{-t}+a_{2} t e^{-t}
$$

The unknown coefficients $a_{0}, a_{1}$, and $a_{2}$, are computed by performing a least squares fit. Construct and solve the set of simultaneous equations by forming
the regression matrix, $x$, and solving for the coefficients using the backslash operator.

```
X = [ones(size(t)) exp(-t) t.*exp(-t)];
a = X\y
a =
    1.3974
    - 0.8988
    0.4097
```

The fitted model of the data is, therefore,

$$
\mathrm{y}=1.3974-0.8988 \mathrm{e}^{-\mathrm{t}}+0.4097 \mathrm{te}^{-\mathrm{t}}
$$

Now evaluate the model at regularly spaced points and overlay the original data in a plot.

```
T = (0:0.1:2.5)';
Y = [ones(size(T)) exp(-T) T.*exp(-T)]*a;
plot(T,Y,'-',t,y,'o'), grid on
```

This is a much better fit than the second-order polynomial function.

## Multiple Regression

If y is a function of more than one independent variable, the matrix equations that express the relationships among the variables can be expanded to accommodate the additional data.

Suppose we measure a quantity $y$ for several values of parameters $x_{1}$ and $x_{2}$. The observations are entered as

```
x1 = [ .2 .5 .6 .8 1.0 1.1]';
x2 = [l.1 .3 .4 4 .9 1.1 1.4]';
y = [.17 .26 .28 .23 .27 .24]';
```

A multivariate model of the data is

$$
y=a_{0}+a_{1} x_{1}+a_{2} x_{2}
$$

Multiple regression solves for unknown coefficients $a_{0}, a_{1}$, and $a_{2}$, by performing a least squares fit. Construct and solve the set of simultaneous equations by forming the regression matrix, $x$, and solving for the coefficients using the backslash operator.

```
X = [ones(size(x1)) x1 x2];
a = X\y
a =
    0.1018
    0.4844
    -0.2847
```

The least squares fit model of the data is

$$
y=0.1018+0.4844 x_{1}-0.2847 x_{2}
$$

To validate the model, find the maximum of the absolute value of the deviation of the data from the model.

```
Y = X*a;
MaxErr = max(abs(Y - y))
MaxErr =
    0.0038
```

This is sufficiently small to be confident the model reasonably fits the data.

## Case Study: Curve Fitting

This section provides an overview of some of MATLAB's basic data analysis capabilities in the form of a case study. The examples that follow work with a collection of census data, using MATLAB functions to experiment with fitting curves to the data:

- Polynomial fit
- Analyzing residuals
- Exponential fit
- Error bounds

This section also tells you how to use the Basic Fitting interface to perform curve fitting tasks.

## Loading the Data

The file census .mat contains U.S. population data for the years 1790 through 1990. Load it into MATLAB.
load census
Your workspace now contains two new variables, cdate and pop:

- cdate is a column vector containing the years from 1790 to 1990 in increments of 10 .
- pop is a column vector with the U.S. population figures that correspond tothe years in cdate.

## Polynomial Fit

A first try in fitting the census data might be a simple polynomial fit. Two MATLAB functions help with this process.

Curve Fitting Function Summary

| Function | Description |
| :--- | :--- |
| polyfit | Polynomial curve fit. |
| polyval | Evaluation of polynomial fit. |

MATLAB's polyfit function generates a "best fit" polynomial (in the least squares sense) of a specified order for a given set of data. For a polynomial fit of the fourth-order

```
p = polyfit(cdate,pop,4)
Warning: Polynomial is badly conditioned. Remove repeated data
points or try centering and scaling as described in HELP POLYFIT.
p =
    1.0e+05 *
        0.0000 -0.0000 0.0000 -0.0126 6.0020
```

The warning arises because the polyfit function uses the cdate values as the basis for a matrix with very large values (it creates a Vandermonde matrix in its calculations - see the polyfit M-file for details). The spread of the cdate values results in scaling problems. One way to deal with this is to normalize the cdate data.

## Preprocessing: Normalizing the Data

Normalization is a process of scaling the numbers in a data set to improve the accuracy of the subsequent numeric computations. A way to normalize cdate is to center it at zero mean and scale it to unit standard deviation.

```
sdate = (cdate - mean(cdate))./std(cdate)
```

Now try the fourth-degree polynomial model using the normalized data.

```
p = polyfit(sdate,pop,4)
p =
    0.7047 0.9210 23.4706 73.8598 62.2285
```

Evaluate the fitted polynomial at the normalized year values, and plot the fit against the observed data points.

```
pop4 = polyval(p,sdate);
plot(cdate,pop4,'-',cdate,pop,'+'), grid on
```

Another way to normalize data is to use some knowledge of the solution and units. F or example, with this data set, choosing 1790 to be year zero would also have produced satisfactory results.

## Analyzing Residuals

A measure of the "goodness" of fit is the residual, the difference between the observed and predicted data. Compare the residuals for the various fits, using normalized cdate values. It's evident from studying the fit plots and residuals that it should be possible to do better than a simple polynomial fit with this data set.

## Comparison Plots of Fit and Residual

Comparison Plots of Fit and Residual (Continued)

## Exponential Fit

By looking at the population data plots on the previous pages, the population data curve is somewhat exponential in appearance. To take advantage of this, let's try to fit the logarithm of the population values, again working with normalized year values.

```
logp1 = polyfit(sdate,log10(pop),1);
logpred1 = 10.^polyval(logp1,sdate);
semilogy(cdate,logpred1,' -',cdate,pop, '+');
grid on
```

Now try the logarithm analysis with a second-order model.

```
logp2 = polyfit(sdate,log10(pop),2);
logpred2 = 10.^polyval(logp2,sdate);
semilogy(cdate,logpred2,'-',cdate,pop,'+'); grid on
```

This is a more accurate model. The upper end of the plot appears to taper off, while the polynomial fits in the previous section continue, concave up, to infinity.

Compare the residuals for the second-order logarithmic model.

The residuals are more random than for the simple polynomial fit. As might be expected, the residuals tend to get larger in magnitude as the population increases. But overall, thelogarithmic model provides a more accurate fit to the population data.

## Error Bounds

Error bounds are useful for determining if your data is reasonably modeled by You can obtain the error bounds by passing an optional second output parameter from polyfit as an input parameter to polyval.
This example uses the census demo data and normalizes the data by centering it at zero mean and scaling it to unit standard deviation. The example then uses polyfit and polyval to produce error bounds for a second-order polynomial model. Year values are normalized. This code uses an interval of $\pm 2 \Delta$, corresponding to a $95 \%$ confidence interval.

```
load census
sdate = (cdate - mean(cdate))./std(cdate)
[p2,S2] = polyfit(sdate,pop,2);
[pop2,del2] = polyval(p2,sdate,S2);
plot(cdate,pop,'+',cdate,pop2,'g-',cdate,pop2+2*del2,'r:',...
    cdate,pop2-2*del2,'r:'), grid on
```

## The Basic Fitting Interface

MATLAB supports curvefitting through the BasicFitting interface. Using this interface, you can quickly perform many curve fitting tasks within the same easy-to-use environment. The interface is designed so that you can:

- Fit data using a spline interpolant, a shape-preserving interpolant, or a polynomial up to degree 10.
- Plot multiple fits simultaneously for a given data set.
- Plot the fit residuals.
- Examine the numerical results of a fit.
- Evaluate (interpolate or extrapolate) a fit.
- Annotate the plot with the numerical fit results and the norm of residuals.
- Save the fit and evaluated results to the MATLAB workspace.

Depending on your specific curve fitting application, you can use the Basic Fitting interface, the command line functionality, or both.

You can use the Basic Fitting interface only with 2-D data. However, if you plot multiple data sets as a subplot, and at least one data set
is 2-D, then the interface is enabled.

Note For the HP, IBM, and SGI platforms, the Basic Fitting interface is not supported for Release 12.

## O verview of the Basic Fitting Interface

The full Basic Fitting interface is shown below. To reproduce this state, follow these three steps:

1 Plot some data.
2 Select Basic Fitting from the Tools menu.
3 Click the $\rightarrow$ button twice.

Select data - This parameter list is populated with the names of all the data sets you display in the figure window associated with the Basic Fitting interface.

Use this list to select the current data set. The current data set is defined as the data set that is to be fit. Y ou can fit only one data set at a time. However, you can perform multiple fits for the current data set. Use the Plot Editor to change the name of a data set.

Center and scale X data - If checked, the data is centered at zero mean and scaled to unit standard deviation. Y ou may need to center and scale your data to improve the accuracy of the subsequent numerical computations. A warning is displayed if a fit produces results that may be inaccurate.

Plot fits - This panel allows you to visually explore one or more fits to the current data set:

- Check to display fits on figure - Select the fits you want to display for the current data set. There are two types of fits to choose from: interpolants and polynomials. The spline interpolant uses the spline function, while the
shape-preserving interpolant uses the pchip function. Refer to the pchip online help for a comparison of these two functions. The polynomial fits use the polyfit function. You can choose as many fits for a given data set as you want.

If your data set has N points, then you should use polynomials with, at most, N coefficients. If your fit uses polynomials with morethan N coefficients, the interface automatically sets a sufficient number of coefficients to 0 during the calculation so that the system is not underdetermined.

- Show equations - If checked, the fit equation is displayed on the plot.
- Significant digits - Select the significant digits associated with the equation display.
- Plot residuals - If checked, the fit residuals are displayed. The fit residuals are defined as the difference between the ordinate data point and the resulting fit for each abscissa data point. You can display the residuals as a bar plot, as a scatter plot, or as a line plot in the same figure window as the data or in a separate figure window. If you use subpl ots to plot multiple data sets, then residuals can be plotted only in a separate figure window.
- Show norm of residuals - If checked, the norm of residuals are displayed. The norm of residuals is a measure of the goodness of fit, where a smaller value indicates a better fit than a larger value. It is calculated using the norm function, norm( $\mathrm{V}, 2$ ), where V is the vector of residuals.
Numerical results - This panel allows you to explore the numerical results of a single fit to the current data set without plotting the fit:
- Fit - Select the equation to fit to the current data set. The fit results are displayed in the list box below the menu. Note that selecting an equation in this menu does not affect the state of the Plot fits panel. Therefore, if you want to display the fit in the data plot, you may need to select the associated check box in Plot fits.
- Coefficients and norm of residuals - Display the numerical results for the equation selected in Fit. Note that when you first open the Numerical Results panel, the results of the last fit you selected in Plot fits are displayed.
- Save to workspace - Launch a dialog box that allows you to save the fit results to workspace variables.
- Find $\mathbf{Y}=\mathbf{f}(\mathbf{X})$ - Interpolate or extrapolate the current fit.
- Enter value(s) - Enter a MATLAB expression to evaluate for the current fit. The expression is evaluated after you press the Evaluate button, and the results are displayed in the associated table. The current fit is displayed in the Fit menu.
- Save to workspace - Launch a dialog box that allows you to save the evaluated results to workspace variables.
- Plot results - If checked, the evaluated results are displayed on the data plot.

## Example: Using the Basic Fitting Interface

This example illustrates the features of the Basic Fitting interface by fitting a cubic polynomial to the census data. Y ou may want to repeat this example using different equations and compare results. To launch the interface:

1 Plot some data.

```
plot(cdate,pop,'ro')
```

2 Select Basic Fitting from the Tools menu in the figure.

## Configure the Basic Fitting interface to:

- Fit a cubic polynomial to the data.
- Display the equation in the data plot.
- Plot the fit residuals as a bar plot, and display the residuals as a subplot of the data figure window.
- Display the norm of the residuals.

This configuration is shown below.

The Plot fits panel allows you to visually explore multiple fits to the current data set. F or comparison, try fitting additional equations to the census data by selecting the appropriatecheck boxes. If an equation produces results that may be numerically inaccurate, a warning is displayed. In this case, you should select the Center and scale $\mathbf{X}$ data check box to improve the numerical accuracy.

The resulting fit and the residuals are shown below.

The plot legend indicates the name of the data set and the equation. The legend is automatically updated as you add or remove data sets or fits. Additionally, fits are displayed using a default set of line styles and colors. Y ou can change any of the default plot settings using the Plot Editor. However, any changes you make are undone if you subsequently perform another fit. To retain changes, you should wait until after you have finished fitting your data.

Note If you change the name of a data set in the legend, then the name is automatically changed in the Select data menu.

By sel ecting the $\rightarrow$ button, you can examine the fit coefficients and the norm of the residuals.

The Fit menu allows you to explore numerical fit results for the current data set without plotting the fit. F or comparison, you can display the numerical results for other fits by selecting the desired equation. Note that if you want to display a fit in the data plot, you have to select the associated check box in Plot fits.
You can save the fit results to the MATLAB workspace by selecting the Save to workspace button.

The fit structure is shown below.

```
fit1
fit1 =
    type: 'polynomial degree 3'
    coeff: [3.8555e-006 -0.0153 17.7815 -4.8519e+003]
```

You may want to use this structure for subsequent display or analysis. For example, you can use the saved coefficients and the polyval function to evaluate the cubic polynomial at the command line.

By selecting the $\rightarrow$ button again, you can evaluate the current fit at the specified abscissa values. The current fit is displayed in the Fit menu. In this example, the population for the years 2000 to 2050 is evaluated in increments of 10 , and then displayed in the data plot.

The evaluated data is shown below.

You can save the evaluated data to the MATLAB workspace by selecting the Save to workspace button.

## Difference Equations and Filtering

MATLAB has functions for working with difference equations and filters. These functions operate primarily on vectors.

Vectors are used to hold sampled-data signals, or sequences, for signal processing and data analysis. For multi-input systems, each row of a matrix corresponds to a sample point with each input appearing as columns of the matrix.

The function

$$
y=\text { filter }(b, a, x)
$$

processes the data in vector x with the filter described by vectors a and b , creating filtered data $y$.

The filter command can be thought of as an efficient implementation of the difference equation. The filter structure is the general tapped delay-line filter described by the difference equation below, where $n$ is the index of the current sample, na is the order of the polynomial described by vector a and nb is the order of the polynomial described by vector $b$. The output $y(n)$, is a linear combination of current and previous inputs, $x(n) \times(n-1)$..., and previous outputs, $y(n-1) y(n-2)$...

$$
\begin{aligned}
a(1) y(n)= & b(1) x(n)+b(2) x(n-1)+\ldots+b(n b) x(n-n b+1) \\
& -a(2) y(n-1)-\ldots-a(n a) y(n-n a+1)
\end{aligned}
$$

Suppose, for example, we want to smooth our traffic count data with a moving average filter to see the average traffic flow over a 4-hour window. This process is represented by the difference equation

$$
y(n)=\frac{1}{4} x(n)+\frac{1}{4} x(n-1)+\frac{1}{4} x(n-2)+\frac{1}{4} x(n-3)
$$

The corresponding vectors are

```
a = 1;
b =[[l/4 1/4 1/4 1/4}]
```

Note Enter the format command, format rat, to display and enter data using the rational format.

Executing the command
load count.dat
creates the matrix count in the workspace.
For this example, extract the first column of traffic counts and assign it to the vector $x$.

```
x = count(:,1);
```

The 4-hour moving-average of the data is efficiently calculated with
$y=$ filter (b, $a, x) ;$
Compare the original data and the smoothed data with an overlaid plot of the two curves.
$\mathrm{t}=1$ : length $(\mathrm{x})$;
plot(t,x,'-.',t,y,'-'), grid on
legend('Original Data','Smoothed Data',2)

The filtered data represented by the solid line is the 4-hour moving average of the observed traffic count data represented by the dashed line.

For practical filtering applications, the Signal Processing Tool box includes numerous functions for designing and analyzing filters.

## Fourier Analysis and the Fast Fourier Transform (FFT)

Fourier analysis is extremely useful for data analysis, as it breaks down a signal into constituent sinusoids of different frequencies. For sampled vector data, Fourier analysis is performed using the discrete Fourier transform (DFT).

The fast Fourier transform (FFT) is an efficient algorithm for computing the DFT of a sequence; it is not a separate transform. It is particularly useful in areas such as signal and image processing, where its uses range from filtering, convolution, and frequency analysis to power spectrum estimation.
This section:

- Summarizes the Fourier transform functions
- Introduces Fourier transform analysis with an example about sunspot activity
- Calculates magnitude and phase of transformed data
- Discusses the dependence of execution time on length of the transform

## Function Summary

MATLAB provides a collection of functions for computing and working with Fourier transforms.

FFT Function Summary

| Function | Description |
| :--- | :--- |
| fft | Discrete Fourier transform. |
| fft2 | Two-dimensional discrete Fourier transform. |
| fftn | N-dimensional discrete Fourier transform. |
| ifft | Inverse discrete Fourier transform. |
| ifft2 | Two-dimensional inverse discrete Fourier transform. |
| ifftn | N-dimensional inverse discrete Fourier transform. |
| abs | Magnitude. |

## FFT Function Summary (Continued)

| Function | Description |
| :--- | :--- |
| angle | Phase angle. |
| unwrap | Unwrap phase angle in radians. |
| fftshift | Move zeroth lag to center of spectrum. |
| cplxpair | Sort numbers into complex conjugate pairs. |
| nextpow2 | Next higher power of two. |

## Introduction

For length $N$ input sequence $x$, the DFT is a length $N$ vector, $X$. fft and ifft implement the relationships

$$
\begin{array}{ll}
X(k)=\sum_{n=1}^{N} x(n) e^{-j 2 \pi(k-1)\left(\frac{n-1}{N}\right)} & 1 \leq k \leq N \\
x(n)=\frac{1}{N} \sum_{k=1}^{N} X(k) e^{j 2 \pi(k-1)\left(\frac{n-1}{N}\right)} & 1 \leq n \leq N
\end{array}
$$

Note Since the first element of a MATLAB vector has an index 1 , the summations in the equations above are from 1 to N . These produce identical results as traditional Fourier equations with summations from 0 to $\mathrm{N}-1$.

If $x(n)$ is real, we can rewrite the above equation in terms of a summation of sine and cosine functions with real coefficients

$$
x(n)=\frac{1}{N} \sum_{k=1}^{N} a(k) \cos \left(\frac{2 \pi(k-1)(n-1)}{N}\right)+b(k) \sin \left(\frac{2 \pi(k-1)(n-1)}{N}\right)
$$

where

$$
a(k)=\operatorname{real}(X(k)), b(k)=-\operatorname{imag}(X(k)), 1 \leq n \leq N
$$

## Finding an FFT

The FFT of a column vector $x$

```
x = [4 3 7 -9 1 0 0 0]' ;
```

is found with

$$
y=f f t(x)
$$

which results in

```
y =
    6.0000
    11.4853 - 2.7574i
    -2.0000 -12.0000i
    -5.4853 +11.2426i
    18.0000
    -5.4853 -11.2426i
    -2.0000 +12.0000i
    11.4853 + 2.7574i
```

Notice that although the sequence x is real, y is complex. The first component of the transformed data is the constant contribution and the fifth element corresponds to the N yquist frequency. The last three values of y correspond to negative frequencies and, for the real sequence $x$, they are complex conjugates of three components in the first half of $y$.

## Example: Using FFT to Calculate Sunspot Periodicity

Suppose, wewant to analyze the variations in sunspot activity over the last 300 years. You are probably aware that sunspot activity is cyclical, reaching a maximum about every 11 years. Let's confirm that.
Astronomers have tabulated a quantity called the Wolfer number for almost 300 years. This quantity measures both number and size of sunspots.

Load and plot the sunspot data.
load sunspot.dat
year $=\operatorname{sunspot}(:, 1)$;

```
wolfer = sunspot(:,2);
plot(year,wolfer)
title('Sunspot Data')
```

Sunspot Data

Now take the FFT of the sunspot data.

```
Y = fft(wolfer);
```

The result of this transform is the complex vector, Y . The magnitude of Y squared is called the power and a plot of power versus frequency is a "periodogram." Remove thefirst component of $Y$, which is simply the sum of the data, and plot the results.

```
N = length(Y);
Y(1) = [];
power = abs(Y(1:N/2)).^2;
nyquist = 1/2;
freq = (1:N/2)/(N/2)*nyquist;
plot(freq,power), grid on
xlabel('cycles/year')
title('Periodogram')
```

The scale in cycles/year is somewhat inconvenient. Let's plot in years/cycle and estimate what one cycle is. For convenience, plot the power versus period (where period $=1 . /$ freq) from 0 to 40 years/cycle.

```
period = 1./freq;
plot(period,power), axis([0 40 0 2e7]), grid on
ylabel('Power')
xlabel('Period(Years/Cycle)')
```

In order to determine the cycle more precisely,
[mp,index] = max(power);
period(index)
ans $=$
11.0769

## Magnitude and Phase of Transformed Data

Important information about a transformed sequence includes its magnitude and phase. The MATLAB functions abs and angle calculate this information.

To try this, create a time vector $t$, and use this vector to create a sequence $x$ consisting of two sinusoids at different frequencies.

```
t = 0:1/100:10-1/100;
x = sin(2*pi*15*t) + sin(2*pi*40*t);
```

Now use the fft function to compute the DFT of the sequence. The code bel ow calculates the magnitude and phase of the transformed sequence. It uses the abs function to obtain the magnitude of the data, the angle function to obtain the phase information, and unwrap to remove phase jumps greater than pi to their 2*pi complement.

```
y = fft(x);
m = abs(y);
p = unwrap(angle(y));
```

Now create a frequency vector for the x-axis and plot the magnitude and phase.

```
f = (0:length(y)-1)'*100/length(y);
subplot(2,1,1), plot(f,m),
ylabel('Abs. Magnitude'), grid on
subplot(2,1,2), plot(f,p*180/pi)
ylabel('Phase [Degrees]'), grid on
xlabel('Frequency [Hertz]')
```

The magnitude plot is perfectly symmetrical about the Nyquist frequency of 50 hertz. The useful information in the signal is found in the range 0 to 50 hertz.

## FFT Length Versus Speed

You can add a second argument to fft to specify a number of points $n$ for the transform

$$
y=f f t(x, n)
$$

With this syntax, fft pads $x$ with zeros if it is shorter than $n$, or truncates it if it is longer than $n$. If you do not specify $n, f f t$ defaults to the length of the input sequence.

The execution time for fft depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

The inverse FFT function ifft also accepts a transform length argument.
For practical application of the FFT, the Signal Processing Tool box includes numerous functions for spectral analysis.

## Function Functions

Example: Computing the Length of a Curve ..... 14-19
Example: Double Integration ..... 14-20

All of the functions described in this chapter are called function functions because they accept a function as an input arguments. You can pass such a function either as a function handle or as an inline object that defines a mathematical function. The function that is passed in is referred to as the objective function.

This chapter includes:

## Function Summary

A summary of some function functions

## Representing Functions in MATLAB

Some guidelines for representing functions in MATLAB

## Plotting Mathematical Functions

A discussion about using fplot to plot mathematical functions

## Minimizing Functions and Finding Zeros

A discussion of high-level function functions that perform optimization-related tasks

## N umerical Integration (Q uadrature)

A discussion of the MATLAB quadrature functions

Note See the "Differential Equations" and "Sparse Matrices" chapters for information about the use of other function functions.

Note For information about function handles, see the function_handle (@), func2str, and str2func reference pages, and the "Function Handles" section of "Programming and Data Types" in the MATLAB documentation.

## Function Summary

The function functions are located in the MATLAB funfun directory.
This table provides a brief description of the functions discussed in this chapter. Related functions are grouped by category.

| Function Summary |  |  |
| :--- | :--- | :--- |
| Category | Function | Description |
| Plotting | fplot | Plot function. |
| Optimization <br> and zero finding | fminbnd | Minimize function of one variable with <br> bound constraints. |
|  | fminsearch | Minimize function of several variables. |
| Numerical | fzero | quad |
| integration | quadl zero of function of one variable. |  |
|  | dblquad | Simpson quadrature. <br> Numerically evaluate integral, adaptive <br> Lobatto quadrature. |

## Representing Functions in MATLAB

MATLAB can represent mathematical functions by expressing them as MATLAB functions in M-files or as inline objects. For example, consider the function

$$
f(x)=\frac{1}{(x-0.3)^{2}+0.01}+\frac{1}{(x-0.9)^{2}+0.04}-6
$$

This function can be used as input to any of the function functions.

## As MATLAB Functions

You can find the function above in the $M$-file named humps.m.

```
function y = humps(x)
y = 1./((x - 0.3).^2 + 0.01) + 1./((x - 0.9).^2 + 0.04) - 6;
```

To evaluate the function humps at 2.0, use @ to obtain a function handle for humps, and then pass the function handle to feval.

```
fh = @humps;
feval(fh,2.0)
ans =
    -4.8552
```

## As Inline 0 bjects

A second way to represent a mathematical function at the command line is by creating an inline object from a string expression. F or example, you can create an inline object of the humps function

```
f = inline('1./((x-0.3).^2 + 0.01) + 1./((x-0.9).^2 + 0.04)-6');
```

You can then evaluate $f$ at 2.0.
f(2.0)
ans =
$-4.8552$
You can also create functions of more than one argument with inline by specifying the names of the input arguments along with the string expression. For example, the following function has two input arguments $x$ and $y$.

```
f= inline('y*sin(x)+x*cos(y)','x','y')
f(pi,2*pi)
ans =
    3.1416
```

## Plotting Mathematical Functions

The fplot function plots a mathematical function between a given set of axes limits. You can control the $x$-axis limits only, or both the $x$ - and $y$-axis limits.
For example, to plot the humps function over the x-axis range [-5 5], use
fplot(@humps,[-5 5])
grid on

You can zoom in on the function by selecting y-axis limits of - 10 and 25, using fplot(@humps,[-5 5-10 25])
grid on

You can also pass an inline for fplot to graph, as in

```
fplot(inline('2*sin(x+3)'),[-1 1])
```

You can plot more than one function on the same graph with one call to fplot. If you use this with a function, then the function must take a column vector $x$ and return a matrix where each column corresponds to each function, evaluated at each value of $x$.

If you pass an inline object of several functions to fplot, the inline object also must return a matrix where each column corresponds to each function evaluated at each value of $x$, as in

```
fplot(inline('[2*sin(x+3), humps(x)]'),[-5 5])
```

which plots the first and second functions on the same graph.

Note that the inline

```
f= inline('[2*sin(x+3), humps(x)]')
```

evaluates to a matrix of two col umns, one for each function, when $x$ is a column vector.

```
f([1;2;3])
```

## returns

$$
\begin{array}{ll}
-1.5136 & 16.0000 \\
-1.9178 & -4.8552 \\
-0.5588 & -5.6383
\end{array}
$$

## Minimizing Functions and Finding Zeros

MATLAB provides a number of high-level function functions that perform optimization-related tasks. This section describes:

- Minimizing a function of one variable
- Minimizing a function of several variables
- Setting minimization options
- Finding a zero of a function of one variable
- Converting your code to MATLAB Version 5 syntax

The MATLAB optimization functions are:
fminbnd Minimize a function of one variable on a fixed interval
fminsearch Minimize a function of several variables
fzero Find zero of a function of one variable
lsqnonneg Linear least squares with nonnegativity constraints
optimget Get optimization options structure parameter values
optimset Create or edit optimization options parameter structure

F or more optimization capabilities, see the Optimization Tool box.

## Minimizing Functions of One Variable

Given a mathematical function of a single variable coded in an M-file, you can use the fminbnd function to find a local minimizer of the function in a given interval. F or example, to find a minimum of the humps function in the range $(0.3,1)$, use
$\mathrm{x}=\mathrm{fminbnd}($ @humps, 0.3,1)
which returns

```
x =
    0.6370
```

You can ask for a tabular display of output by passing a fourth argument created by the optimset command to fminbnd

```
x = fminbnd(@humps,0.3,1,optimset('Display','iter'))
```

which gives the output

| Func-count | $x$ | $f(x)$ | Procedure |
| :---: | ---: | :---: | :--- |
| 1 | 0.567376 | 12.9098 | initial |
| 2 | 0.732624 | 13.7746 | golden |
| 3 | 0.465248 | 25.1714 | golden |
| 4 | 0.644416 | 11.2693 | parabolic |
| 5 | 0.6413 | 11.2583 | parabolic |
| 6 | 0.637618 | 11.2529 | parabolic |
| 7 | 0.636985 | 11.2528 | parabolic |
| 8 | 0.637019 | 11.2528 | parabolic |
| 9 | 0.637052 | 11.2528 | parabolic |

```
X =
    0.6370
```

This shows the current value of $x$ and the function value at $f(x)$ each time a function evaluation occurs. For fminbnd, one function evaluation corresponds to one iteration of the algorithm. The last column shows what procedure is being used at each iteration, either a golden section search or a parabolic interpolation.

## Minimizing Functions of Several Variables

The fminsearch function is similar to fminbnd except that it handles functions of many variables, and you specify a starting vector $x_{0}$ rather than a starting interval. fminsearch attempts to return a vector $x$ that is a local minimizer of the mathematical function near this starting vector.

Totry fminsearch, create a function three_var of three variables, $x, y$, and $z$.

```
function b = three_var(v)
x = v(1);
y = v(2);
z = v(3);
b = x.^2 + 2.5*sin(y) - z^2*x^2* y^2;
```

Now find a minimum for this function using $x=-0.6, y=-1.2$, and $z=0.135$ as the starting values.

```
v = [-0.6 -1.2 0.135];
```

```
a = fminsearch(@three_var,v)
a =
    0.0000 -1.5708 0.1803
```

## Setting Minimization Options

You can specify control options that set some minimization parameters by calling fminbnd with the syntax

```
x = fminbnd(fun,x1,x2,options)
```

or fminsearch with the syntax
$x=$ fminsearch(fun, $x 0$,options)
options is a structure used by the optimization functions. Use optimset to set the values of the options structure.

```
options = optimset('Display','iter');
```

fminbnd and fminsearch use only the options parameters shown in the following table. See the optimset reference page for a complete list of the parameters that are used in the Optimization Tool box.

| options. Display | A flag that determines if intermediate steps in the <br> minimization appear on the screen. If set to 'iter', <br> intermediate steps are displayed; if set to 'off ', no <br> intermediate solutions are displayed, if set to final, |
| :--- | :--- |
| displays just the final output. |  |

The number of function evaluations, the number of iterations, and the algorithm are returned in the structure output when you provide fminbnd or fminsearch with a fourth output argument, as in
[x,fval,exitflag,output] = fminbnd(@humps, 0.3,1);
or

```
[x,fval,exitflag,output] = fminsearch(@three_var,v);
```

## Finding Zeros of Functions

The fzero function attempts to find a zero of one equation with one variable. You can call this function with either a one-element starting point or a two-element vector that designates a starting interval. If you give fzero a starting point $x_{0}$, fzero first searches for an interval around this point where the function changes sign. If the interval is found, then fzero returns a value near where the function changes sign. If no such interval is found, fzero returns NaN. Alternatively, if you know two points where the function value differs in sign, you can specify this starting interval using a two-element vector; fzero is guaranteed to narrow down the interval and return a value near a sign change.

Use fzero to find a zero of the humps function near -0.2

```
a = fzero(@humps,-0.2)
a =
-0.1316
```

F or this starting point, fzero searches in the neighborhood of -0.2 until it finds a change of sign between -0.10949 and -0.264 . This interval is then narrowed down to -0.1316 . Y ou can verify that -0.1316 has a function value very close to zero using

```
humps(a)
ans =
    8.8818e -16
```

Suppose you know two places where the function value of humps differs in sign such as $x=1$ and $x=-1$. You can use
humps(1)

```
ans =
    1 6
humps(-1)
ans =
    -5.1378
```

Then you can give fzero this interval to start with and fzero then returns a point near where the function changes sign. You can display information as fzero progresses with

```
options = optimset('Display','iter');
a = fzero(@humps,[-1 1],options)
```

| Func-count | x | $f(x)$ | Procedure |
| :---: | :---: | :---: | :---: |
| 1 | -1 | -5.13779 | initial |
| 1 | 1 | 16 | initial |
| 2 | -0.513876 | -4.02235 | interpolation |
| 3 | 0.243062 | 71.6382 | bisection |
| 4 | -0.473635 | -3.83767 | interpolation |
| 5 | -0.115287 | 0.414441 | bisection |
| 6 | -0.150214 | -0.423446 | interpolation |
| 7 | -0.132562 | -0.0226907 | interpolation |
| 8 | -0.131666 | -0.0011492 | interpolation |
| 9 | -0.131618 | $1.88371 \mathrm{e}-07$ | interpolation |
| 10 | -0.131618 | -2.7935e-11 | interpolation |
| 11 | -0.131618 | 8.88178e-16 | interpolation |
| 12 | -0.131618 | -9.76996e-15 | interpolation |

$\mathrm{a}=$
$-0.1316$
The steps of the algorithm include both bisection and interpolation under the Procedure column. If the example had started with a scalar starting point instead of an interval, the first steps after the initial function evaluations would have included some search steps while fzero searched for an interval containing a sign change.

You can specify a relative error tolerance using optimset. In the call above, passing in the empty matrix causes the default relative error tolerance of eps to be used.

## Tips

Optimization problems may take many iterations to converge. Most optimization problems benefit from good starting guesses. Providing good starting guesses improves the execution efficiency and may help locate the global minimum instead of a local minimum.

Sophisticated problems are best solved by an evolutionary approach, whereby a problem with a smaller number of independent variables is solved first. Solutions from lower order problems can generally be used as starting points for higher order problems by using an appropriate mapping.

The use of simpler cost functions and less stringent termination criteria in the early stages of an optimization problem can also reduce computation time. Such an approach often produces superior results by avoiding local minima.

## Troubleshooting

Below is a list of typical problems and recommendations for dealing with them.

| Problem | Recommendation |
| :--- | :--- |
| The solution found by fminbnd <br> or fminsearch does not appear <br> to be a global minimum. | There is no guaranteethat you havea global minimum unless <br> your problem is continuous and has only one minimum. <br> Starting the optimization from a number of different starting <br> points (or intervals in the case of fminbnd) may help to locate <br> the global minimum or verify that there is only one minimum. <br> Use different methods, where possible, to verify results. |
| Sometimes an optimization <br> problem has values of x for <br> which it is impossible to <br> evaluate f. | Modify your function to include a penalty function to give a <br> large positive value to f when infeasibility is encountered. |
| The minimization routine <br> appears to enter an infinite loop <br> or returns a solution that is not <br> a minimum (or not a zero in the <br> case of fzero). | Your objective function (fun) may be returning Inf, NaN, or <br> complex values. The optimization routines expect only real <br> numbers to be returned. Any other values may cause <br> unexpected results. Insert code into your objective function <br> M-file to verify that only real numbers are returned (use the <br> functions isreal and isfinite). |

## Converting Your Optimization Code to MATLAB Version 5 Syntax

Most of the function names and calling sequences changed in Version 5 to accommodate new functionality and to clarify the roles of the input and output variables.

This table lists the optimization functions provided by MATLAB and indicates the functions whose names have changed in Version 5.

| Old (Version 4) Name | New (Version 5) Name |
| :--- | :--- |
| fmin | fminbnd |
| fmins | fminsearch |
| foptions | optimget, optimset |
| fzero | fzero (name unchanged) |
| nnls | lsqnonneg |

This section:

- Tells you how to override default parameter settings with the new optimset and optimget functions.
- Explains the reasons for the new calling sequences and explains how to convert your code.
In addition to the information in this section, consult the individual function reference pages for information about the new functions and about the arguments they take.

## Using optimset and optimget

The optimset function replaces foptions for overriding default parameter settings. optimset creates an options structurethat contains parameters used in the optimization routines. If, on the first call to an optimization routine, the options structure is not provided, or is empty, a set of default parameters is generated. See the optimset reference page for details.

## New Calling Sequences

Version 5 of MATLAB makes these changes in the calling sequences:

- Each function takes an options structure to adjust parameters to the optimization functions (see optimset, optimget).
- The new default output gives information if the function does not converge. (theVersion 4 default was no output, Version 5 used 'final' as the default, the new default is options.display = 'notify').
- Each function returns an exitflag that describes the termination state.
- Each function now has an output structure that contains information about the problem solution relevant to that function.
The sections below describe how to convert from the old function names and calling sequences to the new ones. The calls shown are the most general cases, involving all possible input and output arguments. Note that many of these arguments are optional. See the function reference pages for more information.

Converting from fmin to fminbnd. In Version 4, you used this call to fmin.
[X,OPTIONS] = fmin('FUN',x1,x2,OPTIONS,P1,P2,...);

In Version 5, you call fminbnd like this.

$$
\begin{array}{r}
{[X, \text { FVAL }, \text { EXITFLAG }, \text { OUTPUT }]=\text { fminbnd (@FUN }, x 1, x 2, \ldots} \\
\\
\text { OPTIONS }, \mathrm{P} 1, \mathrm{P} 2, \ldots) ;
\end{array}
$$

Converting from fmins to fminsearch. In Version 4, you used this call to fmins.

```
[X,OPTIONS] = fmins('FUN',x0,OPTIONS,[],P1,P2,...);
```

In Version 5, you call fminsearch like this.

$$
\begin{array}{r}
{[X, \text { FVAL, EXITFLAG }, \text { OUTPUT }]=\text { fminsearch(@FUN }, x 0, \ldots} \\
\text { OPTIONS }, \mathrm{P} 1, \mathrm{P} 2, \ldots) ;
\end{array}
$$

Converting to the new form of fzero. In Version 4, you used this call to fzero.

```
X = fzero('F',X,TOL,TRACE,P1,P2,...);
```

In Version 5, replace the TRACE and TOL arguments with

```
if TRACE == 0,
    val = 'none';
elseif TRACE == 1
    val = 'iter';
end
OPTIONS = optimset('Display',val,'TolX',TOL);
```

Now call fzero like this.

```
[X,FVAL,EXITFLAG,OUTPUT] = fzero(@F,X,OPTIONS,P1,P2,...);
```

Converting from nnls to Isqnonneg. In Version 4, you used this call to nnls. [ $\mathrm{X}, \mathrm{LAMBDA}$ ] $=\mathrm{nnls}(\mathrm{A}, \mathrm{b}, \mathrm{tol})$;

In Version 5, replace the tol argument with

```
OPTIONS = optimset('Display','none','TolX',tol);
```

Now call lsqnonneg like this.
[X,RESNORM,RESIDUAL,EXITFLAG,OUTPUT,LAMBDA] = lsqnonneg(A, b, XO, OPTIONS) ;

## Numerical Integration (Quadrature)

The area beneath a section of a function $F(x)$ can be determined by numerically integrating $\mathrm{F}(\mathrm{x})$, a process referred to as quadrature. The MATLAB quadrature functions are:

| quad | Use adaptive Simpson quadrature |
| :--- | :--- |
| quadl | Use adaptive Lobatto quadrature |
| dblquad | Numerically evaluate double integral |

To integrate the function defined by humps.m from 0 to 1 , use

```
q = quad(@humps,0,1)
q =
    29.8583
```

Both quad and quadl operate recursively. If either method detects a possible singularity, it prints a warning.

You can include a fourth argument for quad or quadl that specifies a relative error tolerance for theintegration. If a nonzerofifth argument is passed to quad or quadl, the function evaluations are traced.

Two examples illustrate use of these functions:

- Computing the length of a curve
- Double integration

## Example: Computing the Length of a Curve

You can usequad or quadl to compute the length of a curve. Consider the curve parameterized by the equations

$$
x(t)=\sin (2 t), \quad y(t)=\cos (t), \quad z(t)=t
$$

where $t \in[0,3 \pi]$.
A three-dimensional plot of this curve is

```
t = 0:0.1:3*pi;
plot3(sin(2*t),cos(t),t)
```

The arc length formula says the length of the curve is the integral of the norm of the derivatives of the parameterized equations

$$
\int_{0}^{3 \pi} \sqrt{4 \cos (2 t)^{2}+\sin (t)^{2}+1} d t
$$

The function hcurve computes the integrand

```
function f = hcurve(t)
f = sqrt(4* cos(2*t).^2 + sin(t).^2 + 1);
```

Integrate this function with a call to quad

```
len = quad(@hcurve,0,3*pi)
len =
    1.7222e+01
```

The length of this curve is about 17.2.

## Example: Double Integration

Consider the numerical solution of

```
ymax xmax
    \int{}\mp@subsup{\int}{ymin}{}f(x,y)dxd
```

For this example $f(x, y)=y \sin (x)+x \cos (y)$. The first step is to build the function to be evaluated. The function must be capable of returning a vector output when given a vector input. You must also consider which variable is in the inner integral, and which goes in the outer integral. In this example, the inner variable is $x$ and the outer variable is $y$ (the order in the integral is dxdy). In this case, the integrand function is

```
function out = integrnd(x,y)
out = y*sin(x) + x* cos(y);
```

To perform the integration, two functions are available in the funfun directory. The first, dblquad, is called directly from the command line. This M-file evaluates the outer loop using quad. At each iteration, quad calls the second hel per function that evaluates the inner loop.

To evaluate the double integral, use

```
result = dblquad(@integrnd,xmin,xmax,ymin,ymax);
```

The first argument is a string with the name of the integrand function. The second to fifth arguments are
xmin Lower limit of inner integral
$x \max \quad$ Upper limit of the inner integral
ymin Lower limit of outer integral
ymax Upper limit of the outer integral

Here is a numeric example that illustrates the use of dblquad.

```
xmin = pi;
xmax = 2*pi;
ymin = 0;
ymax = pi;
result = dblquad(@integrnd,xmin,xmax,ymin,ymax)
```

The result is -9.8698.
By default, dblquad calls quad. To integrate the previous example using quadl (with the default values for the tolerance argument), use

```
result = dblquad(@integrnd,xmin,xmax,ymin,ymax,[],@quadl);
```

Alternatively, any user-defined quadrature function name can be passed to dblquad as long as the quadrature function has the same calling and return arguments as quad.

This chapter treats the numerical solution of differential equations using MATLAB. It includes:

## Initial Value Problems for ODEs and DAEs

Describes the solution of ordinary differential equations (ODEs) and differential-algebraic equations (DAEs), wherethe solution of interest satisfies initial conditions at a given initial value of the independent variable.

## Boundary Value Problems for ODEs

Describes the solution of ODEs, where the solution of interest satisfies certain boundary conditions. The boundary conditions specify a relationship between the values of the solution at the initial and final values of the independent variable.

## Partial Differential Equations

Describes the solution of initial-boundary value problems for systems of parabolic and elliptic partial differential equations (PDEs) in one spatial variable and time.

## Selected Bibliography

Lists published materials that support concepts described in this chapter.

Note In function tables, commonly used functions are listed first, followed by more advanced functions. The same is true of property tables.

## Initial Value Problems for ODEs and DAEs

This section describes how to use MATLAB to solve initial value problems (IVPs) of ordinary differential equations (ODEs) and differential-algebraic equations (DAEs). It provides:

- A summary of the MATLAB ODE solvers, related functions, and examples
- An introduction to ODEs and initial value problems
- Descriptions of the ODE solvers and their basic syntax
- General instructions for representing an IVP in MATLAB
- A discussion about changing default integration properties toimprove solver performance
- Examples of the kinds of IVP problems you can solve in MATLAB
- Answers to some frequently asked questions about the MATLAB ODE solvers, and some troubleshooting suggestions

## ODE Function Summary

## Initial Value ODE Problem Solvers

These are the MATLAB initial value problem solvers. The table lists the kind of problem you can solve with each solver, and the method each solver uses.

| Solver | Solves These Kinds of Problems | Method |
| :--- | :--- | :--- |
| ode45 | Nonstiff differential equations | Runge-Kutta |
| ode23 | Nonstiff differential equations | Runge-Kutta |
| ode113 | Nonstiff differential equations | Adams |
| ode15s | Stiff differential equations and DAEs | NDFs (BDFs) |
| ode23s | Stiff differential equations | Rosenbrock |
| ode23t | Moderately stiff differential equations <br> and DAEs | Trapezoidal rule |
| ode23tb | Stiff differential equations | TR-BDF2 |

## ODE Solution Evaluation

If you call an ODE solver with one output argument, it returns a structure that you can use to evaluate the solution at any point on the interval of integration.

| Function | Description |
| :--- | :--- |
| deval | Evaluate the numerical solution using output of ODE solvers. |

## ODE Option Handling

An options structure contains named integration properties whose values are passed to the solver, and which affect problem solution. Use these functions to create, alter, or access an options structure.

| Function | Description |
| :--- | :--- |
| odeset | Create or alter options structure for input to ODE solvers. |
| odeget | Extract properties from options structure created with odeset. |

## ODE Solver 0 utput Functions

If an output function is specified, the solver calls the specified function after every successful integration step. You can use odeset to specify one of these sample functions as the OutputFcn property, or you can modify them to create your own functions.

| Function | Description |
| :--- | :--- |
| odeplot | Time-series plot |
| odephas2 | Two-dimensional phase plane plot |
| odephas3 | Three-dimensional phase plane plot |
| odeprint | Print to command window |

## ODE Initial Value Problem Examples

These examples illustrate the kinds of problems you can solve in MATLAB. From the MATLAB Help browser, click the example name to see the code in an editor. Type the example name at the command line to run it.

Note The Differential Equations Examples browser enables you to view the codefor the ODE examples and DAE examples. You can also run the examples from the browser. Click on these links to invoke the browser, or type odeexamples('ode') or odeexamples('dae') at the command line.

| Example | Description |
| :--- | :--- |
| amp1dae | Stiff DAE - electrical circuit |
| ballode | Simple event location - bouncing ball |
| batonode | ODE with time- and state-dependent mass matrix - motion <br> of a baton |
| brussode | Stiff large problem - diffusion in a chemical reaction (the <br> Brusselator) |
| burgersode | ODE with strongly state-dependent mass matrix - Burger's <br> equation solved using a moving mesh technique |
| fem1ode | Stiff problem with a time-dependent mass matrix - finite <br> element method |
| fem2ode | Stiff problem with a constant mass matrix - finite element <br> method |
| hb1dae | Stiff DAE from a conservation law <br> hb1odeStiff problem solved on a very long interval - Robertson <br> chemical reaction |
| orbitode | Advanced event location - restricted three body problem |

| Example | Description |
| :--- | :--- |
| rigidode | Nonstiff problem - Euler equations of a rigid body without <br> external forces |
| vdpode | Parameterizable van der Pol equation (stiff for large $\mu$ ) |

## Introduction to Initial Value ODE Problems

## What Is an Ordinary Differential Equation

The MATLAB ODE solvers are designed to handle ordinary differential equations. An ordinary differential equation contains one or more derivatives of a dependent variable $y$ with respect to a single independent variable $t$, usually referred to as time. The derivative of $y$ with respect to $t$ is denoted as $y^{\prime}$, the second derivative as $y^{\prime \prime}$, and so on. Often $y(t)$ is a vector, having elements $\mathrm{y}_{1}, \mathrm{y}_{2}, \ldots, \mathrm{y}_{\mathrm{n}}$.

## Using Initial Conditions to Specify the Solution of Interest

Generally there are many functions $y(t)$ that satisfy a given ODE, and additional information is necessary to specify the solution of interest. In an initial value problem, the solution of interest satisfies a specific initial condition, that is, $y$ is equal to $y_{0}$ at a given initial time $t_{0}$. An initial value problem for an ODE is then

$$
\begin{align*}
& y^{\prime}=f(t, y) \\
& y\left(t_{0}\right)=y_{0} \tag{15-1}
\end{align*}
$$

If the function $f(t, y)$ is sufficiently smooth, this problem has one and only one solution. Generally there is no analytic expression for the solution, so it is necessary to approximate $y(t)$ by numerical means, such as using one of the MATLAB ODE solvers.

## Initial Value Problem Solvers

TheMATLAB ODE solver functions implement numerical integration methods for solving IVPs for ODEs (Equation 15-1). Beginning at the initial time with initial conditions, they step through the time interval, computing a solution at each time step. If the solution for a time step satisfies the solver's error
tolerance criteria, it is a successful step. Otherwise, it is a failed attempt; the solver shrinks the step size and tries again.

This section describes:

- MATLAB solvers for nonstiff ODE problems and solvers for stiff ODE problems
- ODE solver basic syntax
- Additional ODE solver arguments
"Mass Matrix and DAE Properties" on page 15-27 explains how to solve more general problems.

You can also use the MATLAB Help browser to get information on the syntax for any MATLAB function, as well as information on example files for these solvers.

## Solvers for N onstiff Problems

There are three solvers designed for nonstiff problems:
ode45 Based on an explicit Runge-Kutta $(4,5)$ formula, the Dormand-Prince pair. It is a onestep solver - in computing $y\left(t_{n}\right)$, it needs only the solution at the immediately preceding time point, $y\left(t_{n-1}\right)$. In general, ode45 is the best function to apply as a "first try" for most problems.
ode23 Based on an explicit Runge-Kutta $(2,3)$ pair of Bogacki and Shampine. It may be more efficient than ode45 at crude tolerances and in the presence of mild stiffness. Like ode45, ode23 is a one-step solver.
ode113 Variable order Adams-Bashforth-M oulton PECE solver. It may be more efficient than ode45 at stringent tolerances and when the ODE function is particularly expensive to evaluate. ode113 is a multistep solver - it normally needs the solutions at several preceding time points to compute the current solution.

## Solvers for Stiff Problems

Not all difficult problems arestiff, but all stiff problems are difficult for solvers not specifically designed for them. Solvers for stiff problems can be used exactly
like the other solvers. However, you can often significantly improve the efficiency of these sol vers by providing them with additional information about the problem. (See "Improving ODE Solver Performance" on page 15-16.)

There are four solvers designed for stiff problems:
ode15s Variable-order solver based on the numerical differentiation formulas (NDFs). Optionally it uses the backward differentiation formulas, BDFs, (also known as Gear's method). Like ode113, ode15s is a multistep solver. If you suspect that a problem is stiff or if ode45 failed or was very inefficient, try ode15s.
ode23s Based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than ode15s at crude tolerances. It can solve some kinds of stiff problems for which ode15s is not effective.
ode23t An implementation of the trapezoidal rule using a "free" interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping.
ode23tb An implementation of TR-BDF 2, an implicit Runge-K utta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order 2. Like ode23s, this solver may be more efficient than ode15s at crude tolerances.

## ODE Solver Basic Syntax

All of the ODE solver functions share a syntax that makes it easy to try any of the different numerical methods if it is not apparent which is the most appropriate. To apply a different method to the same problem, simply change the ODE solver function name. The simplest syntax, common to all the solver functions, is

```
[t,y] = solver(odefun,tspan,y0)
```

where solver is one of the ODE solver functions listed previously.

The basic input arguments are:
odefun Function that evaluates the system of ODEs. It has the form

```
dydt = odefun(t,y)
```

where $t$ is a scalar, and dydt and y are column vectors.
tspan Vector specifying the interval of integration. The solver imposes theinitial conditions at tspan(1), and integrates from tspan(1) to tspan(end).

For tspan vectors with two elements [t0 tf], the solver returns the solution evaluated at every integration step. For tspan vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying tspan with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from tspan(1) to tspan(end). All solvers in the MATLAB ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in tspan, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying tspan with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.
yo Vector of initial conditions for the problem
See also "I ntroduction to Initial Value ODE Problems" on page 15-6.

The output arguments are:
t Column vector of time points
y Solution array. Each row in y corresponds to the solution at a time returned in the corresponding row of $t$.

## Additional O DE Solver Arguments

F or more advanced applications, you can also specify as input arguments solver options and additional problem parameters.
options Structure of optional parameters that change the default integration properties. This is the fourth input argument.

$$
[t, y]=\text { solver(odefun,tspan,y0,options) }
$$

"I mproving ODE Solver Performance" on page 15-16 tells you how to create the structure and describes the properties you can specify.
p1, p2... Parameters that the solver passes to odefun.

```
[t,y] = solver(odefun,tspan,y0,options,p1,p2...)
```

The solver passes any input parameters that follow the options argument to odefun and any functions you specify in options. Use options = [ ] as a placeholder if you set no options. The function odefun must have the form

$$
\text { dydt }=\operatorname{odefun}(t, y, p 1, p 2, \ldots)
$$

See "Passing Additional Parameters to an ODE F unction" on page 15-13 for an example.

## Representing ODE Problems

This section describes the process for solving initial value ODE problems using one of the MATLAB ODE solvers. It uses the van der Pol equation:

- To describe the steps needed to solve an ODE problem using MATLAB
- As an example of a stiff ODE problem

It also tells you how to evaluate the solution at specific points.

Note See "ODE Solver Basic Syntax" on page 15-8 for more information.

## Example: Solving an IVP ODE in MATLAB (van der Pol Equation, Nonstiff)

This example explains and illustrates the steps you need to solve an initial value ODE problem using MATLAB.

1 Rewrite the Problem as a System of First-O rder ODEs. ODEs often invol ve a number of dependent variables, as well as derivatives of order higher than one. To use the MATLAB ODE solvers, you must rewrite such equations as an equivalent system of first-order differential equations of the form

$$
y^{\prime}=f(t, y)
$$

You can write any ordinary differential equation

$$
y^{(n)}=f\left(t, y, y^{\prime}, \ldots, y^{(n-1)}\right)
$$

as a system of first-order equations by making the substitutions

$$
y_{1}=y, \quad y_{2}=y^{\prime}, \quad \ldots, \quad y_{n}=y^{(\mathrm{n}-1)}
$$

The result is an equivalent system of n first-order ODEs.

$$
\begin{aligned}
& y_{1}^{\prime}=y_{2} \\
& y_{2}^{\prime}= y_{3} \\
& \vdots \\
& y_{n}^{\prime}=f\left(t, y_{1}, y_{2}, \ldots, y_{n}\right)
\end{aligned}
$$

For example, you can rewrite the van der Pol equation (second-order)

$$
y_{1}^{\prime \prime}-\mu\left(1-y_{1}^{2}\right) y_{1}^{\prime}+y_{1}=0
$$

where $\mu>0$ is a scalar parameter, by making the substitution $y^{\prime}{ }_{1}=y_{2}$. The resulting system of first-order ODEs is

$$
\begin{aligned}
& y_{1}^{\prime}=y_{2} \\
& y_{2}^{\prime}=\mu\left(1-y_{1}^{2}\right) y_{2}-y_{1}
\end{aligned}
$$

2 Code the System of First-O rder ODEs in MATLAB. Once you represent the equation as a system of first-order ODEs, you can code it as a function that a MATLAB ODE solver can use. The function must be of the form

```
dydt = odefun(t,y)
```

Although $t$ and $y$ must be the function's first two arguments, the function does not need to use them. The output dydt, a column vector, is the derivative of $y$.
The codebel ow represents the van der Pol system in a MATLAB function, vdp1. The vdp1 function assumes that $\mu=1 . y_{1}$ and $y_{2}$ become elements $y(1)$ and $y(2)$ of a two-element vector.

```
function dydt = vdp1(t,y)
dydt = [y(2); (1-y(1)^2)*y(2)-y(1)];
```

Note that, although vdp1 must accept the arguments $t$ and $y$, it does not use $t$ in its computations.

3 Apply a Solver to the Problem. Decide which solver you want to use to solve the problem. Then call the solver and pass it the function you created to describe the first-order system of ODEs, the time interval on which you want to solve the problem, and an initial condition vector. See "Initial Value Problem Solvers" on page 15-6 and the ODE solver reference page for descriptions of the ODE solvers.

For the van der Pol system, you can use ode45 on time interval [0 20] with initial values $y(1)=2$ and $y(2)=0$.

```
[t,y] = ode45(@vdp1,[0 20],[2; 0]);
```

This example uses @ to pass vdp1 as a function handle to ode45. The resulting output is a column vector of time points $t$ and a solution array $y$. Each row in $y$ corresponds to a timereturned in the corresponding row of $t$. Thefirst column of y corresponds to $\mathrm{y}_{1}$, and the second column to $\mathrm{y}_{2}$.

Note Seethe function_handle (@), func2str, and str2func reference pages, and the Function Handles chapter of "Programming and Data Types" in the MATLAB documentation for information about function handles.

4 View the Solver Output. You can simply use the plot command to view the solver output.

```
plot(t,y(:,1),'-',t,y(:,2),'--')
title('Solution of van der Pol Equation, \mu = 1');
```

```
xlabel('time t');
ylabel('solution y');
legend('y_1','y_2')
```

As an alternative, you can use a solver output function to process the output. The solver calls the function specified in the integration property OutputFen after each successful time step. Use odeset to set OutputFcn to the desired function. See "OutputFcn" on page 15-20 for more information.

Passing Additional Parameters to an ODE Function. The solver passes any input parameters that follow the options argument to the ODE function and any function you specify in options. For example:

1 Generalize the van der Pol function by passing it a mu parameter, instead of specifying a value for mu explicitly in the code.

```
function dydt = vdp1(t,y,mu)
dydt = [y(2); mu*(1-y(1)^2)*y(2)-y(1)];
```

2 Pass the parameter mu to the function vdp1 by specifying it after the options argument in the call to the solver. This example uses options = [] as a placeholder.

```
[t,y] = ode45(@vdp1,tspan,y0,[],mu)
```

calls
vdp1(t,y,mu)
See vdpode for a complete example based on these functions.

## Example: The van der Pol Equation, $\mu=1000$ (Stiff)

This example presents a stiff problem. For a stiff problem, solutions can change on a time scale that is very short compared to the interval of integration, but the solution of interest changes on a much longer time scale. Methods not designed for stiff problems are ineffective on intervals where the solution changes slowly because they use time steps small enough to resolve the fastest possible change.

When $\mu$ is increased to 1000, the solution to the van der Pol equation changes dramatically and exhibits oscillation on a much longer time scale.
Approximating the solution of the initial value problem becomes a more difficult task. Because this particular problem is stiff, a solver intended for nonstiff problems, such as ode45, is too inefficient to be practical. A solver such as ode15s is intended for such stiff problems.

The vdp1000 function evaluates the van der Pol system with $\mu=1000$.

```
function dydt = vdp1000(t,y)
dydt = [y(2); 1000*(1-y(1)^2)*y(2)-y(1)];
```

Note This example hardcodes $\mu$ in the ODE function. The vdpode example solves the same problem, but passes a user-specified $\mu$ as an additional argument to the ODE function. See "Additional ODE Solver Arguments" on page 15-10.

Now use the ode15s function to solve the problem with the initial condition vector of [2; 0], but a time interval of [0 3000]. For scaling purposes, plot just the first component of $y(t)$.

```
[t,y] = ode15s(@vdp1000,[0 3000],[2; 0]);
plot(t,y(:,1),'-');
title('Solution of van der Pol Equation, \mu = 1000');
xlabel('time t');
ylabel('solution y_1');
```

Note For detailed instructions for solving an initial value ODE problem in MATLAB, see "E xample: Solving an IVP ODE in MATLAB (van der Pol Equation, Nonstiff)" on page 15-11.

## Evaluating the Solution at Specific Points

The numerical methods implemented in the ODE solvers produce a continuous solution over the interval of integration [a, b]. Y ou can evaluate the approximatesolution, $\mathrm{S}(\mathrm{x})$, at any point in [a, b] using thefunction deval and the structure sol returned by the solver.

```
Sxint = deval(sol,xint)
```

The ODE solvers return the structure sol when called with a single output argument.

The deval function is vectorized. F or a vector xint, the ith column of Sxint approximates the solution $y$ (xint(i)).

## Improving ODE Solver Performance

The default integration properties in the ODE solvers are selected to handle common problems. In some cases, you can improve ODE solver performance by overriding these defaults. Y ou dothis by supplying the solvers with one or more property values in an options structure.

$$
[t, y]=\text { solver(odefun,tspan, yo,options) }
$$

This section:

- Explains how to create, modify, and query an options structure.
- Describes the properties that you can use in an options structure.

In this and subsequent property tables, the most commonly used properties are listed first, followed by more advanced properties.

ODE Property Categories

| Properties Category | Property Name |
| :--- | :--- |
| Error control | RelTol, AbsTol, NormControl |
| Solver output | OutputFcn, OutputSel, Refine, Stats |
| J acobian matrix | Jacobian, JPattern, Vectorized |
| Step-size | InitialStep, MaxStep |

ODE Property Categories

| Properties Category | Property Name |
| :--- | :--- |
| Mass matrix and <br> DAEs | Mass, MStateDependence, MvPattern, <br> MassSingular, InitialSlope |
| Event location | Events |
| ode15s-specific | MaxOrder, BDF |

## Creating and Maintaining an ODE Options Structure

Creating an Options Structure. The odeset function creates an options structure that you can pass as an argument to any of the ODE solvers. To create an options structure, odeset accepts property name/property value pairs using the syntax

```
options = odeset('name1',value1,'name2',value2,...)
```

In the resulting structure, options, the named properties have the specified values. Any unspecified properties contain default values in the solvers. For all properties, it is sufficient to type only the leading characters that uniquely identify the property name. odeset ignores case for property names.

With no input arguments, odeset displays all property names and their possible values. It indicates defaults with \{\}.

Modifying an Existing Options Structure. To modify an existing options structure, oldopts, use

```
options = odeset(oldopts,'name1',value1,...)
```

This sets options equal to the existing structure oldopts, overwrites any values in oldopts that are respecified using name/value pairs, and adds any new pairs to the structure. The modified structure is returned as an output argument. In the same way, the command

```
options = odeset(oldopts,newopts)
```

combines the structures oldopts and newopts. In the output argument, any values in the second argument overwrite those in the first argument.

Querying Options. The odeget function extracts property values from an options structure created with odeset.

```
o = odeget(options,'name')
```

This functions returns the value of the specified property, or an empty matrix [ ], if the property value is unspecified in the options structure.

As with odeset, it is sufficient totype only the leading characters that uniquely identify the property name. Case is ignored for property names.

## Error Control Properties

At each step, the solver estimates the local error e in the ith component of the solution. This error must be less than or equal to the acceptable error, which is a function of the specified relativetolerance, RelTol, and the specified absolute tolerance, AbsTol.

```
|e(i)| \leq max(RelTol*abs(y(i)),AbsTol(i))
```

For routine problems, the ODE solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over "long" intervals and problems that are moderately unstable. Difficult problems may require tighter tolerances than the default values. For relative accuracy, adjust RelTol. For the absolute error tolerance, the scaling of the solution components is important: if $|\mathrm{y}|$ is somewhat smaller than AbsTol, the solver is not constrained to obtain any correct digits in y . You might have to solve a problem more than once to discover the scale of solution components.
Roughly speaking, this means that you want RelTol correct digits in all solution components except those smaller than thresholds AbsTol (i). Even if you are not interested in a component $y$ (i) when it is small, you may have to specify AbsTol (i) small enough to get some correct digits in y(i) so that you can accurately compute more interesting components

The following table describes the error control properties. Use odeset to set the properties.

| ODE Error Control Properties |  |  |
| :--- | :--- | :--- |
| Property | Value | Description |
| RelTol | Positive <br> scalar $\{1 \mathrm{e}-3\}$ | A relative error tolerance that applies to all components of the <br> solution vector y. It is a measure of the error relative to the size <br> of each solution component. Roughly, it controls the number of <br> correct digits in all solution components except those smaller <br> than thresholds AbsTol (i). |
| AbsTol | Positive <br> scalar or <br> vector <br> $\{1 e-6\}$ | The default, 1e-3, corresponds to 0.1\% accuracy. <br> Absolute error tolerances that apply to the individual <br> below which the value of the ith solution component is <br> unimportant. The absolute error tolerances determine the <br> accuracy when the solution approaches zero. Even if you are not <br> interested in a component y (i) when it is small, you may have <br> to specify AbsTol (i) small enough to get some correct digits in <br> y(i) so that you can accurately compute more interesting <br> components. |

## Solver O utput Properties

The solver output properties let you control the output that the solvers generate. Use odeset to set these properties.

## ODE Solver Output Properties

| Property | Value | Description |
| :---: | :---: | :---: |
| OutputFen | Function \{odeplot $\}$ | Installable output function. The solver calls this function after every successful integration step. <br> For example, <br> options = odeset('OutputFcn',@myfun) <br> sets the OutputFcn property to an output function, myfun, that can be passed to an ODE solver. <br> The output function must be of the form <br> status $=$ myfun(t,y,flag) <br> The solver calls the specified output function with the following flags. N ote that the syntax of the call differs with the flag. The function must respond appropriately: <br> init The solver calls myfun(tspan,y0,'init') before beginning the integration to allow the output function to initialize. tspan and y0 are the input arguments to the ODE solver. |

## ODE Solver Output Properties (Continued)

Property Value Description
\{none\} The solver calls status $=$ myfun( $t, y)$ after each integration step on which output is requested. $t$ contains points where output was generated during the step, and $y$ is the numerical solution at the points in $t$. If $t$ is a vector, the ith column of $y$ corresponds to the ith element of $t$.

When length(tspan) > 2 the output is produced at every point in tspan. When length(tspan) $=2$ the output is produced according to the Refine option.
myfun must return a status output value of 0 or 1 . If status $=1$, the solver halts integration. You can use this mechanism, for instance, to implement a Stop button.
done The solver calls myfun([],[],'done') when integration is complete to allow the output function to perform any cleanup chores.

You can use these general purpose output functions or you can edit them to create your own. Type help function at the command line for more information.

- odeplot - time series plotting (default when you call the solver with no output arguments and you have not specified an output function)
- odephas2 - two-dimensional phase plane plotting
- odephas3 - three-dimensional phase plane plotting
- odeprint - print solution as it is computed

Note If you call the solver with no output arguments, the solver does not allocate storage to hold the entire solution history.

## ODE Solver Output Properties (Continued)

| Property | Value | Description |
| :---: | :---: | :---: |
| OutputSel | Vector of indices | Vector of indices specifying which components of the solution vector are to be passed to the output function. For example, if you want to use the odeplot output function, but you want to plot only the first and third components of the solution, you can do this using <br> options = odeset('OutputFcn', @odeplot,'OutputSel',[13]); <br> By default, the solver passes all components of the solution to the output function. |
| Refine | Positive integer | Increases the number of output points by a factor of Refine. If Refine is 1 , the solver returns solutions only at the end of each time step. If Refine is $n>1$, the solver subdivides each time step into $n$ smaller intervals, and returns solutions at each time point. Refine does not apply when length(tspan) $>2$. |
|  |  | Note In all the solvers, the default value of Refine is 1 . Within ode45, however, the default is 4 to compensate for the solver's large step sizes. To override this and see only the time steps chosen by ode45, set Refine to 1. |

The extra values produced for Refine are computed by means of continuous extension formulas. These are specialized formulas used by the ODE solvers to obtain accurate solutions between computed time steps without significant increase in computation time.

## ODE Solver Output Properties (Continued)

| Property | Value | Description |
| :---: | :---: | :---: |
| Stats | on \| \{off \} | Specifies whether the solver should display statistics about its computations. By default, Stats is off. If it is on, after solving the problem the solver displays: <br> - The number of successful steps <br> - The number of failed attempts <br> - The number of times the ODE function was called to evaluate $f(t, y)$ <br> - The number of times that the partial derivatives matrix $\partial \mathrm{f} / \partial \mathrm{y}$ was formed <br> - The number of LU decompositions <br> - The number of solutions of linear systems |

## Jacobian Matrix Properties

The stiff ODE solvers often executefaster if you provide additional information about theJ acobian matrix $\partial \mathrm{f} / \partial \mathrm{y}$, a matrix of partial derivatives of the function that defines the differential equations.

$$
\frac{\partial f}{\partial \mathrm{y}}=\left[\begin{array}{ccc}
\frac{\partial \mathrm{f}_{1}}{\partial \mathrm{y}_{1}} & \frac{\partial \mathrm{f}_{1}}{\partial \mathrm{y}_{2}} & \cdots \\
\frac{\partial \mathrm{f}_{2}}{\partial \mathrm{y}_{1}} & \frac{\partial \mathrm{f}_{2}}{\partial \mathrm{y}_{2}} & \\
\vdots & \vdots &
\end{array}\right]
$$

TheJ acobian matrix properties pertain only to those solvers for stiff problems (ode15s, ode23s, ode23t, and ode23tb) for which theJ acobian matrix $\partial \mathrm{f} / \partial \mathrm{y}$ can be critical to reliability and efficiency. If you do not provide a function to calculate the J acobian, these solvers approximate the J acobian numerically using finite differences. In this case, you may want to use the Vectorized, or JPattern properties.

The following table describes theJ acobian matrix properties. Use odeset to set these properties.

## ODE J acobian Matrix Properties

| Property | Value | Description |
| :---: | :---: | :---: |
| Jacobian | Function \| constant matrix | A constant matrix or a function that evaluates the J acobian. Supplying an analytical J acobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function FJac, where FJac ( $t, y$ ) computes $\partial f / \partial y$, or to the constant value of $\partial f / \partial y$. <br> TheJ acobian for the stiff van der Pol problem shown above can be coded as $\begin{aligned} & \text { function } J=\operatorname{vdp} 1000 \mathrm{jac}(\mathrm{t}, \mathrm{y}) \\ & J=\left[\begin{array}{l} 0 \\ \left(-2000^{*} y(1) * y(2)-1\right) \\ \left(1000^{*}\left(1-y(1)^{\wedge} 2\right)\right) \end{array}\right] ; \end{aligned}$ |
| JPattern | Sparse matrix of $\{0,1\}$ | Sparsity pattern with 1 s where there might be nonzero entries in the J acobian. It is used to generate a sparse J acobian matrix numerically. <br> Set this property to a sparse matrix S with $\mathrm{S}(\mathrm{i}, \mathrm{j})=1$ if component i of $f(t, y)$ depends on component $j$ of $y$, and 0 otherwise. The solver uses this sparsity pattern to generate a sparseJ acobian matrix numerically. If theJ acobian matrix is large and sparse, this can greatly accelerate execution. For an example using the JPattern property, see "Example: Large, Stiff Sparse Problem" on page 15-38 (brussode). |

## ODE Jacobian Matrix Properties (Continued)

Property Value Description

Vectorized on | \{off\} Set on to inform the solver that you have coded the ODE function F so that $\mathrm{F}(\mathrm{t},[\mathrm{y} 1$ y2 ...]) returns $[F(t, y 1) \quad F(t, y 2) \quad . .$.$] . This allows the solver to reduce the$ number of function evaluations required to compute all the columns of the J acobian matrix, and may significantly reduce solution time.

With MATLAB's array notation, it is typically an easy matter to vectorize an ODE function. For example, the stiff van der Pol example shown previously can be vectorized by introducing colon notation into the subscripts and by using the array power (. ${ }^{\wedge}$ ) and array multiplication (. *) operators.

```
function dydt = vdp1000(t,y)
dydt = [y(2,:); 1000*(1-y(1,:).^2).*y(2,:)-y(1,:)];
```

Note Vectorization of the ODE function used by the ODE solvers differs from the vectorization used by the BVP solver, bvp4c. For the ODE solvers, the ODE function is vectorized only with respect to the second argument, while bvp4c requires vectorization with respect the first and second arguments.

## Step-Size Properties

The step-size properties let you specify the size of the first step the solver tries, potentially hel ping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step-size properties. Use odeset to set these properties.

ODE Step Size Properties

| Property | Value | Description |
| :---: | :---: | :---: |
| InitialStep | Positive scalar | Suggested initial step size. InitialStep sets an upper bound on the magnitude of the first step size the solver tries. If you do not set InitialStep, the initial step size is based on the slope of the solution at the initial time tspan(1), and if the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable InitialStep. |
| MaxStep | Positive scalar $\{0.1 * a b s(t 0-t f)\}$ | U pper bound on solver step size. If the differential equation has periodic coefficients or solutions, it may be a good idea to set MaxStep to some fraction (such as $1 / 4$ ) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do not reduce MaxStep: <br> - To produce more output points. This can significantly slow down solution time. Instead, useRefine to compute additional outputs by continuous extension at very low cost. <br> - When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance RelTol, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector AbsTol. (See "Error Control Properties" on page 15-18 for a description of the error tolerance properties.) |

ODE Step Size Properties (Continued)

| Property | Value | Description |
| :---: | :---: | :---: |
|  |  | - To make sure that the solver doesn't step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break thesimulation interval intotwo pieces and call the solvers twice. If you do not know the time at which the change occurs, try reducing the error tolerances RelTol and AbsTol. Use MaxStep as a last resort. |

## Mass Matrix and DAE Properties

The solvers of the ODE suite can solve ODEs of the form

$$
\begin{equation*}
M(t, y) y^{\prime}=f(t, y) \tag{15-2}
\end{equation*}
$$

with a mass matrix $M(t, y)$ that can be sparse.
When $M_{( }(\mathrm{t}, \mathrm{y})$ is nonsingular, the equation above is equivalent to $y^{\prime}=M^{-1} f(t, y)$ and the ODE has a solution for any initial values $y_{0}$ at $t_{0}$. The more general form (Equation 15-2) is convenient when you express a model naturally in terms of a mass matrix. For large, sparse M (t, y) , solving Equation 15-2 directly reduces the storage and runtime needed to solve the problem.

When $M(t, y)$ is singular, then $M(t, y) y^{\prime}=f(t, y)$ is a differential-algebraic equation (DAE). A DAE has a solution only when $\mathrm{y}_{0}$ is consistent, that is, there exists an initial slope $y p_{0}$ such that $M\left(t_{0}, y_{0}\right) y p_{0}=f\left(t_{0}, y_{0}\right)$. If $y_{0}$ and $y p_{0}$ are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. For DAEs of index 1 , solving an initial value problem with consistent initial conditions is much like solving an ODE.

The ode15s and ode23t solvers can solveDAEs of index 1. F or examples of DAE problems, see hb1dae ("Example: Differential-Algebraic Problem" on page 15-47) and amp1dae.

The following table describes the mass matrix and DAE properties. Use odeset to set these properties.

ODE Mass Matrix and DAE Properties

| Property | Value | Description |
| :---: | :---: | :---: |
| Mass | Constant matrix \| function | Constant mass matrix or a function that evaluates the mass matrix $\mathrm{M}(\mathrm{t}, \mathrm{y})$. For problems $M y^{\prime}=f(t, y)$ set this property to the value of the constant mass matrix M. For problems $M(t, y) y^{\prime}=f(t, y)$, set this property to a function mfun, where mfun ( $t, y$ ) evaluates the mass matrix $\mathrm{M}(\mathrm{t}, \mathrm{y})$. When solving DAEs, it is advantageous to formulate the problem so that M is a diagonal matrix (a semi-explicit DAE). The ode23s solver can only solve problems with a constant mass matrix M . <br> F or example problems, see fem1ode ("Example: Finite Element Discretization" on page 15-35), fem2ode, or batonode. |
| MStateDependence | ```none \| {weak} | strong``` | Dependence of the mass matrix on $y$. Set this property to none for problems $M(t) y^{\prime}=f(t, y)$. Both weak and strong indicate $\mathrm{M}(\mathrm{t}, \mathrm{y})$, but weak results in implicit solvers using approximations when solving algebraic equations. |
| MvPattern | Sparse matrix | $\partial(M(t, y) v) / \partial y$ sparsity pattern. Set this property to a sparse matrix S with $\mathrm{S}(\mathrm{i}, \mathrm{j})=1$ if for any k , the ( $\mathrm{i}, \mathrm{k}$ ) component of $\mathrm{M}(\mathrm{t}, \mathrm{y})$ depends on component $j$ of $y$, and 0 otherwise. For use with the ode15s, ode23t, and ode23tb solvers when MStateDependence is strong. See burgersode as an example. |

ODE Mass Matrix and DAE Properties (Continued)

| Property | Value | Description |
| :---: | :---: | :---: |
| MassSingular | $\underset{\substack{\text { yes \| no } \\\{\text { maybe }}}{ }$ | Indicates whether the mass matrix is singular. Set this property to no if the mass matrix is not singular and you are using either the ode15s or ode23t solver. The default value of maybe causes the solver to test whether the problem is a DAE, i.e., whether $M\left(\mathrm{t}_{0}, \mathrm{y}_{0}\right)$ is singular. <br> For an example of a problem with a mass matrix, see "E xample: Finite Element Discretization" on page 15-35 (fem1ode). |
| InitialSlope | Vector \| \{zero vector \} | Vector representing the consistent initial slope $y p_{0}$, where $y p_{0}$ satisfies $M\left(t_{0}, y_{0}\right) y p_{0}=f\left(t_{0}, y_{0}\right)$. The default is the zero vector. <br> This property is for use with the ode15s and ode23t solvers when solving DAEs. |

## Event Location Property

In some ODE problems the times of specific events are important, such as the time at which a ball hits the ground, or the time at which a spaceship returns to the earth. While solving a problem, the MATLAB ODE solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the Events property. Use odeset to set this property.

## ODE Events Property

| String | Value | Description |
| :--- | :--- | :--- |
| Events | Function | MATLAB function that includes one or more event functions. The <br> MATLAB function is of the form |
|  |  | [value,isterminal, direction] $=$ events $(t, y)$ |

value, isterminal, and direction are vectors for which the ith element corresponds to the ith event function:

- value(i) is the value of the ith event function.
- isterminal(i) $=1$ if the integration is to terminate at a zero of this event function and 0 otherwise.
- direction(i) = 0 if all zeros are to be located (the default), +1 if only zeros where the event function is increasing, and - 1 if only zeros where the event function is decreasing.

When you specify an events function, the solver returns three additional outputs, TE, YE, and IE.

```
options = odeset('Events',@events)
[T,Y,TE,YE,IE] = solver(odefun,tspan, y0,options)
```

- TE is a column vector of times at which events occur.
- Rows of YE are the solution values corresponding to times in TE.
- Indices in vector IE specify which event occurred at thetime in TE.

For examples that use an event function, see "Example: Simple Event Location" on page 15-41 (ballode) and "Example: Advanced Event Location" on page 15-44 (orbitode).

## ode15s Properties

ode15s is a variable-order solver for stiff problems. It is based on thenumerical differentiation formulas (NDFs). The NDF s are generally more efficient than the closely related family of backward differentiation formulas (BDFs), also
known as Gear's methods. The ode15s properties let you choose between these formulas, as well as specifying the maximum order for the formula used.

The following table describes the ode15s properties. Use odeset to set these properties.
ode15s Properties

| Property | Value | Description |
| :--- | :--- | :--- |
| MaxOrder | $1\|2\| 3\|4\|\{5\}$ | The maximum order formula used to compute the solution. |
| BDF | on $\mid\{0 f f\}$ | Specifies whether you want to use the BDFs instead of the <br> default NDFs. Set BDF on to have ode15s use the BDF s. |
| For both the NDFs and BDFs, the formulas of orders 1 and <br> 2 are A-stable (the stability region includes the entire left <br> half complex plane). The higher order formulas are not as <br> stable, and the higher the order the worse the stability. <br> There is a class of stiff problems (stiff oscillatory) that is <br> solved more efficiently if MaxOrder is reduced (for example <br> to 2) so that only the most stable formulas are used. |  |  |

## Examples: Applying the ODE Initial Value Problem Solvers

This section contains several examples that illustrate the kinds of problems you can solve in MATLAB:

- Simple nonstiff problem (rigidode)
- Stiff problem (vdpode)
- Finite element discretization (fem1ode)
- L arge, stiff sparse problem (brussode)
- Simple event location (ballode)
- Advanced event location (orbitode)
- Differential-algebraic problem (hb1dae)

## Example: Simple N onstiff Problem

rigidode illustrates the solution of a standard test problem proposed by K rogh for solvers intended for nonstiff problems [7].

The ODEs are the Euler equations of a rigid body without external forces.

$$
\begin{aligned}
& y_{1}^{\prime}=y_{2} y_{3} \\
& y_{2}^{\prime}=-y_{1} y_{3} \\
& y_{3}^{\prime}=-0.51 y_{1} y_{2}
\end{aligned}
$$

For your convenience, the entire problem is defined and solved in a single $M$-file. The differential equations are coded as a subfunction $f$. Because the example calls the ode45 solver without output arguments, the solver uses the default output function odeplot to plot the solution components.

To run this example from the MATLAB Help browser, click on the example name. Otherwise, type rigidode at the command line.

```
function rigidode
%RIGIDODE Euler equations of a rigid body without external forces
tspan = [0 12];
yO = [0; 1; 1];
% Solve the problem using ode45
ode45(@f,tspan,y0);
%
function dydt = f(t,y)
dydt = [ y(2)*y(3)
    -y(1)*y(3)
    -0.51*y(1)*y(2) ];
```

## Example: Stiff Problem (van der Pol Equation)

vdpode illustrates the solution of the van der Pol problem described in "Example: The van der Pol Equation, $\mu=1000$ (Stiff)" on page 15-14. The differential equations

$$
\begin{aligned}
& y_{1}^{\prime}=y_{2} \\
& y_{2}^{\prime}=\mu\left(1-y_{1}^{2}\right) y_{2}-y_{1}
\end{aligned}
$$

involve a constant parameter $\mu$.
As $\mu$ increases, the problem becomes more stiff, and the period of oscillation becomes larger. When $\mu$ is 1000 the equation is in relaxation oscillation and the problem is very stiff. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff (quasi-discontinuities).

By default, the solvers in the ODE suite that are intended for stiff problems approximateJ acobian matrices numerically. However, this example provides a subfunction $J(t, y, m u)$ to evaluate the J acobian matrix $\partial f / \partial y$ analytically at
( $t, y$ ) for $\mu=m u$. The use of an analytic J acobian can improve the reliability and efficiency of integration.

To run this example from the MATLAB Help browser, click on the example name. Otherwise, type vdpode at the command line. At the command line, you can specify a value of $\mu$ as an argument to vdpode. The default is $\mu=1000$.

```
function vdpode(MU)
%VDPODE Parameterizable van der Pol equation (stiff for large MU)
if nargin < 1
    MU = 1000; % default
end
tspan = [0; max(20,3*MU)]; % Several periods
y0 = [2; 0];
options = odeset('Jacobian',@J);
[t,y] = ode15s(@f,tspan,y0,options,MU);
plot(t,y(:,1));
title(['Solution of van der Pol Equation, \mu = ' num2str(MU)]);
xlabel('time t');
ylabel('solution y_1');
axis([tspan(1) tspan(end) -2.5 2.5]);
function dydt = f(t,y,mu)
dydt = [ y(2)
    mu*(1-y(1)^2)*y(2)-y(1) ];
```

function dfdy $=\mathrm{J}(\mathrm{t}, \mathrm{y}, \mathrm{mu})$
dfdy $=[\quad 0 \quad 1$
$\left.-2 * m u * y(1) * y(2)-1 \quad m u *\left(1-y(1)^{\wedge} 2\right)\right] ;$

## Example: Finite Element Discretization

fem1ode illustrates the solution of ODEs that result from a finite element discretization of a partial differential equation. The value of $N$ in the call fem1ode ( N ) controls the discretization, and the resulting system consists of N equations. By default, N is 19.

This example involves a mass matrix. The system of ODE s comes from a method of lines solution of the partial differential equation

$$
\mathrm{e}^{-\mathrm{t}} \frac{\partial \mathrm{u}}{\partial \mathrm{t}}=\frac{\partial^{2} \mathrm{u}}{\partial \mathrm{x}^{2}}
$$

with initial condition $u(0, x)=\sin (x)$ and boundary conditions $u(t, 0)=u(t, \pi)=0$. An integer $N$ is chosen, $h$ is defined as $\pi /(N+1)$, and the solution of the partial differential equation is approximated at $x_{k}=k h$ for $k=0,1, \ldots, N+1$ by

$$
u\left(t, x_{k}\right) \approx \sum_{k=1}^{N} c_{k}(t) \phi_{k}(x)
$$

Here $\phi_{\mathrm{k}}(\mathrm{x})$ is a piecewise linear function that is 1 at $\mathrm{x}_{\mathrm{k}}$ and 0 at all the other $x_{j}$. A Galerkin discretization leads to the system of ODEs

$$
M(t) C^{\prime}=J c \text { where } c(t)=\left[\begin{array}{l}
c_{1}(t) \\
c_{N}(t)
\end{array}\right]
$$

and the tridiagonal matrices $\mathrm{M}(\mathrm{t})$ and J are given by

$$
M_{i j}= \begin{cases}2 h / 3 \exp (-t) & \text { if } i=j \\ h / 6 \exp (-t) & \text { if } i=j \pm 1 \\ 0 & \text { otherwise }\end{cases}
$$

and

$$
J_{i j}= \begin{cases}-2 / h & \text { if } i=j \\ 1 / h & \text { if } i=j \pm 1 \\ 0 & \text { otherwise }\end{cases}
$$

The initial values $c(0)$ are taken from the initial condition for the partial differential equation. The problem is solved on the time interval $[0, \pi]$.

In fem1ode the properties

```
options = odeset('Mass',@mass,'MStateDep','none','Jacobian',J)
```

indicate that the problem is of the form $\mathrm{M}(\mathrm{t}) \mathrm{y}^{\prime}=\mathrm{J} \mathrm{y}$. The subfunction mass ( $t, N$ ) evaluates the time-dependent mass matrix $M(t)$ and $J$ is the constant J acobian.
To run this example from the MATLAB Help browser, click on the example name. Otherwise, type fem1 ode at the command line. At the command line, you can specify a value of N as an argument to fem1ode. The default is $\mathrm{N}=19$.

```
function fem1ode(N)
%FEM10DE Stiff problem with a time-dependent mass matrix
```

```
if nargin < 1
    N = 19;
end
h = pi/(N+1);
y0 = sin(h*(1:N)');
tspan = [0; pi];
% The Jacobian is constant.
e = repmat(1/h,N,1); % e=[(1/h) ... (1/h)];
d = repmat (-2/h,N,1); % d=[(-2/h) ... (-2/h)];
J = spdiags([e d e], -1:1, N, N);
options = odeset('Mass',@mass,'MStateDependence','none', ...
    'Jacobian',J);
[t,y] = ode15s(@f,tspan,y0,options,N);
surf((1:N)/(N+1),t,y);
set(gca,'ZLim',[0 1]);
view(142.5,30);
title(['Finite element problem with time-dependent mass ' ...
        'matrix, solved by ODE15S']);
xlabel('space ( x/\pi )');
ylabel('time');
zlabel('solution');
%--------------------------------------------------------------------
function out = f(t,y,N)
h = pi/(N+1);
e = repmat(1/h,N,1); % e=[(1/h) ... (1/h)];
d = repmat (-2/h,N,1); % d=[(-2/h) ... (-2/h)];
J = spdiags([e d e], -1:1, N, N);
out = J*y;
%------------------------------------------------------------------
function M = mass(t,N)
h = pi/(N+1);
e = repmat(exp(-t)*h/6,N,1); % e(i)=exp(-t)*h/6
e4 = repmat(4*exp(-t)*h/6,N,1);
M = spdiags([e e4 e], -1:1, N, N);
```

## Finite element problem with time-dependent mass matrix, solved by ODE15S

## Example: Large, Stiff Sparse Problem

brussode illustrates the solution of a (potentially) large stiff sparse problem. The problem is the classic "Brusselator" system [3] that models diffusion in a chemical reaction

$$
\begin{aligned}
& u_{i}^{\prime}=1+u_{i}^{2} v_{i}-4 u_{i}+\alpha(N+1)^{2}\left(u_{i-1}-2 u_{i}+u_{i+1}\right) \\
& v_{i}^{\prime}=3 u_{i}-u_{i}^{2} v_{i}+\alpha(N+1)^{2}\left(v_{i-1}-2 v_{i}+v_{i+1}\right)
\end{aligned}
$$

and is solved on the time interval $[0,10]$ with $\alpha=1 / 50$ and

$$
\left.\begin{array}{l}
u_{i}(0)=1+\sin \left(2 \pi x_{i}\right) \\
v_{i}(0)=3
\end{array}\right\} \text { with } x_{i}=i /(N+1), \text { for } i=1, \ldots, N
$$

There are 2 N equations in the system, but the J acobian is banded with a constant width 5 if the equations are ordered as $u_{1}, v_{1}, u_{2}, v_{2}, \ldots$

In the call brussode ( N ), where N corresponds to N , the parameter $\mathrm{N} \geq 2$ specifies the number of grid points. The resulting system consists of 2 N equations. By default, N is 20 . The problem becomes increasingly stiff and the $J$ acobian increasingly sparse as N increases.
The subfunction $f(t, y, N)$ returns the derivatives vector for the Brusselator problem. The subfunction jpattern( $N$ ) returns a sparse matrix of 1 s and 0 s showing the locations of nonzeros in theJ acobian $\partial f / \partial y$. The example assigns this matrix to the property JPattern, and the solver uses the sparsity pattern to generate the J acobian numerically as a sparse matrix. Providing a sparsity pattern can significantly reduce the number of function evaluations required to generate the J acobian and can accelerate integration. For the Brusselator problem, if the sparsity pattern is not supplied, 2 N evaluations of the function are needed to compute the $2 \mathrm{~N}-$ by- 2 NJ acobian matrix. If the sparsity pattern is supplied, only four evaluations are needed, regardless of the value of $N$.

To run this example from the MATLAB Help browser, click on the example name. Otherwise, type brussode at the command line. At the command line, you can specify a value of N as an argument to brussode. The default is $\mathrm{N}=20$.

```
function brussode(N)
%BRUSSODE Stiff problem modeling a chemical reaction
if nargin<1
    N = 20;
end
tspan = [0; 10];
y0 = [1+sin((2*pi/(N+1))*(1:N)); repmat(3,1,N)];
options = odeset('Vectorized','on','JPattern',jpattern(N));
[t,y] = ode15s(@f,tspan,y0,options,N);
u = y(:,1:2:end);
x = (1:N)/(N+1);
surf(x,t,u);
view(-40,30);
xlabel('space');
ylabel('time');
```

```
zlabel('solution u');
title(['The Brusselator for N = ' num2str(N)]);
% -----------------------------------------------------------------
function dydt = f(t,y,N)
c = 0.02 * (N+1)^2;
dydt = zeros(2*N,size(y,2)); % preallocate dy/dt
% Evaluate the two components of the function at one edge of
% the grid (with edge conditions).
i = 1;
dydt(i,:) = 1 + y(i+1,:).*y(i,:).^2 - 4*y(i,:) + ...
    c*(1-2*y(i,:)+y(i+2,:));
dydt(i+1,:) = 3*y(i,:) - y(i+1,:).*y(i,:).^2 + ...
    c*(3-2*y(i+1,:)+y(i+3,:));
% Evaluate the two components of the function at all interior
% grid points.
i = 3:2:2*N-3;
dydt(i,:) = 1 + y(i+1,:).*y(i,:).^2 - 4*y(i,:) + ...
    c*(y(i-2,:)-2*y(i,:)+y(i+2,:));
dydt(i+1,:) = 3*y(i,:) - y(i+1,:).*y(i,:).^2 + ...
    c*(y(i-1,:)-2*y(i+1,:)+y(i+3,:));
% Evaluate the two components of the function at the other edge
% of the grid (with edge conditions).
i = 2*N-1;

S = spdiags(B,-2:2,2*N,2*N);
```

## Example: Simple Event Location

ballode models the motion of a bouncing ball. This example illustrates the event location capabilities of the ODE solvers.

The equations for the bouncing ball are

$$
\begin{aligned}
& y_{1}^{\prime}=y_{2} \\
& y_{2}^{\prime}=-9.8
\end{aligned}
$$

In this example, the event function is coded in a subfunction events

```
[value,isterminal,direction] = events(t,y)
```

which returns:

- A value of the event function
- Theinformation whether or not the integration should stop (isterminal = 1 or 0 , respectively) when value $=0$
- The desired directionality of the zero crossings:
-1 Detect zero crossings in the negative direction only
0 Detect all zero crossings
1 Detect zero crossings in the positive direction only
The length of value, isterminal, and direction is the same as the number of event functions. The ith element of each vector, corresponds to the ith event function. F or an example of more advanced event location, see orbitode ("Example: Advanced Event Location" on page 15-44).

In ballode, setting the Events property to @events causes the sol ver to stop the integration (isterminal = 1) when the ball hits the ground (the height $y(1)$ is 0 ) during its fall (direction = -1). The example then restarts the integration with initial conditions corresponding to a ball that bounced.

To run this example from the MATLAB Help browser, click on the example name. Otherwise, type ballode at the command line.

```
function ballode
%BALLODE Run a demo of a bouncing ball.
tstart = 0;
tfinal = 30;
y0 = [0; 20];
refine = 4;
options = odeset('Events',@events,'OutputFcn', @odeplot,...
    'OutputSel', 1,'Refine',refine);
set(gca,'xlim',[0 30],'ylim',[0 25]);
box on
hold on;
tout = tstart;
yout = yo.';
teout = [];
yeout = [];
ieout = [];
for i = 1:10
    % Solve until the first terminal event.
    [t,y,te,ye,ie] = ode23(@f,[tstart tfinal],y0,options);
```

```
    if ~ishold
    hold on
    end
    % Accumulate output.
    nt = length(t);
    tout = [tout; t(2:nt)];
    yout = [yout; y(2:nt,:)];
    teout = [teout; te]; % Events at tstart are never reported.
    yeout = [yeout; ye];
    ieout = [ieout; ie];
    ud = get(gcf,'UserData');
    if ud.stop
        break;
    end
    % Set the new initial conditions, with .9 attenuation.
    y0(1) = 0;
    y0(2) = -.9*y(nt,2);
    % A good guess of a valid first time step is the length of
    % the last valid time step, so use it for faster computation.
    options = odeset(options,'InitialStep',t(nt)-t(nt-refine),...
        'MaxStep',t(nt)-t(1));
    tstart = t(nt);
end
plot(teout,yeout(:,1),'ro')
xlabel('time');
ylabel('height');
title('Ball trajectory and the events');
hold off
odeplot([],[],'done');
%
function dydt = f(t,y)
dydt = [y(2); -9.8];
%
function [value,isterminal,direction] = events(t,y)
% Locate the time when height passes through zero in a
% decreasing direction and stop integration.
```

```
value = y(1); % Detect height = 0
isterminal = 1; % Stop the integration
direction = -1; % Negative direction only
```

## Example: Advanced Event Location

orbitode illustrates the solution of a standard test problem for those solvers that are intended for nonstiff problems. It traces the path of a spaceship traveling around the moon and returning to the earth. (Shampine and Gordon [7], p.246).

The orbitode problem is a system of the four equations shown below

$$
\begin{aligned}
& y_{1}^{\prime}=y_{3} \\
& y_{2}^{\prime}=y_{4} \\
& y_{3}^{\prime}=2 y_{4}+y_{1}-\frac{\mu^{*}\left(y_{1}+\mu\right)}{r_{1}^{3}}-\frac{\mu\left(y_{1}-\mu^{*}\right)}{r_{2}^{3}} \\
& y_{4}^{\prime}=-2 y_{3}+y_{2}-\frac{\mu^{*} y_{2}}{r_{1}^{3}}-\frac{\mu y_{2}}{r_{2}^{3}}
\end{aligned}
$$

where

$$
\begin{aligned}
\mu & =1 / 82.45 \\
\mu^{*} & =1-\mu \\
r_{1} & =\sqrt{\left(y_{1}+\mu\right)^{2}+y_{2}^{2}} \\
r_{2} & =\sqrt{\left(y_{1}-\mu^{*}\right)^{2}+y_{2}^{2}}
\end{aligned}
$$

The first two solution components are coordinates of the body of infinitesimal mass, so plotting one against the other gives the orbit of the body. The initial conditions have been chosen to make the orbit periodic. The value of $\mu$ corresponds to a spaceship traveling around the moon and the earth. M oderately stringent tol erances are necessary to reproduce the qualitative behavior of the orbit. Suitable values are 1e-5 for RelTol and 1e-4 for AbsTol.

The events subfunction includes event functions which locate the point of maximum distance from the starting point and the time the spaceship returns to the starting point. Note that the events are located accurately, even though the step sizes used by the integrator are not determined by the location of the events. In this example, the ability to specify the direction of the zero crossing is critical. Both the point of return to the initial point and the point of maximum distancehave the sameevent function value, and the direction of the crossing is used to distinguish them.

To run this example from the MATLAB Help browser, click on the example name. Otherwise, type orbitode at the command line. The example uses the
output function odephase2 to produce the two-dimensional phase plane plot and let you to see the progress of the integration.

```
function orbitode
%ORBITODE Restricted three-body problem
tspan = [0 7];
y0 = [1.2; 0; 0; -1.04935750983031990726];
options = odeset('RelTol',1e-5,'AbsTol',1e-4,...
    'OutputFcn',@odephas2,'Events',@events);
[t,y,te,ye,ie] = ode45(@f,tspan,y0,options);
plot(y(:,1),y(:, 2),ye(:,1),ye(:, 2), '0');
title ('Restricted three body problem')
ylabel ('y(t)')
xlabel ('x(t)')
%
function dydt = f(t,y)
mu = 1 / 82.45;
mustar = 1 - mu;
r13 = ((y(1) + mu)^2 + y(2)^2) ^ 1.5;
r23 = ((y(1) - mustar)^2 + y(2)^2) ^ 1.5;
dydt = [ y(3)
    y(4)
        2*y(4) + y(1) - mustar*((y(1)+mu)/r13) - ...
                                mu*((y(1)-mustar)/r23)
        -2*y(3) + y(2) - mustar*(y(2)/r13) - mu*(y(2)/r23) ];
%
function [value,isterminal,direction] = events(t,y)
% Locate the time when the object returns closest to the
% initial point y0 and starts to move away, and stop integration.
% Also locate the time when the object is farthest from the
% initial point y0 and starts to move closer.
%
% The current distance of the body is
%
% DSQ = (y(1)-y0(1))^2 + (y(2)-y0(2))^2
% = <y(1:2)-y0,y(1:2)-y0>
%
```

```
% A local minimum of DSQ occurs when d/dt DSQ crosses zero
% heading in the positive direction. We can compute d(DSQ)/dt as
%
% d(DSQ)/dt = 2*(y(1:2)-y0)'*dy(1:2)/dt = 2*(y(1:2)-y0)'*y(3:4)
%
y0 = [1.2; 0];
dDSQdt = 2 * ((y(1:2)-y0)' * y(3:4));
value = [dDSQdt; dDSQdt];
isterminal = [1; 0]; % Stop at local minimum
direction = [1; -1]; % [local minimum, local maximum]
```

## Example: Differential-Algebraic Problem

hb1dae reformulates the hb1ode example as a differential-algebraic equation (DAE) problem. The Robertson problem coded in hb1ode is a classic test problem for codes that solve stiff ODEs.

$$
\begin{aligned}
& y_{1}^{\prime}=-0.04 y_{1}+10^{4} y_{2} y_{3} \\
& y_{2}^{\prime}=0.04 y_{1}-10^{4} y_{2} y_{3}-3 \cdot 10^{7} y_{2}^{2} \\
& y_{3}^{\prime}=3 \cdot 10^{7} y_{2}^{2}
\end{aligned}
$$

Note The Robertson problem appears as an example in the prolog to LSODI [4].

In hb1ode, the problem is solved with initial conditions $y_{1}(0)=1, y_{2}(0)=0$, $y_{3}(0)=0$ to steady state. These differential equations satisfy a linear conservation law that is used to reformulate the problem as the DAE

$$
\begin{aligned}
& y_{1}^{\prime}=-0.04 y_{1}+10^{4} y_{2} y_{3} \\
& y_{2}^{\prime}=0.04 y_{1}-10^{4} y_{2} y_{3}-3 \cdot 10^{7} y_{2}^{2} \\
& 0=y_{1}+y_{2}+y_{3}-1
\end{aligned}
$$

Obviously these equations do not have a solution for $y(0)$ with components that do not sum to 1 . The problem has the form of $M y^{\prime}=f(t, y)$ with

$$
M=\left[\begin{array}{lll}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 0
\end{array}\right]
$$

$M$ is obviously singular, but hb1dae does not inform the solver of this. The solver must recognize that the problem is a DAE, not an ODE. Similarly, although consistent initial conditions are obvious, the example uses an inconsistent value $y_{3}(0)=10^{-3}$ to illustrate computation of consistent initial conditions.

To run this example from the MATLAB Help browser, click on the example name. Otherwise, type hb1dae at the command line. Note that hb1dae:

- Imposes a much smaller absolute error tolerance on $y_{2}$ than on the other components. This is because $y_{2}$ is much smaller than the other components and its major change takes place in a relatively short time.
- Specifies additional points at which the solution is computed to more clearly show the behavior of $y_{2}$.
- Multiplies $y_{2}$ by $10^{4}$ to make $y_{2}$ visible when plotting it with the rest of the solution.
- Uses a logarithmic scale to plot the solution on the long time interval.

```
function hb1dae
%HB1DAE Stiff differential-algebraic equation (DAE)
% A constant, singular mass matrix
M = [1 0 0
    0 1 0
    O 0 0];
% Use an inconsistent initial condition to test initialization.
y0 = [1; 0; 1e-3];
tspan = [0 4*logspace(-6,6)];
% Use the LSODI example tolerances. The 'MassSingular' property
% is left at its default 'maybe' to test the automatic detection
% of a DAE.
options = odeset('Mass',M,'RelTol',1e-4,...
    'AbsTol',[1e-6 1e-10 1e-6],'Vectorized','on');
[t,y] = ode15s(@f,tspan,y0,options);
y(:,2) = 1e4*y(:,2);
semilogx(t,y);
ylabel('1e4 * y(:,2)');
title(['Robertson DAE problem with a Conservation Law, '...
    'solved by ODE15S']);
xlabel('This is equivalent to the stiff ODEs coded in HB1ODE.');
% -----------------------------------------------------------------
```

```
function out = f(t,y)
out = [ -0.04*y(1,:) + 1e4*y(2,:).*y(3,:)
    0.04*y(1,:) - 1e4*y(2,:).*y(3,:) - 3e7*y(2,:).^2
        y(1,:) + y(2,:) + y(3,:) - 1 ];
```

## Questions and Answers, and Troubleshooting

This section contains a number of tables that answer questions about the use and operation of the MATLAB ODE solvers:

- General ODE solver questions
- Problem size, memory use, and computation speed
- Time steps for integration
- Error tolerance and other options
- Solving different kinds of problems
- Troubleshooting

## General ODE Solver Questions

| Question | Answer |
| :--- | :--- |
| How do the ODE solvers <br> differ from quad or quadl? | quad and quadl solve problems of the form $y^{\prime}=f(t)$. The ODE <br> solvers handle more general problems $y^{\prime}=f(t, y)$, or problems <br> that involve a mass matrix $M(t, y) y^{\prime}=f(t, y)$. |
| Can I solve ODE systems in <br> which there are more <br> equations than unknowns, <br> or vice versa? | No. |

Problem Size, Memory Use, and Computation Speed

## Question <br> How large a problem can I solve with the ODE suite?

I'm solving a very large system, but only care about a couple of the components of $y$. Is there any way to avoid storing all of the elements?

## Answer

The primary constraints are memory and time. At each time step, the solvers for nonstiff problems allocate vectors of length $n$, where $n$ is the number of equations in the system. The solvers for stiff problems allocate vectors of length $n$, but also an n-by-n $J$ acobian matrix. For these solvers it may be advantageous to use the sparse option.

If the problem is nonstiff, or if you are using the sparse option, it may be possible to solve a problem with thousands of unknowns. In this case, however, storage of the result can be problematic. Try asking the solver to evaluate the solution at specific points only, or call the solver with no output arguments and use an output function to monitor the solution.

Yes. The user-installable output function capability is designed specifically for this purpose. When you call the solver with no output arguments, the solver does not allocate storage to hold the entire solution history. Instead, the solver calls OutputFcn( $t, y$ ) at each time step. To keep the history of specific elements, write an output function that stores or plots only the elements you care about.

| Problem Size, Memory Use, and Computation Speed (Continued) |  |
| :--- | :--- |
| Question | Answer |
| What is the startup cost of | The biggest startup cost occurs as the solver attempts to find a |
| the integration and how | step size appropriate to the scale of the problem. If you happen to |
| can I reduce it? | know an appropriate step size, use the InitialStep property. For |
|  | example, if you repeatedly call the integrator in an event location |
|  | loop, the last step that was taken before the event is probably on |
|  | scale for the next integration. See ballode for an example. |

Time Steps for Integration

| Question | Answer |
| :--- | :--- |
| The first step size that the <br> integrator takes is too <br> large, and it misses <br> important behavior. | You can specify the first step size with the InitialStep property. <br> The integrator tries this value, then reduces it if necessary. |
| Can I integrate with fixed <br> step sizes? | No. |

Error Tolerance and Other Options

| Question | Answer |
| :--- | :--- |
| How dol choose RelTol and <br> AbsTol? | RelTol, the relative accuracy tolerance, controls the number of <br> correct digits in the answer. AbsTol, the absolute error tolerance, <br> controls the difference between the answer and the solution. At <br> each step, the error e in component i of the solution satisfies |
|  | $\|e(i)\|<=$ max (RelTol*abs (y (i)), AbsTol (i)) ) |
|  | Roughly speaking, this means that you want RelTol correct <br> digits in all solution components except those smaller than <br> thresholds AbsTol (i). Even if you are not interested in a <br> component y (i) when it is small, you may have to specify <br> AbsTol(i) small enough to get some correct digits in y (i) so that <br> you can accurately compute more interesting components. |
| I want answers that are <br> correct to the precision of <br> the computer. Why can't I <br> simply set RelTol to eps? | You can get close to machine precision, but not that close. The <br> solvers do not allow RelTol near eps because they try to <br> approximate a continuous function. At tolerances comparable to <br> eps, the machine arithmetic causes all functions to look <br> discontinuous. |
| How dol tell the solver that <br> I don't care about getting <br> an accurate answer for one <br> of the solution components? | You can increase the absolute error tolerance corresponding to <br> this solution component. If the tolerance is bigger than the <br> component, this specifies no correct digits for the component. The <br> solver may have to get some correct digits in this component to <br> compute other components accurately, but it generally handles <br> this automatically. |

## Solving Different Kinds of Problems

| Question | Answer |
| :---: | :---: |
| Can the solvers handle partial differential equations (PDEs) that have been discretized by the method of lines? | Yes, because the discretization produces a system of ODEs. Depending on the discretization, you might have a form involving mass matrices - MATLAB ODE solvers provide for this. Often the system is stiff. This is to be expected when the PDE is parabolic and when there are phenomena that happen on very different time scales such as a chemical reaction in a fluid flow. In such cases, use one of the four solvers: ode15s, ode23s, ode23t, ode23tb. If there are many equations, set the JPattern property. This might make the difference between success and failure due to the computation being too expensive. When the system is not stiff, or not very stiff, ode23 or ode45 is more efficient than ode15s, ode23s, ode23t, or ode23tb. For an example that uses JPattern, see "Example: Large, Stiff Sparse Problem" on page 15-38. <br> Parabolic-elliptic partial differential equations in 1-D can be solved directly with the MATLAB PDE solver, pdepe. See "Partial Differential Equations" on page 15-82 for more information. |
| Can I solve differential-algebraic equation (DAE) systems? | Yes. The solvers ode15s and ode23t can solve some DAEs of the form $M(t, y) y^{\prime}=f(t, y)$ where $M(t, y)$ is singular. The DAEs must be of index 1 . For examples, see amp1dae or hb1dae. |
| Can I integrate a set of sampled data? | Not directly. You have to represent the data as a function by interpolation or some other scheme for fitting data. The smoothness of this function is critical. A piecewise polynomial fit like a spline can look smooth to the eye, but rough to a solver; the solver takes small steps where the derivatives of the fit have jumps. Either use a smooth function to represent the data or use one of the lower order solvers (ode23, ode23s, ode23t, ode23tb) that is less sensitive to this. |

## Solving Different Kinds of Problems (Continued)

| Question | Answer |
| :--- | :--- |
| Can I solve <br> delay-differential <br> equations? | Not directly. In some cases it is possible to use the initial value <br> problem solvers to solve delay-differential equations by breaking <br> the simulation interval into smaller intervals the length of a <br> single delay. For more information about this approach, see [6]. |
| What doI do when I have <br> the final and not the initial <br> value? | All the solvers of the MATLAB ODE suite allow you to solve <br> backwards or forwards in time. The syntax for the solvers is |
|  | $[t, y]=$ ode45 (odefun, $[$ to tf $], y 0) ;$ <br> and the syntax accepts t0 $>\mathrm{tf}.$. |

## Troubleshooting

Question
The solution doesn't look like what I expected.

## Answer

If you're right about its appearance, you need to reduce the error tolerances from their default values. A smaller relative error tolerance is needed to compute accurately the solution of problems integrated over "long" intervals, as well as solutions of problems that are moderately unstable. You should check whether there are solution components that stay smaller than their absolute error tolerance for some time. If so, you are not asking for any correct digits in these components. This may be acceptable for these components, but failing to compute them accurately may degrade the accuracy of other components that depend on them.

My plots aren't smooth enough.

Increase the value of Refine from its default of 4 in ode45 and 1 in the other solvers. The bigger the value of Refine, the more output points. Execution speed is not affected much by the value of Refine.

## Troubleshooting (Continued)

## Question

I'm plotting the solution as it is computed and it looks fine, but the code gets stuck at some point.

My integration proceeds very slowly, using too many time steps.

I know that the solution undergoes a radical change at time $t$ where

```
t0 \leq t \leq tf
```

but the integrator steps past without "seeing" it.

## Answer

First verify that the ODE function is smooth near the point where the code gets stuck. If it isn't, the solver must take small steps to deal with this. It may help to break tspan into pieces on which the ODE function is smooth.

If the function is smooth and the code is taking extremely small steps, you are probably trying to solve a stiff problem with a solver not intended for this purpose. Switch to ode15s, ode23s, ode23t, or ode23tb.

First, check that your tspan is not too long. Remember that the solver uses as many time points as necessary to produce a smooth solution. If the ODE function changes on a time scale that is very short compared to the tspan, the solver uses a lot of time steps. Long-time integration is a hard problem. Break tspan into smaller pieces.

If the ODE function does not change noticeably on the tspan interval, it could be that your problem is stiff. Try using ode15s, ode23s, ode23t, or ode23tb.

Finally, make sure that the ODE function is written in an efficient way. The solvers evaluate the derivatives in the ODE function many times. The cost of numerical integration depends critically on the expense of evaluating the ODE function. Rather than recompute complicated constant parameters at each evaluation, store them in globals or calculate them once outside the function and pass them in as additional parameters.

If you know there is a sharp change at time $t$, it might help to break the tspan interval into two pieces, [t0 t] and [t tf], and call the integrator twice.

If the differential equation has periodic coefficients or solution, you might restrict the maximum step size to the length of the period so the integrator won't step over periods.

## Boundary Value Problems for ODEs

This section describes how to use MATLAB to solve boundary value problems (BVPs) of ordinary differential equations (ODEs). It provides:

- A summary of the MATLAB BVP functions and examples
- An introduction to BVPs
- A description of the BVP solver and its syntax
- General instructions for representing a BVP in MATLAB
- A discussion and examples about using continuation to solve a difficult problem
- A discussion about changing default integration properties to improve solver performance

## BVP Function Summary

O DE Boundary Value Problem Solver

| Solver | Description |
| :--- | :--- |
| bvp4c | Solve two-point boundary value problems for ordinary <br> differential equations. |

BVP Helper Functions

| Function | Description |
| :--- | :--- |
| bvpinit | Form the initial guess for bvp4c. |
| deval | Evaluate the numerical solution using the output of bvp4c. |

## BVP Option Handling

An options structure contains named properties whose values are passed to the solver, and which affect problem solution. Use these functions to create, alter, or access an options structure.

| Function | Description |
| :--- | :--- |
| bvpset | Create/alter the BVP options structure. |
| bvpget | Extract properties from options structure created with bvpset. |

## ODE Boundary Value Problem Examples

These examples illustrate the kind of problems you can solve using the MATLAB BVP solver. From the MATLAB Help browser, click the example name to see the code in an editor. Type the example name at the command line to run it.

Note The Differential Equations Examples browser enables you to view the code for the BVP examples, and also run them. Click on the link to invoke the browser, or type odeexamples ('bvp') at the command line.

| Example | Description |
| :--- | :--- |
| fsbvp | Falkner-Skan BVP on an infinite interval |
| mat4bvp | Fourth eigenfunction of Mathieu's equation |
| shockbvp | Solution with a shock layer near $x=0$ |
| twobvp | BVP with exactly two solutions |

Additional examples are provided with thetutorial by Shampine, Reichelt, and Kierzenka, "Solving Boundary Value Problems for Ordinary Differential Equations in MATLAB with bvp4c." The tutorial and the examples are available at ftp://ftp.mathworks.com/pub/doc/papers/bvp/.This tutorial illustrates techniques for solving nontrivial real-life problems.

## Introduction to Boundary Value ODE Problems

The BVP solver is designed to handle systems of ordinary differential equations

$$
y^{\prime}=f(x, y)
$$

where x is the independent variable, y is the dependent variable, and $\mathrm{y}^{\prime}$ represents $\mathrm{dy} / \mathrm{dx}$.
See "What Is an Ordinary Differential Equation" on page 15-6 for general information about ODEs.

## Using Boundary Conditions to Specify the Solution of Interest

In a boundary value problem, the solution of interest satisfies certain boundary conditions. These conditions specify a relationship between the values of the solution at more than one $x$. bvp4c is designed to solve two-point BVPs, i.e., problems where the solution sought on an interval [a, b] must satisfy the boundary conditions
$g(y(a), y(b))=0$
Unlike initial value problems, a boundary value problem may not have a solution, may have a finite number of solutions, or may have infinitely many solutions. As an integral part of the process of solving a BVP, you need to provide a guess for the required solution. The quality of this guess can be critical for the solver performance and even for a successful computation.
There may be other difficulties when solving BVPs, such as problems imposed on infinite intervals or problems that involve singular coefficients. Often BVPs involve unknown parameters pthat have to be determined as part of solving the problem

$$
\begin{aligned}
& y^{\prime}=f(x, y, p) \\
& g(y(a), y(b), p)=0
\end{aligned}
$$

In this case, the boundary conditions must suffice to determine the value of $p$.

## Boundary Value Problem Solver

This section describes:

- The BVP solver, bvp4c
- BVP solver basic syntax
- Additional BVP solver arguments

You can also use the MATLAB Help browser to get information about the syntax for MATLAB functions.

## The BVP Solver

The function bvp4c solves two-point boundary value problems for ordinary differential equations (ODEs). It integrates a system of first-order ordinary differential equations

$$
y^{\prime}=f(x, y)
$$

on the interval [a, b] , subject to general two-point boundary conditions

$$
b c(y(a), y(b))=0
$$

It can also accommodate unknown parameters for problems of the form

$$
\begin{aligned}
& y^{\prime}=f(x, y, p) \\
& b c(y(a), y(b), p)=0
\end{aligned}
$$

In this case, the number of boundary conditions must besufficient to determine the solution and the unknown parameters. For more information, see "Finding Unknown Parameters" on page 15-67.
bvp4c produces a solution that is continuous on [a, b] and has a continuous first derivative there. You can use the function deval and the output of bvp4c to evaluate the solution at specific points on the interval of integration.
bvp4c is a finite difference code that implements the 3-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a $\mathrm{C}^{1}$-continuous solution that is fourth-order accurate uniformly in the interval of integration. Mesh selection and error control arebased on the residual of the continuous solution.

The collocation technique uses a mesh of points to divide the interval of integration into subintervals. The solver determines a numerical solution by
solving a global system of algebraic equations resulting from the boundary conditions, and the collocation conditions imposed on all the subintervals. The solver then estimates the error of the numerical solution on each subinterval. If the solution does not satisfy the tolerance criteria, the solver adapts the mesh and repeats the process. The user must provide the points of the initial mesh as well as an initial approximation of the solution at the mesh points.

## BVP Solver Basic Syntax

The basic syntax of the BVP solver is

```
sol = bvp4c(odefun,bcfun,solinit)
```

The input arguments are:
odefun Function that evaluates the differential equations. It has the basic form

$$
d y d x=\operatorname{odefun}(x, y)
$$

where $x$ is a scalar, and dydx and $y$ are column vectors. odefun can also accept a vector of unknown parameters and a variable number of known parameters.
bcfun Function that evaluates the residual in the boundary conditions. It has the basic form

```
res = bcfun(ya,yb)
```

where ya and $y b$ are column vectors representing $y$ (a) and $y(b)$, and res is a column vector of the residual in satisfying the boundary conditions. bcfun can also accept a vector of unknown parameters and a variable number of known parameters.
solinit Structure with fields $x$ and $y$ :
$x \quad$ Ordered nodes of the initial mesh. Boundary conditions are imposed at $\mathrm{a}=$ solinit. $\mathrm{x}(1)$ and $\mathrm{b}=$ solinit. $\mathrm{x}(\mathrm{end})$.
$y \quad$ Initial guess for the solution with solinit.y(: ,i) a guess for the solution at the node solinit.x(i).

The structure can have any name, but the fields must be named $x$ and y . It can also contain a vector that provides an initial guess for unknown parameters. You can form solinit with the helper function bvpinit. See the bvpinit reference page for details.

The output argument sol is a structure created by the solver. In the basic case the structure has fields $x, y$, and $y p$.

```
sol.x Nodes of the mesh selected by bvp4c
sol.y Approximation to }\textrm{y}(\textrm{x})\mathrm{ at the mesh points of sol. }\textrm{x
sol.yp Approximation to }\mp@subsup{y}{}{\prime}(x)\mathrm{ at the mesh points of sol.x
sol.parameters Value of unknown parameters, if present, found by the
solver.
sol.solver 'bvp4c'
```

The function deval uses the output structure sol to evaluate the numerical solution at any point from [a, b].

## Additional BVP Solver Arguments

F or moreadvanced applications, you can also specify as input arguments solver options and additional known parameters.
options Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
sol = bvp4c(odefun,bcfun,solinit,options)
```

"Creating and Maintaining a BVP Options Structure" on page 15-76 tells you how to create the structure and describes the properties you can specify.
p1,p2... Known parameters that the solver passes to odefun and bcfun.

```
sol = bvp4c(odefun,bcfun,solinit,options,p1,p2...)
```

The solver passes any input parameters that follow the options argument to odefun and bcfun every time it calls them. Use options = [ ] as a placeholder if you set no options. In the odefun argument list, known parameters follow $x, y$, and a vector of unknown parameters (parameters), if present.

```
dydx = odefun(x,y,p1,p2,...)
dydx = odefun(x,y,parameters,p1,p2,...)
```

In the bcfun argument list, known parameters follow ya, yb, and a vector of unknown parameters, if present.

```
res = bcfun(ya,yb,p1,p2,\ldots)
res = bcfun(ya,yb,parameters,p1,p2,...)
```

See "Example: Using Continuation to Solve a Difficult BVP" on page 15-68 for an example.

## Representing BVP Problems

This section describes:

- The process for solving boundary value problems (BVPs) using the MATLAB solver, bvp4c
- Finding unknown parameters
- Evaluating the solution at specific points

## Example: Mathieu's Equation

This example determines the fourth eigenvalue of Mathieu's Equation. It illustrates how to write second-order differential equations as a system of two first-order ODE s and how to use bvp4c to determine an unknown parameter $\lambda$.
The task is to compute the fourth ( $q=5$ ) eigenvalue $\lambda$ of Mathieu's equation

$$
y^{\prime \prime}+(\lambda-2 q \cos 2 x) y=0
$$

Because the unknown parameter $\lambda$ is present, this second-order differential equation is subject to thre boundary conditions

$$
\begin{aligned}
y(0) & =1 \\
y^{\prime}(0) & =0 \\
y^{\prime}(\pi) & =0
\end{aligned}
$$

Note The demo mat4bvp contains the complete code for this example. The demo uses subfunctions to place all functions required by bvp4c in a single M-file. To run this example type mat4bvp at the command line. See "BVP Solver Basic Syntax" on page 15-61 for more information.

1 Rewrite the Problem as a First-0 rder System. To use bvp4c, you must rewrite the equations as an equivalent system of first-order differential equations. Using a substitution $y_{1}=y$ and $y_{2}=y^{\prime}$, the differential equation is written as a system of two first-order equations

$$
\begin{aligned}
& y_{1}^{\prime}=y_{2} \\
& y_{2}^{\prime}=-(\lambda-2 q \cos 2 x) y_{1}
\end{aligned}
$$

Note that the differential equations depend on the unknown parameter $\lambda$. The boundary conditions become

$$
\begin{aligned}
y_{1}(0)-1 & =0 \\
y_{2}(0) & =0 \\
y_{2}(\pi) & =0
\end{aligned}
$$

2 Code the System of First-Order ODEs in MATLAB. Once you represent the equation as a first-order system, you can code it as a function that bvp4c can use. Because there is an unknown parameter, the function must be of the form

```
dydx = odefun(x,y,parameters)
```

The code below represents the system in the MATLAB function, mat4ode.

```
function dydx = mat4ode(x,y,lambda)
q = 5;
dydx = [ y(2)
    -(lambda - 2*q*}\operatorname{cos(2*x))*y(1) ];
```

See "Finding Unknown Parameters" on page 15-67 for more information about using unknown parameters with bvp4c.

3 Code the Boundary Conditions Function. You must also code the boundary conditions in a MATLAB function. Because there is an unknown parameter, the function must be of the form

```
res = bcfun(ya,yb,parameters)
```

The code below represents the boundary conditions in the MATLAB function, mat4bc.

```
function res = mat4bc(ya,yb,lambda)
res = [ ya(2)
    yb(2)
    ya(1)-1 ];
```

4 Create an Initial Guess. To form the guess structure solinit with bvpinit, you need to provide initial guesses for both the solution and the unknown parameter.

Thefunction mat4init provides an initial guess for the solution. mat4init uses $y=\cos 4 x$ because this function satisfies the boundary conditions and has the correct qualitative behavior (the correct number of sign changes).

```
function yinit = mat4init(x)
yinit = [ cos(4*x)
    -4*}\operatorname{sin}(4*x) ]
```

In the call to bvpinit, the third argument, lambda, provides an initial guess for the unknown parameter $\lambda$.

```
lambda = 15;
solinit = bvpinit(linspace(0,pi,10),@mat4init,lambda);
```

This example uses @ to pass mat4init as a function handle to bvpinit.

Note See the function_handle (@), func2str, and str2func reference pages, and the "Function Handles" chapter of "Programming and Data Types" in the MATLAB documentation for information about function handles.

5 Apply the BVP Solver. The mat4bvp example calls bvp4c with the functions mat4ode and mat4bc and the structure solinit created with bvpinit.

```
sol = bvp4c(@mat4ode,@mat4bc,solinit);
```

6 View the Results. Complete the example by displaying the results:

- Print the value of the unknown parameter $\lambda$ found by bvp4c.
fprintf('The fourth eigenvalue is approximately \%7.3f. $\mathrm{n}^{\prime}$,... sol.parameters)
- Use deval to evaluate the numerical solution at 100 equally spaced points in the interval $[0, \pi]$, and plot its first component. This component approximates $\mathrm{y}(\mathrm{x})$.

```
xint = linspace(0,pi);
Sxint = deval(sol,xint);
plot(xint,Sxint(1,:))
axis([0 pi -1 1.1])
title('Eigenfunction of Mathieu''s equation.')
xlabel('x')
ylabel('solution y')
```

See "E valuating the Solution at Specific Points" on page 15-68 for information about using deval.

Thefollowing plot shows theeigenfunction associated with the final eigenvalue $\lambda=17.097$.

Eigenfunction of Mathieu's equation.

## Finding Unknown Parameters

The bvp4c solver can find unknown parameters p for problems of the form

$$
\begin{aligned}
& y^{\prime}=f(x, y, p) \\
& b c(y(a), y(b), p)=0
\end{aligned}
$$

You must provide bvp4c an initial guess for any unknown parameters in the vector solinit. parameters. When you call bvpinit to create the structure solinit, specify the initial guess as a vector in the additional argument parameters.

```
solinit = bvpinit(x,v,parameters)
```

The bvp4c function arguments odefun and bcfun must each have a third argument.

```
dydx = odefun(x,y,parameters)
res = bcfun(ya,yb,parameters)
```

The bvp4c solver calculates intermediate values of unknown parameters at each iteration, and passes the latest values to odefun and bcfun in the
parameters arguments. The solver returns the final values of these unknown parameters in sol. parameters. See "Example: Mathieu's Equation" on page 15-63.

## Evaluating the Solution at Specific Points

The collocation method implemented in bvp4c produces a $C^{1}$-continuous solution over the whole interval of integration [a, b]. You can evaluate the approximate solution, $\mathrm{S}(\mathrm{x})$, at any point in [a, b] using the hel per function deval and the structure sol returned by bvp4c.

```
Sxint = deval(sol,xint)
```

The deval function is vectorized. F or a vector xint, the ith column of Sxint approximates the solution $y$ (xint(i)).

## Using Continuation to Make a Good Initial Guess

To solve a boundary value problem, you need to provide an initial guess for the solution. The quality of your initial guess can be critical to the solver performance, and to being able to solve the problem at all. However, coming up with a sufficiently good guess can be the most challenging part of solving a boundary value problem. Certainly, you should apply the knowledge of the problem's physical origin. Often a problem can be solved as a sequence of relatively simpler problems, i.e., a continuation. This section provides examples that illustrate how to use continuation to:

- Solve a difficult BVP.
- Verify a solution's consistent behavior.

## Example: Using Continuation to Solve a Difficult BVP

This example solves the differential equation

$$
\varepsilon y^{\prime \prime}+x y^{\prime}=\varepsilon \pi^{2} \cos (\pi x)-\pi x \sin (\pi x)
$$

for $\varepsilon=10^{-4}$, on the interval [-1 1], with boundary conditions $y(-1)=-2$ and $y(1)=0$. For $0<\varepsilon<1$, the solution has a transition layer at $x=0$. Because of this rapid change in the solution for small values of $\varepsilon$, the problem becomes difficult to solve numerically.

The example solves the problem as a sequence of relatively simpler problems, i.e., a continuation. The solution of one problem is used as the initial guess for solving the next problem.

Note The demo shockbvp contains the complete code for this example. The demo uses subfunctions to place all required functions in a single $M$-file. To run this example type shockbvp at the command line. See "BVP Solver Basic Syntax" on page 15-61 and "Representing BVP Problems" on page 15-63 for more information.

Note This problem appears in [1] to illustrate the mesh selection capability of a well established BVP code COLSYS.

1 Code the ODE and Boundary Condition Functions. Code the differential equation and the boundary conditions as functions that bvp4c can use. Because there is an additional known parameter $\varepsilon$, the functions must be of the form

```
dydx = odefun(x,y,p1)
res = bcfun(ya,yb,p1)
```

The code below represents the differential equation and the boundary conditions in the MATLAB functions shockODE and shockBC. Note that shockODE is vectorized to improve solver performance. The additional parameter $\varepsilon$ is represented by e.

```
function dydx = shockODE(x,y,e)
pix = pi*x;
dydx = [ y(2,:)
    -x/e.*y(2,:) - pi^2*cos(pix) - pix/e.*sin(pix) ];
function res = shockBC(ya,yb,e)
res = [ ya(1)+2
    yb(1) ];
```

The example passes e as an additional input argument to bvp4c.

```
sol = bvp4c(@shockODE,@shockBC,sol,options,e);
```

bvp4c then passes this argument to the functions shockODE and shockBC when it evaluates them. See "Additional BVP Solver Arguments" on page 15-62 for more information.

2 Provide Analytical Partial Derivatives. For this problem, the solver benefits from using analytical partial derivatives. The code bel ow represents the derivatives in functions shockJac and shockBCJac.

```
function jac = shockJac(x,y,e)
jac = [ 0 1
    0 -x/e ];
function [dBCdya,dBCdyb] = shockBCJac(ya,yb,e)
dBCdya = [ 1 0
    0 0 ];
dBCdyb = [ 0 0
    1 0 ];
```

shockJac and shockBCJac must accept the additional argument e, because bvp4c passes the additional argument to all the functions the user supplies.

Tell bvp4c to use these functions to evaluate the partial derivatives by setting the options FJacobian and BCJacobian. Also set 'Vectorized' to 'on' to indicate that the differential equation function shockODE is vectorized.

```
options = bvpset('FJacobian',@shockJac,...
    'BCJacobian',@shockBCJac,...
    'Vectorized','on');
```

3 Create an Initial Guess. Y ou must provide bvp4c with a guess structure that contains an initial mesh and a guess for values of the solution at the mesh points. A constant guess of $y(x) \equiv 1$ and $y^{\prime}(x) \equiv 0$, and a mesh of five equally spaced points on $[-11]$ suffice to solve the problem for $\varepsilon=10^{-2}$. Use bvpinit to form the guess structure.

```
sol = bvpinit([-1 -0.5 0 0.5 1],[1 0]);
```

4 Use Continuation to Solve the Problem. To obtain the solution for the parameter $\varepsilon=10^{-4}$, the example uses continuation by solving a sequence of problems for $\varepsilon=10^{-2}, 10^{-3}, 10^{-4}$. The solver bvp4c does not perform continuation automatically, but the code's user interface has been designed to make
continuation easy. The code uses the output sol that bvp4c produces for one value of $e$ as the guess in the next iteration.

```
e = 0.1;
for i=2:4
    e = e/10;
    sol = bvp4c(@shockODE,@shockBC,sol,options,e);
end
```

5 View the Results. Complete the example by displaying the final solution

```
plot(sol.x,sol.y(1,:))
axis([-1 1 -2.2 2.2])
title(['There is a shock at x = 0 when \epsilon = '...
    sprintf('%.e',e) '.'])
xlabel('x')
ylabel('solution y')
```

## Example: Using Continuation to Verify a Solution's Consistent Behavior

Falkner-Skan BVPs arise from similarity solutions of viscous, incompressible, laminar flow over a flat plate. An example is

$$
f^{\prime \prime \prime}+f^{\prime \prime}+\beta\left(1-\left(f^{\prime}\right)^{2}\right)=0
$$

for $\beta=0.5$ on the interval $[0, \infty)$ with boundary conditions $f(0)=0$, $f^{\prime}(0)=0$, and $f^{\prime}(\infty)=1$.

The BVP cannot be solved on an infinite interval, and it would be impractical to solve it for even a very large finite interval. So, the example tries to solve a sequence of problems posed on increasingly larger intervals to verify the solution's consistent behavior as the boundary approaches $\infty$.

The example imposes the infinite boundary condition at a finite point called infinity. The example then uses continuation in this end point to get convergence for increasingly larger values of infinity. It uses bvpinit to extrapolatethesolution sol for one value of infinity as an initial guess for the new value of infinity. The plot of each successive solution is superimposed over those of previous solutions so they can easily be compared for consistency.

Note The demo fsbvp contains the complete code for this example. The demo uses subfunctions to place all required functions in a single M-file. To run this example type fsbvp at the command line. See "BVP Solver Basic Syntax" on page 15-61 and "Representing BVP Problems" on page 15-63 for more information.

1 Code the ODE and Boundary Condition Functions. Code the differential equation and the boundary conditions as functions that bvp4c can use.

```
function dfdeta = fsode(eta,f)
beta = 0.5;
dfdeta = [ f(2)
    f(3)
    -f(1)*f(3) - beta*(1 - f(2)^2) ];
function res = fsbc(f0,finf)
res = [f0(1)
    f0(2)
```

```
finf(2) - 1];
```

2 Create an Initial Guess. Y ou must provide bvp4c with a guess structure that contains an initial mesh and a guess for values of the solution at the mesh points. A crude mesh of five points and a constant guess that satisfies the boundary conditions are good enough to get convergence when infinity $=3$.

```
infinity = 3;
maxinfinity = 6;
solinit = bvpinit(linspace(0,infinity,5),[0 0 1]);
```

4 Solve on the Initial Interval. The example obtains the solution for infinity $=3$. It then prints the computed value of $f^{\prime \prime}(0)$ for comparison with the value reported by Cebeci and Keller [2].

```
sol = bvp4c(@fsode,@fsbc,solinit);
eta = sol.x;
f = sol.y;
fprintf('\n');
fprintf('Cebeci & Keller report that f''''(0) = 0.92768.\n')
fprintf('Value computed using infinity = %g is '...
    '%7.5f.\n',Bnew,f(3,1))
```

The example prints

```
Cebeci & Keller report that f''(0) = 0.92768.
Value computed using infinity = 3 is 0.92915.
```

5 Setup the Figure and Plot the Initial Solution.

```
figure
plot(eta,f(2,:),eta(end),f(2, end),'o');
axis([0 maxinfinity 0 1.4]);
title('Falkner-Skan equation, positive wall shear, \beta = 0.5.')
xlabel('\eta')
ylabel('df/d\eta')
hold on
drawnow
shg
```

6 Use Continuation to Solve the Problem and Plot Susbsequent Solutions. The example then solves the problem for infinity $=4,5,6$. It uses bvpinit to extrapolate the solution sol for one value of infinity as an initial guess for the next value of infinity. F or each iteration, the example prints the computed value of $f^{\prime \prime}(0)$ and superimposes a plot of the solution in the existing figure.

```
for Bnew = infinity+1:maxinfinity
    solinit = bvpinit(sol,[0 Bnew]); % Extend solution to Bnew.
    sol = bvp4c(@fsode,@fsbc,solinit);
    eta = sol.x;
    f = sol.y;
    fprintf('Value computed using infinity = %g is '...
    '%7.5f.\n',Bnew,f(3,1))
    plot(eta,f(2,:),eta(end),f(2,end),'o');
    drawnow
end
hold off
```

The example prints

```
Value computed using infinity = 4 is 0.92774.
Value computed using infinity = 5 is 0.92770.
Value computed using infinity = 6 is 0.92770.
```

Note that the values approach 0.92768 as reported by Cebeci and Keller. The superimposed plots confirm the consistency of the solution's behavior.

## Improving BVP Solver Performance

The default integration properties in the BVP solver bvp4c are selected to handle common problems. In some cases, you can improve solver performance by changing these defaults. To do this, supply bvp4c with one or more property values in an options structure.

```
sol = bvp4c(odefun,bcfun,solinit,options)
```

This section:

- Explains how to create, modify, and query an options structure
- Describes the properties that you can use in an options structure

In this and subsequent property tables, the most commonly used property categories are listed first, followed by more advanced categories.

BVP Property Categories

| Properties Category | Property Names |
| :--- | :--- |
| Error control | RelTol, AbsTol |
| Vectorization | Vectorized |
| Analytical partial derivatives | FJacobian, BCJacobian |
| Mesh size | NMax |
| Output displayed | Stats |

Note For other ways to improve solver efficiency, check "Using Continuation to Make a Good Initial Guess" on page 8-68 and the tutorial, "Solving Boundary Value Problems for Ordinary Differential Equations in MATLAB with bvp4c," available at ftp://ftp.mathworks.com/pub/doc/papers/bvp/.

## Creating and Maintaining a BVP 0 ptions Structure

The bvpset function creates an options structure that you can supply to bvp4c. You can use bvpget to query the options structure for the value of a specific property.

Creating an Options Structure. The bvpset function accepts property name/ property value pairs using the syntax

```
options = bvpset('name1',value1,'name2',value2,...)
```

This creates a structure options in which the named properties have the specified values. Unspecified properties retain their default values. For all properties, it is sufficient to type only the leading characters that uniquely identify the property name. bvpset ignores case for property names.

With no arguments, bvpset displays all property names and their possible values, indicating defaults with braces \{\}.

Modifying an Existing Options Structure. To modify an existing options argument, use

```
    options = bvpset(oldopts,'name1',value1,...)
```

This overwrites any values in oldopts that are specified using name/value pairs. The modified structure is returned as the output argument. In the same way, the command

```
options = bvpset(oldopts,newopts)
```

combines the structures oldopts and newopts. In options, any values set in newopts overwrite those in oldopts.

Querying an Options Structure. The bvpget function extracts a property value from an options structure created with bvpset.

```
o = bvpget(options,'name')
```

This returns the value of the specified property, or an empty matrix [ ] if the property value is unspecified in the options structure.

As with bvpset, it is sufficient totype only the leading characters that uniquely identify the property name; case is ignored for property names.

## Error Tolerance Properties

Because bvp4c uses a collocation formula, the numerical solution is based on a mesh of points at which the collocation equations are satisfied. Mesh selection and error control are based on the residual of this solution, such that the computed solution $S(x)$ is the exact solution of a perturbed problem $S^{\prime}(x)=f(x, S(x))+r e s(x)$. On each subinterval of the mesh, a norm of the residual in the ith component of the solution, res(i), is estimated and is required to be less than or equal to a tolerance. This tolerance is a function of the relative and absolute tolerances, RelTol and AbsTol, defined by the user.

```
|(res(i)/max(abs(f(i)),AbsTol(i)/RelTol))| \leq RelTol
```

The fol lowing table describes the error tolerance properties. Use bvpset to set these properties.

## BVP Error Tolerance Properties

| Property | Value | Description |
| :--- | :--- | :--- |
| RelTol | Positive scalar <br> $\{1 e-3\}$ | A relative error tolerance that applies to all components of the <br> residual vector. It is a measure of the residual relative to the <br> size of $f(x, y)$. The default, $1 \mathrm{e}-3$, corresponds to $0.1 \%$ <br> accuracy. |
| AbsTol | Positive scalar <br> or vector $\{1 e-6\}$ | Absolute error tolerances that apply to the corresponding <br> components of the residual vector. AbsTol (i) is a threshold <br> below which the values of the corresponding components are <br> unimportant. If a scalar value is specified, it applies to all <br> components. |

## Vectorization

The following table describes the BVP vectorization property. Vectorization of the ODE function used by bvp4c differs from the vectorization used by theODE solvers:

- For bvp4c, the ODE function must be vectorized with respect to the first argument as well as the second one, so that $\mathrm{F}([\mathrm{x} 1 \mathrm{x} 2 \ldots],.[y 1$ y2 ...] $)$ returns [F(x1,y1) $F(x 2, y 2) \ldots]$.
- bvp4c benefits from vectorization even when analytical J acobians are provided. For stiff ODE solvers, vectorization is ignored when analytical J acobians are used.

Use bvpset to set this property.

| Property | Value | Description |
| :---: | :---: | :---: |
| Vectorized | on \| \{off \} | Set on to inform bvp4c that you have coded the ODE function $F$ so that $\mathrm{F}([\mathrm{x} 1 \mathrm{x} 2 \ldots],[\mathrm{y} 1 \mathrm{y} 2 \ldots])$ returns $[F(x 1, y 1) \quad F(x 2, y 2) \ldots]$. This allows the solver to reduce the number of function evaluations, and may significantly reduce solution time. <br> With MATLAB's array notation, it is typically an easy matter to vectorize an ODE function. In the shockbvp example shown previously, the shockODE function has been vectorized using colon notation into the subscripts and by using the array multiplication (.*) operator. ```function \(d y d x=\operatorname{shockODE}(x, y, e)\) pix = pi*x; dydx = [ \(\mathrm{y}(2,:)\) -x/e.*y(2,:)-pi^2*cos(pix)-pix/e.*sin(pix)``` |

## Analytical Partial Derivatives

By default, the bvp4c solver approximates all partial derivatives with finite differences. bvp4c can be more efficient if you provide analytical partial derivatives $\partial \mathrm{f} / \partial \mathrm{y}$ of the differential equations, and analytical partial derivatives, $\partial \mathrm{bc} / \partial \mathrm{ya}$ and $\partial \mathrm{bc} / \partial \mathrm{yb}$, of the boundary conditions. If the problem involves unknown parameters, you must also provide partial derivatives, $\partial \mathrm{f} / \partial \mathrm{p}$ and $\partial \mathrm{bc} / \partial \mathrm{p}$, with respect to the parameters.
The following table describes the analytical partial derivatives properties. Use bvpset to set these properties.

BVP Analytical Partial Derivative Properties

| Property | Value | Description |
| :---: | :---: | :---: |
| FJacobian | Function | The function computes the analytical partial derivatives of $f(x, y)$. When solving $y^{\prime}=f(x, y)$, set this property to @f $j$ ac if dfdy $=\mathrm{fjac}(x, y)$ evaluates theJ acobian $\partial f / \partial y$. If the problem involves unknown parameters $p,[d f d y, d f d p]=f j a c(x, y, p)$ must also return the partial derivative $\partial \mathrm{f} / \partial \mathrm{p}$. |
| BCJacobian | Function | The function computes the analytical partial derivatives of bc(ya, yb). F or boundary conditions bc(ya, yb), set this property to @bcjac if [dbcdya, dbcdyb] = bcjac (ya, yb) evaluates the partial derivatives $\partial \mathrm{bc} / \partial \mathrm{ya}$, and $\partial \mathrm{bc} / \partial \mathrm{yb}$. If the problem involves unknown parameters $p$, <br> [dbcdya, dbcdyb,dbcdp] = bcjac(ya,yb,p) must also return the partial derivative $\partial b c / \partial p$. |

## Mesh Size Property

bvp4c solves a system of algebraic equations to determine the numerical solution to a BVP at each of the mesh points. The size of the algebraic system depends on the number of differential equations ( $n$ ) and the number of mesh points in the current mesh ( N ). When the allowed number of mesh points is exhausted, the computation stops, bvp4c displays a warning message and returns the solution it found so far. This solution does not satisfy the error tolerance, but it may provide an excellent initial guess for computations restarted with relaxed error tolerances or an increased value of NMax.

The following table describes the mesh size property. Use bvpset to set this property.

BVP Mesh Size Property

| Property | Value | Description |
| :--- | :--- | :--- |
| NMax | positive integer | Maximum number of mesh points allowed when solving the |
|  | $\{f l o o r(1000 / n)\}$ | BVP, where $n$ is the number of differential equations in the <br> problem. The default value of NMax limits the size of the |
|  |  | algebraic system to about 1000 equations. For systems of a <br> few differential equations, the default value of NMax should <br> be sufficient to obtain an accurate solution. |
|  |  |  |

## Solution Statistic Property

The Stats property lets you view solution statistics.
The following tabledescribes the solution statistics property. Use bvpset to set this property.

BVP Solution Statistic Property

| Property | Value | Description |
| :--- | :--- | :--- |
| Stats | on $\mid\{0 f f\}$ | Specifies whether statistics about the computations are <br> displayed. If the stats property is on, after solving the <br> problem, bvp4c displays: |
|  |  | - The number of points in the mesh |
|  | - The maximum residual of the solution |  |
|  | - The number of times it called the differential equation |  |

## Partial Differential Equations

This section describes how to use MATLAB to solve initial-boundary value problems for partial differential equations (PDEs). It provides:

- A summary of the MATLAB PDE functions and examples
- An introduction to PDEs
- A description of the PDE solver and its syntax
- General instructions for representing a PDE in MATLAB, including an example
- A discussion about changing default integration properties to improve solver performance
- An example of solving a real-life problem

## PDE Function Summary

## MATLAB PDE Solver

This is the MATLAB PDE solver.

## PDE Initial-Boundary Value Problem Solver

pdepe Solve initial-boundary value problems for systems of parabolic and elliptic PDEs in one space variable and time.

## PDE Helper Function

## PDE Helper Function

pdeval Evaluate the numerical solution of a PDE using the output of pdepe.

## PDE Examples

These examples illustrate some problems you can solve using the MATLAB PDE solver. From the MATLAB Help browser, dick the example name to see the code in an editor. Type the example name at the command line to run it.

Note The Differential Equations Examples browser enables you to view the code for thePDE examples, and also run them. Click on the link to invoke the browser, or type odeexamples( 'pde ' ) at the command line.

| Example | Description |
| :--- | :--- |
| pdex1 | Simple PDE that illustrates the straightforward formulation, <br> computation, and plotting of the solution |
| pdex2 | Problem that involves discontinuities |
| pdex3 | Problem that requires computing values of the partial <br> derivative |
| pdex4 | System of two PDEs whose solution has boundary layers at <br> both ends of the interval and changes rapidly for small $t$ |
| pdex5 | System of PDEs with step functions as initial conditions |

## Introduction to PDE Problems

pdepe solves systems of PDEs in one spatial variable $x$ and time $t$, of the form

$$
\begin{equation*}
c\left(x, t, u, \frac{\partial u}{\partial x}\right) \frac{\partial u}{\partial t}=x^{-m} \frac{\partial}{\partial x}\left(x^{m} f\left(x, t, u, \frac{\partial u}{\partial x}\right)\right)+s\left(x, t, u, \frac{\partial u}{\partial x}\right) \tag{15-3}
\end{equation*}
$$

The PDEs hold for $\mathrm{t}_{0} \leq \mathrm{t} \leq \mathrm{t}_{\mathrm{f}}$ and $\mathrm{a} \leq \mathrm{x} \leq \mathrm{b}$. The interval [a, b] must be finite. m can be 0 , 1 , or 2 , corresponding to slab, cylindrical, or spherical symmetry, respectively. If $m>0$, then $a \geq 0$ must also hold.

In Equation 15-3, $f(x, t, u, \partial u / \partial x)$ is a flux term and $s(x, t, u, \partial u / \partial x)$ is a source term. The coupling of the partial derivatives with respect to time is restricted to multiplication by a diagonal matrix $\mathrm{c}(\mathrm{x}, \mathrm{t}, \mathrm{u}, \partial \mathrm{u} / \partial \mathrm{x})$. The diagonal elements of this matrix are either identically zero or positive. An element that is identically zero corresponds to an elliptic equation and otherwise to a parabolic equation. There must be at least one parabolic equation. An element of $c$ that corresponds to a parabolic equation can vanish at isolated values of $x$
if they are mesh points. Discontinuities in c and/or s dueto material interfaces are permitted provided that a mesh point is placed at each interface.

At the initial time $t=t_{0}$, for all $x$ the solution components satisfy initial conditions of the form

$$
\begin{equation*}
\mathrm{u}\left(\mathrm{x}, \mathrm{t}_{0}\right)=\mathrm{u}_{0}(\mathrm{x}) \tag{15-4}
\end{equation*}
$$

At the boundary $\mathrm{x}=\mathrm{a}$ or $\mathrm{x}=\mathrm{b}$, for all t the solution components satisfy a boundary condition of the form

$$
\begin{equation*}
p(x, t, u)+q(x, t) f\left(x, t, u, \frac{\partial u}{\partial x}\right)=0 \tag{15-5}
\end{equation*}
$$

$q(x, t)$ is a diagonal matrix with elements that are either identically zero or never zero. Note that the boundary conditions are expressed in terms of the flux $f$ rather than $\partial u / \partial x$. Also, of the two coefficients, only $p$ can depend on $u$.

## MATLAB Partial Differential Equation Solver

This section describes:

- The PDE solver, pdepe
- PDE solver basic syntax
- Additional PDE solver arguments

## The PDE Solver

The MATLAB PDE solver, pdepe, solves initial-boundary value problems for systems of parabolic and elliptic PDEs in the one space variable $x$ and time $t$. There must be at least one parabolic equation in the system.

The pdepe solver converts the PDEs to ODEs using a second-order accurate spatial discretization based on a set of nodes specified by the user. The discretization method is described in [8]. The time integration is done with ode15s. The pdepe solver exploits the capabilities of ode15s for solving the differential-algebraicequations that arise when Equation 15-3 contains elliptic equations, and for handlingJ acobians with a specified sparsity pattern. ode15s changes both the time step and the formula dynamically.

After discretization, elliptic equations give rise to algebraic equations. If the elements of the initial conditions vector that correspond to elliptic equations
are not "consistent" with the discretization, pdepe tries to adjust them before beginning the time integration. For this reason, the solution returned for the initial time may have a discretization error comparable to that at any other time. If the mesh is sufficiently fine, pdepe can find consistent initial conditions closetothe given ones. If pdepe displays a message that it has difficulty finding consistent initial conditions, try refining the mesh. No adjustment is necessary for elements of the initial conditions vector that correspond to parabolic equations.

## PDE Solver Basic Syntax

The basic syntax of the solver is

```
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)
```

Note Correspondences given are to terms used in "I ntroduction to PDE Problems" on page 15-83.

The input arguments are:
m Specifies the symmetry of the problem. m can be $0=$ slab, 1 =cylindrical, or $2=$ spherical. It corresponds to m in Equation 15-3.
pdefun Function that defines the components of the PDE. It computes the terms c, f, and s in Equation 15-3, and has the form

```
[c,f,s] = pdefun(x,t,u,dudx)
```

where $x$ and $t$ are scalars, and $u$ and dudx are vectors that approximate the solution $u$ and its partial derivative with respect to $x . c, f$, and s are column vectors. c stores the diagonal elements of the matrix $c$.
icfun Function that evaluates the initial conditions. It has the form

$$
u=\operatorname{icfun}(x)
$$

When called with an argument $x$, icfun evaluates and returns the initial values of the solution components at $x$ in the column vector $u$.
bcfun Function that evaluates the terms $p$ and $q$ of the boundary conditions. It has the form

$$
[p l, q l, p r, q r]=\operatorname{bcfun}(x l, u l, x r, u r, t)
$$

where ul is the approximate solution at the left boundary $\times \mathrm{l}=\mathrm{a}$ and ur is the approximate solution at the right boundary $\mathrm{xr}=\mathrm{b}$. pl and ql are column vectors corresponding to $p$ and the diagonal of $q$ evaluated at $x l$. Similarly, pr and qr correspond to xr . When $\mathrm{m}>0$ and $\mathrm{a}=0$, boundedness of the solution near $\mathrm{x}=0$ requires that the flux f vanish at $\mathrm{a}=0$. pdepe imposes this boundary condition automatically and it ignores values returned in pl and ql .
xmesh Vector [ $x 0, x_{1}, \ldots, x n$ ] specifying the points at which a numerical solution is requested for every value in tspan. $x 0$ and xn correspond to $a$ and $b$, respectively.

Second-order approximation to the solution is made on the mesh specified in xmesh. Generally, it is best to use closely spaced mesh points where the solution changes rapidly. pdepe does not select the mesh in $x$ automatically. You must provide an appropriate fixed mesh in xmesh. The cost depends strongly on the length of xmesh. When $m>0$, it is not necessary to use a fine mesh near $x=0$ to account for the coordinate singularity.
The elements of xmesh must satisfy $\mathrm{x} 0<\mathrm{x} 1<\ldots<\mathrm{xn}$. The length of $x$ mesh must be $\geq 3$.
tspan Vector [t0, t1, ..., tf] specifying the points at which a solution is requested for every value in xmesh. to and $t f$ correspond to $t_{0}$ and $t_{f}$, respectively.
pdepe performs the time integration with an ODE solver that selects both the time step and formula dynamically. The solutions at the points specified in tspan are obtained using the natural continuous extension of the integration formulas. The elements of tspan merely specify where you want answers and the cost depends weakly on the length of tspan.

The elements of tspan must satisfy t0 <t1<... <tf. The length of tspan must be $\geq 3$.

The output argument sol is a three-dimensional array, such that:

- $\operatorname{sol}(:,:, k)$ approximates component $k$ of the solution $u$.
- sol( $i,:, k)$ approximates component $k$ of the solution at time tspan(i) and mesh points xmesh(:).
- sol(i, $\mathrm{j}, \mathrm{k})$ approximates component $k$ of the solution at time tspan(i) and the mesh point xmesh(j).

## Additional PDE Solver Arguments

For moreadvanced applications, you can al so specify as input arguments solver options and additional parameters that are passed to the PDE functions.
options Structure of optional parameters that change the default integration properties. This is the seventh input argument.

```
sol = pdepe(m,pdefun,icfun,bcfun,...
    xmesh,tspan,options)
```

See "I mproving PDE Solver Performance" on page 15-93 for more information.
p1, p2... Parameters that the solver passes to pdefun, icfun, and bcfun.

```
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,...
    options,p1,p2...)
```

The solver passes any input parameters that follow the options argument to pdefun, icfun, and bcfun every time it calls them. Use options = [ ] as a placeholder if you set no options. In the pdefun argument list, parameters follow $x, t, u$, and dudx.

```
f = pdefun(x,t,u,dudx,p1,p2,...)
```

In the icfun argument list, parameters follow $x$.

```
res = icfun(x,p1,p2,\ldots.)
```

In the bcfun argument list, parameters follow xl, ul, xr, ur, and t.

```
res = bcfun(xl,ul,xr,ur,t,p1,p2,\ldots..)
```

See the pdex3 demo for an example.

## Representing PDE Problems

This section describes:

- The process for solving PDE problems using the MATLAB solver, pdepe
- Evaluating the solution at specific points

## Example: A Single PDE

This example illustrates the straightforward formulation, solution, and plotting of the solution of a single PDE

$$
\pi^{2} \frac{\partial u}{\partial t}=\frac{\partial^{2} u}{\partial x^{2}}
$$

This equation holds on an interval $0 \leq x \leq 1$ for times $t \geq 0$. At $t=0$, the solution satisfies the initial condition

$$
u(x, 0)=\sin \pi x
$$

At $x=0$ and $x=1$, the solution satisfies the boundary conditions

$$
\begin{aligned}
& u(0, t)=0 \\
& \pi e^{-t}+\frac{\partial u}{\partial x}(1, t)=0
\end{aligned}
$$

Note The demo pdex1 contains the complete code for this example. The demo uses subfunctions to place all functions it requires in a single M-file. To run the demo type pdex1 at the command line. See "PDE Solver Basic Syntax" on page 15-85 for more information.

1 Rewrite the PDE. Write the PDE in the form

$$
c\left(x, t, u, \frac{\partial u}{\partial x}\right) \frac{\partial u}{\partial t}=x^{-m} \frac{\partial}{\partial x}\left(x^{m} f\left(x, t, u, \frac{\partial u}{\partial x}\right)\right)+s\left(x, t, u, \frac{\partial u}{\partial x}\right)
$$

This is the form shown in Equation 15-3 and expected by pdepe. See "Introduction to PDE Problems" on page 15-83 for more information. For this example, the resulting equation is

$$
\pi^{2} \frac{\partial u}{\partial t}=x^{0} \frac{\partial}{\partial x}\left(x^{0} \frac{\partial u}{\partial x}\right)+0
$$

with parameter $\mathrm{m}=0$ and the terms

$$
\begin{aligned}
& \mathrm{c}\left(\mathrm{x}, \mathrm{t}, \mathrm{u}, \frac{\partial \mathrm{u}}{\partial \mathrm{x}}\right)=\pi^{2} \\
& \mathrm{f}\left(\mathrm{x}, \mathrm{t}, \mathrm{u}, \frac{\partial \mathrm{u}}{\partial \mathrm{x}}\right)=\frac{\partial \mathrm{u}}{\partial \mathrm{x}} \\
& \mathrm{~s}\left(\mathrm{x}, \mathrm{t}, \mathrm{u}, \frac{\partial \mathrm{u}}{\partial \mathrm{x}}\right)=0
\end{aligned}
$$

2 Code the PDE in MATLAB. Once you rewrite the PDE in the form shown above (E quation 15-3) and identify theterms, you can code the PDE in a function that pdepe can use. The function must be of the form

```
[c,f,s] = pdefun(x,t,u,dudx)
```

where c, f , and s correspond to the $\mathrm{c}, \mathrm{f}$, and s terms. The code bel ow computes $c, f$, and $s$ for the example problem.

```
function [c,f,s] = pdex1pde(x,t,u,DuDx)
c = pi^2;
f = DuDx;
s = 0;
```

3 Code the Initial Conditions Function. You must code the initial conditions in a MATLAB function of the form

```
u = icfun(x)
```

The code below represents the initial conditions in the MATLAB function pdex1ic.

```
function u0 = pdex1ic(x)
uO = sin(pi*x);
```

4 Code the Boundary Conditions Function. You must also code the boundary conditions in a MATLAB function of the form
[pl,ql,pr,qr] = bcfun(xl,ul,xr,ur,t)

The boundary conditions, written in the same form as Equation 15-5, are

$$
\mathrm{u}(0, \mathrm{t})+0 \cdot \frac{\partial \mathrm{u}}{\partial \mathrm{x}}(0, \mathrm{t})=0 \quad \text { at } \mathrm{x}=0
$$

and

$$
\pi e^{-t}+1 \cdot \frac{\partial u}{\partial x}(1, t)=0 \quad \text { at } x=1
$$

The code bel ow evaluates the components $\mathrm{p}(\mathrm{x}, \mathrm{t}, \mathrm{u})$ and $\mathrm{q}(\mathrm{x}, \mathrm{t})$ of the boundary conditions in the MATLAB function pdex1bc.

```
function [pl,ql,pr,qr] = pdex1bc(xl,ul,xr,ur,t)
pl = ul;
ql = 0;
pr = pi * exp(-t);
qr = 1;
```

In the function pdex1bc, pl and ql correspond to the left boundary conditions ( $x=0$ ), and $p r$ and qr correspond to the right boundary condition ( $x=1$ ).

5 Select Mesh Points for the Solution. Before you use the MATLAB PDE solver, you need to specify the mesh points ( $\mathrm{t}, \mathrm{x}$ ) at which you want pdepe to evaluate the solution. Specify the points as vectors $t$ and $x$.
The vectors $t$ and $x$ play different roles in the solver (see "MATLAB Partial Differential Equation Solver" on page 15-84). In particular, the cost and the accuracy of the solution depend strongly on the length of the vector $x$. However, the computation is much less sensitive to the values in the vector $t$.

This example requests the solution on the mesh produced by 20 equally spaced points from the spatial interval [ 0,1 ] and five values of $t$ from the time interval [0,2].

```
x = linspace(0,1,20);
t = linspace(0,2,5);
```

6 Apply the PDE Solver. The example calls pdepe with $m=0$, the functions pdex1pde, pdex1ic, and pdex1bc, and the mesh defined by $x$ and $t$ at which pdepe is to evaluate the solution. The pdepe function returns the numerical solution in a three-dimensional array sol, where sol (i, j,k) approximates the $k$ th component of the solution, $u_{k}$, evaluated at $t(i)$ and $x(j)$.

```
m = 0;
sol = pdepe(m,@pdex1pde,@pdex1ic,@pdex1bc,x,t);
```

This example uses @ to pass pdex1pde, pdex1ic, and pdex1bc as function handles to pdepe.

Note See the function_handle (@), func2str, and str2func reference pages, and the "Function Handles" chapter of "Programming and Data Types" in the MATLAB documentation for information about function handles.

7 View the Results. Complete the example by displaying the results:

- Extract and display the first solution component. In this example, the solution u has only one component, but for illustrative purposes, the example "extracts" it from the three-dimensional array. The surface plot shows the behavior of the solution.
$u=\operatorname{sol}(:,:, 1)$;
$\operatorname{surf}(x, t, u)$
title('Numerical solution computed with 20 mesh points')
xlabel('Distance x')
ylabel('Time t')

Numerical solution computed with 20 mesh points.

- Display a solution profile at $t_{f}$, the final value of $t$. In this example, $\mathrm{t}_{\mathrm{f}}=\mathrm{t}=2$. See "Evaluating the Solution at Specific Points" on page 15-93 for more information.

```
figure
plot(x,u(end,:))
title('Solution at t = 2')
xlabel('Distance x')
ylabel('u(x,2)')
```

## Evaluating the Solution at Specific Points

After obtaining and plotting the solution above, you might be interested in a solution profile for a particular value of $t$, or the time changes of the solution at a particular point $x$. The kth column $u(:, k)$ (of the solution extracted in step 7) contains the time history of the solution at $x(k)$. The jth row $u(j,:)$ contains the solution profile at $\mathrm{t}(\mathrm{j})$.

Using the vectors x and $\mathrm{u}(\mathrm{j},:$ ), and the helper function pdeval, you can evaluate the solution $u$ and its derivative $\partial u / \partial x$ at any set of points xout

```
[uout,DuoutDx] = pdeval(m,x,u(j,:),xout)
```

The example pdex3 uses pdeval to evaluate the derivative of the solution at xout $=0$. See pdeval for details.

## Improving PDE Solver Performance

The default integration properties in the MATLAB PDE solver are selected to handle common problems. In some cases, you can improve solver performance by overriding these defaults. Y ou do this by supplying pdepe with one or more property values in an options structure.

```
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)
```

Use odeset to create the options structure. Only those options of the underlying ODE solver shown in the following table are available for pdepe. The defaults obtained by leaving off the input argument options are generally satisfactory. "I mproving ODE Solver Performance" on page 15-16 tells you how to create the structure and describes the properties.

## PDE Property Categories

| Properties Category | Property Name |
| :--- | :--- |
| Error control | RelTol, AbsTol, NormControl |
| Step-size | InitialStep, MaxStep |

## Example: Electrodynamics Problem

This example illustrates the solution of a system of partial differential equations. The problem is taken from electrodynamics. It has boundary layers at both ends of the interval, and the solution changes rapidly for small $t$.
The PDEs are

$$
\begin{aligned}
& \frac{\partial u_{1}}{\partial t}=0.024 \frac{\partial^{2} u_{1}}{\partial x^{2}}-F\left(u_{1}-u_{2}\right) \\
& \frac{\partial u_{2}}{\partial t}=0.170 \frac{\partial^{2} u_{2}}{\partial x^{2}}+F\left(u_{1}-u_{2}\right)
\end{aligned}
$$

where $F(y)=\exp (5.73 y)-\exp (-11.46 y)$. The equations hold on an interval $0 \leq x \leq 1$ for times $t \geq 0$.

The solution u satisfies the initial conditions

$$
\begin{aligned}
& u_{1}(x, 0) \equiv 1 \\
& u_{2}(x, 0) \equiv 0
\end{aligned}
$$

and boundary conditions

$$
\begin{aligned}
& \frac{\partial u_{1}}{\partial \mathrm{x}}(0, \mathrm{t}) \equiv 0 \\
& \mathrm{u}_{2}(0, \mathrm{t}) \equiv 0 \\
& \mathrm{u}_{1}(1, \mathrm{t}) \equiv 1 \\
& \frac{\partial \mathrm{u}_{2}}{\partial \mathrm{x}}(1, \mathrm{t}) \equiv 0
\end{aligned}
$$

Note The demo pdex4 contains the complete code for this example. The demo uses subfunctions to place all required functions in a single M-file. To run this example type pdex4 at the command line. See "PDE Solver Basic Syntax" on page 15-85 and "Representing PDE Problems" on page 15-88 for more information.

1 Rewrite the PDE. In the form expected by pdepe, the equations are

$$
\left[\begin{array}{l}
1 \\
1
\end{array}\right] * \frac{\partial}{\partial t}\left[\begin{array}{l}
u_{1} \\
u_{2}
\end{array}\right]=\frac{\partial}{\partial x}\left[\begin{array}{l}
0.024\left(\partial u_{1} / \partial x\right) \\
0.170\left(\partial u_{2} / \partial x\right)
\end{array}\right]+\left[\begin{array}{r}
-\mathrm{F}\left(\mathrm{u}_{1}-\mathrm{u}_{2}\right) \\
\mathrm{F}\left(\mathrm{u}_{1}-\mathrm{u}_{2}\right)
\end{array}\right]
$$

The boundary conditions on the partial derivatives of $u$ have to be written in terms of the flux. In the form expected by pdepe, the left boundary condition is

$$
\left[\begin{array}{c}
0 \\
u_{2}
\end{array}\right]+\left[\begin{array}{l}
1 \\
0
\end{array}\right] *\left[\begin{array}{l}
0.024\left(\partial u_{1} / \partial x\right) \\
0.170\left(\partial u_{2} / \partial x\right)
\end{array}\right]=\left[\begin{array}{l}
0 \\
0
\end{array}\right]
$$

and the right boundary condition is

$$
\left[\begin{array}{c}
u_{1}-1 \\
0
\end{array}\right]+\left[\begin{array}{l}
0 \\
1
\end{array}\right] *\left[\begin{array}{c}
0.024\left(\partial u_{1} / \partial x\right) \\
0.170\left(\partial u_{2} / \partial x\right)
\end{array}\right]=\left[\begin{array}{l}
0 \\
0
\end{array}\right]
$$

2 Code the PDE in MATLAB. After you rewrite the PDE in the form shown above, you can code it as a function that pdepe can use. The function must be of the form

$$
[c, f, s]=\operatorname{pdefun}(x, t, u, d u d x)
$$

where c, f, and s correspond to the c , f, and s terms in Equation 15-3.

```
function [c,f,s] = pdex4pde(x,t,u,DuDx)
c = [1; 1];
f = [0.024; 0.17] .* DuDx;
y = u(1) - u(2);
F = exp(5.73*y)-exp(-11.47*y);
s = [-F; F];
```

3 Code the Initial Conditions Function. Theinitial conditions function must be of the form

```
u = icfun(x)
```

The code below represents the initial conditions in the MATLAB function pdex4ic.

```
function u0 = pdex4ic(x);
uO = [1; 0];
```

4 Code the Boundary Conditions Function. The boundary conditions functions must be of the form

```
[pl,ql,pr,qr] = bcfun(xl,ul,xr,ur,t)
```

The codebelow evaluates the components $\mathrm{p}(\mathrm{x}, \mathrm{t}, \mathrm{u})$ and $\mathrm{q}(\mathrm{x}, \mathrm{t})$ (Equation 15-5) of the boundary conditions in the MATLAB function pdex4bc.

```
function [pl,ql,pr,qr] = pdex4bc(xl,ul,xr,ur,t)
pl = [0; ul(2)];
ql = [1; 0];
pr = [ur(1)-1; 0];
qr = [0; 1];
```

5 Select Mesh Points for the Solution. The solution changes rapidly for small t. The program selects the step size in time to resolve this sharp change, but to see this behavior in the plots, output times must be selected accordingly. There are boundary layers in the solution at both ends of [0,1], so mesh points must be placed there to resolve these sharp changes. Often some experimentation is needed to select the mesh that reveals the behavior of the solution.

```
x = [0 0.005 0.01 0.05 0.1 0.2 0.5 0.7 0.9 0.95 0.99 0.995 1];
t = [0 0.005 0.01 0.05 0.1 0.5 1 1.5 2];
```

6 Apply the PDE Solver. The example calls pdepe with $m=0$, the functions pdex4pde, pdex4ic, and pdex4bc, and the mesh defined by $x$ and $t$ at which pdepe is to evaluate the solution. The pdepe function returns the numerical solution in a three-dimensional array sol, where sol (i, j, k) approximates the $k$ th component of the solution, $u_{k}$, evaluated at $t(i)$ and $x(j)$.

```
m = 0;
sol = pdepe(m,@pdex4pde,@pdex4ic,@pdex4bc,x,t);
```

7 View the Results. The surface plots show the behavior of the solution components.

```
u1 = sol(:,:,1);
u2 = sol(:,:,2);
figure
surf(x,t,u1)
title('u1(x,t)')
xlabel('Distance x')
ylabel('Time t')
```

```
figure
surf(x,t,u2)
title('u2(x,t)')
xlabel('Distance x')
ylabel('Time t')
```

MATLAB supports sparsematrices, matrices that contain a small proportion of nonzero elements. This characteristic provides advantages in both matrix storage space and computation time.

This chapter explains how to create sparse matrices in MATLAB, and how to use them in both specialized and general mathematical operations. It includes:

## Function Summary

A summary of the sparse matrix functions

## Introduction

An introduction to sparse matrices in MATLAB

## Viewing Sparse Matrices

How to obtain quantitative and graphical information about sparse matrices

## Example: Adjacency Matrices and Graphs

Examples that use adjacency matrices to demonstrate sparse matrices

## Sparse Matrix 0 perations

A discussion of functions that perform operations specific to sparse matrices

## Selected Bibliography

Published materials that support concepts described in this chapter

## Function Summary

The sparse matrix functions are located in the sparfun directory in the MATLAB toolbox directory.

| Function Summary |  | Function |
| :--- | :--- | :--- |
| Category | Description |  |
| Elementary sparse <br> matrices | speye | Sparse identity matrix. |
|  | sprand | Sparse uniformly distributed random matrix. |
|  | sprandn | Sparse normally distributed random matrix. |
| Full to sparse | sprandsym | Sparse random symmetric matrix. |
| conversion | spdiags | Sparse matrix formed from diagonals. |
|  | full | Create sparse matrix. |
| Working with | find | Convert sparse matrix to full matrix. |
| sparse matrices | spconvert | Import from sparse matrix external format. |
|  | nonzeros | Number of nonzero matrix elements. |
| nzmax | Amount of storage allocated for nonzero matrix elements. |  |
|  | spones | Replace nonzero sparse matrix elements with ones. |
|  | spalloc | Allocate space for sparse matrix. |
|  | issparse | True for sparse matrix. |
| spfun | Apply function to nonzero matrix elements. |  |
|  | spy | Visualize sparsity pattern. |

## Function Summary (Continued)

| Category | Function | Description |
| :--- | :--- | :--- |
| Graph theory | gplot | Plot graph, as in "graph theory." |
|  | etree | Elimination tree. |
|  | etreeplot | Plot elimination tree. |
|  | treelayout | Lay out tree or forest. |
| Reordering | treeplot | Plot picture of tree. |
|  | colamd | Column approximate minimum degree permutation. |
|  | colmmd | Column minimum degree permutation. |
|  | symamd | Symmetric approximate minimum degree permutation. |
|  | symrcm | Symmetric minimum degree permutation. |
| colperm | Column permutation. |  |
| randperm | Random permutation. |  |
| dinperm | Dulmage-Mendelsohn permutation. |  |
|  | eigs | A few eigenvalues. |
| svds | A few singular values. |  |
|  | luinc | Incomplete LU factorization. |
|  | cholinc | Incomplete Cholesky factorization. |
| normest | Estimate the matrix 2-norm. |  |
| condest | 1-norm condition number estimate. |  |
| sprank | Structural rank. |  |

## Function Summary (Continued)

| Category | Function | Description |
| :--- | :--- | :--- |
| Linear equations <br> (iterative methods) | bicg | BiConjugate Gradients Method. |
|  | bicgstab | BiConjugate Gradients Stabilized Method. |
|  | cgs | Conjugate Gradients Squared Method. |
|  | gmres | Generalized Minimum Residual Method. |
|  | lsqr | LSQR implementation of Conjugate Gradients on the <br> Normal Equations. |
|  | minres | Minimum Residual Method. |
| pcg | Preconditioned Conjugate Gradients Method. |  |
|  | qmr | Quasi-Minimal Residual Method. |
| symmlq | Symmetric LQ method |  |
| Miscellaneous | spaugment | Form least squares augmented system. |
|  | spparms | Set parameters for sparse matrix routines. |
|  | symbfact | Symbolic factorization analysis. |

## Introduction

Sparse matrices are a special class of matrices that contain a significant number of zero-valued elements. This property allows MATLAB to:

- Store only the nonzero elements of the matrix, together with their indices.
- Reduce computation time by eliminating operations on zero elements.

This section provides information about:

- Sparse matrix storage
- General storage information
- Creating sparse matrices
- Importing sparse matrices

## Sparse Matrix Storage

For full matrices, MATLAB stores internally every matrix element. Zero-valued elements require the same amount of storage space as any other matrix element. For sparse matrices, however, MATLAB stores only the nonzero elements and their indices. F or large matrices with a high percentage of zero-valued elements, this scheme significantly reduces the amount of memory required for data storage.

MATLAB uses three arrays internally to store sparse matrices with real elements. Consider an m-by-n sparse matrix with nnz nonzero entries stored in arrays of length nzmax:

- The first array contains all the nonzero elements of the array in floating-point format. The length of this array is equal to nzmax.
- The second array contains the corresponding integer row indices for the nonzero elements stored in the first nnz entries. This array also has length equal to nzmax.
- The third array contains n integer pointers to the start of each column in the other arrays and an additional pointer that marks the end of those arrays. The length of the third array is $n+1$.

This matrix requires storage for nzmax floating-point numbers and nzmax $+n+1$ integers. At 8 bytes per floating-point number and 4 bytes per integer, the total number of bytes required to store a sparse matrix is

```
8*nzmax + 4*(nzmax+n+1)
```

Sparse matrices with complex elements are also possible. In this case, MATLAB uses a fourth array with nnz elements to store the imaginary parts of the nonzero elements. An element is considered nonzero if either its real or imaginary part is nonzero.

## General Storage Information

The whos command provides high-level information about matrix storage, including size and storage class. For example, this whos listing shows information about sparse and full versions of the same matrix.

| whos |  |  |  |
| :--- | ---: | ---: | :--- |
| Name | Size | Bytes Class |  |
|  |  |  |  |
| M_full | $1100 \times 1100$ | 9680000 | double array |
| M_sparse | $1100 \times 1100$ | 4404 | sparse array |

Grand total is 1210000 elements using 9684404 bytes
Notice that the number of bytes used is much less in the sparse case, because zero-valued elements are not stored. In this case, the density of the sparse matrix is 4404/9680000, or approximately $.00045 \%$.

## Creating Sparse Matrices

MATLAB never creates sparse matrices automatically. Instead, you must determine if a matrix contains a large enough percentage of zeros to benefit from sparse techniques.

The density of a matrix is the number of non-zero elements divided by the total number of matrix elements. Matrices with very low density are often good candidates for use of the sparse format.

## Converting Full to Sparse

You can convert a full matrix to sparse storage using the sparse function with a single argument.

```
S = sparse(A)
```

| For example |  |  |  |
| :---: | :---: | :---: | :---: |
| $\mathrm{A}=$ [ 0 | 0 | 0 | 5 |
| 0 | 2 | 0 | 0 |
| 1 | 3 | 0 | 0 |
| 0 | 0 | 4 | 0]; |
| S = sparse(A) |  |  |  |
| produces |  |  |  |
| S = |  |  |  |
| $(3,1)$ |  |  | 1 |
| $(2,2)$ |  |  | 2 |
| $(3,2)$ |  |  | 3 |
| $(4,3)$ |  |  | 4 |
| $(1,4)$ |  |  | 5 |

The printed output lists the nonzero elements of s, together with their row and column indices. The elements are sorted by columns, reflecting the internal data structure.

You can convert a sparse matrix to full storage using the full function, provided the matrix order is not too large. For example $A=$ full $(S)$ reverses the example conversion.

Converting a full matrix to sparse storage is not the most frequent way of generating sparse matrices. If the order of a matrix is small enough that full storage is possible, then conversion to sparse storage rarely offers significant savings.

## Creating Sparse Matrices Directly

Y ou can createa sparse matrix from a list of nonzero el ements using the sparse function with five arguments.

$$
S=\operatorname{sparse}(i, j, s, m, n)
$$

i and j are vectors of row and column indices, respectively, for the nonzero elements of the matrix. $s$ is a vector of nonzero values whose indices are specified by the corresponding ( $i, j$ ) pairs. $m$ is the row dimension for the resulting matrix, and n is the column dimension.

The matrix $S$ of the previous example can be generated directly with

```
S = sparse([3 2 3 4 1],[1 2 2 3 4],[1 2 3 4 5],4,4)
S =
\((3,1) \quad 1\)
\((2,2) \quad 2\)
    (3,2) 3
    (4,3) 4
    (1,4) 5
```

The sparse command has a number of alternate forms. The example above uses a form that sets the maximum number of nonzero elements in the matrix to length (s). If desired, you can append a sixth argument that specifies a larger maximum, allowing you to add nonzero elements later without reallocating the sparse matrix.

## Example: Generating a Second Difference 0 perator

The matrix representation of the second difference operator is a good example of a sparse matrix. It is a tridiagonal matrix with $-2 s$ on the diagonal and 1 s on the super- and subdiagonal. There are many ways to generate it - here's one possibility.

```
D = sparse(1:n,1:n,-2*ones(1,n),n,n);
E = sparse(2:n,1:n-1,ones(1,n-1),n,n);
S = E+D+E'
```

For $n=5$, MATLAB responds with
S =

| $(1,1)$ | -2 |
| :--- | ---: |
| $(2,1)$ | 1 |
| $(1,2)$ | 1 |
| $(2,2)$ | -2 |
| $(3,2)$ | 1 |
| $(2,3)$ | 1 |
| $(3,3)$ | -2 |
| $(4,3)$ | 1 |
| $(3,4)$ | 1 |
| $(4,4)$ | -2 |

## Creating Sparse Matrices from Their Diagonal Elements

Creating sparse matrices based on their diagonal elements is a common operation, so the function spdiags handles this task. Its syntax is

```
S = spdiags(B,d,m,n)
```

To create an output matrix $s$ of size $m$-by-n with elements on $p$ diagonals:

- $B$ is a matrix of size min $(m, n)$-by-p. The columns of $B$ are the values to populate the diagonals of $s$.
- $d$ is a vector of length $p$ whose integer elements specify which diagonals of $s$ to populate.

That is, the elements in column $j$ of $B$ fill the diagonal specified by element $j$ of $d$.

[^0]As an example, consider the matrix $B$ and the vector $d$.
$B=\left[\begin{array}{ccc}41 & 11 & 0 \\ 52 & 22 & 0 \\ 63 & 33 & 13 \\ 74 & 44 & 24\end{array}\right] ;$
$d=[-3$
2];
Use these matrices to create a 7-by-4 sparse matrix A.
$A=$ spdiags $(B, d, 7,4)$
$A=$
$(1,1)$

In its full form, A looks like this.

```
full(A)
ans =
\begin{tabular}{rrrr}
11 & 0 & 13 & 0 \\
0 & 22 & 0 & 24 \\
0 & 0 & 33 & 0 \\
41 & 0 & 0 & 44 \\
0 & 52 & 0 & 0 \\
0 & 0 & 63 & 0 \\
0 & 0 & 0 & 74
\end{tabular}
```

spdiags can also extract diagonal elements from a sparse matrix, or replace matrix diagonal elements with new values. Type help spdiags for details.

## Importing Sparse Matrices from Outside MATLAB

You can import sparse matrices from computations outside MATLAB. Use the spconvert function in conjunction with the load command to import text files containing lists of indices and nonzero elements. For example, consider a three-column text file T . dat whose first column is a list of row indices, second column is a list of column indices, and third column is a list of nonzero values. These statements load T. dat into MATLAB and convert it into a sparse matrix s:

```
load T.dat
S = spconvert(T)
```

The save and load commands can also process sparse matrices stored as binary data in MAT-files.

## Viewing Sparse Matrices

MATLAB provides a number of functions that let you get quantitative or graphical information about sparse matrices.

This section provides information about:

- Obtaining information about nonzero elements
- Viewing graphs of sparse matrices
- Finding indices and values of nonzero elements

## Information About Nonzero Elements

There are several commands that provide high-level information about the nonzero elements of a sparse matrix:

- nnz returns the number of nonzero elements in a sparse matrix.
- nonzeros returns a column vector containing all the nonzero elements of a sparse matrix.
- nzmax returns the amount of storage space allocated for the nonzero entries of a sparse matrix.

To try some of these, load the supplied sparse matrix west0479, one of the Harwell-Boeing collection.

| load west0479 <br> whos <br> Name | Size | Bytes Class |  |
| :--- | ---: | :--- | :--- |
| west0479 | $479 \times 479$ | 24576 | sparse array |

This matrix models an eight-stage chemical distillation column.
Try these commands.
nnz(west0479)
ans =

1887
format short e

```
west0479
west0479 =
    (25,1) 1.0000e+00
    (31,1) -3.7648e-02
    (87,1) -3.4424e-01
    (26,2) 1.0000e+00
    (31,2) -2.4523e-02
    (88,2) -3.7371e-01
    (27,3) 1.0000e+00
    (31,3) -3.6613e-02
    (89,3) -8.3694e-01
    (28,4) 1.3000e+02
        .
        .
        .
nonzeros(west0479);
        ans =
            1.0000e+00
            -3.7648e-02
            -3.4424e-01
            1.0000e+00
            -2.4523e-02
            -3.7371e-01
            1.0000e+00
            -3.6613e-02
            -8.3694e-01
            1.3000e+02
                .
                .
                        .
```

Note Use Ctrl+C to stop the nonzeros listing at any time.

Note that initially nnz has the same value as nzmax by default. That is, the number of nonzero elements is equivalent to the number of storage locations allocated for nonzeros. However, MATLAB does not dynamically release memory if you zero out additional array elements. Changing the value of some matrix elements to zero changes the value of nnz, but not that of nzmax.

However, you can add as many nonzero elements to the matrix as desired. Y ou are not constrained by the original value of nzmax.

## View ing Sparse Matrices Graphically

It is often useful to use a graphical format to view the distribution of the nonzero elements within a sparse matrix. MATLAB's spy function produces a template view of the sparsity structure, where each point on the graph represents the location of a nonzero array element.

For example,
spy (west0479)

## The find Function and Sparse Matrices

F or any matrix, full or sparse, the find function returns the indices and values of nonzero elements. Its syntax is

$$
[i, j, s]=\text { find(S) }
$$

find returns the row indices of nonzero values in vector i, the column indices in vector $j$, and the nonzero values themselves in the vector $s$. The example below uses find to locate the indices and values of the nonzeros in a sparse matrix. The sparse function uses the find output, together with the size of the matrix, to recreate the matrix.

```
[i,j,s] = find(S)
[m,n] = size(S)
S = sparse(i,j,s,m,n)
```

## Example: Adjacency Matrices and Graphs

This section includes:

- An introduction to adjacency matrices
- Instructions for graphing adjacency matrices with gplot
- A Bucky ball example, including information about using spy plots to illustrate fill-in and distance
- An airflow model example

## Introduction to Adjacency Matrices

The formal mathematical definition of a graph is a set of points, or nodes, with specified connections between them. An economic model, for example, is a graph with different industries as the nodes and direct economic ties as the connections. The computer software industry is connected to the computer hardware industry, which, in turn, is connected to the semiconductor industry, and so on.

This definition of a graph lends itself to matrix representation. The adjacency matrix of an undirected graph is a matrix whose ( $i, j$ )th and ( $j, i$ ) th entries are 1 if node $i$ is connected to node $j$, and 0 otherwise. For example, the adjacency matrix for a diamond-shaped graph looks like

Since most graphs have relatively few connections per node, most adjacency matrices are sparse. The actual locations of the nonzero elements depend on how the nodes are numbered. A change in the numbering leads to permutation
of the rows and columns of the adjacency matrix, which can have a significant effect on both the time and storage requirements for sparse matrix computations.

## Graphing Using Adjacency Matrices

MATLAB's gplot function creates a graph based on an adjacency matrix and a related array of coordinates. To try gplot, create the adjacency matrix shown above by entering

```
A = [0 1 0 1; 1 0 1 0; 0 1 0 1; 1 0 1 0];
```

The columns of gplot's coordinate array contain the Cartesian coordinates for the corresponding node. F or the diamond example, create the array by entering

```
xy = [1 3; 2 1; 3 3; 2 5];
```

This places the first node at location (1,3), the second at location $(2,1)$, the third at location $(3,3)$, and the fourth at location $(2,5)$. To view the resulting graph, enter
gplot(A, xy)

## The Bucky Ball

One interesting construction for graph analysis is the Bucky ball. This is composed of 60 points distributed on the surface of a sphere in such a way that the distance from any point to its nearest neighbors is the same for all the points. Each point has exactly three neighbors. The Bucky ball models four different physical objects:

- The geodesic dome popularized by Buckminster Fuller
- The $\mathrm{C}_{60}$ molecule, a form of pure carbon with 60 atoms in a nearly spherical configuration
- In geometry, the truncated icosahedron
- In sports, the seams in a soccer ball

The Bucky ball adjacency matrix is a 60-by-60 symmetric matrix B. B has three nonzero elements in each row and column, for a total of 180 nonzero values. This matrix has important applications related to the physical objects listed earlier. F or example, the eigenvalues of $B$ are involved in studying the chemical properties of $\mathrm{C}_{60}$.

To obtain the Bucky ball adjacency matrix, enter
B = bucky;

At order 60, and with a density of $5 \%$, this matrix does not require sparse techniques, but it does provide an interesting example.

You can also obtain the coordinates of the Bucky ball graph using

$$
[B, v]=\text { bucky; }
$$

This statement generates v, a list of xyz-coordinates of the 60 points in 3-space equidistributed on the unit sphere. Thefunction gplot uses these points to plot the Bucky ball graph.

```
gplot(B,v)
axis equal
```

It is not obvious how to number the nodes in the Bucky ball so that the resulting adjacency matrix reflects the spherical and combinatorial symmetries of the graph. The numbering used by bucky.m is based on the pentagons inherent in the ball's structure.

The vertices of one pentagon are numbered 1 through 5 , the vertices of an adjacent pentagon are numbered 6 through 10, and so on. The picture on the following page shows the numbering of half of the nodes (one hemisphere); the numbering of the other hemisphere is obtained by a reflection about the equator. Use gplot to produce a graph showing half the nodes. You can add the node numbers using a for loop.

```
k = 1:30;
gplot(B(k,k),v);
axis square
for j = 1:30, text(v(j,1),v(j,2), int2str(j)); end
```

To view a template of the nonzero locations in the Bucky ball's adjacency matrix, use the spy function:
spy (B)

The node numbering that this model uses generates a spy plot with 12 groups of five elements, corresponding to the 12 pentagons in the structure. E ach node is connected to two other nodes within its pentagon and one node in some other pentagon. Since the nodes within each pentagon have consecutive numbers, most of the elements in the first super- and sub-diagonals of $B$ are nonzero. In addition, the symmetry of the numbering about the equator is apparent in the symmetry of the spy plot about the antidiagonal.

## Graphs and Characteristics of Sparse Matrices

Spy plots of the matrix powers of B illustrate two important concepts related to sparse matrix operations, fill-in and distance. spy plots help illustrate these concepts.

```
spy(B^2)
spy(B^3)
spy(B^4)
spy(B^8)
```

Fill-in is generated by operations like matrix multiplication. The product of two or more matrices usually has more nonzero entries than the individual terms, and so requires more storage. As p increases, $\mathrm{B}^{\wedge} \mathrm{p}$ fills in and spy ( $\mathrm{B}^{\wedge} \mathrm{p}$ ) gets more dense.

The distance between two nodes in a graph is the number of steps on the graph necessary to get from one node to the other. The spy plot of the p-th power of $B$ shows the nodes that are a distance $p$ apart. As $p$ increases, it is possible to get to moreand more nodes in $p$ steps. For the Bucky ball, $\mathrm{B}^{\wedge} 8$ is almost completely full. Only the antidiagonal is zero, indicating that it is possible to get from any node to any other node, except the one directly opposite it on the sphere, in eight steps.

## An Airflow Model

A calculation performed at NASA's Research Institute for Applications of Computer Science involves modeling the flow over an airplane wing with two trailing flaps.

In a two-dimensional model, a triangular grid surrounds a cross section of the wing and flaps. The partial differential equations are nonlinear and involve several unknowns, including hydrodynamic pressure and two components of vel ocity. Each step of the nonlinear iteration requires the solution of a sparse linear system of equations. Since both the connectivity and the geometric location of the grid points are known, the gplot function can produce thegraph shown above.

In this example, there are 4253 grid points, each of which is connected to between 3 and 9 others, for a total of 28831 nonzeros in the matrix, and a density equal to 0.0016 . This spy plot shows that the node numbering yields a definite band structure.

## Sparse Matrix Operations

M ost of MATLAB's standard mathematical functions work on sparse matrices just as they do on full matrices. In addition, MATLAB provides a number of functions that perform operations specific to sparse matrices. This section discusses:

- Computational considerations
- Standard mathematical operations
- Permutation and reordering
- Factorization
- Simultaneous linear equations
- Eigenvalues and singular values

## Computational Considerations

The computational complexity of sparse operations is proportional to nnz, the number of nonzero elements in the matrix. Computational complexity also depends linearly on the row size $m$ and column size $n$ of the matrix, but is independent of the product $\mathrm{m} * \mathrm{n}$, the total number of zero and nonzero elements.

The complexity of fairly complicated operations, such as the solution of sparse linear equations, involves factors like ordering and fill-in, which are discussed in the previous section. In general, however, the computer time required for a sparse matrix operation is proportional to the number of arithmetic operations on nonzero quantities.

## Standard Mathematical Operations

Sparse matrices propagate through computations according to these rules:

- Functions that accept a matrix and return a scalar or vector always produce output in full storageformat. For example, the size function always returns a full vector, whether its input is full or sparse.
- Functions that accept scalars or vectors and return matrices, such as zeros, ones, rand, and eye, always return full results. This is necessary to avoid introducing sparsity unexpectedly. The sparse analog of zeros ( $\mathrm{m}, \mathrm{n}$ ) is simply sparse ( $m, n$ ). The sparse analogs of rand and eye are sprand and speye, respectively. There is no sparse analog for the function ones.
- Unary functions that accept a matrix and return a matrix or vector preserve the storage class of the operand. If $s$ is a sparse matrix, then chol $(S)$ is also a sparse matrix, and diag ( $S$ ) is a sparse vector. Columnwise functions such as max and sum al so return sparse vectors, even though these vectors may be entirely nonzero. I mportant exceptions to this rule are the sparse and full functions.
- Binary operators yield sparse results if both operands are sparse, and full results if both are full. For mixed operands, the result is full unless the operation preserves sparsity. If $S$ is sparse and $F$ is full, then $S+F, S * F$, and $F \backslash S$ are full, while S. *F and S\&F are sparse. In some cases, the result might be sparse even though the matrix has few zero elements.
- Matrix concatenation using either the cat function or square brackets produces sparse results for mixed operands.
- Submatrix indexing on the right side of an assignment preserves the storage format of the operand unless the result is a scalar. $T=S(i, j)$ produces a sparse result if $s$ is sparse and either $i$ or $j$ is a vector. It produces a full scalar if both $i$ and $j$ are scalars. Submatrix indexing on the left, as in $T(i, j)=S$, does not change the storage format of the matrix on the left.

## Permutation and Reordering

A permutation of the rows and columns of a sparse matrix s can be represented in two ways:

- A permutation matrix $P$ acts on the rows of $S$ as $P * S$ or on the columns as S*P'.
- A permutation vector $p$, which is a full vector containing a permutation of $1: n$, acts on the rows of $s$ as $S(p,:)$, or on the columns as $S(:, p)$.

For example, the statements

```
p = [llllll
I = eye(5,5);
P = I(p,:);
e = ones(4,1);
S = diag(11:11:55) + diag(e,1) + diag(e,-1)
```

```
produce
\(p=\)
    \(\begin{array}{lllll}1 & 3 & 4 & 2 & 5\end{array}\)
\(P=\)
\begin{tabular}{lllll}
1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1
\end{tabular}
\(S=\)
\begin{tabular}{rrrrr}
11 & 1 & 0 & 0 & 0 \\
1 & 22 & 1 & 0 & 0 \\
0 & 1 & 33 & 1 & 0 \\
0 & 0 & 1 & 44 & 1 \\
0 & 0 & 0 & 1 & 55
\end{tabular}
```

You can now try some permutations using the permutation vector $p$ and the permutation matrix $P$. For example, the statements $S(p,:)$ and $P * S$ produce ans $=$

| 11 | 1 | 0 | 0 | 0 |
| ---: | ---: | ---: | ---: | ---: |
| 0 | 1 | 33 | 1 | 0 |
| 0 | 0 | 1 | 44 | 1 |
| 1 | 22 | 1 | 0 | 0 |
| 0 | 0 | 0 | 1 | 55 |

Similarly, S(:,p) and S*P' produce ans =

| 11 | 0 | 0 | 1 | 0 |
| ---: | ---: | ---: | ---: | ---: |
| 1 | 1 | 0 | 22 | 0 |
| 0 | 33 | 1 | 1 | 0 |
| 0 | 1 | 44 | 0 | 1 |
| 0 | 0 | 1 | 0 | 55 |

If $P$ is a sparse matrix, then both representations use storage proportional to $n$ and you can apply either to S in time proportional to $\mathrm{nnz}(\mathrm{S})$. The vector representation is slightly more compact and efficient, so the various sparse matrix permutation routines all return full row vectors with the exception of the pivoting permutation in LU (triangular) factorization, which returns a matrix compatible with earlier versions of MATLAB.

To convert between the two representations, let I = speye( n ) be an identity matrix of the appropriate size. Then,

```
P = I(p,:)
P' = I(:,p)
p = (1:n)*P'
p = (P*(1:n)')'
```

The inverse of $P$ is simply $R=P^{\prime}$. You can compute the inverse of $p$ with $r(p)=1: n$.

```
r(p) = 1:5
```

$r=$

| 1 | 4 | 2 | 3 | 5 |

## Reordering for Sparsity

Reordering the columns of a matrix can often make its LU or QR factors sparser. Reordering the rows and columns can often make its Cholesky, factors sparser. The simplest such reordering is to sort the columns by nonzero count. This is sometimes a good reordering for matrices with very irregular structures, especially if there is great variation in the nonzero counts of rows or columns.

The function $p=$ colperm(S) computes this column-count permutation. The colperm M-file has only a single line.

```
[ignore,p] = sort(full(sum(spones(S))));
```

This line performs these steps:
1 The inner call to spones creates a sparse matrix with ones at the location of every nonzero element in S .

2 The sum function sums down the columns of the matrix, producing a vector that contains the count of nonzeros in each column.

3 full converts this vector to full storage format.
4 sort sorts the values in ascending order. The second output argument from sort is the permutation that sorts this vector.

## Reordering to Reduce Bandwidth

The reverse Cuthill-McK ee ordering is intended to reduce the profile or bandwidth of the matrix. It is not guaranteed to find the smallest possible bandwidth, but it usually does. The function symrcm (A) actually operates on the nonzero structure of the symmetric matrix $A+A^{\prime}$, but the result is also useful for asymmetric matrices. This ordering is useful for matrices that come from one-dimensional problems or problems that are in some sense "long and thin."

## Minimum Degree Ordering

The degree of a node in a graph is the number of connections to that node. This is the same as the number of off-diagonal nonzero elements in the corresponding row of the adjacency matrix. The minimum degree algorithm generates an ordering based on how these degrees are altered during Gaussian elimination or Cholesky factorization. It is a complicated and powerful al gorithm that usually leads to sparser factors than most other orderings, including column count and reverse Cuthill-McK ee.
MATLAB functions implement two methods for each of two types of matrices: symamd and symmmd for symmetric matrices, and colamd and colmmd for nonsymmetric matrices. colamd and colmmd also work for symmetric matrices of the form $\mathrm{A}^{*} \mathrm{~A}^{\prime}$ or $\mathrm{A}^{\prime}{ }^{*} \mathrm{~A}$.

Because the most time-consuming part of a minimum degree ordering algorithm is keeping track of the degree of each node, all four functions use an approximation to the degree, rather the exact degree. As a result:

- F actorizations obtained using colmmd and symmmd tend to have more nonzero elements than if the implementation used exact degrees.
- colamd and symamd use a tighter approximation than colmmd and symmmd. They generate orderings that are as good as could be obtained using exact degrees.
- colamd and symamd are faster than colmmd and symmmd, respectively. This is true particularly for very large matrices.

You can change various parameters associated with details of the algorithms using the spparms function.

For details on the algorithms used by colmmd and symmmd, see [4]. F or details on the algorithms used by colamd and symamd, see [5]. The approximate degree used in colamd and symamd is based on [1].

## Factorization

This section discusses four important factorization techniques for sparse matrices:

- LU, or triangular, factorization
- Cholesky factorization
- QR, or orthogonal, factorization
- Incomplete factorizations

## LU Factorization

If $S$ is a sparse matrix, the statement below returns three sparse matrices $L, U$, and $P$ such that $P * S=L * U$.

$$
[L, U, P]=\operatorname{lu}(S)
$$

lu obtains the factors by Gaussian elimination with partial pivoting. The permutation matrix $P$ has only $n$ nonzero elements. As with dense matrices, the statement $[\mathrm{L}, \mathrm{U}]=\mathrm{lu}(\mathrm{S})$ returns a permuted unit lower triangular matrix and an upper triangular matrix whose product is $S$. By itself, $l u(S)$ returns $L$ and $U$ in a single matrix without the pivot information.

The sparse Lu factorization does not pivot for sparsity, but it does pivot for numerical stability. In fact, both the sparse factorization (line 1) and the full factorization (line 2) bel ow producethe same $L$ and $U$, even though the time and storage requirements might differ greatly.

```
[L,U] = lu(S) % Sparse factorization
[L,U] = sparse(lu(full(S))) % Full factorization
```

You can control pivoting in sparse matrices using

> lu(S,thresh)
where thresh is a pivot threshold in [0,1]. Pivoting occurs when the diagonal entry in a column has magnitude less than thresh times the magnitude of any sub-diagonal entry in that column. thresh $=0$ forces diagonal pivoting. thresh $=1$ is the default.

MATLAB automatically allocates the memory necessary to hold the sparse $L$ and $U$ factors during the factorization. MATLAB does not use any symbolic LU prefactorization to determine the memory requirements and set up the data structures in advance.

Reordering and Factorization. If you obtain a good column permutation $p$ that reduces fill-in, perhaps from symrcm or colamd, then computing lu(S(: , p) ) takes less time and storage than computing lu(S). Two permutations are the symmetric reverse Cuthill-McK ee ordering and the symmetric minimum degree ordering.

```
r = symrcm(B);
m = symamd(B);
```

The three spy plots produced by the lines below show the three adjacency matrices of the Bucky Ball graph with these three different numberings. The local, pentagon-based structure of the original numbering is not evident in the other three.

```
spy(B)
spy(B(r,r))
spy(B(m,m))
```

The reverse Cuthill-McK ee ordering, $r$, reduces the bandwidth and concentrates all the nonzero elements near the diagonal. The approximate minimum degree ordering, m, produces a fractal-like structure with large blocks of zeros.

To see the fill-in generated in the LU factorization of the Bucky ball, use speye ( $n, n$ ), the sparse identity matrix, to insert -3 s on the diagonal of $B$.

```
B = B - 3*speye(n,n);
```

Since each row sum is now zero, this new $B$ is actually singular, but it is still instructive to compute its LU factorization. When called with only one output argument, lu returns the two triangular factors, $L$ and $U$, in a single sparse matrix. The number of nonzeros in that matrix is a measure of the time and storage required to solve linear systems invol ving $B$. Here are the nonzero counts for the three permutations being considered.

$$
\begin{array}{lll}
\text { Original } & l u(B) & 1022 \\
\text { Reverse Cuthill-McK ee } & l u(B(r, r)) & 968 \\
\text { Approximate minimum degree } & l u(B(m, m)) & 636
\end{array}
$$

Even though this is a small example, the results are typical. The original numbering scheme leads to the most fill-in. The fill-in for the reverse Cuthill-McK ee ordering is concentrated within the band, but it is almost as
extensive as the first two orderings. For the minimum degree ordering, the relatively large blocks of zeros are preserved during the elimination and the amount of fill-in is significantly less than that generated by the other orderings. The spy plots below reflect the characteristics of each reordering.

## Cholesky Factorization

If $s$ is a symmetric (or Hermitian), positive definite, sparse matrix, the statement below returns a sparse, upper triangular matrix $R$ so that $R^{\prime} * R=S$.

$$
R=\operatorname{chol}(S)
$$

chol does not automatically pivot for sparsity, but you can compute minimum degree and profile limiting permutations for use with $\operatorname{chol}(\mathrm{S}(\mathrm{p}, \mathrm{p}))$.
Since the Cholesky al gorithm does not use pivoting for sparsity and does not require pivoting for numerical stability, chol does a quick calculation of the amount of memory required and allocates all the memory at the start of the factorization. You can use symbfact, which uses the same al gorithm as chol, to calculate how much memory is allocated.

## Q R Factorization

MATLAB computes the complete $Q R$ factorization of a sparse matrix s with

$$
[Q, R]=\operatorname{qr}(S)
$$

but this is usually impractical. The orthogonal matrix $Q$ often fails to have a high proportion of zero elements. A more practical alternative, sometimes known as "the Q-less QR factorization," is available.

With one sparse input argument and one output argument

$$
R=\operatorname{qr}(S)
$$

returns just the upper triangular portion of the QR factorization. The matrix R provides a Cholesky factorization for the matrix associated with the normal equations,

$$
R^{\prime *} R=S^{\prime *} S
$$

However, the loss of numerical information inherent in the computation of $S^{\prime *}$ s is avoided.

With two input arguments having the same number of rows, and two output arguments, the statement

$$
[C, R]=\operatorname{qr}(S, B)
$$

applies the orthogonal transformations to $B$, producing $C=Q^{\prime *} B$ without computing Q .
The Q-less QR factorization allows the solution of sparse least squares problems

$$
\operatorname{minimize}\|A x-b\|
$$

with two steps

$$
\begin{aligned}
& {[c, R]=\operatorname{qr}(A, b)} \\
& x=R \backslash c
\end{aligned}
$$

If $A$ is sparse, but not square, MATLAB uses these steps for the linear equation solving backslash operator

$$
x=A \backslash b
$$

Or, you can do the factorization yourself and examine R for rank deficiency.
It is also possible to solve a sequence of least squares linear systems with different right-hand sides, $b$, that are not necessarily known when $R=\operatorname{qr}(A)$ is computed. The approach solves the "semi-normal equations"

$$
R^{\prime *} R^{*} x=A^{\prime *} b
$$

with

$$
x=R \backslash\left(R^{\prime} \backslash\left(A^{\prime} * b\right)\right)
$$

and then employs one step of iterative refinement to reduce roundoff error

```
r=b - A*x
e = R\(R'\(A'*r))
x = x + e
```

## Incomplete Factorizations

The luinc and cholinc functions provide approximate, incomplete factorizations, which are useful as preconditioners for sparse iterative methods.

The luinc function produces two different kinds of incomplete LU factorizations, one involving a drop tolerance and one involving fill-in level. If A is a sparse matrix, and tol is a small tolerance, then

$$
[\mathrm{L}, \mathrm{U}]=\operatorname{luinc}(\mathrm{A}, \mathrm{tol})
$$

computes an approximate $L U$ factorization where all elements less than tol times the norm of the relevant column are set to zero. Alternatively,

$$
[\mathrm{L}, \mathrm{U}]=\operatorname{luinc}\left(\mathrm{A}, \mathrm{'}^{\prime}\right)
$$

computes an approximate $L U$ factorization wherethe sparsity pattern of $L+U$ is a permutation of the sparsity pattern of $A$.
For example,
load west0479
A = west0479;
$n n z(A)$
$n n z(l u(A))$
nnz(luinc (A, 1e-6))
nnz(luinc(A, '0'))
shows that A has 1887 nonzeros, its complete LU factorization has 16777 nonzeros, its incomplete LU factorization with a drop tolerance of $1 \mathrm{e}-6$ has 10311 nonzeros, and its lu('0') factorization has 1886 nonzeros.

The luinc function has a few other options. See the luinc reference page for details.

The cholinc function provides drop tolerance and level 0 fill-in Cholesky factorizations of symmetric, positive definite sparse matrices. See the cholinc reference page for more information.

## Simultaneous Linear Equations

Systems of simultaneous linear equations can be solved by two different classes of methods:

- Direct methods. These are usually variants of Gaussian elimination and are often expressed as matrix factorizations such as LU or Cholesky factorization. The algorithms involve access to the individual matrix elements.
- Iterative methods. Only an approximate solution is produced after a finite number of steps. The coefficient matrix is involved only indirectly, through a matrix-vector product or as the result of an abstract linear operator.

## Direct Methods

Direct methods are usually faster and more generally applicable, if there is enough storage available to carry them out. Iterative methods are usually applicable to restricted cases of equations and depend upon properties like diagonal dominance or the existence of an underlying differential operator. Direct methods are implemented in the core of MATLAB and are made as efficient as possible for general classes of matrices. Iterative methods are usually implemented in MATLAB M-files and may make use of the direct solution of subproblems or preconditioners.

The usual way to access direct methods in MATLAB is not through the lu or chol functions, but rather with the matrix division operators / and $\backslash$. If $A$ is square, the result of $X=A \backslash B$ is the solution to the linear system $A * X=B$. If $A$ is not square, then a least squares solution is computed.
If $A$ is a square, full, or sparse matrix, then $A \backslash B$ has the same storage class as B. Its computation involves a choice among several algorithms:

- If $A$ is triangular, perform a triangular solve for each column of $B$.
- If A is a permutation of a triangular matrix, permuteit and perform a sparse triangular solve for each column of $B$.
- If $A$ is symmetric or Hermitian and has positivereal diagonal elements, find a symmetric minimum degree order $p=\operatorname{symmm}(A)$, and attempt to compute
the Cholesky factorization of $A(p, p)$. If successful, finish with two sparse triangular solves for each column of $B$.
- Otherwise (if A is not triangular, or is not Hermitian with positive diagonal, or if Cholesky factorization fails), find a column minimum degree order $p=\operatorname{colmmd}(A)$. Compute the LU factorization with partial pivoting of $A(:, p)$, and perform two triangular solves for each column of $B$.

For a square matrix, MATLAB tries these possibilities in order of increasing cost. The tests for triangularity and symmetry are relatively fast and, if successful, allow for faster computation and more efficient memory usage than the general purpose method.
For example, consider the sequence below.

$$
\begin{aligned}
& {[L, U]=\operatorname{lu}(A) ;} \\
& y=L \backslash b ; \\
& x=U \backslash y
\end{aligned}
$$

In this case, MATLAB uses triangular solves for both matrix divisions, since L is a permutation of a triangular matrix and $U$ is triangular.

Using a Different Preordering. If $A$ is not triangular or a permutation of a triangular matrix, backslash ( $\backslash$ ) uses colmmd and symmmd to determine a minimum degree order. Use the function spparms to turn off the minimum degree preordering if you want to use a better preorder for a particular matrix.

If $A$ is sparse and $x=A \backslash b$ can use LU factorization, you can use a column ordering other than colmmd to solve for $x$, as in the following example.

```
spparms('autommd',0);
q = colamd(A);
x = A (:,q) \ b;
x(q) = x;
spparms('autommd',1);
```

If A can be factorized using Cholesky factorization, then $x=A \backslash b$ can be computed efficiently using

```
spparms('autommd',0);
p = symamd(A);
x = A(p,p) \ b (p);
x (p) = x;
spparms('autommd',1);
```

In the examples above, the spparms (' autommd ' , 0) statement turns the automatic colmmd or symmmd ordering off. The spparms ('autommd', 1 ) statement turns it back on, just in case you use $A \backslash b$ later without specifying an appropriate pre-ordering. spparms with no arguments reports the current settings of the sparse parameters.

## Iterative Methods

Nine functions are available that implement iterative methods for sparse systems of simultaneous linear systems.

Functions for Iterative Methods for Sparse Systems

| Function | Method |
| :--- | :--- |
| bicg | Biconjugate gradient |
| bicgstab | Biconjugate gradient stabilized |
| cgs | Conjugate gradient squared |
| gmres | Generalized minimum residual |
| lsqr | LSQR implementation of Conjugate Gradients on the <br> Normal Equations |
| minres | Minimum residual |
| pcg | Preconditioned conjugate gradient |
| qmr | Quasiminimal residual |
| symmlq | Symmetric LQ |

These methods are designed to solve $A x=b$ or $\min \|b-A x\|$. For the Preconditioned Conjugate Gradient method, pcg, A must be a symmetric, positive definite matrix. minres and symmlq can be used on symmetric indefinite matrices. F or lsqr, the matrix need not be square. The other five can handle nonsymmetric, square matrices.
All nine methods can make use of preconditioners. The linear system

$$
A x=b
$$

is replaced by the equivalent system

$$
M^{-1} A x=M^{-1} b
$$

The preconditioner $M$ is chosen to accelerate convergence of the iterative method. In many cases, the preconditioners occur naturally in the mathematical model. A partial differential equation with variable coefficients may be approximated by one with constant coefficients, for example. Incomplete matrix factorizations may be used in the absence of natural preconditioners.
The five-point finite difference approximation to Laplace's equation on a square, two-dimensional domain provides an example. The following statements use the preconditioned conjugate gradient method preconditioner $M=R^{*} R$, where $R$ is the incomplete Cholesky factor of $A$.

```
A = delsq(numgrid('S',50));
b = ones(size(A,1),1);
tol = 1.e-3;
maxit = 10;
R = cholinc(A,tol);
[x,flag,err,iter,res] = pcg(A,b,tol,maxit,R',R);
```

Only four iterations are required to achieve the prescribed accuracy.
Background information on these iterative methods and incomplete factorizations is available in [2] and [7].

## Eigenvalues and Singular Values

Two functions are available which compute a few specified eigenvalues or singular values. svds is based on eigs which uses ARPACK [6].

Functions to Compute a Few Eigenvalues or Singular Values

| Function | Description |
| :--- | :--- |
| eigs | Few eigenvalues |
| svds | Few singular values |

Thesefunctions are most frequently used with sparse matrices, but they can be used with full matrices or even with linear operators defined by M-files.

The statement
[V,lambda] = eigs(A,k,sigma)
finds the $k$ eigenvalues and corresponding eigenvectors of the matrix $A$ which are nearest the "shift" sigma. If sigma is omitted, the eigenvalues largest in magnitude are found. If sigma is zero, the eigenvalues smallest in magnitude are found. A second matrix, B, may be included for the generalized eigenvalue problem

$$
\mathrm{Av}=\lambda \mathrm{Bv}
$$

The statement

$$
[U, S, V]=\operatorname{svds}(A, k)
$$

finds the $k$ largest singular values of $A$ and

$$
[U, S, V]=\operatorname{svds}(A, k, 0)
$$

finds the $k$ smallest singular values.
For example, the statements

```
L = numgrid('L',65);
A = delsq(L);
```

set up the five-point Laplacian difference operator on a 65-by-65 grid in an L-shaped, two-dimensional domain. The statements

```
size(A)
nnz(A)
```

show that A is a matrix of order 2945 with 14,473 nonzero elements.
The statement

$$
[\mathrm{v}, \mathrm{~d}]=\operatorname{eigs}(\mathrm{A}, 1,0) ;
$$

computes the smallest eigenvalue and eigenvector. Finally,

```
L(L>0) = full(v(L(L>0)));
x = -1:1/32:1;
contour(x,x,L,15)
axis square
```

distributes the components of the eigenvector over the appropriate grid points and produces a contour plot of the result.

The numerical techniques used in eigs and svds are described in [6].

## Programming and Data Types

MATLAB is a high-level Ianguage that includes data structures, functions, control flow statements, input/output, and object-oriented capabilities. This section presents MATLAB's programming features and techniques in the following chapters:

- M-File Programming - describes language constructs and how to create MATLAB programs (M-files). It covers data types, flow control, array indexing, optimizing performance, and other topics.
- Character Arrays - covers MATLAB's support for string data, including how to create character arrays and cell arrays of strings, ways to represent strings, how to perform common string operations, and conversion between string and numeric formats.
- Multidimensional Arrays - discusses the use of MATLAB arrays having more than two dimensions. It covers array creation, array indexing, data organization, and how MATLAB functions operate on these arrays.
- Structures and Cell Arrays - describes two MATLAB data types that provide hierarchical storagefor dissimilar kinds of data. Structures contain different kinds of data organized by named fields. Cell arrays consist of cells that themselves contain MATLAB arrays.
- Function Handles - describes how you use the MATLAB function handle to capture certain information about a function, including function references, that you can then use to executethe function from anywherein theMATLAB environment.
- MATLAB Classes and Objects - presents MATLAB's object-oriented programming capabilities. Classes and objects enable you to add new data types and new operations to MATLAB. This section also includes examples of how to implement well-behaved classes in MATLAB.

## Related Information

The following sections provide information that is also useful to MATLAB programmers. This documentation is available in MATLAB's online help.

- Graphics - describes how to plot vector and matrix data in 2-D and 3-D representations, how to annotate, print, and export plots, and how to use graphics objects and their figure and axes properties.
- Calling C and F ortran Programs from MATLAB - describes how to build C and F ortran subroutines into callable MEX files.
- Calling MATLAB from C and F ortran Programs - discusses how to use the MATLAB engine library to call MATLAB from $C$ and Fortran programs.
- CallingJ ava from MATLAB - describes how to use the MATLAB interface to J ava classes and objects.
- Importing and Exporting Data - describes techniques for importing data to and exporting data from the MATLAB environment.
- ActiveX and DDE Support - describes how to use ActiveX and Dynamic Data Exchange (DDE) with MATLAB.
- Serial Port I/O - describes how to communicate with peripheral devices such as modems, printers, and scientific instruments that you connect to your computer's serial port.

MATLAB provides a full programming language that enables you to write a series of MATLAB statements into a file and then execute them with a single command. You write your program in an ordinary text file, giving the file a name of filename.m. The term you use for filename becomes the new command that MATLAB associates with the program. The file extension of .m makes this a MATLAB M-file.

This chapter explains the basics of how to write script and function programs in M-files. It covers the following topics:

- "MATLAB Programming: A Quick Start"
- "Scripts"
- "Functions"
- "Local and Global Variables"
- "Data Types"
- "Operators"
- "Flow Control"
- "Subfunctions"
- "Private Functions"
- "Subscripting and Indexing"
- "String Evaluation"
- "Command/F unction Duality"
- "E mpty M atrices"
- "Errors and Warnings"
- "Dates and Times"
- "Obtaining User Input"
- "Shell Escape F unctions"
- "Optimizing MATLAB Code"

## MATLAB Programming: A Quick Start

M-files can be scripts that simply execute a series of MATLAB statements, or they can be functions that al so accept arguments and produce output. Y ou create $M$-files using a text editor, then use them as you would any other MATLAB function or command.

The process looks like this:

1 Create an M-file using a text editor.

```
function c = myfile(a,b)
c = sqrt((a.^2)+(b.^2))
```

2 Call the M-file from the command line, or from within another M -file.

```
a = 7.5
b = 3.342
c = myfile(a,b)
c =
    8.2109
```

## Kinds of M-Files

There are two kinds of M-files.

| Script M-Files | Function M-Files |
| :--- | :--- |
| - Do not accept input arguments or <br> return output arguments | - Can accept input arguments and <br> return output arguments |
| - Operate on data in the workspace | - Internal variables are local to the <br> function by default |
| - Useful for automating a series of <br> steps you need to perform many <br> times <br> - Useful for extending the <br> MATLAB language for your <br> application |  |

## What's in an M-File?

This section shows you the basic parts of a function M-file, so you can familiarize yourself with MATLAB programming and get started with some examples.

```
function f = fact(n) % Function definition line
% FACT Factorial. % H1 line
% FACT(N) returns the factorial of N, H! % Help text
% usually denoted by N!
% Put simply, FACT(N) is PROD(1:N).
f = prod(1:n); % Function body
```

This function has some elements that are common to all MATLAB functions:

- A function definition line. This line defines the function name, and the number and order of input and output arguments.
- An H1 line. H1 stands for "help 1" line. MATLAB displays the H1 line for a function when you use lookfor or request help on an entire directory.
- Help text. MATLAB displays the help text entry together with the H 1 line when you request help on a specific function.
- The function body. This part of the function contains code that performs the actual computations and assigns values to any output arguments.

Refer to "Functions" on page 17-8 for more detail on the parts of a MATLAB function.

## Providing Help for Your Programs

You can provide user information for the programs you write by including a help text section at the beginning of your $M$-file. This section starts on theline following the function definition and ends at the first blank line. Each line of the help text must begin with a comment (\%) character. MATLAB displays this information whenever you type

```
help m-file_name
```

You can also make help entries for an entire directory by creating a file with the special name Contents.m that resides in the directory. This file must contain only comment lines; that is, every line must begin with a percent sign. MATLAB displays the lines in a contents.m file whenever you type
help directory_name
If a directory does not contain a Contents.mfile, typing help directory_name displays the first help line (the H 1 line) for each M -file in the directory.

## Creating M-Files: Accessing Text Editors

M-files are ordinary text files that you create using a text editor. MATLAB provides a built-in editor, although you can use any text editor you like.

Note To open the editor on the PC, from the File menu, choose New, and then M-File.

Another way to edit an M-file is from the MATLAB command line using the edit function. F or example,

```
    edit foo
```

opens the editor on the file foo.m. Omitting a filename opens the editor on an untitled file.

You can create the fact function shown on the previous page by opening your text editor, entering the lines shown, and saving the text in a file called fact.m in your current directory.

Once you've created this file, here are some things you can do:

- List the names of the files in your current directory
what
- List the contents of M-file fact.m

```
type fact
```

- Call the fact function
fact(5)
ans $=$

120

Note Save any M-files you create and any MATLAB-supplied M-files that you edit in a directory that is not in the MATLAB directory tree. If you keep your files in the MATLAB directory tree, they may be overwritten when you install a new version of MATLAB. Also note that the locations of files in the MATLAB/ toolbox directory tree are loaded and cached in memory at the beginning of each MATLAB session to improve performance. If you do save a new or edited file in the MATLAB/toolbox directory tree, restart MATLAB or use the rehash function to reload the directory and update the cache before you use the file.

## Scripts

Scripts are the simplest kind of $M$-file because they have no input or output arguments. They're useful for automating series of MATLAB commands, such as computations that you have to perform repeatedly from the command line. Scripts operate on existing data in the workspace, or they can create new data on which to operate. Any variables that scripts create remain in the workspace after the script finishes so you can use them for further computations.

## Simple Script Example

These statements calculate rho for several trigonometric functions of theta, then create a series of polar plots.

```
% An M-file script to produce % Comment lines
% "flower petal" plots
theta = -pi:0.01:pi; %Computations
rho(1,:) = 2*sin(5*theta).^2;
rho(2,:) = cos(10*theta).^3;
rho(3,:) = sin(theta).^2;
rho(4,:) = 5*cos(3.5*theta).^3;
for k = 1:4
    polar(theta,rho(k,:)) % Graphics output
    pause
end
```

Try entering these commands in an M-file called petals.m. This file is now a MATLAB script. Typing petals at the MATLAB command line executes the statements in the script.

After the script displays a plot, press Return to move to the next plot. There are no input or output arguments; petals creates the variables it needs in the MATLAB workspace. When execution completes, the variables ( $i$, theta, and rho) remain in the workspace. To see a listing of them, enter whos at the command prompt.

## Functions

Functions are M -files that accept input arguments and return output arguments. They operate on variables within their own workspace. This is separate from the workspace you access at the MATLAB command prompt.
This section covers the following topics regarding functions:

- "Simple Script Example"
- "Basic Parts of a Function M-File"
- "Function Names"
- "How Functions Work"
- "Checking the Number of Function Arguments"
- "Passing Variable Numbers of Arguments"

## Simple Function Example

The average function is a simple $M$-file that calculates the average of the elements in a vector.

```
function y = average(x)
% AVERAGE Mean of vector elements.
% AVERAGE(X), where X is a vector, is the mean of vector elements.
% Non-vector input results in an error.
[m,n] = size(x);
if (~((m == 1) | ( }\textrm{n}==1)) | (m == 1 & n == 1))
    error('Input must be a vector')
end
y = sum(x)/length(x); % Actual computation
```

If you would like, try entering these commands in an M-file called average.m. The average function accepts a single input argument and returns a single output argument. To call the average function, enter
average(z)
ans =

50

## Basic Parts of a Function M-File

A function M-file consists of:

- "The Function Definition Line"
- "The H 1 Line"
- "Help Text"
- "The Function Body"
- "Comments"

## The Function Definition Line

The function definition line informs MATLAB that the M-file contains a function, and specifies the argument calling sequence of the function. The function definition line for the average function is

All MATLAB functions have a function definition line that follows this pattern.
If the function has multiple output values, enclose the output argument list in square brackets. Input arguments, if present, are enclosed in parentheses. Use commas to separate multiple input or output arguments. Here's a more complicated example.

```
function [x,y,z] = sphere(theta,phi,rho)
```

If there is no output, leave the output blank
function printresults(x)
or use empty square brackets

```
function [] = printresults(x)
```

The variables that you pass to the function do not need to have the same name as those in the function definition line.

## The H1 Line

The H 1 line, so named because it is the first help text line, is a comment line immediately following the function definition line. Because it consists of comment text, the H 1 line begins with a percent sign, "\%." F or the average function, the H 1 line is
\% AVERAGE Mean of vector elements.
This is thefirst line of text that appears when a user types help function_name at the MATLAB prompt. Further, the lookfor function searches on and displays only the H 1 line. Because this line provides important summary information about the M-file, it is important to make it as descriptive as possible.

## Help Text

You can create online help for your M-files by entering text on one or more comment lines, beginning with the line immediately following the H 1 line. The help text for the average function is

```
% AVERAGE(X), where X is a vector, is the mean of vector elements.
```

\% Nonvector input results in an error.

When you type help function_name, MATLAB displays the comment lines that appear between the function definition line and the first non-comment (executable or blank) line. The help system ignores any comment lines that appear after this help block.
For example, typing help sin results in
SIN Sine.
$\operatorname{SIN}(\mathrm{X})$ is the sine of the elements of X .

## The Function Body

The function body contains all the MATLAB code that performs computations and assigns values to output arguments. The statements in the function body can consist of function calls, programming constructs like flow control and interactive input/output, calculations, assignments, comments, and blank lines.

F or example, the body of the average function contains a number of simple programming statements.

```
[m,n] = size(x);
if (~((m == 1) | ( }n==1)) | (m == 1 & n == 1)) % Flow contro
    error('Input must be a vector') % Error message display
end
y = sum(x)/length(x); % Computation and assignment
```

## Comments

As mentioned earlier, comment lines begin with a percent sign (\%). Comment lines can appear anywhere in an M-file, and you can append comments to the end of a line of code. F or example,

```
% Add up all the vector elements.
y = sum(x) % Use the sum function.
```

The first comment line immediately following the function definition line is considered the H 1 line for the function. The H 1 line and any comment lines immediately following it constitute the online help entry for the file.

In addition to comment lines, you can insert blank lines anywhere in an $M$-file. Blank lines are ignored. However, a blank line can indicate the end of the help text entry for an M-file.

## Function Names

MATLAB function names have the same constraints as variable names. MATLAB uses the first 31 characters of names. Function names must begin with a letter; the remaining characters can be any combination of letters, numbers, and underscores. Some operating systems may restrict function names to shorter lengths.

The name of the text file that contains a MATLAB function consists of the function name with the extension .m appended. For example,
average.m
If the filename and the function definition line name are different, the internal name is ignored.

Thus, while the function namespecified on the function definition line does not have to be the same as the filename, we strongly recommend that you use the same name for both.

## How Functions Work

You can call function M-files from either the MATLAB command line or from within other M-files. Be sure to include all necessary arguments, enclosing input arguments in parentheses and output arguments in square brackets.

This section provides the following information on calling MATLAB functions:

- "Function Name Resolution"
- "What Happens When You Call a Function"
- "Creating P-Code Files"
- "How MATLAB Passes Function Arguments"
- "Function Workspaces"

## Function Name Resolution

When MATLAB comes upon a new name, it resolves it into a specific function by following these steps:

1 Checks to see if the name is a variable.
2 Checks to see if the name is a subfunction, a MATLAB function that resides in the same $M$-file as the calling function. Subfunctions are discussed in the section, "Subfunctions" on page 17-43.

3 Checks to see if the name is a privatefunction, a MATLAB function that resides in a private directory, a directory accessible only to M-files in the directory immediately above it. Private directories are discussed in the section, "Private Functions" on page 17-45.

4 Checks to see if the name is a function on the MATLAB search path. MATLAB uses the first file it encounters with the specified name.

If you duplicate function names, MATLAB executes the one found first using the above rules. It is also possible to overload function names. This uses additional dispatching rules and is discussed in the section, "How MATLAB Determines Which Method to Call" on page 22-67.

## What Happens When You Call a Function

When you call a function $M$-file from either the command line or from within another M-file, MATLAB parses the function into pseudocode and stores it in memory. This prevents MATLAB from having to reparse a function each time you call it during a session. The pseudocode remains in memory until you clear it using the clear function, or until you quit MATLAB.

You can use clear in any of the following ways to remove functions from the MATLAB workspace.

| Syntax | Description |
| :--- | :--- |
| clear function_name | Remove specified function from workspace |
| clear functions | Remove all compiled $M$-functions |
| clear all | Remove all variables and functions |

## Creating P-Code Files

You can save a preparsed version of a function or script, called P-code files, for later MATLAB sessions using the pcode function. For example,

```
pcode average
```

parses average.m and saves the resulting pseudocode to the file named average. p. This saves MATLAB from reparsing average.m the first time you call it in each session.

MATLAB is very fast at parsing so the pcode function rarely makes much of a speed difference.

One situation where pcode does provide a speed benefit is for large GUI applications. In this case, many M-files must be parsed before the application becomes visible.

Another situation for pcode is when, for proprietary reasons, you want to hide al gorithms you've created in your M-file.

## How MATLAB Passes Function Arguments

From the programmer's perspective, MATLAB appears to pass all function arguments by value. Actually, however, MATLAB passes by value only those arguments that a function modifies. If a function does not alter an argument but simply uses it in a computation, MATLAB passes the argument by reference to optimize memory use.

## Function Workspaces

Each M-file function has an area of memory, separate from MATLAB's base workspace, in which it operates. This area is called the function workspace, with each function having its own workspace context.

While using MATLAB, the only variables you can access arethose in the calling context, beit the base workspace or that of another function. The variables that you pass to a function must be in the calling context, and the function returns its output arguments to the calling workspace context. Y ou can however, define variables as global variables explicitly, allowing more than one workspace context to access them.

## Checking the Number of Function Arguments

The nargin and nargout functions let you determine how many input and output arguments a function is called with. You can then use conditional statements to perform different tasks depending on the number of arguments. For example,

```
function c = testarg1(a,b)
if (nargin == 1)
    c = a.^2;
elseif (nargin == 2)
    c = a + b;
end
```

Given a single input argument, this function squares the input value. Given two inputs, it adds them together.

Here's a more advanced examplethat finds thefirst token in a character string. A token is a set of characters delimited by whitespace or some other character. Given one input, the function assumes a default delimiter of whitespace; given two, it lets you specify another delimiter if desired. It also allows for two possible output argument lists.

```
function [token,remainder] = strtok(string,delimiters)
% Function requires at least one input argument
if nargin < 1
    error('Not enough input arguments.');
end
token = []; remainder = [];
len = length(string);
if len == 0
    return
end
% If one input, use white space delimiter
if (nargin == 1)
    delimiters = [9:13 32]; % White space characters
end
i = 1;
% Determine where non-delimiter characters begin
while (any(string(i) == delimiters))
    i = i + 1;
    if (i > len), return, end
end
% Find where token ends
start = i;
while (~any(string(i) == delimiters))
    i = i + 1;
    if (i > len), break, end
end
finish = i - 1;
token = string(start:finish);
% For two output arguments, count characters after
% first delimiter (remainder)
if (nargout == 2)
    remainder = string(finish + 1:end);
end
```

The strtok function is a MATLAB M-file in the strfun directory.

Note The order in which output arguments appear in the function declaration line is important. The argument that the function returns in most cases appears first in the list. Additional, optional arguments are appended to the list.

## Passing Variable Numbers of Arguments

The varargin and varargout functions let you pass any number of inputs or return any number of outputs to a function. This section describes how to use these functions and also covers:

- "Unpacking varargin Contents"
- "Packing varargout Contents"
- "varargin and varargout in Argument Lists"

MATLAB packs all specified input arguments into a cell array, a special kind of MATLAB array that consists of cells instead of array elements. Each cell can hold any size or kind of data - one might hold a vector of numeric data, another in the same array might hold an array of string data, and so on. For output arguments, your function code must pack them into a cell array so that MATLAB can return the arguments to the caller.

Here's an example function that accepts any number of two-element vectors and draws a line to connect them.

```
function testvar(varargin)
for k = 1:length(varargin)
    x(k) = varargin{k}(1); % Cell array indexing
    y(k) = varargin{k}(2);
end
xmin = min(0,min(x));
ymin = min(0,min(y));
axis([xmin fix(max(x))+3 ymin fix(max(y))+3])
plot(x,y)
```

Coded this way, the testvar function works with various input lists; for example,

```
testvar([-1 0],[[3 -5],[4 2],[[1 1])
```

## Unpacking varargin Contents

Because varargin contains all the input arguments in a cell array, it's necessary to use cell array indexing to extract the data. For example,

```
y(i) = varargin{i}(2);
```

Cell array indexing has two subscript components:

- The cell indexing expression, in curly braces
- The contents indexing expression(s), in parentheses

In the code above, the indexing expression \{i\} accesses the i'th cell of varargin. The expression (2) represents the second element of the cell contents.

## Packing varargout Contents

When allowing any number of output arguments, you must pack all of the output into the varargout cell array. Use nargout to determine how many output arguments the function is called with. For example, this code accepts a two-column input array, where the first column represents a set of $x$ coordinates and the second represents y coordinates. It breaks the array into separate [xi yi] vectors that you can pass into the testvar function on the previous page.

```
function [varargout] = testvar2(arrayin)
for k = 1:nargout
    varargout{k} = arrayin(k,:) % Cell array assignment
end
```

The assignment statement inside the for loop uses cell array assignment syntax. The left side of the statement, the cell array, is indexed using curly braces to indicate that the data goes inside a cell. F or complete information on cell array assignment, see the "Structures and Cell Arrays" section.

Here's how to call testvar2.

$$
\begin{aligned}
& a=\{12 ; 34 ; 56 ; 78 ; 90\} ; \\
& {[p 1, p 2, p 3, p 4, p 5]=\text { testvar2(a); }}
\end{aligned}
$$

## varargin and varargout in Argument Lists

varargin or varargout must appear last in the argument list, following any required input or output variables. That is, the function call must specify the required arguments first. For example, these function declaration lines show the correct placement of varargin and varargout.

```
function [out1,out2] = example1(a,b,varargin)
function [i,j,varargout] = example2(x1,y1,x2,y2,flag)
```

## Local and Global Variables

The sameguidelines that apply to MATLAB variables at the command line also apply to variables in M-files:

- You do not need totype or declare variables. Before assigning one variable to another, however, you must be sure that the variable on the right-hand side of the assignment has a value.
- Any operation that assigns a value to a variable creates the variable if needed, or overwrites its current value if it already exists.
- MATLAB variable names consist of a letter followed by any number of letters, digits, and underscores. MATLAB distinguishes between uppercase and lowercase characters, so A and a are not the same variable.
- MATLAB uses only the first 31 characters of variable names.

Ordinarily, each MATLAB function, defined by an M-file, has its own local variables, which are separate from those of other functions, and from those of the base workspace. However, if several functions, and possibly the base workspace, all declare a particular name as global, then they all share a single copy of that variable. Any assignment to that variable, in any function, is available to all the other functions declaring it global.

Suppose you want to study the effect of the interaction coefficients, $\alpha$ and $\beta$, in the Lotka-Volterra predator-prey model.

$$
\begin{aligned}
& y_{1}=y_{1}-\alpha y_{1} y_{2} \\
& y_{2}=-y_{2}+\beta y_{1} y_{2}
\end{aligned}
$$

Create an M-file, lotka.m.

```
function yp = lotka(t,y)
%LOTKA Lotka-Volterra predator-prey model.
global ALPHA BETA
yp = [y(1) - ALPHA*y(1)*y(2); -y(2) + BETA*y(1)*y(2)];
```

Then interactively enter the statements

```
global ALPHA BETA
ALPHA = 0.01
BETA = 0.02
```

```
[t,y] = ode23('lotka',0,10,[1; 1]);
plot(t,y)
```

The two global statements make the values assigned to ALPHA and BETA at the command prompt available inside the function defined by lotka.m. They can be modified interactively and new solutions obtained without editing any files.

For your MATLAB application to work with global variables:

- Declarethe variableas global in every function that requires access to it. To enable the workspace to access the global variable, also declare it as global from the command line.
- In each function, issue the global command before the first occurrence of the variable name. The top of the M -file is recommended.

MATLAB global variable names aretypically longer and more descriptive than local variable names, and sometimes consist of all uppercase characters. These are not requirements, but guidelines to increase the readability of MATLAB code and reduce the chance of accidentally redefining a global variable.

## Persistent Variables

A variable may be defined as persistent so that it does not change valuefrom one call to another. Persistent variables may be used within a function only. Persistent variables remain in memory until the M-file is cleared or changed.
persistent is exactly like global, except that the variable name is not in the global workspace, and the value is reset if the $M$-file is changed or cleared.
Three MATLAB functions support the use of persistent variables.

| Function | Description |
| :--- | :--- |
| mlock | Prevents an M-file from being cleared |
| munlock | Unlocks an M-file that had previously been locked by mlock |
| mislocked | Indicates whether an M-file can be cleared or not |

## Special Values

Several functions return important special values that you can use in your M-files.

| Function | Return Value |
| :--- | :--- |
| ans | Most recent answer (variable). If you do not assign an output <br> variable to an expression, MATLAB automatically stores the <br> result in ans. |
| eps | Floating-point relative accuracy. This is the tolerance <br> MATLAB uses in its calculations. |
| realmax | Largest floating-point number your computer can represent. |
| realmin | Smallest floating-point number your computer can represent. |
| pi | 3.1415926535897... |
| i, j | Imaginary unit. |
| inf | Infinity. Calculations like $\mathrm{n} / 0$, where n is any nonzero real <br> value, result in inf. |
| NaN | Not-a-Number, an invalid numeric value. Expressions like $0 / 0$ <br> and inf /inf result in a NaN, as do arithmetic operations <br> involving a NaN. $n / 0$, where n is complex, also returns NaN. |
| computer | Computer type. |
| version | MATLAB version string. |

Here are several examples that use these values in MATLAB expressions.

```
x = 2*pi;
A = [3+2i 7-8i];
tol = 3*eps;
```

## Data Types

There are 14 fundamental data types (or classes) in MATLAB. Each of these data types is in the form of an array. This array is a minimum of 0 -by- 0 in size and can grow to an n-dimensional array of any size. Two-dimensional versions of these arrays are called matrices.

All of the fundamental data types are shown in lowercase text in the diagram below. An additional, user-defined data type, shown below as user class, is a subset of the structure type.

The char data type holds characters in Unicode representation. A character string is merely a 1-by-n array of characters. You can use char to hold an array of strings as long as each string in the array has the same length. (This is because MATLAB arrays must be rectangular.) To hold an array of strings of unequal length, use a cell array.
Numeric data types include signed and unsigned integers, single- and doubleprecision floating point, and sparse matrices of double-precision. The following hold true for numeric data types in MATLAB:

- All MATLAB computations are done in double-precision.
- Integer and single precision arrays offer more memory efficient storage than double-precision.
- All data types support basic array operations, such as subscripting and reshaping.
- To perform mathematical operations on integer or single precision arrays, you must convert them to double precision using the double function.

A cell array provides a storage mechanism for dissimilar kinds of data. You can store arrays of different types and/or sizes within the cells of a cell array. For example, you can store a 1-by-50 char array, a 7-by-13 double array, and a 1-by-1 uint32 in cells of the same cell array. You access data in a cell array using the same matrix indexing used on other MATLAB matrices and arrays.

The MATLAB structure data type is similar to the cell array in that it also stores dissimilar kinds of data. But, in this case, it stores the data in named fields rather than in cells. This enables you to attach a name to the groups of data stored within the structure. Y ou access data in a structure using these same field names.

MATLAB data types areimplemented as classes. You can al so create MATLAB classes of your own. These user-defined classes inherit from the MATLAB structure class and are shown in the previous diagram as a subset of structure.

MATLAB provides an interface to the J ava programming language that enables you to create objects fromJ ava classes and call J ava methods on these objects. AJ ava class is a MATLAB data type. Therearebuilt-in and third-party classes that are already available through the MATLAB interface. Y ou can also create your own J ava class definitions and bring them into MATLAB.

A function handle holds information to be used in referencing a function. When you create a function handle, MATLAB captures all the information about the function that it needs to locate and execute, or evaluate, it later on. Typically, a function handle is passed in an argument list to other functions. It is then used in conjunction with feval to evaluate the function to which the handle bel ongs.

The following table describes the data types in more detail.

| Data Type | Example | Description |
| :--- | :--- | :--- |
| single | $3^{*} 10^{\wedge} 38$ | Single-precision numeric array. Single precision <br> requires less storage than double precision, but <br> has less precision and a smaller range. This data <br> type cannot be used in mathematical operations. |

| Data Type | Example | Description |
| :---: | :---: | :---: |
| double | $\begin{aligned} & 3 * 10^{\wedge} 300 \\ & 5+6 i \end{aligned}$ | Double-precision numeric array. This is the most common MATLAB variable type. |
| sparse | speye(5) | Sparse double-precision matrix (2-D only). The sparse matrix stores matrices with only a few nonzero elements in a fraction of the space required for an equivalent full matrix. Sparse matrices invoke special methods especially tailored to solve sparse problems. |
| int8, uint8, int16, uint16, int32, uint32 | uint8(magic (3) ) | Signed and unsigned integer arrays that are 8,16 , and 32 bits in length. Enables you to manipulate integer quantities in a memory efficient manner. These data types cannot be used in mathematical operations. |
| char | 'Hello' | Character array (each character is 16 bits long). This array is also referred to as a string. |
| cell | \{17 'hello' eye(2) \} | Cell array. Elements of cell arrays contain other arrays. Cell arrays collect related data and information of a dissimilar size together. |
| structure | $\begin{aligned} & \text { a.day = 12; } \\ & \text { a.color = 'Red'; } \\ & \text { a.mat = magic (3); } \end{aligned}$ | Structure array. Structure arrays have field names. The fields contain other arrays. Like cell arrays, structures collect related data and information together. |
| user class | inline('sin(x)') | MATLAB class. This user-defined class is created using MATLAB functions. |
| java class | java.awt.Frame | J ava class. You can use classes already defined in the J ava API or by a third party, or create your own classes in the J ava language. |
| function handle | @humps | Handle to a MATLAB function. A function handle can be passed in an argument list and evaluated using feval. |

## Keywords

MATLAB reserves certain words for its own use as keywords of the language. Tolist the keywords, type

```
iskeyword
ans =
    'break'
    'case'
    'catch'
    'continue'
    'else'
    'elseif'
    'end'
    'for'
    'function'
    'global'
    'if'
    'otherwise'
    'persistent'
    'return'
    'switch'
    'try'
    'while'
```

See the online function reference pages for help tolearn how to use any of these keywords.

You should not use MATLAB keywords other than for their intended purpose. F or example, a keyword should not be used as follows:

```
while = 5;
??? while = 5;
    |
Error: Expected a variable, function, or constant, found "=".
```

## Operators

MATLAB's operators fall into three categories:

- Arithmetic operators that perform numeric computations, for example, adding two numbers or raising the elements of an array to a given power.
- Relational operators that compare operands quantitatively, using operators like "less than" and "not equal to."
- Logical operators that use the logical operators AND, OR, and NOT.

This section also discusses operator precedence.

## Arithmetic Operators

MATLAB provides these arithmetic operators

| Operator | Description |
| :---: | :---: |
| + | Addition |
| - | Subtraction |
| .* | Multiplication |
| . 1 | Right division |
| . 1 | Left division |
| + | Unary plus |
| - | Unary minus |
| : | Colon operator |
| .^ | Power |
| . ${ }^{\prime}$ | Transpose |
| ' | Complex conjugate transpose |
| * | Matrix multiplication |
| 1 | Matrix right division |

| Operator | Description |
| :--- | :--- |
| $\backslash$ | Matrix left division |
| $\wedge$ | Matrix power |

## Arithmetic 0 perators and Arrays

Except for some matrix operators, MATLAB's arithmetic operators work on corresponding elements of arrays with equal dimensions. For vectors and rectangular arrays, both operands must be the same size unless one is a scalar. If one operand is a scalar and the other is not, MATLAB applies the scalar to every element of the other operand - this property is known as scalar expansion.

This example uses scalar expansion to compute the product of a scalar operand and a matrix.

```
A = magic(3)
A =
    8 1 6
    3 5 7
    4 9 2
3 * A
ans =
    24 3 18
    9 15 21
    12 27 6
```

## Relational Operators

MATLAB provides these relational operators.

| Operator | Description |
| :--- | :--- |
| $<$ | Less than |
| $<=$ | Less than or equal to |
| $>$ | Greater than |
| $>=$ | Greater than or equal to |
| $==$ | Equal to |
| $=$ | Not equal to |

## Relational Operators and Arrays

MATLAB's relational operators compare corresponding elements of arrays with equal dimensions. Relational operators always operate el ement-by-element. In this example, the resulting matrix shows where an element of $A$ is equal to the corresponding element of $B$.

```
A = [2 7 6;9 0 5;3 0.5 6];
B = [8 7 0;3 2 5;4 -1 7];
A == B
ans =
    0 1 0
    0 0
    0 0 0
```

For vectors and rectangular arrays, both operands must be the same size unless one is a scalar. F or the case where one operand is a scalar and the other is not, MATLAB tests the scalar against every element of the other operand. Locations where the specified relation is true receive the value 1 . Locations where the relation is false receive the value 0 .

## Relational Operators and Empty Arrays

The relational operators work with arrays for which any dimension has size zero, as long as both arrays are the same size or one is a scalar. However, expressions such as
A == []
return an error if A is not 0-by-0 or 1-by-1.
To test for empty arrays, use the function
isempty (A)

## Logical Operators

This section describes the MATLAB logical operators and also covers:

- "Using Logical Operators on Arrays"
- "Logical Functions"
- "Logical Expressions Using the find Function"

MATLAB provides these logical operators.

| Operator | Description |
| :--- | :--- |
| $\&$ | AND |
| I | OR |
| $\sim$ | NOT |

Note In addition to these logical operators, the ops directory contains a number of functions that perform bitwise logical operations. See online help for more information.

Each logical operator has a specific set of rules that determines the result of a logical expression:

- An expression using the AND operator, $\&$, is true if both operands are logically true. In numeric terms, the expression is true if both operands are nonzero. This example shows the logical AND of the elements in the vector $u$ with the corresponding elements in the vector $v$.

```
u = [11 0 2 3 0 5];
v = [5 6 1 0 0 7];
u & v
ans =
    1 0
```

- An expression using the OR operator, |, is true if one operand is logi cally true, or if both operands are logically true. An OR expression is false only if both operands are false. In numeric terms, the expression is false only if both operands are zero. This example shows the logical OR of the elements in the vector $u$ and with the corresponding elements in the vector $v$.
u | v
ans $=$
$\begin{array}{llllll}1 & 1 & 1 & 1 & 0 & 1\end{array}$
- An expression using the NOT operator, ~, negates the operand. This produces a false result if the operand is true, and true if it is false. In numeric terms, any nonzero operand becomes zero, and any zero operand becomes one. This example shows the negation of the elements in the vector $u$.

```
~u
ans =
0
```

## Using Logical Operators on Arrays

MATLAB's logical operators compare corresponding elements of arrays with equal dimensions. For vectors and rectangular arrays, both operands must be the same size unless one is a scalar. For the case where one operand is a scalar and the other is not, MATLAB tests the scalar against every element of the other operand. Locations where the specified relation is true receive the value 1. L ocations where the relation is false receive the value 0 .

## Logical Functions

In addition to the logical operators, MATLAB provides a number of logical functions.

| Function | Description | Examples |
| :---: | :---: | :---: |
| xor | Performs an exclusive OR on its operands. xor returns true if one operand is true and the other false. In numeric terms, the function returns 1 if one operand is nonzero and the other operand is zero. | $\begin{aligned} & a=1 ; \\ & b=1 ; \\ & \text { xor }(a, b) \\ & \text { ans }= \\ & 0 \end{aligned}$ |
| all | Returns 1 if all of the elements in a vector are true or nonzero. all operates columnwise on matrices. | $\left.\begin{array}{l} A=\left[\begin{array}{llll} 0 & 1 & 2 ; 3 & 5 \end{array}\right] \\ A= \\ 0 \end{array}\right] \begin{array}{rrr}  \\ 3 & 5 & 0 \\ \text { all (A) } & & \\ \text { ans }= & & \\ 0 & 1 & 0 \end{array}$ |
| any | Returns 1 if any of theelements of its argument are true or nonzero; otherwise, it returns 0 . Like all, the any function operates columnwiseon matrices. | $\begin{aligned} & v=\left[\begin{array}{lll} 5 & 0 & 8 \end{array}\right] ; \\ & \text { any }(\mathrm{v}) \end{aligned} \quad \begin{aligned} & \text { ans }= \\ & \frac{1}{1} \end{aligned}$ |

A number of other MATLAB functions perform logical operations. F or example, the isnan function returns 1 for NaNs; the isinf function returns 1 for Infs. See the ops directory for a complete listing of logical functions.

## Logical Expressions Using the find Function

The find function determines the indices of array elements that meet a given logical condition. It's useful for creating masks and index matrices. In its most general form, find returns a single vector of indices. This vector can be used to index into arrays of any size or shape. For example,

| $\mathrm{A}=\operatorname{magic}(4)$ |  |  |  |
| :---: | :---: | :---: | :---: |
| $A=$ |  |  |  |
| 16 | 2 | 3 | 13 |
| 5 | 11 | 10 | 8 |
| 9 | 7 | 6 | 12 |
| 4 | 14 | 15 | 1 |
| i $=$ find ( $\mathrm{A}>8 \mathrm{8}$ ) |  |  |  |
| $\mathrm{A}(\mathrm{i})=100$ |  |  |  |
| A $=$ |  |  |  |
| 100 | 2 | 3 | 100 |
| 5 | 100 | 100 | 8 |
| 100 | 7 | 6 | 100 |
| 4 | 100 | 100 | 1 |

You can also use find to obtain both the row and column indices for a rectangular matrix, as well as the array values that meet the logical condition. Use the help facility for more information on find.

## Operator Precedence

You can build expressions that use any combination of arithmetic, relational, and logical operators. Precedence levels determine the order in which MATLAB evaluates an expression. Within each precedence level, operators have equal precedence and are evaluated from left to right. The precedence
rules for MATLAB operators are shown in this list, ordered from highest precedence level to lowest precedence level:

## 1 Parentheses ()

2 Transpose(. ' ), power(. $\wedge)$, complex conjugate transpose('), matrix power(^)
3 Unary plus (+), unary minus (-), logical negation (~)
4 Multiplication (.*), right division (./), left division(. <br>), matrix multiplication (*), matrix right division (/), matrix left division ( $)$

5 Addition (+), subtraction (-)
6 Colon operator (:)
7 Less than (<), less than or equal to (<=), greater than (>), greater than or equal to (>=), equal to (==), not equal to ( $\sim=$ )

8 Logical AND (\&)
9 Logical OR (|)

## 0 verriding Default Precedence

The default precedence can be overridden using parentheses, as shown in this example.

```
A = [3 9 5];
B = [2 1 5];
C = A./B.^2
C =
    0.7500 9.0000 0.2000
C = (A./B).^2
C =
    2.2500 81.0000 1.0000
```

Expressions can also include values that you access through subscripts.
b $=\operatorname{sqrt}(A(2))+2 * B(1)$
b =
7

## Flow Control

There are eight flow control statements in MATLAB:

- if, together with else and elseif, executes a group of statements based on some logical condition.
- switch, together with case and otherwise, executes different groups of statements depending on the value of some logical condition.
- while executes a group of statements an indefinite number of times, based on some logical condition.
- for executes a group of statements a fixed number of times.
- continue passes control to the next iteration of a for or while loop, skipping any remaining statements in the body of the loop.
- break terminates execution of a for or while loop.
- try...catch changes flow control if an error is detected during execution.
- return causes execution to return to the invoking function.

All flow constructs use end to indicate the end of the flow control block.

Note You can often speed up the execution of MATLAB code by replacing for and while loops with vectorized code. See "Optimizing MATLAB Code" on page 17-71.

## if, else, and elseif

if evaluates a logical expression and executes a group of statements based on the value of the expression. In its simplest form, its syntax is

```
if logical_expression
    statements
end
```

If the logical expression is true (1), MATLAB executes all the statements between the if and end lines. It resumes execution at theline following the end statement. If the condition is false (0), MATLAB skips all the statements between the if and end lines, and resumes execution at the line following the end statement.

For example,

```
if rem(a,2) == 0
    disp('a is even')
    b = a/2;
end
```

You can nest any number of if statements.
If the logical expression evaluates to a nonscalar value, all the elements of the argument must be nonzero. For example, assume x is a matrix. Then the statement

```
if X
```

    statements
    end
is equivalent to

```
if all(X(:))
    statements
end
```

The else and elseif statements further conditionalize the if statement:

- The else statement has nological condition. The statements associated with it execute if the preceding if (and possibly elseif condition) is false (0).
- The elseif statement has a logical condition that it evaluates if the preceding if (and possibly elseif condition) is false (0). The statements associated with it execute if its logical condition is true (1). You can have multiple elseifs within an if block.

```
if n < 0 % If n negative, display error message.
    disp('Input must be positive');
elseif rem(n,2) == 0 % If n positive and even, divide by 2.
    A = n/2;
else
    A = (n+1)/2; % If n positive and odd, increment and divide.
end
```

## if Statements and Empty Arrays

An if condition that reduces to an empty array represents a false condition. That is,
if A
S1
else
SO
end
will execute statement SO when A is an empty array.

## sw itch

switch executes certain statements based on the value of a variable or expression. Its basic form is

```
switch expression (scalar or string)
    case value1
        statements % Executes if expression is value1
    case value2
        statements % Executes if expression is value2
    .
    .
    otherwise
        statements % Executes if expression does not
                        % does not match any case
end
```

This block consists of:

- The word switch followed by an expression to evaluate.
- Any number of case groups. These groups consist of the word case followed by a possible value for the expression, all on a single line. Subsequent lines contain the statements to execute for the given value of the expression. These can be any valid MATLAB statement including another switch block. Execution of a case group ends when MATLAB encounters the next case statement or the otherwise statement. Only the first matching case is executed.
- An optional otherwise group. This consists of the word otherwise, followed by the statements to execute if the expression's value is not handled by any of the preceding case groups. Execution of the otherwise group ends at the end statement.
- An end statement.
switch works by comparing the input expression to each case value. F or numeric expressions, a case statement is true if (value==expression). For string expressions, a case statement is true if strcmp (value, expression).

The code below shows a simple example of the switch statement. It checks the variable input_num for certain values. If input_num is $-1,0$, or 1 , the case statements display the value on screen as text. If input_num is none of these values, execution drops to the otherwise statement and the code displays the text 'other value'.

```
switch input_num
    case -1
        disp('negative one');
    case 0
        disp('zero');
    case 1
        disp('positive one');
    otherwise
        disp('other value');
end
```

Note For C Programmers unlike the C language switch construct, MATLAB's switch does not "fall through." That is, if the first case statement is true, other case statements do not execute. Therefore, break statements are not used.
switch can handle multiple conditions in a single case statement by enclosing the case expression in a cell array.

```
switch var
    case 1
        disp('1')
    case {2,3,4}
        disp('2 or 3 or 4')
    case 5
        disp('5')
    otherwise
        disp('something else')
end
```

## while

The while loop executes a statement or group of statements repeatedly as long as the controlling expression is true (1). Its syntax is

```
while expression
    statements
end
```

If the expression evaluates to a matrix, all its elements must be 1 for execution to continue. To reduce a matrix to a scalar value, use the all and any functions.

For example, this while loop finds the first integer $n$ for which $n$ ! ( n factorial) is a 100 -digit number.

```
n = 1;
while prod(1:n) < 1e100
    n = n + 1;
end
```

Exit a while loop at any time using the break statement.

## while Statements and Empty Arrays

A while condition that reduces to an empty array represents a false condition. That is,

```
while A, S1, end
```

never executes statement S 1 when A is an empty array.

## for

The for loop executes a statement or group of statements a predetermined number of times. Its syntax is:

```
for index = start:increment:end
    statements
end
```

The default increment is 1. Y ou can specify any increment, including a negative one. F or positive indices, execution terminates when the value of the index exceeds the end value; for negative increments, it terminates when the index is less than the end value.

For example, this loop executes five times.

```
for i = 2:6
    x(i) = 2*x(i-1);
end
```

You can nest multiple for loops.

```
for i = 1:m
    for j = 1:n
            A(i,j) = 1/(i + j - 1);
        end
end
```

Note You can often speed up the execution of MATLAB code by replacing for and while loops with vectorized code. See "Vectorization of Loops" on page 1-91 for details.

## Using Arrays as Indices

The index of a for loop can be an array. F or example, consider an m-by-n array
A. The statement

```
for i = A
    statements
end
```

sets i equal to the vector $A(:, k)$. F or the first loop iteration, $k$ is equal to 1 ; for the second $k$ is equal to 2 , and so on until $k$ equals $n$. That is, the loop iterates for a number of times equal to the number of columns in $A$. For each iteration, $i$ is a vector containing one of the columns of $A$.

## continue

The continue statement passes control to the next iteration of the for or while loop in which it appears, skipping any remaining statements in the body of the loop. In nested loops, continue passes control to the next iteration of the for or while loop enclosing it.

The example below shows a continue loop that counts the lines of code in the file, magic.m, skipping all blank lines and comments. A continue statement is used to advance to the next line in magic.m without incrementing the count whenever a blank line or comment line is encountered.

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) | strncmp(line,'%',1)
        continue
    end
    count = count + 1;
end
disp(sprintf('%d lines',count));
```

## break

The break statement terminates the execution of a for loop or while loop. When a break statement is encountered, execution continues with the next statement outside of the loop. In nested loops, break exits from the innermost loop only.

The example bel ow shows a while loop that reads the contents of thefilefft.m into a MATLAB character array. A break statement is used to exit the while loop when the first empty line is encountered. The resulting character array contains the M -file help for the fft program.

```
fid = fopen('fft.m','r');
s = '';
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line)
        break
    end
    s = strvcat(s,line);
end
disp(s)
```

## try ... catch

The general form of a try ... catch statement sequence is

```
try,
        statement,
        ...,
        statement,
catch,
    statement,
    ...,
    statement,
end
```

In this sequence the statements between try and catch are executed until an error occurs. The statements between catch and end are then executed. Use lasterr to see the cause of the error. If an error occurs between catch and end, MATLAB terminates execution unless another try ... catch sequence has been established.

## return

return terminates the current sequence of commands and returns control to the invoking function or to the keyboard. return is also used to terminate keyboard mode. A called function normally transfers control to the function that invoked it when it reaches the end of the function. return may be inserted within the called function to force an early termination and to transfer control to the invoking function.

## Subfunctions

Function M-files can contain codefor morethan onefunction. Thefirst function in the file is the primary function, the function invoked with the $M$-file name. Additional functions within thefile are subfunctions that are only visible to the primary function or other subfunctions in the same file.

Each subfunction begins with its own function definition line. The functions immediately follow each other. The various subfunctions can occur in any order, as long as the primary function appears first.

```
function [avg,med] = newstats(u) % Primary function
% NEWSTATS Find mean and median with internal functions.
n = length(u);
avg = mean(u,n);
med = median(u,n);
function a = mean(v,n) % Subfunction
% Calculate average.
a = sum(v)/n;
function m = median(v,n) % Subfunction
% Calculate median.
w = sort(v);
if rem(n,2) == 1
    m = w((n+1)/2);
else
    m = (w(n/2)+w(n/2+1))/2;
end
```

The subfunctions mean and median calculate the average and median of the input list. The primary function newstats determines the length of the list and calls the subfunctions, passing to them the list length n. Functions within the sameM-file cannot access the same variables unless you declare them as global within the pertinent functions, or pass them as arguments. In addition, the help facility can only access the primary function in an M-file.

When you call a function from within an M-file, MATLAB first checks the file to see if the function is a subfunction. It then checks for a private function (described in the following section) with that name, and then for a standard M-file on your search path. Because it checks for a subfunction first, you can
supersede existing M-files using subfunctions with the same name, for example, mean in the above code. Function names must be unique within an M-file, however.

## Private Functions

Private functions are functions that reside in subdirectories with the special name private. They are visible only to functions in the parent directory. For example, assume the directory newmath is on the MATLAB search path. A subdirectory of newmath called private can contain functions that only the functions in newmath can call. Because private functions are invisible outside of the parent directory, they can use the same names as functions in other directories. This is useful if you want to create your own version of a particular function while retaining the original in another directory. Because MATLAB looks for private functions before standard $M$-file functions, it will find a private function named test.m before a nonprivate $M$-file named test.m.

You can create your own private directories simply by creating subdirectories called private using the standard procedures for creating directories or fol ders on your computer. Do not place these private directories on your path.

## Subscripting and Indexing

## Subscripting

This section explains how to use subscripting to access and assign to elements of a MATLAB matrix. It covers the following:

- Accessing Single Elements of a Matrix
- Accessing Multiple Elements of a Matrix
- Expanding the Size of a Matrix
- Deleting Rows and Columns
- Concatenating Matrices

## Accessing Single Elements of a Matrix

The element in row $i$ and column $j$ of $A$ is denoted by $A(i, j)$. For example, suppose $A=\operatorname{magic}(4)$, Then $A(4,2)$ is the number in the fourth row and second column. For our magic square, $A(4,2)$ is 14 .

| $\mathrm{A}=$ magic(4) |  |  |  |
| :---: | :---: | :---: | :---: |
| $A=$ |  |  |  |
| 16 | 2 | 3 | 13 |
| 5 | 11 | 10 | 8 |
| 9 | 7 | 6 | 12 |
| 4 | 14 | 15 | 1 |
| A $(4,2)$ |  |  |  |

14
It is also possible to refer to the elements of a matrix with a single subscript, $\mathrm{A}(\mathrm{k})$. This is the usual way of referencing row and column vectors. But it can also apply to a fully two-dimensional matrix, in which case the array is regarded as one long column vector formed from the columns of the original matrix.

So, for our magic square, $\mathrm{A}(8)$ is another way of referring to the value 14 stored in $A(4,2)$.

A(8)
ans $=$
14

## Accessing Multiple Elements of a Matrix

It is possible to compute the sum of the elements in the fourth column of A by typing

```
A(1,4) + A(2,4) + A(3,4) + A(4,4)
```

You can reduce the size of this expression using the col on operator. Subscript expressions involving colons refer to portions of a matrix.

$$
A(1: m, n)
$$

refers to the elements in rows 1 through $m$ of column $n$ of the A matrix. Using this notation, you can compute the sum of the fourth column of A more succinctly.

```
sum(A(1:4,4))
```

The colon by itself refers to all theelements in a row or column of a matrix. The keyword end refers to the last row or column. Using the following syntax, you can compute this same column sum without having to specify row and column numbers.

```
sum(A(:,end))
ans =
    34
```

By adding an additional colon operator, you can refer to nonconsecutive elements in a matrix. The m:3:n in this expression means to make the assignment to every third element in the matrix.

```
B = A;
\(B(1: 3:\) end \()=-10\)
B =
\begin{tabular}{rrrr}
-10 & 2 & 3 & -10 \\
5 & 11 & -10 & 8 \\
9 & -10 & 6 & 12 \\
-10 & 14 & 15 & -10
\end{tabular}
```

You can repeatedly access an array el ement using the ones function. To create a new 2-by-6 matrix out of the the 9th element of A,
$B=A(9 *$ ones $(2,6))$
B =

| 3 | 3 | 3 | 3 | 3 | 3 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 3 | 3 | 3 | 3 | 3 | 3 |

## Expanding the Size of a Matrix

If you try to access an element outside of the matrix, it is an error
$B=A(4,5)$
Index exceeds matrix dimensions
However, if you store a value in an element outside of the matrix, the size of the matrix increases to accommodate the new element.

```
\(B=A ;\)
\(B(4,5)=17\)
B =
\begin{tabular}{rrrrr}
16 & 2 & 3 & 13 & 0 \\
5 & 11 & 10 & 8 & 0 \\
9 & 7 & 6 & 12 & 0 \\
4 & 14 & 15 & 1 & 17
\end{tabular}
```

Similarly, you can expand a matrix by assigning to a series of matrix elements.

```
B(2:5,5:6) = 5
B =
```

| 16 | 2 | 3 | 13 | 0 | 0 |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 5 | 11 | 10 | 8 | 5 | 5 |
| 9 | 7 | 6 | 12 | 5 | 5 |
| 4 | 14 | 15 | 1 | 5 | 5 |
| 0 | 0 | 0 | 0 | 5 | 5 |

## Deleting Rows and Columns

You can delete rows and columns from a matrix using just a pair of square brackets. Start with
X = A;

Then, to delete the second column of $x$, use

$$
X(:, 2)=[]
$$

This changes $x$ to

$$
\begin{array}{lrr}
X= & & \\
16 & 3 & 13 \\
5 & 10 & 8 \\
9 & 6 & 12 \\
4 & 15 & 1
\end{array}
$$

If you delete a single element from a matrix, the result isn't a matrix anymore. So expressions like

$$
X(1,2)=[]
$$

result in an error. However, using a single subscript deletes a single element, or sequence of elements, and reshapes the remaining elements into a row vector. So

$$
x(2: 2: 10)=[]
$$

results in
X =
$\begin{array}{lllllll}16 & 9 & 3 & 6 & 13 & 12 & 1\end{array}$

## Concatenating Matrices

Concatenation is the process of joining small matrices together to make bigger ones. In fact, you made your first matrix by concatenating its individual elements. The pair of square brackets, [ ], is the concatenation operator. For an example, start with the 4-by-4 magic square, $A$, and form

$$
B=[A \quad A+32 ; A+48 \quad A+16]
$$

The result is an 8-by-8 matrix, obtained by joining the four submatrices.
B =

| 16 | 2 | 3 | 13 | 48 | 34 | 35 | 45 |
| ---: | ---: | ---: | ---: | :--- | :--- | :--- | :--- |
| 5 | 11 | 10 | 8 | 37 | 43 | 42 | 40 |
| 9 | 7 | 6 | 12 | 41 | 39 | 38 | 44 |
| 4 | 14 | 15 | 1 | 36 | 46 | 47 | 33 |
| 64 | 50 | 51 | 61 | 32 | 18 | 19 | 29 |
| 53 | 59 | 58 | 56 | 21 | 27 | 26 | 24 |
| 57 | 55 | 54 | 60 | 25 | 23 | 22 | 28 |
| 52 | 62 | 63 | 49 | 20 | 30 | 31 | 17 |

This matrix is half way to being another magic square. Its elements are a rearrangement of the integers 1:64. Its column sums are the correct value for an 8 -by-8 magic square.
sum (B)
ans =
$\begin{array}{lllllllll}260 & 260 & 260 & 260 & 260 & 260 & 260 & 260\end{array}$
But, its row sums, sum ( $B^{\prime}$ ) ', are not all the same. Further manipulation is necessary to make this a valid 8 -by- 8 magic square.

## Advanced Indexing

MATLAB stores each array as a column of values regardless of the actual dimensions. This column consists of the array columns, appended end to end.

For example, MATLAB stores

```
A = [2 6 9; 4 2 8; 3 0 1]
```

as
2
4
3
6
2
0
9
8
1
Accessing A with a single subscript indexes directly into the storage column. A(3) accesses the third value in the column, the number 3. A(7) accesses the seventh value, 9 , and so on.

If you supply more subscripts, MATLAB calculates an index into the storage column based on the dimensions you assigned to the array. F or example, assume a two-dimensional array like A has size [d1 d2], where d1 is the number of rows in thearray and $d 2$ is the number of columns. If you supply two subscripts ( $i, j$ ) representing row-column indices, the offset is

$$
(j-1) * d 1+i
$$

Given the expression $A(3,2)$, MATLAB calculates the offset into A's storage column as $(2-1) * 3+3$, or 6 . Counting down six elements in the column accesses the value 0 .

## Indexing Into Multidimensional Arrays

This storage and indexing scheme also extends to multidimensional arrays. In this case, MATLAB operates on a page-by-page basis to create the storage column, again appending elements columnwise.

For example, consider a 5-by-4-by-3-by-2 array c.

Again, a single subscript indexes directly into this column. For example, C (4) produces the result
ans =

0
If you specify two subscripts ( $i, j$ ) indicating row-column indices, MATLAB calculates the offset as described above. Two subscripts always access the first page of a multidimensional array, provided they are within the range of the original array dimensions.

If more than one subscript is present, all subscripts must conform to the original array dimensions. For example, $C(6,2)$ is invalid, because all pages of c have only five rows.

If you specify more than two subscripts, MATLAB extends its indexing scheme accordingly. F or example, consider four subscripts (i,j,k,l) into a four-dimensional array with size [d1 d2 d3 d4]. MATLAB calculates the offset into the storage column by

```
(l-1) (d3) (d2) (d1) +(k-1) (d2) (d1) + (j-1) (d1) +i
```

For example, if you index the array $C$ using subscripts ( $3,4,2,1$ ), MATLAB returns the value 5 (index 38 in the storage column).

In general, the offset formula for an array with dimensions [ $\begin{array}{llll}d_{1} & d_{2} & d_{3} & \ldots\end{array} d_{n}$ ] using any subscripts ( $s_{1} s_{2} s_{3} \ldots s_{n}$ ) is

$$
\left(s_{n}-1\right)\left(d_{n-1}\right)\left(d_{n-2}\right) \ldots\left(d_{1}\right)+\left(s_{n-1}-1\right)\left(d_{n-2}\right) \ldots\left(d_{1}\right)+\ldots+\left(s_{2}-1\right)\left(d_{1}\right)+s_{1}
$$

Because of this scheme, you can index an array using any number of subscripts. You can append any number of 1 s to the subscript list because these terms become zero. For example,

$$
C(3,2,1,1,1,1,1,1)
$$

is equivalent to

$$
C(3,2)
$$

## String Evaluation

String evaluation adds power and flexibility to the MATLAB language, letting you perform operations like executing user-supplied strings and constructing executable strings through concatenation of strings stored in variables.

## eval

The eval function evaluates a string that contains a MATLAB expression, statement, or function call. In its simplest form, the eval syntax is

```
eval('string')
```

For example, this code uses eval on an expression to generate a Hilbert matrix of order $n$.

```
t = '1/(i+j-1)';
for i = 1:n
    for j = 1:n
        a(i,j) = eval(t);
    end
end
```

Here's an example that uses eval on a statement.

```
eval('t = clock');
```

## Constructing Strings for Evaluation

Y ou can concatenate strings to create a complete expression for input to eval. This code shows how eval can create 10 variables named P1, P2, ...P10, and set each of them to a different value.

```
for i=1:10
    eval(['P',int2str(i),'= i.^2'])
end
```

## feval

The feval function differs from eval in that it executes a function rather than a MATLAB expression. The function to be executed is specified in the first argument by either a function handle or a string containing the function name.

You can use feval and the input function to choose one of several tasks defined by M-files. This example uses function handles for the sin, cos, and log functions.

```
fun = [@sin; @cos; @log];
k = input('Choose function number: ');
x = input('Enter value: ');
feval(fun(k),x)
```

Note Use feval rather than eval whenever possible. M-files that use feval execute faster and can be compiled with the MATLAB Compiler.

## Command/ Function Duality

MATLAB commands are statements like load help

Many commands accept modifiers that specify operands.
load August17.dat
help magic
type rank
An alternate method of supplying the command modifiers makes them string arguments of functions.

```
load('August17.dat')
help('magic')
type('rank')
```

This is MATLAB's command/ function duality. Any command of the form
command argument
can also be written in the functional form

```
command('argument')
```

The advantage of the functional approach comes when the string argument is constructed from other pieces. The following example processes multiple data files, August1.dat, August2.dat, and so on. It uses the function int2str, which converts an integer to a character string, to help build the filename.

```
for d = 1:31
    s = ['August' int2str(d) '.dat']
    load(s)
% Process the contents of the d-th file
end
```

## Empty Matrices

A matrix having at least one dimension equal to zero is called an empty matrix. The simplest empty matrix is $0-b y-0$ in size. Examples of more complex matrices are those of dimension 0-by-5 or 10-by-0-by-20.

To create a 0-by-0 matrix, use the square bracket operators with no value specified.
$A=[] ;$
whos A
Name Size Bytes Class
A 0x0 0 double array
You can create empty arrays of other sizes using the zeros, ones, rand, or eye functions. To create a 0-by-5 matrix, for example, use

```
E = zeros(0,5)
```

## Operating on an Empty Matrix

The basic model for empty matrices is that any operation that is defined for m -by-n matrices, and that produces a result whose dimension is some function of $m$ and $n$, should still be allowed when $m$ or $n$ is zero. The size of the result should be that same function, evaluated at zero.

For example, horizontal concatenation

$$
C=\left[\begin{array}{ll}
A & B
\end{array}\right]
$$

requires that $A$ and $B$ have the same number of rows. So if $A$ is $m-b y-n$ and $B$ is $m-b y-p$, then C is m -by- $(\mathrm{n}+\mathrm{p})$. This is still true if m or n or p is zero.

Many operations in MATLAB produce row vectors or column vectors. It is possible for the result to be the empty row vector

```
r=zeros(1,0)
```

or the empty column vector

$$
C=\operatorname{zeros}(0,1)
$$

As with all matrices in MATLAB, you must follow the rules concerning compatible dimensions. In the following example, an attempt to add a 1-by-3 matrix to a 0-by-3 empty matrix results in an error.

```
[1 2 3] + ones(0,3)
??? Error using ==> +
Matrix dimensions must agree.
```

Some MATLAB functions, like sum and max, are reductions. For matrix arguments, these functions produce vector results; for vector arguments they produce scalar results. Empty inputs produce the following results with these functions:

- $\operatorname{sum}([])$ is 0
- $\operatorname{prod}([\mathrm{]})$ is 1
- max([ ]) is [ ]
- min([ ]) is [ ]

## Using Empty Matrices with If or While

When the expression part of an if or while statement reduces to an empty matrix, MATLAB evaluates the expression as being false. The following example executes statement so, because A is an empty array.

```
A = ones(25,0,4);
if A
    S1
else
    So
end
```

## Errors and Warnings

In many cases, it's desirable to take specific actions when different kinds of errors occur. For example, you may want to prompt the user for more input, display extended error or warning information, or repeat a calculation using default values. MATLAB's error handling capabilities let your application check for particular error conditions and execute appropriate code depending on the situation.

## Error Handling with eval and lasterr

The basic tools for error-handling in MATLAB are:

- The eval function, which lets you execute a function and specify a second function to execute if an error occurs in the first.
- The lasterr function, which returns a string containing the last error generated by MATLAB.

The eval function provides error-handling capabilities using the twoargument form

```
eval ('trystring','catchstring')
```

If the operation specified by trystring executes properly, eval simply returns. If trystring generates an error, the function evaluates catchstring. Use catchstring to specify a function that determines the error generated by trystring and takes appropriate action.
The trystring/catchstring form of eval is especially useful in conjunction with the lasterr function. lasterr returns a string containing the last error message generated by MATLAB. Use lasterr inside the catchstring function to "catch" the error generated by trystring.

For example, this function uses lasterr to check for a specific error message that can occur during matrix multiplication. The error message indicates that matrix multiplication is impossible because the operands have different inner dimensions. If the message occurs, the code truncates one of the matrices to perform the multiplication.

```
function C = catchfcn(A,B)
l = lasterr;
j = findstr(l,'Inner matrix dimensions')
```

```
if (~isempty(j))
    [m,n] = size(A)
    [p,q] = size(B)
    if (n>p)
        A(:,p+1:n) = []
    elseif (n<p)
        B(n+1:p,:) = []
    end
    C = A*B;
else
    C = 0;
end
```

This example uses the two-argument form of eval with the catchfon function shown above.

```
clear
A = [11 2 3; 6 7 2; 0 1 5];
B = [9 5 6; 0 4 9];
eval('A*B','catchfcn(A,B)')
A = 1:7;
B = randn(9,9);
eval('A*B','catchfcn(A,B)')
```

## Displaying Error and Warning Messages

Use the error and fprintf functions to display error information on the screen. The error function has the syntax

```
error('error string')
```

If you call the error function from inside an $M$-file, error displays the text in the quoted string and causes the $M$-file to stop executing. For example, suppose the following appears inside the M-file myfile.m.

```
if n < 1
    error('n must be 1 or greater.')
end
```

For $n$ equal to 0 , the following text appears on the screen and the $M$-file stops.
??? Error using ==> myfile n must be 1 or greater.

In MATLAB, warnings are similar to error messages, except program execution does not stop. Use the warning function to display warning messages.
warning('warning string')
The function lastwarn displays the last warning message issued by MATLAB.

## Dates and Times

MATLAB provides functions for time and date handling. These functions are in a directory called timefun in the MATLAB Toolbox.

| Category | Function | Description |
| :--- | :--- | :--- |
| Current date and time | clock | Current date and time as date vector |
|  | date | Current date as date string |
| Conversion | now | Current date and time as serial date number |
|  | datenum | Convert to serial date number |
|  | datestr | Convert to string representation of date |
|  | datevec | Date components |
|  | calendar | Calendar |
| datetick | Date formatted tick labels |  |
| eomday | End of month |  |
| Timing | weekday | Day of the week |
|  | cputime | CPU time in seconds |
|  | etime | Elapsed time |
|  | tic, toc | Stopwatch timer |

## Date Formats

This section covers the following topics:

- "Types of Date Formats"
- "Conversions Between Date F ormats"
- "Date String F ormats"
- "Output Formats"

## Types of Date Formats

MATLAB works with three different date formats: date strings, serial date numbers, and date vectors.

When dealing with dates you typically work with date strings (16-Sep-1996). MATLAB works internally with serial date numbers (729284). A serial date represents a calendar date as the number of days that has passed since a fixed base date. In MATLAB, serial date number 1 is J anuary 1,0000. MATLAB also uses serial time to represent fractions of days beginning at midnight; for example, 6 p.m. equals 0.75 serial days. Sothestring ' 16 -Sep-1996, 6:00 pm' in MATLAB is date number 729284.75.

All functions that require dates accept either date strings or serial date numbers. If you are dealing with a few dates at the MATLAB command-line level, date strings are more convenient. If you are using functions that handle large numbers of dates or doing extensive calculations with dates, you will get better performance if you use date numbers.
Date vectors are an internal format for some MATLAB functions; you do not typically use them in calculations. A date vector contains the elements [year month day hour minute second].

MATLAB provides functions that convert date strings to serial date numbers, and vice versa. Dates can also be converted to date vectors.

Here are examples of the three date formats used by MATLAB.

| Date Format | Example |
| :--- | :--- |
| Date string | 02 -Oct-1996 |
| Serial date number | 729300 |
| Date vector | 1996102000 |

## Conversions Between Date Formats

Functions that convert between date formats are shown below.

| Function | Description |
| :--- | :--- |
| datenum | Convert date string to serial date number |
| datestr | Convert serial date number to date string |
| datevec | Split date number or date string into individual <br> date elements |

Here are some examples of conversions from one date format to another.
d1 = datenum('02-Oct-1996')
d1 =
729300
d2 $=$ datestr ( $\mathrm{d} 1+10$ )
d2 $=$
12-0ct-1996
dv1 = datevec(d1)
$\mathrm{dv} 1=$
$\begin{array}{llllll}1996 & 10 & 2 & 0 & 0 & 0\end{array}$
dv2 = datevec(d2)
dv2 =
$\begin{array}{llllll}1996 & 12 & 2 & 0 & 0 & 0\end{array}$

## Date String Formats

The datenum function is important for doing date calculations efficiently. datenum takes an input string in any of several formats, with 'dd-mmm-yyyy', 'mm/dd/yyyy', or 'dd-mmm-yyyy, hh:mm:ss.ss' most common. You can form up to six fields from letters and digits separated by any other characters:

- The day field is an integer from 1 to 31.
- The month field is either an integer from 1 to 12 or an al phabetic string with at least three characters.
- The year field is a non-negative integer: if only two digits are specified, then a year 19yy is assumed; if the year is omitted, then the current year is used as a default.
- The hours, minutes, and seconds fields are optional. They are integers separated by colons or followed by 'AM ' or 'PM '.

For example, if the current year is 1996, then these are all equivalent
'17-May-1996'
'17-May-96'
'17-May '
'May 17, 1996'
'5/17/96'
'5/17'
and both of these represent the same time
'17-May-1996, 18:30'
'5/17/96/6:30 pm'
Note that the default format for numbers-only input follows the American convention. Thus $3 / 6$ is March 6, not J une 3.

If you create a vector of input date strings, use a column vector and be sure all strings are the same length. Fill in with spaces or zeros.

## 0 utput Formats

The function datestr ( $D$, dateform) converts a serial date $D$ to one of 19 different date string output formats showing date, time, or both. The default output for dates is a day-month-year string: 01-Mar-1996. You select an alternative output format by using the optional integer argument dateform.

This table shows the date string formats that corespond to each dateform value.

| dateform | Format | Description |
| :--- | :--- | :--- |
| 0 | 01 -Mar-1996 15:45:17 | day-month-year hour:minute:second |
| 1 | 01 -Mar-1996 | day-month-year |
| 2 | 03/01/96 | month/day/year |
| 3 | Mar | month, three letters |
| 4 | M | month, single letter |
| 5 | 3 | month |
| 6 | $03 / 01$ | month/day |
| 7 | 1 | day of month |
| 8 | Wed | day of week, three letters |
| 9 | W | day of week, single letter |
| 10 | 1996 | year, four digits |
| 11 | 96 | year, two digits |
| 12 | Mar96 | month year |
| 13 | $15: 45: 17$ | hour:minute:second |
| 14 | $03: 45: 17$ PM | hour:minute:second AM or PM |
| 15 | $15: 45$ | hour:minute |
| 16 | $03: 45$ PM | hour:minute AM or PM |
| 17 | Q1-96 | calendar quarter-year |
| 18 | Q1 |  |
|  |  | calendar quarter |

Here are some examples of converting the date March 1, 1996 to various forms using the datestr function.

```
d = '01-Mar-1999'
d =
01-Mar-1999
datestr(d)
ans =
        01-Mar-1999
datestr(d, 2)
ans =
        03/01/99
datestr(d, 17)
ans =
    Q1-99
```

## Current Date and Time

The function date returns a string for today's date.
date
ans $=$
02-Oct-1996

```
The function now returns the serial date number for the current date and time.
now
ans =
    729300.71
datestr(now)
ans =
    02-Oct-1996 16:56:16
datestr(floor(now))
ans =
02-Oct-1996
```

## Obtaining User Input

There are three ways to obtain input from a user during M-file execution. Y ou can:

- Display a prompt and obtain keyboard input.
- Pause until the user presses a key.
- Build a complete graphical user interface.

This section covers the first two topics. The third topic is discussed in online documentation under "Creating Graphical User Interfaces".

## Prompting for Keyboard Input

The input function displays a prompt and waits for a user response. Its syntax is

```
n = input('prompt_string')
```

The function displays the prompt_string, waits for keyboard input, and then returns the value from the keyboard. If the user inputs an expression, the function evaluates it and returns its value. This function is useful for implementing menu-driven applications.
input can also return user input as a string, rather than a numeric value. To obtain string input, append ' $s$ ' to the function's argument list.

```
name = input('Enter address: ','s');
```

## Pausing During Execution

Some M-files benefit from pauses between execution steps. For example, the petals.m script, shown in the "Simple Script Example" section, pauses between the plots it creates, allowing the user to display a plot for as long as desired and then press a key to move to the next plot.

The pause command, with no arguments, stops execution until the user presses a key. To pause for $n$ seconds, use

```
pause(n)
```

## Shell Escape Functions

It is sometimes useful to access your own C or Fortran programs using shell escape functions. Shell escape functions use the shell escape command! to make external stand-al one programs act like new MATLAB functions. A shell escape $M$-function is an $M$-file that:

1 Saves the appropriate variables on disk.
2 Runs an external program (which reads the data file, processes the data, and writes the results back out to disk).

3 L oads the processed file back into the workspace.
For example, look at the code for garfield.m, below. This function uses an external function, gareqn, to find the solution to Garfield's equation.

```
function y = garfield(a,b,q,r)
save gardata a b q r
!gareqn
load gardata
```

This M-file:
1 Saves the input arguments $a, b, q$, and $r$ to a MAT-file in the workspace using the save command.

2 Uses the shell escape operator to access a C, or F ortran program called gareqn that uses the workspace variables to perform its computation. gareqn writes its results to the gardata MAT-file.

3 Loads the gardata MAT-file to obtain the results.

## Optimizing MATLAB Code

This section describes techniques that often improve the execution speed and memory management of MATLAB code:

- Vectorizing loops
- Preallocating Arrays

MATLAB is a matrix language, which means it is designed for vector and matrix operations. F or best performance, you should take advantage of this where possible.

For information on how to conserve memory and improve memory use, see the section, "Making Efficient Use of Memory" on page 17-74.

See "I mproving M-F ile Performance - the Profiler" for information on using the MATLAB Profiler to identify which parts of your code consume the most time.

## Vectorizing Loops

You can speed up your M-file code by vectorizing al gorithms. Vectorization means converting for and while loops to equivalent vector or matrix operations.

## A Simple Example

Here is one way to compute the sine of 1001 values ranging from 0 to 10.

```
i = 0;
for t = 0:.01:10
    i = i+1;
    y(i) = sin(t);
end
```

A vectorized version of the same code is:

```
t = 0:.01:10;
y = sin(t);
```

The second example executes much faster than the first and is the way MATLAB is meant to be used. Test this on your system by creating M-file scripts that contain the code shown, then using the tic and toc commands to time the M-files.

## An Advanced Example

repmat is an example of a function that takes advantage of vectorization. It accepts three input arguments: an array $A$, a row dimension $M$, and a column dimension N .
repmat creates an output array that contains the elements of array A, replicated and "tiled" in an M-by-N arrangement.

```
A = [1 2 3; 4 5 6];
B = repmat (A,2,3);
B =
```

| 1 | 2 | 3 | 1 | 2 | 3 | 1 | 2 | 3 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 4 | 5 | 6 | 4 | 5 | 6 | 4 | 5 | 6 |
| 1 | 2 | 3 | 1 | 2 | 3 | 1 | 2 | 3 |
| 4 | 5 | 6 | 4 | 5 | 6 | 4 | 5 | 6 |

repmat uses vectorization to create the indices that place elements in the output array.

```
function B = repmat(A,M,N)
if nargin < 2
    error('Requires at least 2 inputs.')
elseif nargin == 2
    N = M;
end
```

\% Step 1 Get row and column sizes
[m,n] = size(A);
\% Step 2 Generate vectors of indices from 1 to row/column size mind = (1:m)';
nind $=(1: n)$ ';
\% Step 3 Creates index matrices from vectors above
mind $=\operatorname{mind}(:$, ones (1, M) ) ;
nind $=$ nind(:,ones(1,N));
\% Step 4 Create output array
B = A(mind, nind);

Step 1, above, obtains the row and column sizes of the input array.
Step 2 creates two column vectors. mind contains the integers from 1 through the row size of A. The nind variable contains the integers from 1 through the column size of $A$.

Step 3 uses a MATLAB vectorization trick to replicate a single column of data through any number of columns. The code is

```
B = A(:,ones(1,n_cols))
```

where n_cols is the desired number of columns in the resulting matrix.
Step 4 uses array indexing to create the output array. Each element of the row index array, mind, is paired with each element of the column index array, nind, using the following procedure:

1 The first element of mind, the row index, is paired with each element of nind. MATLAB moves through the nind matrix in a columnwise fashion, so mind $(1,1)$ goes with nind $(1,1)$, then nind $(2,1)$, and so on. The result fills the first row of the output array.

2 Moving columnwise through mind, each element is paired with the elements of nind as above. Each complete pass through the nind matrix fills one row of the output array.

## Preallocating Arrays

You can often improve code execution time by preallocating the arrays that store output results. Preallocation prevents MATLAB from having to resize an array each time you enlarge it. Use the appropriate preallocation function for the kind of array you are working with.

| Array Type | Function | Examples |
| :--- | :--- | :--- |
| Numeric <br> array | zeros | $\mathrm{y}=\operatorname{zeros}(1,100) ;$ |
| Cell array | cell | $\mathrm{B}=\operatorname{cell}(2,3) ;$ |
|  |  | $\mathrm{B}\{1,3\}=1: 3 ;$ |
|  | $\mathrm{B}\{2,2\}=$ ' string ' $;$ |  |

| Array Type | Function | Examples |
| :--- | :--- | :--- |
| Structure <br> array | struct,, <br> repmat | data $=\operatorname{repmat}\left(\operatorname{struct}\left({ }^{\prime} x ',\left[\begin{array}{ll}13\end{array}\right], \ldots\right.\right.$ |

Preallocation also helps reduce memory fragmentation if you work with large matrices. In the course of a MATLAB session, memory can become fragmented due to dynamic memory allocation and deallocation. This can result in plenty of free memory, but not enough contiguous space to hold a large variable. Preallocation helps prevent this by allowing MATLAB to "grab" sufficient space for large data constructs at the beginning of a computation.

## Making Efficient Use of Memory

This section discusses the following ways to conserve memory and improve memory use:

- "Memory Management Functions"
- "Removing a F unction From Memory"
- "Nested Function Calls"
- "Variables and Memory"
- "PC-Specific Topics"
- "UNIX-Specific Topics"
- "What Does "Out of Memory" Mean?"

## Memory Management Functions

MATLAB has five functions to improve how memory is handled:

- clear removes variables from memory.
- pack saves existing variables to disk, then rel oads them contiguously. Because of time considerations, you should not use pack within loops or M -file functions.
- quit exits MATLAB and returns all allocated memory to the system.
- save selectively stores variables to disk.
- load reloads a data file saved with the save command.

> Note save and load are faster than MATLAB low-level fileI/O routines. save and load have been optimized to run faster and reduce memory fragmentation.

On some systems, the whos function displays the amount of free memory remaining. However, be aware that:

- If you delete a variable from the workspace, the amount of free memory indicated by whos usually does not get larger unless the deleted variable occupied the highest memory addresses. The number actually indicates the amount of contiguous, unused memory. Clearing the highest variable makes the number larger, but clearing a variable beneath the highest variable has no effect. This means that you might have more free memory than is indicated by whos.
- Computers with virtual memory do not display the amount of free memory remaining because neither MATLAB nor the hardware imposes limitations.

## Removing a Function From Memory

MATLAB creates a list of $M$ - and MEX-filenames at startup for all files that reside below the matlab/toolbox directories. This list is stored in memory and is freed only when a new list is created during a call to the path function. Function M-file code and MEX-file relocatable code are loaded into memory when the corresponding function is called. The M-file code or relocatable code is removed from memory when:

- The function is called again and a new version now exists.
- The function is explicitly cleared with the clear command.
- All functions are explicitly cleared with the clear functions command.
- MATLAB runs out of memory.

## N ested Function Calls

The amount of memory used by nested functions is the same as the amount used by calling them on consecutive lines. These two examples require the same amount of memory.

```
result = function2(function1(input99));
result = function1(input99);
result = function2(result);
```

## Variables and Memory

Memory is allocated for variables whenever the left-hand side variable in an assignment does not exist. The statement

$$
x=10
$$

allocates memory, but the statement
$x(10)=1$
does not allocate memory if the 10th element of $x$ exists.
To conserve memory:

- Avoid creating large temporary variables, and clear temporary variables when they are no longer needed.
- When working with arrays of fixed size, pre-allocate them rather than having MATLAB resize the array each time you enlarge it.
- Set variables equal to the empty matrix [ ] to free memory, or clear them using

```
clear variable_name
```

- Reuse variables as much as possible.

Global Variables. Declaring variables as global merely puts a flag in a symbol table. It does not use any more memory than defining nonglobal variables. Consider the following example.
global a
a $=5$;
Now there is one copy of a stored in the MATLAB workspace. Typing
clear a
removes a from the MATLAB workspace, but it still exists in the global workspace.

```
clear global a
```

removes a from the global workspace.

## PC-Specific Topics

- There are no functions implemented to manipulate the way MATLAB handles Microsoft Windows system resources. Windows uses system resources to track fonts, windows, and screen objects. Resources can be depleted by using multiple figure windows, multiple fonts, or several Uicontrols. The best way to free up system resources is to close all inactive windows. I conified windows still use resources.
- The performance of a permanent swap file is typically better than a temporary swap file.
- Typically a swap file twice the size of the installed RAM is sufficient.

## UN IX-Specific Topics

- Memory that MATLAB requests from the operating system is not returned to the operating system until the MATLAB process in finished.
- MATLAB requests memory from the operating system when there is not enough memory available in the MATLAB heap to store the current variables. It reuses memory in the heap as long as the size of the memory segment required is available in the MATLAB heap.
F or example, on one machine these statements use approximately 15.4 MB of RAM.

```
a = rand(1e6,1);
b = rand(1e6,1);
```

These statements use approximately 16.4 MB of RAM.

```
c = rand(2.1e6,1);
```

These statements use approximately 32.4 MB of RAM.
$a=\operatorname{rand}(1 e 6,1) ;$
b = rand (1e6,1);
clear

$$
c=\operatorname{rand}(2.1 \mathrm{e} 6,1) ;
$$

This is because MATLAB is not able to fit a 2.1 MB array in the space previously occupied by two 1 MB arrays. The simplest way to prevent overallocation of memory, is to preallocate the largest vector. This series of statements uses approximately 32.4 MB of RAM

```
a = rand(1e6,1);
b = rand(1e6,1);
clear
c = rand(2.1e6,1);
```

while these statements use only about 16.4 MB of RAM

```
c = rand(2.1e6,1);
clear
a = rand(1e6,1);
b = rand(1e6,1);
```

Allocating the largest vectors first allows for optimal use of the available memory.

## What Does "O ut of Memory" Mean?

Typically the Out of Memory message appears because MATLAB asked the operating system for a segment of memory larger than what is currently available. Use any of the techniques discussed in this section to help optimize the available memory. If the Out of Memory message still appears:

- Increase the size of the swap file.
- Make sure that there are no external constraints on the memory accessible to MATLAB (on UNIX systems use the limit command to check).
- Add more memory to the system.
- Reduce the size of your data.

## Character Arrays (Strings)

Character Arrays ..... 18-5
Creating Character Arrays ..... 18-5
Creating Two-Dimensional Character Arrays ..... 18-6
Converting Characters to Numeric Values ..... 18-7
Cell Arrays of Strings ..... 18-8
Converting to a Cell Array of Strings ..... 18-8
String Comparisons ..... 18-10
Comparing Strings For Equality ..... 18-10
Comparing for Equality Using Operators ..... 18-11
Categorizing Characters Within a String ..... 18-12
Searching and Replacing ..... 18-13
String/Numeric Conversion ..... 18-15
Array/String Conversion ..... 18-16

This chapter explains MATLAB's support for string data. It describes the two ways that MATLAB represents strings:

- "Character Arrays"
- "Cell Arrays of Strings"

It also describes the operations that you can perform on string data under the following topics:

- "String Comparisons"
- "Searching and Replacing"
- "String/Numeric Conversion"

This table shows the string functions, which arelocated in the directory named strfun in the MATLAB Toolbox.

| Category | Function | Description |
| :--- | :--- | :--- |
| General | blanks | String of blanks |
|  | cellstr | Create cell array of strings from character array |
|  | char | Create character array (string) |
|  | deblank | Remove trailing blanks |
| String Tests | eval | Execute string with MATLAB expression |
|  | iscellstr | True for cell array of strings |
|  | ischar | True for character array |
|  | isletter | True for letters of alphabet. |
|  | isspace | True for whitespace characters. |

| Category | Function | Description |
| :--- | :--- | :--- |
| Operations | findstr | Find one string within another |
|  | lower | Convert string to lowercase |
|  | strcat | Concatenate strings |
|  | strcmp | Compare strings |
|  | strcmpi | Compare strings, ignoring case |
|  | strjust | Justify string |
|  | strmatch | Find matches for string |
|  | strncmpi | Compare first N characters of strings |
|  | strrep | Replace string with another |
| String to Number | strvcat | Cind token in string |
| Conversion | upper | Concatenate strings vertically |
|  | int2str | Convert string to uppercase |
|  | mat2str | Convert matrix to eval'able string |
| num2str | Convert number to string |  |
|  | sprintf | Write formatted data to string |
| str2double | Convert string to double-precision value |  |
|  | str2num | Convert string to number |
|  | sscanf | Read string under format control |

| Category | Function | Description |
| :--- | :--- | :--- |
| Base Number <br> Conversion | base2dec | Convert base B string to decimal integer |
|  | bin2dec | Convert binary string to decimal integer |
|  | dec2base | Convert decimal integer to base B string |
|  | dec2bin | Convert decimal integer to binary string |
|  | dec2hex | Convert decimal integer to hexadecimal string |
|  | hex2dec | Convert hexadecimal string to decimal integer |
|  | hex2num | Convert IEEE hexadecimal to double-precision <br> number |

## Character Arrays

In MATLAB, the term string refers to an array of characters. MATLAB represents each character internally as its corresponding numeric value. Unless you want to access these values, however, you can simply work with the characters as they display on screen.

This section covers:

- "Creating Character Arrays"
- "Creating Two-Dimensional Character Arrays"
- "Converting Characters to Numeric Values"

## Creating Character Arrays

Specify character data by placing characters inside a pair of single quotes. For example, this line creates a 1-by-13 character array called name.
name $=$ 'Thomas R. Lee';
In the workspace, the output of whos shows

| Name | Size | Bytes | Class |
| :--- | :--- | ---: | :--- |
| name | $1 \times 13$ | 26 | char array |

You can see that a character uses two bytes of storage internally.
The class and ischar functions show name's identity as a character array.

```
class(name)
```

ans =
char
ischar(name)
ans $=$

1

You can also join two or more character arrays together to create a new character array. Use either the string concatenation function, strcat, or the MATLAB concatenation operator, [ ], to do this. The latter preserves any trailing spaces found in the input arrays.

```
name = 'Thomas R. Lee';
title = ' Sr. Developer';
strcat(name,',',title)
ans =
```

Thomas R. Lee, Sr. Developer
You can also concatenate strings vertically with strvcat.

## Creating Two-Dimensional Character Arrays

When creating a two-dimensional character array, be sure that each row has the same length. F or example, this line is legal because both input rows have exactly 13 characters.

```
name = ['Thomas R. Lee' ; 'Sr. Developer']
name =
Thomas R. Lee
Sr. Developer
```

When creating character arrays from strings of different lengths, you can pad the shorter strings with blanks to force rows of equal length.

```
name = ['Thomas R. Lee '; 'Senior Developer'];
```

A simpler way to create string arrays is to use the char function. char automatically pads all strings to the length of the longest input string. In this example, char pads the 13-character input string 'Thomas R. Lee' with three trailing blanks so that it will be as long as the second string.

```
name = char('Thomas R. Lee','Senior Developer')
name =
Thomas R. Lee
```

## Senior Developer

When extracting strings from an array, usethe deblank function to removeany trailing blanks.

```
trimname = deblank(name(1,:))
trimname =
Thomas R. Lee
size(trimname)
ans =
    13
```

## Converting Characters to Numeric Values

Character arrays store each character as a 16-bit numeric value. Use the double function to convert strings to their numeric values, and char to revert to character representation.

```
name = double(name)
name =
    84
name = char(name)
name =
```

Thomas R. Lee

Use str2num to convert a character array to the numeric value represented by that string.

```
str = '37.294e-1';
val = str2num(str)
val =
    3.7294
```

## Cell Arrays of Strings

It's often convenient to store groups of strings in cell arrays instead of standard character arrays. This prevents you from having to pad strings with blanks to create character arrays with rows of equal length. A set of functions enables you to work with cell arrays of strings:

- You can convert between standard character arrays and cell arrays of strings.
- You can apply string comparison operations to cell arrays of strings.

For details on cell arrays see the "Structures and Cell Arrays" chapter.

## Converting to a Cell Array of Strings

The cellstr function converts a character array into a cell array of strings. Consider the character array

```
data = ['Allison Jones';'Development ';'Phoenix '];
```

Each row of the matrix is padded so that all have equal length (in this case, 13 characters).

Now use cellstr to create a column vector of cells, each cell containing one of the strings from the data array.

```
celldata = cellstr(data)
celldata =
```

    'Allison Jones'
    'Development'
    'Phoenix'
    Note that the cellstr function strips off the blanks that pad the rows of the input string matrix.

```
length(celldata{3})
```

ans $=$
7

The iscellstr function determines if the input argument is a cell array of strings. It returns a logical true (1) in the case of celldata.

```
iscellstr(celldata)
```

ans $=$
1
Use char to convert back to a standard padded character array.
strings = char(celldata)
strings =

Allison Jones
Development
Phoenix

## String/ Numeric Conversion

The str2double function converts a cell array of strings tothedouble-precision values represented by the strings.

```
c = {'37.294e-1'; '-58.375'; '13.796'};
str2double(c)
ans =
    3.7294
    -58.3750
    13.7960
```

## String Comparisons

There are several ways to compare strings and substrings:

- Y ou can compare two strings, or parts of two strings, for equality.
- You can compare individual characters in two strings for equality.
- You can categorize every element within a string, determining whether each element is a character or whitespace.

These functions work for both character arrays and cell arrays of strings.

## Comparing Strings For Equality

There are four functions that determine if two input strings are identical:

- strcmp determines if two strings are identical.
- strncmp determines if the first n characters of two strings are identical.
- strcmpi and strncmpi are thesame as strcmp and strncmp, except that they ignore case.

Consider the two strings

```
str1 = 'hello';
str2 = 'help';
```

Strings str1 and str2 are not identical, so invoking strcmp returns 0 (false). For example,

C = strcmp(str1,str2)
C =

0

Note For C programmers, this is an important difference between MATLAB's strcmp and C's strcmp ( ), which returns 0 if the two strings are the same.

The first three characters of str1 and str2 are identical, so invoking strncmp with any value up to 3 returns 1 .

```
C = strncmp(str1,str2,2)
C =
```

1
Thesefunctions work cell-by-cell on a cell array of strings. Consider the two cell arrays of strings

```
A = {'pizza';'chips';'candy'};
B = {'pizza';'chocolate';'pretzels'};
```

Now apply the string comparison functions.
strcmp (A, B)
ans =
1
0
0
strncmp (A, B, 1)
ans $=$

1
1
0

## Comparing for Equality Using Operators

You can use MATLAB relational operators on character arrays, as long as the arrays you are comparing have equal dimensions, or one is a scalar. For example, you can use the equality operator (==) to determine which characters in two strings match.

```
A = 'fate';
B = 'cake';
A == B
ans =
    0 1 0
1
```

All of the relational operators (>, >=, <, <=, ==, !=) compare the values of corresponding characters.

## Categorizing Characters Within a String

There are two functions for categorizing characters inside a string:

- isletter determines if a character is a letter
- isspace determines if a character is whitespace (blank, tab, or new line)

For example, create a string named mystring.
mystring = 'Room 401';
isletter examines each character in the string, producing an output vector of the same length as mystring.

A = isletter(mystring)
$A=$
$\begin{array}{llllllll}1 & 1 & 1 & 1 & 0 & 0 & 0 & 0\end{array}$
The first four elements in A are 1 (true) because the first four characters of mystring areletters.

## Searching and Replacing

MATLAB provides several functions for searching and replacing characters in a string. Consider a string named label.

```
label = 'Sample 1, 10/28/95';
```

The strrep function performs the standard search-and-replace operation. Use strrep to change the date from '10/28' to '10/30'.

```
newlabel = strrep(label,'28','30')
```

newlabel =

Sample 1, 10/30/95
findstr returns the starting position of a substring within a longer string. To find all occurrences of the string 'amp' inside label

```
position = findstr('amp',label)
position =
```

2
The position within label where the only occurrence of 'amp ' begins is the second character.

The strtok function returns the characters before the first occurrence of a delimiting character in an input string. The default delimiting characters are the set of whitespace characters. Y ou can use the strtok function to parse a sentence into words; for example,

```
function all_words = words(input_string)
remainder = input_string;
all_words = '';
while (any(remainder))
    [chopped,remainder] = strtok(remainder);
    all_words = strvcat(all_words,chopped);
end
```

The strmatch function looks through therows of a character array or cell array of strings to find strings that begin with a given series of characters. It returns the indices of the rows that begin with these characters.

```
maxstrings = strvcat('max','minimax','maximum')
maxstrings =
max
minimax
maximum
strmatch('max',maxstrings)
ans =
1
3
```

## String/ Numeric Conversion

MATLAB's string/numeric conversion functions change numeric values into character strings. You can store numeric values as digit-by-digit string representations, or convert a value into a hexadecimal or binary string. Consider a the scalar

```
x = 5317;
```

By default, MATLAB stores the number $x$ as a 1-by-1 double array containing the value 5317. The int2str (integer to string) function breaks this scalar into a 1-by-4 vector containing the string '5317'.
$y=i n t 2 s t r(x) ;$
size(y)
ans $=$

14
A related function, num2str, provides more control over the format of the output string. An optional second argument sets the number of digits in the output string, or specifies an actual format.

```
p = num2str(pi,9)
p =
```

3.14159265

Both int2str and num2str are handy for labeling plots. For example, the following lines use num2str to prepare automated labels for the x-axis of a plot.

```
function plotlabel(x,y)
plot(x,y)
str1 = num2str(min(x));
str2 = num2str(max(x));
out = ['Value of f from ' str1 ' to ' str2];
xlabel(out);
```

Another class of numeric/string conversion functions changes numeric values into strings representing a decimal value in another base, such as binary or
hexadecimal representation. For example, the dec2hex function converts a decimal value into the corresponding hexadecimal string.

```
dec_num = 4035;
hex_num = dec2hex(dec_num)
hex_num =
```

FC3

See the strfun directory for a complete listing of string conversion functions.

## Array/ String Conversion

TheMATLAB function mat2str changes an array to a string that MATLAB can evaluate. This string is useful input for a function such as eval, which evaluates input strings just as if they were typed at the MATLAB command line.

Create a 2-by-3 array A.
$A=\left[\begin{array}{ccccc}1 & 2 & 3 ; & 4 & 5\end{array}\right]$
$A=$

123
$4 \quad 5 \quad 6$
mat2str returns a string that contains the text you would enter to create A at the command line.

```
B = mat2str(A)
B =
[1 2 3; 4 5 6]
```

This chapter discusses multidimensional arrays, MATLAB arrays with more than two dimensions. Multidimensional arrays can be numeric, character, cell, or structure arrays. These arrays are broadly useful-for example, in the representation of multivariate data, or multiple pages of two-dimensional data.

This chapter covers the following topics:

- "Multidimensional Arrays"
- "Computing with Multidimensional Arrays"
- "Organizing Data in Multidimensional Arrays"
- "Multidimensional Cell Arrays"
- "Multidimensional Structure Arrays"

MATLAB provides a number of functions that directly support multidimensional arrays. You can extend this support by creating M-files that work with your data architecture.

| Function | Description |
| :--- | :--- |
| cat | Concatenate arrays. |
| ipermute | Inverse permute array dimensions. |
| ndgrid | Generate arrays for N-D functions and interpolation. |
| ndims | Number of array dimensions. |
| permute | Permute array dimensions. |
| shiftdim | Shift dimensions. |
| squeeze | Remove singleton dimensions. |

## Multidimensional Arrays

Multidimensional arrays in MATLAB are an extension of the normal two-dimensional matrix. Matrices have two dimensions: the row dimension and the column dimension.

row | column |  |  |  |
| :---: | :---: | :---: | :---: |
| $(1,1)$ | $(1,2)$ | $(1,3)$ | $(1,4)$ |
| $(2,1)$ | $(2,2)$ | $(2,3)$ | $(2,4)$ |
| $(3,1)$ | $(3,2)$ | $(3,3)$ | $(3,4)$ |
| $(4,1)$ | $(4,2)$ | $(4,3)$ | $(4,4)$ |

You can access a two-dimensional matrix element with two subscripts: the first representing the row index, and the second representing the column index.

Multidimensional arrays use additional subscripts for indexing. A three-dimensional array, for example, uses three subscripts:

- The first references array dimension 1 , the row.
- The second references dimension 2 , the column.
- The third references dimension 3. This guide uses the concept of a page to represent dimensions 3 and higher.

To access the element in the second row, third column of page 2, for example, you use the subscripts $(2,3,2)$.

As you add dimensions to an array, you also add subscripts. A four-dimensional array, for example, has four subscripts. The first two reference a row-column pair; the second two access the third and fourth dimensions of data.

Note The general multidimensional array functions reside in the datatypes directory.

## Creating Multidimensional Arrays

You can use the same techniques to create multidimensional arrays that you use for two-dimensional matrices. In addition, MATLAB provides a special concatenation function that is useful for building multidimensional arrays.

This section discusses:

- Generating arrays using indexing
- Generating arrays using MATLAB functions
- Using the cat function to build multidimensional arrays

## Generating Arrays Using Indexing

One way to create a multidimensional array is to create a two-dimensional array and extend it. F or example, begin with a simpletwo-dimensional array A.

```
A = [5 7 8; 0 1 9; 4 3 6];
```

A is a 3-by-3 array, that is, its row dimension is 3 and its column dimension is 3. To add a third dimension to $A$,

```
A(:,:,2) = [1 0 4; 3 5 6; 9 8 7]
```

MATLAB responds with

```
A(:,:,1) =
    5 7 7 8
    0 1 9
    4 3 6
A(:,:,2) =
    1 0 4
    3 5 6
    9 8
```

You can continue to add rows, columns, or pages to the array using similar assignment statements.

Extending Multidimensional Arrays. To extend A in any dimension:

- Increment or add the appropriate subscript and assign the desired values.
- Assign the same number of elements to corresponding array dimensions. F or numeric arrays, all rows must have the same number of elements, all pages must have the same number of rows and columns, and so on.

You can take advantage of MATLAB's scalar expansion capabilities, together with the col on operator, to fill an entire dimension with a single value.

```
A(:,:,3) = 5;
A(:,:,3)
ans =
```

| 5 | 5 | 5 |
| :--- | :--- | :--- |
| 5 | 5 | 5 |
| 5 | 5 | 5 |

To turn A into a 3-by-3-by-3-by-2, four-dimensional array, enter

$$
\begin{aligned}
& A(:,:, 1,2)=\left[\begin{array}{lllllllll}
1 & 2 & 3 ; & 4 & 5 & 6 ; & 7 & 8 & 9
\end{array}\right] ; \\
& A(:,:, 2,2)=\left[\begin{array}{llll}
9 & 8 & 7 ; & 6 \\
5 & 4 ; & 3 & 2 \\
1
\end{array}\right] ; \\
& A(:,:, 3,2)=\left[\begin{array}{lllllllll}
1 & 0 & 1 ; & 1 & 1 & 0 ; & 0 & 1 & 1
\end{array}\right] ;
\end{aligned}
$$

Note that after the first two assignments MATLAB pads A with zeros, as needed, to maintain the corresponding sizes of dimensions.

## Generating Arrays Using MATLAB Functions

You can use MATLAB functions such as randn, ones, and zeros to generate multidimensional arrays in the same way you use them for two-dimensional arrays. Each argument you supply represents the size of the corresponding dimension in the resulting array. For example, to create a 4-by-3-by-2 array of normally distributed random numbers.

$$
B=\operatorname{randn}(4,3,2)
$$

To generate an array filled with a single constant value, use the repmat function. repmat replicates an array (in this case, a 1-by-1 array) through a vector of array dimensions.

| $B=\operatorname{repmat}\left(5,\left[\begin{array}{lll}3 & 4 & 2\end{array}\right]\right)$ |  |  |  |
| :---: | :---: | :---: | :---: |
| $B(:,:, 1)=$ |  |  |  |
| 5 | 5 | 5 | 5 |
| 5 | 5 | 5 | 5 |
| 5 | 5 | 5 | 5 |
| $B(:,:, 2)=$ |  |  |  |
| 5 | 5 | 5 | 5 |
| 5 | 5 | 5 | 5 |
| 5 | 5 | 5 | 5 |

Note Any dimension of an array can have size zero, making it a form of empty array. For example, 10-by-0-by-20 is a valid size for a multidimensional array.

## Building Multidimensional Arrays with the cat Function

The cat function is a simple way to build multidimensional arrays; it concatenates a list of arrays along a specified dimension.

```
B = cat(dim,A1,A2...)
```

where A1, A2, and so on are the arrays to concatenate, and dim is the dimension along which to concatenate the arrays. F or example, to create a new array with cat

```
B = cat(3,[2 8; 0 5],[1 3; 7 9])
B(:,:,1) =
    2
    0
B(:,:,2) =
    1 3
    7 9
```

The cat function accepts any combination of existing and new data. In addition, you can nest calls to cat. The lines below, for example, create a four-dimensional array.

```
A = cat(3,[9 2; 6 5],[7 1; 8 4])
B = cat(3,[3 5; 0 1],[5 6; 2 1])
D = cat(4,A,B,cat(3,[1 2; 3 4],[4 3;2 1]))
```

cat automatically adds subscripts of 1 between dimensions, if necessary. For example, to create a 2-by-2-by-1-by-2 array, enter

```
C = cat(4,[1 2; 4 5],[7 8; 3 2])
```

In the previous case, cat inserts as many singleton dimensions as needed to create a four-dimensional array whose last dimension is not a singleton dimension. If the dim argument had been 5 , the previous statement would have produced a 2-by-2-by-1-by-1-by-2 array. This adds additional $1 s$ to indexing
expressions for the array. To access the value 8 in the four-dimensional case, use

## Accessing Multidimensional Array Properties

You can use the following MATLAB functions to get information about multidimensional arrays you have created.

| Information | Function | Example |
| :---: | :---: | :---: |
| Array size | size | ```size(C) ans = 2 cccc``` |
| Array dimensions | ndims | ndims(C) <br> ans = <br> 4 |
| Array storage and format | whos | whos    <br> Name Size Bytes Class <br>     <br> A $2 \times 2 \times 2$ 64 double array <br> B $2 \times 2 \times 2$ 64 double array <br> C $4-D$ 64 double array <br> D $4-D$ 192 double array <br>     <br> Grand total is 48    <br> elements using 384 bytes    |

## Indexing

Many of the concepts that apply to two-dimensional matrices extend to multidimensional arrays as well.

To access a single element of a multidimensional array, use integer subscripts. E ach subscript indexes a dimension-the first indexes the row dimension, the second indexes the column dimension, the third indexes the first page dimension, and so on.

Consider a 10-by-5-by-3 array nddata of random integers:

```
nddata = fix(8*randn(10,5,3));
```

To access element $(3,2)$ on page 2 of nddata, for example, use nddata $(3,2,2)$.
You can use vectors as array subscripts. In this case, each vector element must be a valid subscript, that is, within the bounds defined by the dimensions of the array. To access elements $(2,1),(2,3)$, and $(2,4)$ on page 3 of nddata, use

```
nddata(2,[1 3 4],3);
```

## The Colon and Multidimensional Array Indexing

MATLAB's col on indexing extends to multidimensional arrays. For example, to access the entire third column on page 2 of nddata, use nddata ( $:, 3,2$ ).
The colon operator is also useful for accessing other subsets of data. For example, nddata $(2: 3,2: 3,1)$ results in a 2 -by-2 array, a subset of the data on page 1 of nddata. This matrix consists of the data in rows 2 and 3 , columns 2 and 3 , on the first page of the array.

The colon operator can appear as an array subscript on both sides of an assignment statement. For example, to create a 4-by-4 array of zeros

$$
C=\operatorname{zeros}(4,4)
$$

Now assign a 2-by-2 subset of array nddata to the four elements in the center of C .

$$
C(2: 3,2: 3)=\operatorname{nddata}(2: 3,1: 2,2)
$$

## Avoiding Ambiguity in Multidimensional Indexing

Some assignment statements, such as

$$
A(:,:, 2)=1: 10
$$

are ambiguous because they do not provide enough information about the shape of the dimension to receive the data. In the case above, the statement tries to assign a one-dimensional vector to a two-dimensional destination. MATLAB produces an error for such cases. To resolve the ambiguity, be sure you provide enough information about the destination for the assigned data, and that both data and destination have the same shape. For example,

$$
A(1,:, 2)=1: 10
$$

## Reshaping

Unless you change its shape or size, a MATLAB array retains the dimensions specified at its creation. Y ou change array size by adding or del eting elements. You change array shape by respecifying the array's row, column, or page dimensions while retaining the same elements. The reshape function performs the latter operation. For multidimensional arrays, its form is

```
B = reshape(A,[s1 s2 s3 ...])
```

s1, s2, and so on represent the desired size for each dimension of the reshaped matrix. Note that a reshaped array must have the same number of elements as the original array (that is, the product of the dimension sizes is constant).

M reshape(M, [6 5])

| 1 | 3 | 5 | 7 | 5 |
| :--- | :--- | :--- | :--- | :--- |
| 9 | 6 | 7 | 5 | 5 |
| 8 | 5 | 2 | 9 | 3 |
| 2 | 4 | 9 | 8 | 2 |
| 0 | 3 | 3 | 8 | 1 |
| 1 | 0 | 6 | 4 | 3 |

The reshape function operates in a columnwise manner. It creates the reshaped matrix by taking consecutive elements down each column of the original data construct.

## C reshape(C, [6 2])

Here are several new arrays from reshaping nddata.

```
B = reshape(nddata,[6 25])
C = reshape(nddata,[5 3 10])
D = reshape(nddata,[5 3 2 5])
```

## Removing Singleton Dimensions

MATLAB creates singleton dimensions if you explicitly specify them when you create or reshape an array, or if you perform a calculation that results in an array dimension of one.

```
B = repmat(5,[2 2 3 1 4]);
size(B)
ans =
    2 3 1 1 4
```

The squeeze function removes singleton dimensions from an array.

```
C = squeeze(B);
size(C)
ans =
    2 3 4
```

The squeeze function does not affect two-dimensional arrays; row vectors remain rows.

## Permuting Array Dimensions

The permute function reorders the dimensions of an array.

```
B = permute(A,dims);
```

dims is a vector specifying the new order for the dimensions of $A$, where 1 corresponds to the first dimension (rows), 2 corresponds to the second dimension (columns), 3 corresponds to pages, and so on.

| A |  |  | $B=$ permute( $\left.A_{,}\left[\begin{array}{lll}2 & 1 & 3\end{array}\right]\right)$ |  |  |  | C = permute(A,[ 3121$])$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{A}(:,:, 1)=$ |  |  | $B(:,:, 1)=$ |  |  |  | $C(:,:, 1)=$ |  |  |  |
| 1 | 2 | 3 | 1 | 4 | 7 | Row and column | 1 | 2 | 3 | Row and page |
| 4 | 5 | 6 |  | 5 | 8 | subscripts are | 0 | 5 | 4 | subscripts are |
| 7 | 8 | 9 |  | 6 | 9 | reversed |  |  |  | reversed. |
| A(:, : , 2) = |  |  | $B(:,:, 2)=$ |  |  | ( page-by-page transposition). | $C(:,:, 2)=$ ersed. |  |  |  |
|  |  |  | 4 | 5 | 6 |  |  |
| 0 | 5 | 4 |  |  |  | 0 | 2 | 9 |  | 2 | 7 | 6 |  |
| 2 | 7 | 6 | 5 | 7 | 3 |  |  |  |  |  |
| 9 | 3 | 1 | 4 | 6 | 1 |  | $C(:,:, 3)$ |  |  |  |
|  |  |  |  |  |  |  | 7 | 8 | 9 |  |
|  |  |  |  |  |  |  | 9 | 3 | 1 |  |

For a more detailed look at the permute function, consider a four-dimensional array A of size 5-by-4-by-3-by-2. Rearrange the dimensions, placing the column dimension first, followed by the second page dimension, the first page dimension, then the row dimension. The result is a 4 by 2 by 3 by 5 array.

$B=\operatorname{permute}\left(A,\left[\begin{array}{llll}2 & 4 & 3 & 1\end{array}\right]\right)$

Move dimension 2 of A to first subscript position of $B$, dimension 4 to second sub. script position, and so on.

The order of dimensions in permute's argument list determines the size and shape of the output array. In this example, the second dimension moves to the first position. Because the second dimension of the original array had size four, the output array's first dimension also has size four.

You can think of permute's operation as an extension of the transpose function, which switches the row and column dimensions of a matrix. For permute, the order of the input dimension list determines the reordering of the subscripts. In the example above, element ( $4,2,1,2$ ) of A becomes element $(2,2,1,4)$ of $B$, element $(5,4,3,2)$ of $A$ becomes element $(4,2,3,5)$ of $B$, and so on.

## Inverse Permutation

The ipermute function is the inverse of permute. Given an input array A and a vector of dimensions $v$, ipermute produces an array $B$ such that permute ( $B, v$ ) returns A .

For example, these statements create an array E that is equal to the input array C .

```
D = ipermute(C,[1 4 2 3]);
E = permute(D,[\begin{array}{llll}{1}&{4}&{2}&{3}\end{array}])
```

You can obtain the original array after permuting it by calling ipermute with the same vector of dimensions.

## Computing with Multidimensional Arrays

Many of MATLAB's computational and mathematical functions accept multidimensional arrays as arguments. These functions operate on specific dimensions of multidimensional arrays; that is, they operate on individual elements, on vectors, or on matrices.

## Operating on Vectors

Functions that operate on vectors, like sum, mean, and soon, by default typically work on the first nonsingleton dimension of a multidimensional array. Most of these functions optionally let you specify a particular dimension on which to operate. There are exceptions, however. F or example, the cross function, which finds the cross product of two vectors, works on the first nonsingleton dimension having length three.

Note In many cases, these functions have other restrictions on the input arguments - for example, some functions that accept multiple arrays require that the arrays be the same size. Refer to the online help for details on function arguments.

## Operating Element-by-Element

MATLAB functions that operate element-by-element on two-dimensional arrays, like the trigonometric and exponential functions in the elfun directory, work in exactly the same way for multidimensional cases. F or example, the sin function returns an array the same size as the function's input argument. E ach element of the output array is the sine of the corresponding element of the input array.

Similarly, the arithmetic, logical, and relational operators all work with corresponding elements of multidimensional arrays that are the same size in every dimension. If one operand is a scalar and one an array, the operator applies the scalar to each element of the array.

## Operating on Planes and Matrices

Functions that operate on planes or matrices, such as the linear algebra and matrix functions in the matfun directory, do not accept multidimensional arrays as arguments. That is, you cannot use the functions in the matfun directory, or the array operators *,^, <br>, or / , with multidimensional arguments. Supplying multidimensional arguments or operands in these cases results in an error.

You can use indexing to apply a matrix function or operator to matrices within a multidimensional array. F or example, create a three-dimensional array A

```
A = cat(3,[1 2 3;9 8 7;4 6 5],[0 3 2;8 8 4;5 3 5],[6 4 7;6 8 5;...
5 4 3]);
```

Applying the eig function to the entire multidimensional array results in an error.

```
eig(A)
```

??? Error using ==> eig
Input arguments must be 2-D.

You can, however, apply eig to planes within the array. For example, use col on notation to index just one page (in this case, the second) of the array.

```
eig(A(:,:,2))
ans =
    -2.6260
    12.9129
    2.7131
```

Note In the first case, subscripts are not colons, you must use squeeze to avoid an error. For example, eig ( $\mathrm{A}(2,:,:))$ results in an error because the size of the input is $\left[\begin{array}{lll}1 & 3 & 3\end{array}\right]$. The expression eig (squeeze $\left.(A(2,:,:))\right)$, however, passes a valid two-dimensional matrix to eig.

## Organizing Data in Multidimensional Arrays

You can use multidimensional arrays to represent data in two ways:

- As planes or pages of two-dimensional data. You can then treat these pages as matrices.
- As multivariate or multidimensional data. F or example, you might have a four-dimensional array where each element corresponds to either a temperature or air pressure measurement taken at one of a set of equally spaced points in a room.

For example, consider an RGB image. For a single image, a multidimensional array is probably the easiest way to store and access data.

To access an entire plane of the image, use

```
red_plane = RGB(:,:,1);
```

To access a subimage, use

```
subimage = RGB(20:40,50:85,:);
```

The RGB image is a good example of data that needs to be accessed in planes for operations like display or filtering. In other instances, however, the data itself might be multidimensional. For example, consider a set of temperature measurements taken at equally spaced points in a room. Here the location of each value is an integral part of the data set - the physical placement in three-space of each element is an aspect of the information. Such data also lends itself to representation as a multidimensional array.

Now to find the average of all the measurements, use

```
mean(mean(mean(TEMP)));
```

To obtain a vector of the "middle" values (element $(2,2)$ ) in the room on each page, use

$$
B=\operatorname{TEMP}(2,2,:) ;
$$

## Multidimensional Cell Arrays

Like numeric arrays, the framework for multidimensional cell arrays in MATLAB is an extension of the two-dimensional cell array model. Y ou can use the cat function to build multidimensional cell arrays, just as you use it for numeric arrays.

For example, create a simple three-dimensional cell array $C$.

$$
\begin{aligned}
& \mathrm{A}\{1,1\}=[12 ; 45] ; \\
& \mathrm{A}\{1,2\}=\text { 'Name'; } \\
& \mathrm{A}\{2,1\}=2-4 i ; \\
& \mathrm{A}\{2,2\}=7 ; \\
& \mathrm{B}\{1,1\}=\text { 'Name }^{\prime} ; \\
& \mathrm{B}\{1,2\}=3 ; \\
& \mathrm{B}\{2,1\}=0: 1: 3 ; \\
& \mathrm{B}\{2,2\}=[45] \\
& \mathrm{C}=\operatorname{cat}(3, \mathrm{~A}, \mathrm{~B}) ;
\end{aligned}
$$

The subscripts for the cells of clook like

## Multidimensional Structure Arrays

Multidimensional structure arrays are extensions of rectangular structure arrays. Like other types of multidimensional arrays, you can build them using direct assignment or the cat function.

```
patient(1,1,1).name = 'John Doe';patient(1,1,1).billing = 127.00;
patient(1,1,1).test = [79 75 73; 180 178 177.5; 220 210 205];
patient(1,2,1).name = 'Ann Lane';patient(1,2,1).billing = 28.50;
patient(1,2,1).test = [68 70 68; 118 118 119; 172 170 169];
patient(1,1,2).name = 'Al Smith';patient(1,1,2).billing = 504.70;
patient(1,1,2).test = [80 80 80; 153 153 154; 181 190 182];
patient(1,2,2).name = 'Dora Jones';patient(1,2,2).billing =
1173.90;
patient(1,2,2).test = [73 73 75; 103 103 102; 201 198 200];
```

## Applying Functions to Multidimensional Structure Arrays

To apply functions to multidimensional structure arrays, operate on fields and field elements using indexing. For example, find the sum of the columns of the test array in patient (1, 1, 2).
sum((patient(1,1,2).test));
Similarly, add all the billing fields in the patient array.
total $=$ sum([patient.billing]);

Structures are collections of different kinds of data organized by named fields. Cell arrays area special class of MATLAB array whose elements consist of cells that themselves contain MATLAB arrays. Both structures and cell arrays provide a hierarchical storage mechanism for dissimilar kinds of data. They differ from each other primarily in the way they organize data. You access data in structures using named fields, while in cell arrays, data is accessed through matrix indexing operations.

This table describes the MATLAB functions for working with structures and cell arrays..

| Category | Function | Description |
| :--- | :--- | :--- |
| Structure functions | deal | Deal inputs to outputs |
|  | fieldnames | Get structure field names. |
|  | getfield | Get structure field contents. |
|  | isfield | True if field is in structure array. |
|  | isstruct | True for structures. |
|  | rmfield | Remove structure field. |
| setfield | Set structure field contents. |  |
| Cell array functions | struct | Create or convert to structure array. |
|  | struct2cell | Convert structure array into cell array. |
| cell2struct | Convert cell array into structure array. |  |
|  | celldisp | Display cell array contents. |
| cellfun | Apply a cell function to a cell array. |  |
| cellplot | Display graphical depiction of cell array. |  |
| deal | Deal inputs to outputs. |  |
| iscell | Truefor cell array. |  |

| Category | Function | Description |
| :--- | :--- | :--- |
|  | num2cell | Convert numeric array into cell array. |
| Cell array of strings <br> functions | deblank | Remove trailing blanks from a string |
|  | intersect | Set the intersection of two vectors |
|  | ismember | Detect members of a set |
| setdiff | Return the set difference of two vectors |  |
| setxor | Set the exclusive-or of two vectors |  |
| sort | Sort elements in ascending order |  |
| strcat | Concatentate strings |  |
| strcmp | Compare strings |  |
| strmatch | Find possible matches for a string |  |
| union | Set the union of two vectors |  |
| unique | Set the unique elements of a vector |  |

## Structures

Structures are MATLAB arrays with named "data containers" called fied ds. The fields of a structure can contain any kind of data. For example, one field might contain a text string representing a name, another might contain a scal ar representing a billing amount, a third might hold a matrix of medi cal test results, and so on.

Like standard arrays, structures are inherently array oriented. A single structure is a 1 -by-1 structure array, just as the value 5 is a 1 -by-1 numeric array. You can build structure arrays with any valid size or shape, including multidimensional structure arrays.

Note The examples in this section focus on two-dimensional structure arrays. For examples of higher-dimension structure arrays, see Chapter 19, "Multidimensional Arrays"

The following list summarizes the contents of this section:

- "Building Structure Arrays"
- "Accessing Data in Structure Arrays"
- "Finding the size of Structure Arrays"
- "Adding Fields to Structures"
- "Del eting Fields from Structures"
- "Applying Functions and Operators"
- "Writing Functions to Operate on Structures"
- "Organizing Data in Structure Arrays"
- "Nesting Structures"

## Building Structure Arrays

You can build structures in two ways:

- Using assignment statements
- Using the struct function

## Building Structure Arrays Using Assignment Statements

You can build a simple 1-by-1 structure array by assigning data to individual fields. MATLAB automatically builds the structure as you go along. F or example, create the 1-by-1 patient structure array shown at the beginning of this section.

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

Now entering
patient
at the command line results in
name: 'John Doe'
billing: 127
test: [3×3 double]
patient is an array containing a structure with three fields. To expand the structure array, add subscripts after the structure name.

```
patient(2).name = 'Ann Lane';
patient(2).billing = 28.50;
patient(2).test = [68 70 68; 118 118 119; 172 170 169];
```

The patient structure array now has size [1 2]. Note that once a structure array contains more than a single element, MATLAB does not display individual field contents when you type the array name. Instead, it shows a summary of the kind of information the structure contains.

```
patient
patient =
1x2 struct array with fields:
    name
    billing
    test
```

You can also use the fieldnames function to obtain this information. fieldnames returns a cell array of strings containing field names.

As you expand the structure, MATLAB fills in unspecified fields with empty matrices so that:

- All structures in the array have the same number of fields.
- All fields have the same field names.

For example, entering patient (3).name = 'Alan Johnson' expands the patient array to size [1 3]. Now both patient (3). billing and patient (3).test contain empty matrices.

Note Field sizes do not have to conform for every element in an array. In the patient example, the name fields can have different lengths, the test fields can be arrays of different sizes, and so on.

## Building Structure Arrays Using the struct Function

You can preallocate an array of structures with the struct function. Its basic form is

```
str_array = struct('field1',val1,'field2',val2, ...)
```

where the arguments are field names and their corresponding values. A field value can be a single value, represented by any MATLAB data construct, or a cell array of values. All field values in the argument list must be of the same scale (single value or cell array).

You can use different methods for preallocating structure arrays. These methods differ in the way in which the structure fields are initialized. As an
example, consider the allocation of a 1-by-3 structure array, weather, with the structurefields temp and rainfall. Threedifferent methods for allocating such an array are shown in this table.

| Method | Syntax | Initialization |
| :---: | :---: | :---: |
| struct | ```weather(3) = struct('temp',72,'rainfall',0.0);``` | weather (3) is initialized with the field values shown. The fields for the other structures in the array, weather(1) and weather (2), are initialized to the empty matrix. |
| struct with repmat | ```weather = repmat(struct('temp',72, 'rainfall',0.0),1,3);``` | All structures in the weather array are initialized using one set of field values. |
| struct with cell array syntax | ```weather = struct('temp',{68,80,72}, rainfall',{0.2,0.4,0.0});``` | The structures in the weather array are initialized with distinct field values specified with cell arrays. |

## Accessing Data in Structure Arrays

Using structure array indexing, you can access the value of any field or field element in a structure array. Likewise, you can assign a value to any field or field element. For the examples in this section, consider this structure array.

You can access subarrays by appending standard subscripts to a structure array name. F or example, the line below results in a 1-by-2 structure array.

```
mypatients = patient(1:2)
1x2 struct array with fields:
    name
    billing
    test
```

The first structure in the mypatients array is the same as the first structure in the patient array.

```
mypatients(1)
ans =
    name: 'John Doe'
    billing: 127
    test: [3\times3 double]
```

To access a field of a particular structure, include a period (.) after the structure name followed by the field name.

```
str = patient(2).name
str =
Ann Lane
```

To access elements within fields, append the appropriate indexing mechanism to the field name. That is, if the field contains an array, use array subscripting; if the field contains a cell array, use cell array subscripting, and so on.

```
test2b = patient(3).test(2,2)
test2b =
```

153
Use the same notations to assign values to structure fields, for example,

```
patient(3).test(2,2) = 7;
```

You can extract field values for multiple structures at a time. For example, the line below creates a 1-by-3 vector containing all of the billing fields.

```
bills = [patient.billing]
bills =
    127.0000 28.5000 504.7000
```

Similarly, you can create a cell array containing the test data for the first two structures.

```
tests = {patient(1:2).test}
tests =
    [3x3 double] [3x3 double]
```

## Accessing Field Values Using setfield and getfield

Direct indexing is usually the most efficient way to assign or retrieve field values. If, however, you only know the field name as a string - for example, if you have used the fieldnames function to obtain the field name within an M-file- you can use the setfield and getfield functions to do the samething.
getfield obtains a value or values from a field or field element
f = getfield(array,\{array_index\},'field',\{field_index\})
where the field_index is optional, and array_index is optional for a 1-by-1 structure array. The function syntax corresponds to

```
f = array(array_index).field(field_index);
```

For example, to access the name field in the second structure of the patient array, use:

```
str = getfield(patient,{2},'name');
```

Similarly, setfield lets you assign values to fields using the syntax

```
f = setfield(array,{array_index},'field',{field_index},value)
```

## Finding the size of Structure Arrays

Use the size function to obtain thesize of a structurearray, or of any structure field. Given a structure array name as an argument, size returns a vector of array dimensions. Given an argument in the form array ( $n$ ). field, the size function returns a vector containing the size of the field contents.

For example, for the 1-by-3 structure array patient, size (patient) returns the vector [13]. Thestatement size (patient (1,2). name) returns the length of the name string for element $(1,2)$ of patient.

## Adding Fields to Structures

You can add a field to every structurein an array by adding the field to a single structure. For example, to add a social security number field to the patient array, use an assignment like

```
patient(2).ssn = '000-00-0000';
```

Now patient (2).ssn has the assigned value. Every other structure in the array also has the ssn field, but these fields contain theempty matrix until you explicitly assign a value to them.

## Deleting Fields from Structures

You can remove a given field from every structure within a structure array using the rmfield function. Its most basic form is

```
struc2 = rmfield(array,'field')
```

where array is a structure array and 'field' is the name of a field to remove from it. To remove the name field from the patient array, for example, enter:

```
patient = rmfield(patient,'name');
```

## Applying Functions and Operators

Operate on fields and field elements the same way you operate on any other MATLAB array. Use indexing to access the data on which to operate. For example, this statement finds the mean across the rows of the test array in patient(2).

```
mean((patient(2).test)');
```

There are sometimes multiple ways to apply functions or operators across fields in a structure array. One way to add all the billing fields in the patient array is

```
total = 0;
for k = 1:length(patient)
    total = total + patient(k).billing;
end
```

To simplify operations like this, MATLAB enables you to operate on all like-named fields in a structure array. Simply enclose the array.field expression in square brackets within the function call. For example, you can sum all the billing fields in the patient array using

```
total = sum ([patient.billing]);
```

This is equivalent to using the comma-separated list.

```
total = sum ([patient(1).billing, patient(2).billing...]);
```

This syntax is most useful in cases where the operand field is a scalar field.

## Writing Functions to Operate on Structures

You can write functions that work on structures with specific field architectures. Such functions can access structure fields and elements for processing.

Note When writing M-file functions to operate on structures, you must perform your own error checking. That is, you must ensure that the code checks for the expected fields.

As an example, consider a collection of data that describes measurements, at different times, of the levels of various toxins in a water source. The data consists of fifteen separate observations, where each observation contains three separate measurements.

You can organize this data into an array of 15 structures, where each structure has three fields, one for each of the three measurements taken.

The function concen, shown below, operates on an array of structures with specific characteristics. Its arguments must contain the fields lead, mercury, and chromium.

```
function [r1,r2] = concen(toxtest);
% Create two vectors. r1 contains the ratio of mercury to lead
% at each observation. r2 contains the ratio of lead to chromium.
r1 = [toxtest.mercury]./[toxtest.lead];
r2 = [toxtest.lead]./[toxtest.chromium];
% Plot the concentrations of lead, mercury, and chromium
% on the same plot, using different colors for each.
lead = [toxtest.lead];
mercury = [toxtest.mercury];
chromium = [toxtest.chromium];
plot(lead,'r'); hold on
plot(mercury,'b')
plot(chromium,'y'); hold off
```

Try this function with a sample structure array like test.

```
test(1).lead = .007; test(2).lead = .031; test(3).lead = .019;
test(1).mercury = .0021; test(2).mercury = .0009;
test(3).mercury = .0013;
test(1).chromium = .025; test(2).chromium = .017;
test(3).chromium = .10;
```

## Organizing Data in Structure Arrays

The key to organizing structure arrays is to decide how you want to access subsets of the information. This, in turn, determines how you build the array that holds the structures, and how you break up the structure fields.

For example, consider a 128-by-128 RGB image stored in three separate arrays; RED, GREEN, and BLUE.

There are at least two ways you can organize such data into a structure array.

## Plane Organization

In case 1 above, each field of the structure is an entire plane of the image. You can create this structure using

$$
\begin{aligned}
& \text { A.r }=\text { RED; } \\
& \text { A. }=\text { GREEN; } \\
& \text { A.b }=\text { BLUE; }
\end{aligned}
$$

This approach allows you to easily extract entire image planes for display, filtering, or other tasks that work on the entire image at once. To access the entire red plane, for example, use

```
red_plane = A.r;
```

Plane organization has the additional advantage of being extensible to multiple images in this case. If you have a number of images, you can store them $\operatorname{as} A(2), A(3)$, and so on, each containing an entire image.

The disadvantage of plane organization is evident when you need to access subsets of the planes. To access a subimage, for example, you need to access each field separately.

```
red_sub = A.r(2:12,13:30);
grn_sub = A.g(2:12,13:30);
blue_sub = A.b(2:12,13:30);
```

## Element-by-Element Organization

Case 2 has the advantage of allowing easy access to subsets of data. To set up the data in this organization, use

```
for m = 1:size(RED,1)
    for n = 1:size(RED,2)
        B(m,n).r = RED(m,n);
        B(m,n).g = GREEN(m,n);
        B(m,n).b = BLUE (m,n);
    end
end
```

With element-by-element organization, you can access a subset of data with a single statement.

```
Bsub = B(1:10,1:10);
```

To access an entire plane of the image using the element-by-element method, however, requires a loop.

```
red_plane = zeros(128,128);
for k = 1:(128*128)
    red_plane(k) = B(k).r;
end
```

Element-by-element organization is not the best structure array choice for most image processing applications; however, it can be the best for other applications wherein you will routinely need to access corresponding subsets of structurefields. The example in the following section demonstrates this type of application.

## Example - A Simple Database

Consider organizing a simple database.

Each of the possible organizations has advantages depending on how you want to access the data:

- Plane organization makes it easier to operate on all field values at once. For example, to find the average of all the values in the amount field,
- Using plane organization

$$
\text { avg }=\text { mean(A.amount) } ;
$$

- Using element-by-element organization

$$
\text { avg }=\operatorname{mean}([\text { B.amount }]) ;
$$

- Element-by-element organization makes it easier to access all the information related to a single client. Consider an M-file, client.m, which displays the name and address of a given client on screen.
Using plane organization, pass individual fields.
function client(name, address)
disp(name)
disp(address)
To call the client function,

```
client(A.name(2,:),A.address(2,:))
```

Using element-by-element organization, pass an entire structure.

```
function client(B)
disp(B)
```

To call the client function, client (B(2))

- Element-by-element organization makes it easier to expand the string array fields. If you do not know the maximum string length ahead of time for plane organization, you may need to frequently recreate the name or address field to accommodate longer strings.

Typically, your data does not dictate the organization scheme you choose. Rather, you must consider how you want to access and operate on the data.

## Nesting Structures

A structure field can contain another structure, or even an array of structures. Once you have created a structure, you can use the struct function or direct assignment statements to nest structures within existing structure fields.

## Building Nested Structures with the struct Function

To build nested structures, you can nest calls to the struct function. F or example, create a 1-by-1 structure array.

```
A = struct('data',[3 4 7; 8 0 1],'nest',...
    struct('testnum','Test 1', 'xdata',[4 2 8],...
    'ydata',[7 1 6]));
```

You can build nested structure arrays using direct assignment statements. These statements add a second element to the array.

```
A(2).data = [9 3 2; 7 6 5];
A(2).nest.testnum = 'Test 2';
A(2).nest.xdata = [3 4 2];
A(2).nest.ydata = [5 0 9];
```

## Indexing N ested Structures

To index nested structures, append nested field names using dot notation. The first text string in the indexing expression identifies the structure array, and subsequent expressions access field names that contain other structures.
F or example, the array A created earlier has three levels of nesting:

- To access the nested structure inside A(1), use A(1) . nest.
- To access the xdata field in the nested structure in $\mathrm{A}(2)$, use A(2).nest.xdata.
- To access element 2 of the ydata field in A(1), use A(1). nest. ydata(2).

## Cell Arrays

A cell array is a MATLAB array for which the elements are cells, containers that can hold other MATLAB arrays. F or example, onecell of a cell array might contain a real matrix, another an array of text strings, and another a vector of complex values.

You can build cell arrays of any valid sizeor shape, including multidimensional structure arrays.

Note The examples in this section focus on two-dimensional cell arrays. For examples of higher-dimension cell arrays, see Chapter 19, "Multidimensional Arrays".

The following list summarizes the contents of this section:

- "Cell Arrays of Structures"

## Creating Cell Arrays

You can create cell arrays by:

- Using assignment statements
- Preallocating the array using the cell function, then assigning data to cells

## Using Assignment Statements

You can build a cell array by assigning data to individual cells, one cell at a time. MATLAB automatically builds the array as you go along. There are two ways to assign data to cells:

- Cell indexing

Enclose the cell subscripts in parentheses using standard array notation. Enclose the cell contents on the right side of the assignment statement in curly braces, " $\}$." F or example, create a 2-by-2 cell array A.

```
A(1,1) = {[1 4 3; 0 5 8; 7 2 9]};
A(1,2) = {'Anne Smith'};
A(2,1) = {3+7i};
A(2,2) = {-pi:pi/10:pi};
```

Note The notation " $\}$ " denotes the empty cell array, just as " $[$ ]" denotes the empty matrix for numeric arrays. You can use the empty cell array in any cell array assignments.

- Content indexing

Enclose the cell subscripts in curly braces using standard array notation. Specify the cell contents on the right side of the assignment statement.

```
A{1,1} = [1 4 3; 0 5 8; 7 2 9];
A{1,2} = 'Anne Smith';
A{2,1} = 3+7i;
A{2,2} = -pi:pi/10:pi;
```

The various examples in this guide do not use one syntax throughout, but attempt to show representative usage of cell and content addressing. You can use the two forms interchangeably.

Note If you already have a numeric array of a given name, don't try to create a cell array of the same name by assignment without first clearing the numeric array. If you do not clear the numeric array, MATLAB assumes that you are trying to "mix" cell and numeric syntaxes, and generates an error. Similarly, MATLAB does not clear a cell array when you make a single assignment to it. If any of the examples in this section give unexpected results, clear the cell array from the workspace and try again.

MATLAB displays the cell array A in a condensed form.
$A=$

| $[3 \times 3$ double] | 'Anne Smith' |
| ---: | :--- |
| $[3.0000+7.0000 i]$ | $[1 \times 21$ double $]$ |

To display the full cell contents, use the celldisp function. F or a high-level graphical display of cell architecture, use cellplot.

If you assign data to a cell that is outside the dimensions of the current array, MATLAB automatically expands the array to include the subscripts you specify. It fills any intervening cells with empty matrices. F or example, the assignment below turns the 2-by-2 cell array A into a 3-by-3 cell array.

$$
A(3,3)=\{5\} ;
$$

| cell 1,1 | cell 1,2 | cell 1,3 |
| :---: | :---: | :---: |
| 速 $\begin{array}{\|lll\|}1 & 4 & 3 \\ 0 & 5 & 8 \\ 7 & 2 & 9\end{array}$ | Anne Smith' | [ ] |
| cell 2,1 | cell 2,2 | cell 2,3 |
| 3+7i | [-3.14...3.14] | [ ] |
| cell 3,1 | cell 3,2 | cell 3,3 |
| [ ] | [ ] | 5 |

## Cell Array Syntax: Using Braces

The curly braces, " $\}$ ", are cell array constructors, just as square brackets are numeric array constructors. Curly braces behave similarly to square brackets, except that you can nest curly braces to denote nesting of cells (see "Nesting Cell Arrays" for details).
Curly braces use commas or spaces to indicate column breaks and semicolons to indicate row breaks between cells. For example,

```
C = {[1 2], [3 4]; [5 6], [7 8]};
```

results in

| cell $\mathbf{1 , 1}$ <br> $[12]$ | $\left.\begin{array}{c}\text { cell } \mathbf{1 , 2} \\ {[34}\end{array}\right]$ |
| :---: | :---: |
| cell 2,1 | cell 2,2 |
| $\left[\begin{array}{l}5 \\ 5\end{array}\right]$ | $\left[\begin{array}{l}7 \\ \hline\end{array}\right]$ |

Use square brackets to concatenate cell arrays, just as you do for numeric arrays.

## Preallocating Cell Arrays with the cell Function

The cell function allows you to preallocate empty cell arrays of the specified size. F or example, this statement creates an empty 2-by-3 cell array.

$$
B=\operatorname{cell}(2,3) ;
$$

Use assignment statements to fill the cells of $B$.

$$
B(1,3)=\{1: 3\} ;
$$

## Obtaining Data from Cell Arrays

You can obtain data from cell arrays and store the result as either a standard array or a new cell array. This section discusses:

- Accessing cell contents using content indexing
- Accessing a subset of cells using cell indexing

## Accessing Cell Contents Using Content Indexing

You can use content indexing on the right side of an assignment to access some or all of the data in a single cell. Specify the variable to receive the cell contents on the left side of the assignment. Enclose the cell index expression on the right side of the assignment in curly braces. This indicates that you are assigning cell contents, not the cells themselves.

Consider the 2-by-2 cell array N .

```
N{1,1} = [1 2; 4 5];
N{1,2} = 'Name';
N{2,1} = 2-4i;
N{2,2} = 7;
```

You can obtain the string in $N\{1,2\}$ using

```
c = N{1,2}
```

c =

Name

Note In assignments, you can use content indexing to access only a single cell, not a subset of cells. For example, the statements $A\{1,:\}=$ value and $B$ $=A\{1,:\}$ are both invalid. However, you can use a subset of cells any place you would normally use a comma-separated list of variables (for example, as function inputs or when building an array). See the "Replacing Lists of Variables with Cell Arrays" section for details.

To obtain subsets of a cell's contents, concatenate indexing expressions. For example, to obtain element $(2,2)$ of the array in cell $N\{1,1\}$, use:

```
d = N{1,1}(2,2)
d =
```

5

## Accessing a Subset of Cells Using Cell Indexing

Use cell indexing to assign any set of cells to another variable, creating a new cell array. Use the colon operator to access subsets of cells within a cell array.

| cell 1,1 <br> 3 | cell 1,2 <br> 5 | cell 1,3 <br> 9 |
| :---: | :---: | :---: |
| cell 2,1 <br> 5 | cell 2,2 <br> 6 | cell 2,3 <br> 0 |
| cell 3,1 <br> 4 | cell 3,2 <br> 7 | cell 3,3 <br> 2 |

## Deleting Cells

You can delete an entire dimension of cells using a single statement. Like standard array del etion, use vector subscripting when deleting a row or column of cells and assign the empty matrix to the dimension.

$$
\text { A(cell_subscripts) }=[]
$$

When deleting cells, curly braces do not appear in the assignment statement at all.

## Reshaping Cell Arrays

Like other arrays, you can reshape cell arrays using the reshape function. The number of cells must remain the same after reshaping; you cannot use reshape to add or remove cells.

```
A = cell(3,4);
size(A)
ans =
    3 4
B = reshape(A,6,2);
size(B)
ans =
    6 2
```

## Replacing Lists of Variables with Cell Arrays

Cell arrays can replace comma-separated lists of MATLAB variables in:

- Function input lists
- Function output lists
- Display operations
- Array constructions (square brackets and curly braces)

If you use the colon to index multiple cells in conjunction with the curly brace notation, MATLAB treats the contents of each cell as a separate variable. For example, assume you have a cell array T where each cell contains a separate vector. The expression $\mathrm{T}\{1: 5\}$ is equivalent to a comma-separated list of the vectors in the first five cells of $T$.

Consider the cell array $c$.

```
C(1) = {[\begin{array}{lll}{1}&{2}&{3}\end{array}]};
C(2) = {[\begin{array}{lll}{1}&{0}&{1}\end{array}];
C(3) = {1:10};
```

```
C(4) = {[9 8 7]};
C(5) = {3};
```

To convolve the vectors in C(1) and C(2) using conv,

$$
\begin{aligned}
& d=\operatorname{conv}(C\{1: 2\}) \\
& d=
\end{aligned}
$$

$$
\begin{array}{lllll}
1 & 2 & 4 & 2 & 3
\end{array}
$$

Display vectors two, three, and four with
C $\{2: 4\}$
ans $=$
101
ans $=$
$\begin{array}{llllllllll}1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10\end{array}$
ans $=$
$\begin{array}{lll}9 & 8 & 7\end{array}$
Similarly, you can create a new numeric array using the statement

```
B = [C{1}; C{2}; C{4}]
B =
1 2 3
    1 0 1
    9 8 7
```

You can also use content indexing on the left side of an assignment to create a new cell array where each cell represents a separate output argument.

$$
[D\{1: 2\}]=\operatorname{eig}(B)
$$

```
D =
[3x3 double] [3x3 double]
```

You can display the actual eigenvalues and eigenvectors using $D\{1\}$ and $D\{2\}$.

Note The varargin and varargout arguments allow you to specify variable numbers of input and output arguments for MATLAB functions that you create. Both varargin and varargout are cell arrays, allowing them to hold various sizes and kinds of MATLAB data. See "Passing Variable Numbers of Arguments" on page 17-16 for details.

## Applying Functions and Operators

Use indexing to apply functions and operators to the contents of cells. For example, use content indexing to call a function with the contents of a single cell as an argument.

```
A{1,1} = [1 2; 3 4];
A{1,2} = randn(3,3);
A{1,3} = 1:5;
B = sum(A{1,1})
B =
\(4 \quad 6\)
```

To apply a function to several cells of a non-nested cell array, use a loop.

```
for k = 1:length(A)
    M{k} = sum(A{1,k});
end
```

## Organizing Data in Cell Arrays

Cell arrays are useful for organizing data that consists of different sizes or kinds of data. Cell arrays are better than structures for applications where:

- You need to access multiple fields of data with one statement.
- Y ou want to access subsets of the data as comma-separated variable lists.
- You don't have a fixed set of field names.
- You routinely remove fields from the structure.

As an example of accessing multiple fields with one statement, assume that your data consists of:

- A 3-by-4 array consisting of measurements taken for an experiment.
- A 15-character string containing a technician's name.
- A 3-by-4-by-5 array containing a record of measurements taken for the past five experiments.

For many applications, the best data construct for this data is a structure. However, if you routinely access only the first two fields of information, then a cell array might be more convenient for indexing purposes.

This example shows how to access the first and second elements of the cell array TEST.

```
[newdata,name] = deal(TEST{1:2})
```

This example shows how to access the first and second elements of the structure TEST.

```
newdata = TEST.measure
name = TEST.name
```

The varargin and varargout arguments are examples of the utility of cell arrays as substitutes for comma-separated lists. Create a 3-by-3 numeric array A.

```
A = [0 1 2;4 0 7;3 1 2];
```

Now apply the normest (2-normestimate) function to A, and assign thefunction output to individual cells of B.

```
[B{1:2}] = normest(A)
B =
```

All of the output values from the function are stored in separate cells of B. B (1) contains the norm estimate; $\mathrm{B}(2)$ contains the iteration count.

## Nesting Cell Arrays

A cell can contain another cell array, or even an array of cell arrays. (Cells that contain noncell data are called leaf cells.) Y ou can use nested curly braces, the cell function, or direct assignment statements to create nested cell arrays. You can then access and manipulate individual cells, subarrays of cells, or cell elements.

## Building Nested Arrays with Nested Curly Braces

You can nest pairs of curly braces to create a nested cell array. F or example,

```
clear A
A(1,1) = {magic(5)};
A(1,2) = {{[5 2 8; 7 3 0; 6 7 3] 'Test 1'; [2-4i 5+7i] {17 []}}}
A =
[5x5 double] {2x2 cell}
```

Note that the right side of the assignment is enclosed in two sets of curly braces. Thefirst set represents cell $(1,2)$ of cell array A. The second "packages" the 2-by-2 cell array inside the outer cell.

## Building Nested Arrays with the cell Function

To nest cell arrays with the cell function, assign the output of cell to an existing cell:

1 Create an empty 1-by-2 cell array.
A = cell(1,2);
2 Create a 2-by-2 cell array inside $A(1,2)$.
$\mathrm{A}(1,2)=\{\operatorname{cell}(2,2)\} ;$
3 Fill A, including the nested array, using assignments.

```
A(1,1) = {magic(5)};
A{1,2}(1,1) = {[5 2 8; 7 3 0; 6 7 3]};
```

```
A{1,2}(1,2) = {'Test 1'};
A{1,2}(2,1) = {[2-4i 5+7i]};
A{1,2}(2,2) = {cell(1,2)}
A{1,2}{2,2}(1) = {17};
```

N ote the use of curly braces until the final level of nested subscripts. This is required because you need to access cell contents to access cells within cells.

You can also build nested cell arrays with direct assignments using the statements shown in step 3 above.

## Indexing Nested Cell Arrays

To index nested cells, concatenate indexing expressions. The first set of subscripts accesses the top layer of cells, and subsequent sets of parentheses access successively deeper layers.

For example, array A has three levels of nesting:

- To access the 5-by-5 array in cell $(1,1)$, use A\{1,1\}.
- To access the 3-by-3 array in position (1, 1) of cell $(1,2)$, use $A\{1,2\}\{1,1\}$.
- To access the 2-by-2 cell array in cell $(1,2)$, use A\{1,2\}.
- To access the empty cell in position $(2,2)$ of cell $(1,2)$, use A\{1,2\}\{2,2\}\{1,2\}.

## Converting Betw een Cell and Numeric Arrays

Use for loops to convert between cell and numeric formats. F or example, create a cell array F .

```
F{1,1} = [1 2; 3 4];
F{1,2} = [-1 0; 0 1];
```

```
F{2,1} = [7 8; 4 1];
F{2,2} = [4i 3+2i; 1-8i 5];
```

Now use three for loops to copy the contents of F into a numeric array NUM.

```
for k = 1:4
    for m = 1:2
        for n = 1:2
            NUM(m,n,k)=F{k}(m,n);
        end
    end
end
```

Similarly, you must use for loops to assign each value of a numeric array to a single cell of a cell array.

```
G = cell(1,16);
for m = 1:16
    G{m} = NUM(m);
end
```

## Cell Arrays of Structures

Use cell arrays to store groups of structures with different field architectures.

```
c_str = cell(1,2);
c_str{1}.label = '12/2/94 - 12/5/94';
c_str{1}.obs = [47 52 55 48; 17 22 35 11];
c_str{2}.xdata = [l-0.03 0.41 1.98 2.12 17.11];
c_str{2}.ydata = [-3 5 18 0 9];
c_str{2}.zdata = [0.6 0.8 1 2.2 3.4];
```

Cell 1 of the c_str array contains a structure with two fields, one a string and the other a vector. Cell 2 contains a structure with three vector fields.

When building cell arrays of structures, you must use content indexing. Similarly, you must use content indexing to obtain the contents of structures within cells. The syntax for content indexing is:

```
cell_array{index}.field
```

F or example, to access the label field of the structure in cell 1 , use c_str\{1\}.label.

## Function Handles

Handles to Nonexistent Functions ..... 21-26
Including Path In the Function Handle Constructor ..... 21-26
Evaluating a Nonscalar Function Handle ..... 21-27
Historical Note - Evaluating Function Names ..... 21-28

A function handle is a MATLAB data type that contains information used in referencing a function. When you create a function handle, MATLAB stores in the handle all the information about the function that it needs to execute, or evaluate, it later on. Typically, a function handle is passed in an argument list to other functions. It is then used in conjunction with feval to evaluate the function to which the handle bel ongs.

A MATLAB function handle is more than just a reference to a function. It often represents a collection of function methods, overloaded to handle different argument types. When you create a handle to a function, MATLAB takes a snapshot of all built-in and $M$-file methods of that name that are on the MATLAB path and in scope at that time, and stores access information for all of those methods in the handle.

When you evaluate a function handle, MATLAB considers only those functions that were stored within the handle when it was created. Other functions that might now be on the path or in scope are not considered. It is the combination of which function methods are mapped to by the handle and what arguments the handle is evaluated with that determines which is the actual function that MATLAB dispatches to.

This chapter addresses the following topics:

- "Benefits of Using Function Handles"
- "Constructing a Function Handle"
- "Evaluating a Function Through Its Handle"
- "Displaying Function Handle Information"
- "Function Handle Operations"
- "Saving and Loading Function Handles"
- "Handling Error Conditions"
- "Historical N ote - Evaluating Function Names"

## Benefits of Using Function Handles

Function handles enable you to do all of the following:

- Pass function access information to other functions
- Capture all methods of an overloaded function
- Allow wider access to subfunctions and private functions
- Ensure reliability when evaluating functions
- Reduce the number of files that define your functions
- Improve performance in repeated operations
- Manipulate handles in arrays, structures, and cell arrays

This section also includes an example of using a simple function handle. See "A Simple Function Handle" on page 21-5.

## Pass Function Access Information to 0 ther Functions

You can pass a function handle as an argument in a call to another function. The handle contains access information that enables the receiving function to call the function for which the handle was constructed.
You can evaluate a function handle from within another function even if the handle's function is not in the scope of the evaluating function. This is because the function performing the evaluation has all the information it needs within the function handle.

For the same reason, you can also evaluate a function handle even when the handle's function is no longer on the MATLAB search path.

You must use the MATLAB feval command to evaluate the function in a function handle. When you pass a function handle as an argument into another function, then the function receiving the handle uses feval to evaluate the function handle.

## Capture All Methods of An Overloaded Function

Because many MATLAB functions are overloaded, a function handle often maps to a number of code sources (e.g., built-in code, M-files), that implement the function. A function handle stores the access to all of the overloaded sources, or methods, that are on the MATLAB path at the time the handle is created.

When you evaluate an overloaded function handle, MATLAB follows the usual rules of selecting which method to evaluate, basing the selection on the argument types passed in the function call. See "How MATLAB Determines Which Method to Call" on page 22-67, for more information on how MATLAB selects overloaded functions.

For example, there are three built-in functions and one $M$-file function that define the abs function on the standard MATLAB path. A function handle created for the abs function contains access information on all four of these function sources. If you evaluate the function with an argument of the double type, then the built-in function that takes a double argument is executed.

## Allow Wider Access to Subfunctions and Private Functions

By definition, all MATLAB functions have a certain scope. They are visible to other MATLAB entities within that scope, but not visible outside of it. Y ou can invoke a function directly from another function that is within its scope, but not from a function outside that scope.

Subfunctions and private functions are, by design, limited in their visibility to other MATLAB functions. You can invoke a subfunction only by another function that is defined within the same M-file. You can invoke a private function only from a function in the directory immediately above the \private subdirectory.

When you create a handle to a function that has limited scope, the function handle stores all the information MATLAB needs to evaluate the function from any location in the MATLAB environment. If you create a handle to a subfunction while the subfunction is in scope, (that is, you create it from within the $M$-file that defines the subfunction), you can then pass the handle to code that resides outside of that $M$-fileand evaluate the subfunction from beyond its usual scope. The similar case holds true for private functions.

## Ensure Reliability W hen Evaluating Functions

Function handles allow you more control over what methods get executed when a function is evaluated. If you create a function handle for a function with overloaded methods, making sure that only the intended methods are within scope when the handle is created gives you control over which methods are executed when MATLAB evaluates the handle. This can isolate you from methods that might be in scope at the time of evaluation that you didn't know about.

## Reduce the Number of Files That Define Your Functions

You can use function handles to help reduce the number of $M$-files required to define your functions. The problem with grouping a number of functions in one M -file is that this defines them as subfunctions, and thus reduces their scope in MATLAB. Using function handles to access these subfunctions removes this limitation. This enables you to group functions as you want and reduce the number of files you have to manage.

## Improve Performance in Repeated 0 perations

MATLAB performs a lookup on a function at the time you create a function handle and then stores this access information in the handle itself. Once defined, you can use this handle in repeated evaluations without incurring the performance delay associated with function lookup each time.

## Manipulate Handles in Arrays, Structures, and Cell Arrays

As a standard MATLAB data type, a function handle can be manipulated and operated on in the same manner as other MATLAB data types. Y ou can create arrays, structures, or cell arrays of function handles. Access individual function handles within these data structures in the same way that you access elements of a numeric array or structure.

Create n-dimensional arrays of handles using either of the concatenation methods used to form other types of MATLAB arrays, [ ] or cat. All operations involving matrix manipulation are supported for function handles.

## A Simple Function Handle

The repmat function is an elementary matrix function, which is defined in MATLAB with the single M-file, repmat.m. If you create a function handle to the repmat function, MATLAB stores in the handle the information it will need later to evaluate the function. Included in this information is the repmat.m source file path, toolbox \matlab\elmat \repmat.m.

Once you create a function handle, it is not affected by certain changes you might make in your MATLAB environment. For example, if you construct a handle to the repmat function and, later, write additional repmat.m methods to overload the function, the handle still sees only the original function. Also, if you remove the path to repmat.m from the search path, MATLAB is still able to locate and evaluate the function using the handle that you created prior to the path change.

Since repmat is not an overloaded function in this case, evaluation of the function through its handle is fairly simple. You call feval on the function handle, also passing any arguments the function should act upon. MATLAB executes the one function whose access information is stored in the handle.

## Constructing a Function Handle

Construct a function handle in MATLAB using the at sign, @, before the function name. The following example creates a function handle for the humps function and assigns it to the variable fhandle.

```
fhandle = @humps;
```

Pass the handle to another function in the same way you would pass any argument. This example passes the function handle just created to fminbnd, which then minimizes over the interval $[0.3,1]$.

```
x = fminbnd(fhandle, 0.3, 1)
x =
    0.6370
```

The fminbnd function evaluates the @humps function handle using feval. A small portion of the fminbnd $M$-file is shown below. In line 1 , the funfon input parameter receives the function handle, @humps, that was passed in. The feval statement, in line 113, evaluates the handle.

```
1 function [xf,fval,exitflag,output] = ...
        fminbnd(funfcn,ax,bx,options,varargin)
            .
113 fx = feval(funfcn,x,varargin{:});
```

Note When creating a function handle, you may only use the function name after the @ sign. This must not include any path information. The following syntax is invalid: fhandle $=$ @ $\backslash$ home \user $4 \backslash$ humps.

## Maximum Length of a Function Name

Function names used in handles are unique up to 31 characters. If the function name exceeds that length, MATLAB truncates the latter part of the name.

```
fhandle = @function_name_that_exceeds_thirty_one_characters
fhandle =
    @function_name_that_exceeds_thir
```

For function handles created for J ava constructors, the length of any segment of the package name or class name must not exceed 31 characters. (The term segment refers to any portion of the name that lies before, between, or after a dot. F or example, there are three segments in java.lang.String.) There is no limit to the overall length of the string specifying the package and class.

Thefol lowing statement is valid, even though the length of the overall package and class specifier exceeds 31 characters.
fhandle = @java.awt.datatransfer.StringSelection

## Evaluating a Function Through Its Handle

Execute the target function of a function handle using the MATLAB feval command. The syntax for using this command with a function handle is

```
feval(fhandle, arg1, arg2, ..., argn)
```

This acts similarly to a direct call to the function represented by fhandle, passing arguments arg1 through argn. The principal differences are:

- A function handle can be evaluated from within any function that you pass it to.
- The code source that MATLAB selects for evaluation depends upon which overloaded methods of the function were on the MATLAB path and in scope at the time the handle was constructed. (Argument types al so affect method selection.) Path and scope are not considered at the time of evaluation.
- MATLAB does the work of initial function lookup at the time the function handle is constructed. This does not need to be done each time MATLAB evaluates the handle.

Note The feval command does not operate on nonscalar function handles. Passing a nonscalar function handle to feval results in an error.

## Function Evaluation and Overloading

To understand the relationship between function handles and overloading, it is hel pful to review, briefly, the nature of MATLAB function calls. Because of overloading, it is useful to think of a single MATLAB function as comprising a number of code sources (for example, built-in code, M-files). When you call a MATLAB function without feval, the choice of which source is called depends upon two factors:

- The methods that are visible on the path at the time of the call
- The classes of the arguments to the function

MATLAB evaluates function handles in a similar manner. In most cases, a function handle represents a collection of methods that overload the function.

When you evaluate a function handle using feval, the choice of the particular method called depends on:

- The methods that were visible on the path at the time the handle was constructed
- The classes of the arguments passed with the handle to the feval command

## Examples of Function Handle Evaluation

This section provides two examples of how function handles are used and evaluated.

## Example 1-A Simple Function Handle

The following example defines a function, called plot_fhandle, that receives a function handle and data, and then performs an evaluation of the function handle on that data.

```
function x = plot_fhandle(fhandle, data)
plot(data, feval(fhandle, data))
```

When you call plot_fhandle with a handle to the sin function and the argument shown below, the resulting evaluation produces the following plot.

```
plot_fhandle(@sin, -pi:0.01:pi)
```

## Example 2 - Function Handles and Subfunctions

The M-file in this example defines a primary function, fitcurvedemo, and a subfunction called expfun. The subfunction, by definition, is visible only within the scope of its own M-file. This, of course, means that it is available for use only by other functions within that M -file.

The author of this code would like to use expfun outside the confines of this one M -file. This example creates a function handle to the expfun subfunction, storing access information for the subfunction so that it can be called from anywhere in the MATLAB environment. The function handle is passed to fminsearch, which successfully evaluates the subfunction outside of its usual scope.

The code shown below defines fitcurvedemo and subfunction, expfun. Line 6 constructs a function handle to expfun and assigns it to the variable, fun. In line 16, a call to fminsearch passes the function handle outside the normal scope of a subfunction. The fminsearch function uses feval to evaluate the subfunction through its handle.

```
1 function Estimates = fitcurvedemo
% FITCURVEDEMO
% Fit curve to data where user chooses equation to fit.
% Define function and starting point of fitting routine.
fun = @expfun;
Starting = rand(1, 2);
% First, we create the data.
t = 0:.1:10; t=t(:); % to make 't' a column vector
Data = 40 * exp(-.5 * t) + randn(size(t));
m = [t Data];
% Now, we can call FMINSEARCH:
options = optimset('fminsearch'); % Use FMINSEARCH defaults
Estimates = fminsearch(fun, Starting, options, t, Data);
% To check the fit
plot(t, Data, '*')
hold on
plot(t, Estimates(1) * exp(-Estimates(2) * t), 'r')
xlabel('t')
```

```
23 ylabel('f(t)')
24 title(['Fitting to function ', func2str(fun)]);
25 legend('data', ['fit using ', func2str(fun)])
26 hold off
27
28
29
30 function sse = expfun(params, t, Data)
31 % Accepts curve parameters as inputs, and outputs fitting the
32 % error for the equation y = A * exp(-lambda * t);
33 A = params(1);
34 lambda = params(2);
35
36 Fitted_Curve = A .* exp(-lambda * t);
37
38
39 % When curve fitting, a typical quantity to minimize is the sum
40 % of squares error
41 sse = sum(Error_Vector .^ 2);
```

## Displaying Function Handle Information

The functions command returns information about a function handle that might be useful for debugging. Calling functions on a function handle returns the function name, type, filename, and all of the methods for the function that were in scope at the time the function handle was created.

The information returned from functions is in the form of a MATLAB structure. The fields of this structure are listed in the following table.

| Field Name | Field Description |
| :--- | :--- |
| function | Function name. |
| type | Function type. See the table in section, "Function Type" <br> on page 21-14. |
| file | The file to be executed when the function handle is <br> evaluated with a nonoverloaded data type. For built-in <br> functions, it reads 'MATLAB built - in function.' |
| methods | All overloaded methods of the function that are bound to <br> the function handle. This field exists only for functions <br> of type, overloaded. |

For example, to obtain information on a function handle for the display function,

```
f = functions(@display)
ans =
    function: 'display'
        type: 'overloaded'
        file: 'MATLAB built-in function'
    methods: [1x1 struct]
```

Individual fields of the structure are accessible using the dot selection notation used to access MATLAB structure fields.

```
f.type
ans =
    'overloaded'
```

The methods field is a separate structure containing one fieldname for each class that overloads the function. The value of each field is the path and name of the file that defines the function.

```
f.methods
ans =
    polynom: '\home\user4\@polynom\display.m'
    inline: 'matlabroot\toolbox\matlab\funfun\@inline\display.m'
        serial: 'matlabroot\toolbox\matlab\iofun\@serial\display.m'
    avifile: 'matlabroot\toolbox\matlab\iofun\@avifile\display.m'
f.methods.polynom
ans =
    polynom: '\home\user4\@polynom\display.m'
```

Note The functions command does not operate on nonscalar function handles. Passing a nonscalar function handle to functions results in an error.

## Fields Returned by the Functions Command

The functions command returns a MATLAB structure with the fields function, type, file, and, for overloaded functions, methods. This section describes each of those fields.

## Function Name

The function field is a character array that holds the name of the function corresponding to the function handle.

## Function Type

The type field is a character array that holds one of five possible strings listed in the following table.

| Function Type | Type Description |
| :--- | :--- |
| simple | Nonoverloaded MATLAB built-in or M-file, or any <br> function for which the type cannot be determined until <br> it is evaluated |
| subfunction | MATLAB subfunction |
| private | MATLAB private function |
| constructor | Constructor to a MATLAB class |
| overloaded | Overloaded built-in, M-file function, or constructor |

The contents of the next two fields, file and methods, depend upon the function type.

## Function File

The file field is a character array that holds one of the following:

- The string, 'MATLAB built-in function', for built-in functions
- The path and name of the file that implements the default function, for nonbuilt-in functions

The default function is the one function implementation that is not specialized to operate on any particular data type. Unless the arguments in the function call specify a class that has a specialized version of the function defined, it is the default function that gets called.
The examplebel ow operates on a function handlefor the deblank function. The function has a default implementation in the strfun directory. This is shown in f.file. It also has an overloaded method in the @cell directory. This is shown in f.methods.cell.

```
f = functions(@deblank)
f =
    function: 'deblank'
        type: 'overloaded'
        file: 'matlabroot\toolbox\matlab\strfun\deblank.m'
```

```
    methods: [1x1 struct]
f.methods
ans =
    cell: 'matlabroot\toolbox\matlab\strfun\@cell\deblank.m'
```

If you evaluate the @deblank function handle with a cell argument, MATLAB calls the deblank method in the @cell directory. But, for any other argument types, MATLAB calls the default M-file shown in the file field.

## Function Methods

The methods field exists only for functions of type, overloaded. This field is a separate MATLAB structure that identifies all overloaded methods that are bound to the function handle.

The structure contains one field for each method of the function handle. The field names are the classes that overload the function. Each field value is a character array holding the path and name of the source file that defines the method.

For example, a function handle for the display function may be bound to the M -files shown below. The functions command returns a methods structure having a field for each class overloading the function: polynom, inline, serial, and avifile. For each class, it shows the path and name of the method source file.

```
f = functions(@display);
f.methods
ans =
    polynom: '\home\user4\@polynom\display.m'
    inline: 'matlabroot\toolbox\matlab\funfun\@inline\display.m'
        serial: 'matlabroot\toolbox\matlab\iofun\@serial\display.m'
    avifile: 'matlabroot\toolbox\matlab\iofun\@avifile\display.m'
```

Note The set of methods returned by functions is determined at the time a function handle is created. This depends on the state of the MATLAB path and also which functions are in scope when the handle is created.

## Types of Function Handles

The information returned by functions varies depending on the type of function represented by the function handle. This section explains what is returned for each type of function. The categories of function handles are:

- Simplefunction handles
- Overloaded function handles
- Constructor function handles
- Subfunction handles
- Private function handles

## Simple Function Handles

These are handles to nonoverloaded MATLAB built-in or M-filefunctions. Any function handles for which the function type has not yet been determined (e.g., J ava methods, nonexistent functions), also fall into this category.

## Structure fields:

```
function: function name
    type: 'simple'
    file: 'MATLAB built-in function' for built-ins
        path and name of the default M-file for nonbuilt-ins
(there is no methods field)
```

## Examples:

Using functions on a function handle to a built-in function
functions(@ones)
ans $=$
function: 'ones'
type: 'simple'
file: 'MATLAB built-in function'
Using functions on a function handle to a nonbuilt-in function

```
functions(@fzero)
ans =
    function: 'fzero'
        type: 'simple'
        file: 'matlabroot\toolbox\matlab\funfun\fzero.m'
```

## Overloaded Function Handles

These are handles to MATLAB built-in or M-file functions that are overloaded implementations for different classes.

## Structure fields:

```
function: function name
    type: 'overloaded'
    file: 'MATLAB built-in function' for built-ins
        path and name of the default M-file for nonbuilt-ins
    methods: [1x1 struct]
```

## Examples:

Using functions on a function handle to a built-in function

```
functions(@display)
ans =
    function: 'display'
            type: 'overloaded'
            file: 'MATLAB built-in function'
        methods: [1x1 struct]
```

Using functions on a function handle to a nonbuilt-in function

```
functions(@deblank)
ans =
    function: 'deblank'
            type: 'overloaded'
            file: 'matlabroot\toolbox\matlab\strfun\deblank.m'
            methods: [1x1 struct]
```

## Constructor Function Handles

These are handles to functions that construct objects of MATLAB classes.

## Structure fields:

```
function: function name
    type: 'constructor'
    file: path and name of the constructor M-file
(there is no methods field)
```

## Example:

Using functions on a function handle to a constructor function

```
functions(@inline)
ans =
    function: 'inline'
        type: 'constructor'
        file: 'matlabroot\toolbox\matlab\funfun\@inline\inline.m'
```

## Subfunction Handles

These are handles to MATLAB subfunctions, which are functions defined within an M -file that are only visible to the primary function of that M -file. When you use functions on a subfunction handle, the file field of the return structure contains the path and name of the $M$-file in which the subfunction is defined.

## Structure fields:

```
function: function name
    type: 'subfunction'
    file: path and name of the M-file defining the subfunction
(there is no methods field)
```

## Example:

The getLocalHandle M-file, shown below, defines a primary function and a subfunction, named subfunc.

```
% -- File GETLOCALHANDLE.M --
function subhandle = getLocalHandle()
subhandle = @subfunc; % return handle to subfunction
function subfunc()
disp 'running subfunc'
```

A call to getLocalHandle returns a function handle to the subfunction. When you pass that handle to functions, it returns the following information.

```
fhandle = getLocalHandle;
functions(fhandle)
ans =
    function: 'subfunc'
```

```
type: 'subfunction'
file: '\home\user4\getLocalHandle.m'
```

## Private Function Handles

These are handles to MATLAB private functions, which are functions defined in a private subdirectory that are only visible to functions in the parent directory. When you use functions on a privatefunction handle, the file field of the return structure contains the path and name of the $M$-file in the private subdirectory that defines the function.

## Structure fields:

```
function: function name
    type: 'private'
    file: path and name of the M-file in \private
(there is no methods field)
```

## Example:

The getPrivateHandle function, shown below, returns a handle to a private function named privatefunc.

```
% -- File GETPRIVATEHANDLE.M --
function privhandle = getPrivateHandle()
privhandle = @privatefunc; % return handle to private function
```

The following function, privatefunc, resides in the $\backslash$ private subdirectory.

```
% -- File \PRIVATE\PRIVATEFUNC.M --
function privatefunc()
disp 'running privatefunc'
```

A call to getPrivateHandle returns a handle to the function, privatefunc, defined in \private. When you pass that handle to functions, it returns the following information.

```
fhandle = getPrivateHandle;
functions(fhandle)
ans =
    function: 'privatefunc'
        type: 'private'
        file: '\home\user4\private\privatefunc.m'
```

## Function Handle Operations

MATLAB provides two functions that enable you to convert between a function handle and a function name string. It also provides functions for testing to see if a variable holds a function handle, and for comparing function handles.

## Converting Function Handles to Function Names

If you need to perform string operations, such as string comparison or display, on a function handle, you can use func2str to obtain the function name in string format. To convert a sin function handle to a string

```
fhandle = @sin;
```

func2str(fhandle)
ans =

Note The func2str command does not operate on nonscalar function handles. Passing a nonscalar function handle to func2str results in an error.

## Example - Displaying the Function Name in an Error Message

The catcherr function shown here accepts function handle and data arguments and attempts to evaluate the function through its handle. If the function fails to execute, catcherr uses sprintf to display an error message giving the name of the failing function. Thefunction name must be a string for sprintf to display it. The code derives the function name from the function handle using func2str.

```
function catcherr(func, data)
try
    ans = feval(func, data);
    disp('Answer is:');
    ans
catch
    sprintf('Error executing function ''%s''\n', func2str(func))
end
```

The first call to catcherr, shown below, passes a handle to the round function and a valid data argument. This call succeeds and returns the expected answer. The second call passes the samefunction handle and an improper data type (a MATLAB structure). Thistime, round fails, causing catcherr to display an error message that includes the failing function name.

```
catcherr(@round, 5.432)
ans =
Answer is 5
xstruct.value = 5.432;
catcherr(@round, xstruct)
Error executing function "round"
```

## Converting Function Names to Function Handles

Using the str2func function, you can construct a function handle from a string containing the name of a MATLAB function. To convert the string, 'sin', into a handle for that function

```
fh = str2func('sin')
fh =
    @sin
```

If you pass a function name string in a variable, the function that receives the variable can convert the function name to a function handle using str2func. The example below passes the variable, funcname, to function makeHandle, which then creates a function handle.

```
function fh = makeHandle(funcname)
fh = str2func(funcname);
% -- end of makeHandle.m file --
makeHandle('sin')
ans =
    @sin
```

You can also perform the str2func operation on a cell array of function name strings. In this case, str2func returns an array of function handles.

```
fh_array = str2func({'sin' 'cos' 'tan'})
fh_array =
    @sin @cos @tan
```

## Example - More Flexible Parameter Checking

In the following example, the myminbnd function expects to receive either a function handle or string in the first argument. If you pass a string, myminbnd constructs a function handle from it using str2func, and then uses that handle in a call to fminbnd.

```
function myminbnd(fhandle, lower, upper)
if ischar(fhandle)
    disp 'converting function string to function handle ...'
    fhandle = str2func(fhandle);
end
fminbnd(fhandle, lower, upper)
```

Whether you call myminbnd with a function handle or function name string, it is able to handle the argument appropriately.

```
myminbnd('humps', 0.3, 1)
converting function string to function handle ...
ans =
    0.6370
```

## Testing for Data Type

The isa function identifies the data type or class of a MATLAB variable or object. Y ou can see if a variable holds a function handle by using isa with the function_handle tag. The following function tests an argument passed in to see if it is a function handle before attempting to evaluate it.

```
function evaluate_handle(arg1, arg2)
if isa(arg1, 'function_handle')
    feval(arg1, arg2);
else
    disp 'You need to pass a function handle';
end
```

## Testing for Equality

You can usethe isequal function to compare two function handles for equality. For example, you want to execute one particular method you have written for an overloaded function. You create a function handle within a confined scope so that it provides access to that method alone. The function shown below,
test_myfun, receives this function handle in the first argument, arg1, and evaluates it.

Before evaluating the handle in arg1, test_myfun checks it against another function handle that has a broader definition. This other handle, @myfun, provides access to all methods for the function. If the function handle in arg1 represents more than the one intended method, an error message is displayed and the function is not evaluated.

```
function test_myfun(arg1, arg2)
if isequal(arg1, @myfun)
    disp 'Function handle holds unexpected context'
else
    feval(arg1, arg2);
end
```

## Saving and Loading Function Handles

You can use the MATLAB save and load functions to save function handles to MAT files, and then load them back into your MATLAB workspace later on. This example shows an array of function handles saved to the file, savefile, and then restored.

```
fh_array = [@sin @cos @tan];
save savefile fh_array;
clear
load savefile
whos
    Name Size Bytes Class
    fh_array 1x3 48 function_handle array
Grand total is 3 elements using 48 bytes
```

## Possible Effects of Changes Made Between Save and Load

If you load a function handle that you saved in an earlier MATLAB session, the following conditions could cause unexpected behavior:

- Any of the M-files that define the function have been moved, and thus no longer exist on the path stored in the handle.
- You load the function handle into an environment different from that in which it was saved. For example, the source for the function either doesn't exist or is located in a different directory than on the system on which the handle was saved.
- You have overloaded the function with additional methods since the save was done. The function handle you just loaded doesn't know about the new methods.

In the first two cases, the function handle is now invalid, since it no longer maps to any existing source code. Although the handleis invalid, MATLAB still performs the load successfully and without displaying a warning. An attempt to evaluate the handle however results in an error.

## Handling Error Conditions

The following are error conditions associated with the use of function handles.

## Handles to Nonex istent Functions

If you create a handle to a function that does not exist, MATLAB catches the error when the handle is evaluated by feval. MATLAB allows you to assign an invalid handle and use it in such operations as func2str, but will catch and report an error when you attempt to use it in a runtimeoperation. For example,

```
fhandle = @no_such_function;
func2str(fhandle)
ans =
no_such_function
feval(fhandle)
??? Error using ==> feval
Undefined function 'no_such_function'.
```

## Including Path In the Function Handle Constructor

You construct a function handle using the at sign, @, or the str2func function. In either case, you specify the function using only the simple function name. The function name cannot include path information. Either of the following successfully creates a handle to the deblank function.
fhandle = @deblank;
fhandle = str2func('deblank');
The next example includes the path to deblank.m, and thus returns an error.

```
fhandle = str2func(which('deblank'))
```

??? Error using ==> str2func
Invalid function name
'matlabroot $\backslash$ toolbox\matlab\strfun\deblank.m'.

## Evaluating a Nonscalar Function Handle

The feval function evaluates function handles only if they are scalar. Calling feval with a nonscalar function handle results in an error.

```
feval([@sin @cos], 5)
??? Error using ==> feval
Function_handle argument must be scalar.
```

## Historical Note - Evaluating Function Names

Evaluating a function by means of a function handle replaces the former MATLAB mechanism of evaluating a function through a string containing the function name. For example, of thefollowing two lines of codethat evaluate the humps function, the second supersedes the first and is considered to be the preferable mechanism to use.

```
feval('humps', 0.5674); % uses a function name string
feval(@humps, 0.5674); % uses a function handle
```

To support backward compatibility, feval still accepts a function name string as a first argument and evaluates the function named in the string. However, function handles offer you the additional performance, reliability, and source file control benefits listed in the section "Benefits of Using Function Handles" on page 21-3.

How MATLAB Determines Which Method to Call ..... 22-67

This chapter describes how to define classes in MATLAB. Classes and objects enable you to add new data types and new operations to MATLAB. The class of a variable describes the structure of the variable and indicates the kinds of operations and functions that can apply tothe variable. An object is an instance of a particular class. The phrase object-oriented programming describes an approach to writing programs that emphasizes the use of classes and objects.
The following topics and examples are presented in this chapter:

- "Classes and Objects: An Overview"
- "Designing User Classes in MATLAB"
- "Overloading Operators and Functions"
- "Example- A Polynomial Class"
- "Building on Other Classes"
- "Example - Assets and Asset Subclasses"
- "Example - The Portfolio Container"
- "Saving and Loading Objects"
- "Example - Defining saveobj and loadobj for Portfolio"
- "Object Precedence"
- "How MATLAB Determines Which Method to Call"

## Classes and Objects: An Overview

You can view classes as new data types having specific behaviors defined for theclass. For example, a polynomial class might redefinethe addition operator $(+)$ so that it correctly performs the operation of addition on polynomials. Operations defined to work with objects of a particular class are known as methods of that class.

You can also view classes as new items that you can treat as single entities. An example is an arrow object that MATLAB can display on graphs (perhaps composed of MATLAB line and patch objects) and that has properties like a Handle Graphics object. You can create an arrow simply by instantiating the arrow class.

You can add classes to your MATLAB environment by specifying a MATLAB structure that provides data storage for the object and creating a class directory containing M-files that operate on the object. These M-files contain the methods for the class. The class directory can also include functions that define the way various MATLAB operators, including arithmetic operations, subscript referencing, and concatenation, apply to the objects. Redefining how a built-in operator works for your class is known as overloading the operator.

## Features of Object-Oriented Programming

When using well-designed classes, object-oriented programming can significantly increase code reuse and make your programs easier to maintain and extend. Programming with classes and objects differs from ordinary structured programming in these important ways:

- Function and operator overloading. You can create methods that override existing MATLAB functions. When you call a function with a user-defined object as an argument, MATLAB first checks to see if there is a method defined for the object's class. If there is, MATLAB calls it, rather than the normal MATLAB function.
- E ncapsulation of data and methods. Object properties are not visible from the command line; you can access them only with class methods. This protects the object properties from operations that are not intended for the object's class.
- Inheritance. You can create class hierarchies of parent and child classes in which the child class inherits data fields and methods from the parent. A
child class can inherit from one parent (singleinheritance) or many parents (multipleinheritance). Inheritance can span one or more generations. Inheritance enables sharing common parent functions and enforcing common behavior amongst all child classes.
- Aggregation. Y ou can create classes using aggregation, in which an object contains other objects. This is appropriate when an object type is part of another object type. For example, a savings account object might be a part of a financial portfolio object.

## MATLAB Data Class Hierarchy

All MATLAB data types are designed to function as classes in object-oriented programming. The diagram bel ow shows the fourteen fundamental data types (or classes) defined in MATLAB. Y ou can add new data types to MATLAB by extending the class hierarchy.

The diagram shows a user class that inherits from the structure class. All classes that you create are structure based since this is the point in the class hierarchy where you can insert your own classes. (F or more information about MATLAB data types, see the section on "Data Types.")

## Creating Objects

You create an object by calling the class constructor and passing it the appropriate input arguments. In MATLAB, constructors have the same name as the class name. For example, the statement,

```
p = polynom([14 0 -2 -5]);
```

creates an object named $p$ belonging to the class polynom. Once you have created a polynom object, you can operate on the object using methods that are defined for the polynom class. See "Example-A Polynomial Class" on page 22-24 for a description of the polynom class.

## Invoking Methods on Objects

Class methods are M-file functions that take an object as one of the input arguments. The methods for a specific class must be placed in the class directory for that class (the @class_name directory). This is the first place that MATLAB looks to find a class method.

The syntax for invoking a method on an object is similar to a function call. Generally, it looks like

```
[out1,out2,...] = method_name(object,arg1,arg2, ...);
```

For example, suppose a user-defined class called polynom has a char method defined for the class. This method converts a polynom object to a character string and returns the string. This statement calls the char method on the polynom object $p$.

$$
s=\operatorname{char}(p)
$$

Using the class function, you can confirm that the returned value s is a character string.

```
class(s)
ans =
    char
S
s =
    x^3-2**-5
```

You can use the methods command to produce a list of all of the methods that are defined for a class.

## Private Methods

Private methods can be called only by other methods of their class. You define private methods by placing the associated M-files in a private subdirectory of the @class_name directory. In the example,

```
@class_name/private/update_obj.m
```

the method update_obj has scope only within the class_name class. This means that update_obj can be called by any method that is defined in the @class_name directory, but it cannot be called from the MATLAB command line or by methods outside of the class directory, including parent methods.

Private methods and private functions differ in that private methods (in fact all methods) have an object as one of their input arguments and private functions do not. Y ou can use private functions as hel per functions, such as described in the next section.

## Helper Functions

In designing a class, you may discover the need for functions that perform support tasks for the class, but do not directly operate on an object. These functions are called helper functions. A hel per function can be a subfunction in a class method file or a private function. When determining which version of a particular function to call, MATLAB looks for these functions in the order listed above. F or more information about the order in which MATLAB calls functions and methods, see "H ow MATLAB Determines Which Method to Call" on page 22-67.

## Debugging Class Methods

You can use the MATLAB debugging commands with object methods in the same way that you use them with other M-files. The only difference is that you need to include the class directory name before the method name in the command call, as shown in this example using dbstop.
dbstop @polynom/char
While debugging a class method, you have access to all methods defined for the class, including inherited methods, private methods, and private functions.

## Changing Class Definition

If you change the class definition, such as the number or names of fields in a class, you must issue a

```
clear classes
```

command to propagate the changes to your MATLAB session. This command also clears all objects from the workspace. See the clear command help entry for more information.

## Setting Up Class Directories

TheM-files defining the methods for a class are collected together in a directory referred to as the class directory. The directory name is formed with the class name preceded by the character @. F or example, one of the examples used in this chapter is a class involving polynomials in a single variable. The name of the class, and the name of the class constructor, is polynom. The M-files defining a polynomial class would be located in directory with the name @polynom.

The class directories are subdirectories of directories on the MATLAB search path, but are not themselves on the path. For instance, the new @polynom directory could be a subdirectory of MATLAB's working directory or your own personal directory that has been added to the search path.

## Adding the Class Directory to the MATLAB Path

After creating the class directory, you need to update the MATLAB path sothat MATLAB can locate the class source files. The class directory should not be directly on the MATLAB path. Instead, you should add the parent directory to the MATLAB path. For example, if the @polynom class directory is located at
c: \my_classes \@polynom
you add the class directory to the MATLAB path with the addpath command

```
addpath c:\my_classes;
```

If you create a class directory with the same name as another class, MATLAB treats the two class directories as a single directory when locating class methods. F or more information, see "How MATLAB Determines Which Method to Call" on page 22-67.

## Data Structure

One of the first steps in the design of a new class is the choice of the data structure to be used by the class. Objects are stored in MATLAB structures. The fields of the structure, and the details of operations on the fields, are visible only within the methods for the class. The design of the appropriate data structure can affect the performance of the code.

## Tips for C++ and Java Programmers

If you are accustomed to programming in other object-oriented languages, such as $C+$ or J ava, you will find that the MATLAB programming language differs from these languages in some important ways:

- In MATLAB, method dispatching is not syntax based, as it is in C++ and J ava. When the argument list contains objects of equal precedence, MATLAB uses the left-most object to select the method to call.
- In MATLAB, there is no equivalent to a destructor method. To remove an object from the workspace, use the clear function.
- Construction of MATLAB data types occurs at runtime rather than compile time. Y ou register an object as belonging to a class by calling the class function.
- When using inheritance in MATLAB, the inheritance relationship is established in the child class by creating the parent object, and then calling the class function. For more information on writing constructors for inheritance relationships, see "Building on Other Classes" on page 22-35.
- When using inheritance in MATLAB, the child object contains a parent object in a property with the name of the parent class.
- In MATLAB, there is no passing of variables by reference. When writing methods that update an object, you must pass back the updated object and use an assignment statement. For instance, this call to the set method updates the name field of the object A and returns the updated object.

```
A = set(A,'name','John Smith');
```

- In MATLAB, there is no equivalent to an abstract class.
- In MATLAB, there is no equivalent to the C++scoping operator.
- In MATLAB, there is no virtual inheritance or virtual base classes.
- In MATLAB, there is no equivalent to $C+$ templates.

## Designing User Classes in MATLAB

This section discusses how to approach the design of a class and describes the basic set of methods that should be included in a class.

## The MATLAB Canonical Class

When you design a MATLAB class, you should include a standard set of methods that enable the class to behave in a consistent and logical way within the MATLAB environment. Depending on the nature of the class you are defining, you may not need to include all of these methods and you may include a number of other methods to realize the class's design goals.

This table lists the basic methods included in MATLAB classes.

| Class Method | Description |
| :--- | :--- |
| class constructor | Creates an object of the class |
| display | Called whenever MATLAB displays the contents <br> of an object (e.g., when an expression is entered <br> without terminating with a semicolon) |
| set and get | Accesses class properties |
| subsref and subsasgn | E nables indexed reference and assignment for <br> user objects |
| end | Supports end syntax in indexing expressions <br> using an object; e.g., A(1: end) |
| subsindex | Supports using an object in indexing expressions |
| converters like double <br> and char | Methods that convert an object to a MATLAB <br> data type |

The following sections discuss the implementation of each type of method, as well as providing references to examples used in this chapter.

## The Class Constructor Method

The @directory for a particular class must contain an M-file known as the constructor for that class. The name of the constructor is the same as the name of the directory (excluding the @prefix and .m extension) that defines the name of the class. The constructor creates the object by initializing the data structure and instantiating an object of the class.

## Guidelines for Writing a Constructor

Class constructors must perform certain functions so that objects behave correctly in the MATLAB environment. In general, a class constructor must handle three possible combinations of input arguments:

- No input arguments
- An object of the same class as an input argument
- The input arguments used to create an object of the class (typically data of some kind)

No Input Arguments. If there are no input arguments, the constructor should create a default object. Since there are no inputs, you have no data from which to create the object, so you simply initialize the object's data structures with empty or default values, call the class function to instantiate the object, and return the object as the output argument. Support for this syntax is required for two reasons:

- When loading objects into the workspace, the load function calls the class constructor with no arguments.
- When creating arrays of objects, MATLAB calls the class constructor to add objects to the array.

Object Input Argument. If the first input argument in the argument list is an object of the same class, the constructor should simply return the object. Use the isa function to determine if an argument is a member of a class. See "Overloading the + Operator" on page 22-29 for an example of a method that uses this constructor syntax.

Data Input A rguments. If the input arguments exist and are not objects of the same class, then the constructor creates the object using the input data. Of course, as in any function, you should perform proper argument checking in your constructor function. A typical approach is to use a varargin input
argument and a switch statement to control program flow. This provides an easy way to accommodate the three cases: no inputs, object input, or the data inputs used to create an object.

It is in this part of the constructor that you assign values to the object's data structure, call the class function to instantiate the object, and return the object as the output argument. If necessary, place the object in an object hierarchy using the superiorto and inferiorto functions.

## Using the class Function in Constructors

Within a constructor method, you use the class function to associate an object structure with a particular class. This is done using an internal class tag that is only accessible using the class and isa functions. For example, this call to the class function identifies the object $p$ to be of type polynom.
p = class(p,'polynom');

## Examples of Constructor Methods

See the following sections for examples of constructor methods:

- "The Polynom Constructor Method" on page 22-24
- "The Asset Constructor Method" on page 22-39
- "The Stock Constructor Method" on page 22-46
- "The Portfolio Constructor Method" on page 22-55

## Identifying Objects Outside the Class Directory

The class and isa functions used in constructor methods can also be used outside of the class directory. The expression

```
isa(a,'class_name');
```

checks whether a is an object of the specified class. For example, if $p$ is a polynom object, each of the following expressions is true.

```
isa(pi,'double');
isa('hello','char');
isa(p,'polynom');
```

Outside of the class directory, the class function takes only one argument (it is only within the constructor that class can have more than one argument).

The expression
class(a)
returns a string containing the class name of a. For example,
class(pi),
class('hello'),
class(p)
return
'double',
'char',
'polynom'
Use the whos function to see what objects are in the MATLAB workspace.
whos

| Name | Size | Bytes Class |
| :--- | :--- | :--- |
| p | $1 \times 1$ | 156 polynom object |

## The display Method

MATLAB calls a method named display whenever an object is the result of a statement that is not terminated by a semicolon. For example, creating the variable a, which is a double, calls MATLAB's display method for doubles.
$\mathrm{a}=5$
a =
5
You should define a display method so MATLAB can display values on the command line when referencing objects from your class. In many classes, display can simply print the variable name, and then use the char converter method to print the contents or value of the variable, since MATLAB displays output as strings. Y ou must define the char method to convert the object's data to a character string.

## Examples of display Methods

See the following sections for examples of display methods:

- "The Polynom display Method" on page 22-28
- "The Asset display Method" on page 22-44
- "The Stock display Method" on page 22-52
- "The Portfolio display Method" on page 22-56

## Accessing Object Data

Y ou need to write methods for your class that provide access to an object's data. Accessor methods can use a variety of approaches, but all methods that change object data always accept an object as an input argument and return a new object with the data changed. This is necessary because MATLAB does not support passing arguments by reference (i.e., pointers). Functions can change only their private, temporary copy of an object. Therefore, to change an existing object, you must create a new one, and then replace the old one.

The following sections provide more detail about implementation techniques for the set, get, subsasgn, and subsref methods.

## The set and get Methods

The set and get methods provide a convenient way to access object data in certain cases. F or example, suppose you have created a class that defines an arrow object that MATLAB can display on graphs (perhaps composed of existing MATLAB line and patch objects).

To produce a consistent interface, you could define set and get methods that operate on arrow objects the way the MATLAB set and get functions operate on built-in graphics objects. The set and get verbs convey what operations they perform, but insulate the user from the internals of the object.

## Examples of set and get Methods

See the following sections for examples of set and get methods:

- "The Asset get Method" on page 22-41 and "The Asset set Method" on page 22-41
- "The Stock get Method" on page 22-48 and "The Stock set Method" on page 22-48

## Property Name Methods

As an alternative to a general set method, you can write a method to handle the assignment of an individual property. The method should have the same name as the property name.

F or example, if you defined a class that creates objects representing employee data, you might have a field in an employee object called salary. Y ou could then define a method called salary.m that takes an employee object and a value as input arguments and returns the object with the specified value set.

## Indexed Reference Using subsref and subsasgn

User classes implement new data types in MATLAB. It is useful to be able to access object data via an indexed reference, as is possible with MATLAB's built-in data types. F or example, if A is an array of class double, A(i) returns the $i^{\text {th }}$ element of $A$.

As the class designer, you can decide what an index reference to an object means. F or example, suppose you define a class that creates pol ynomial objects and these objects contain the coefficients of the polynomial.
An indexed reference to a polynomial object,
p(3)
could return the value of the coefficient of $x^{3}$, the value of the polynomial at $x=3$, or something different depending on the intended design.

You define the behavior of indexing for a particular class by creating two class methods - subsref and subsasgn. MATLAB calls these methods whenever a subscripted reference or assignment is made on an object from the class. If you do not define these methods for a class, indexing is undefined for objects of this class.

In general, the rules for indexing objects are the same as the rules for indexing structure arrays. For details, see "Structures" on page 20-4.

## Handling Subscripted Reference

The use of a subscript or field designator with an object on the right-hand side of an assignment statement is known as a subscripted reference. MATLAB calls a method named subsref in these situations. Object subscripted references can be of three forms - an array index, a cell array index, and a structure field
name:
A(I)
A $\{\mathrm{I}\}$
A.field

Each of these results in a call by MATLAB to the subsref method in the class directory. MATLAB passes two arguments to subsref.
$B=\operatorname{subsref}(A, S)$
The first argument is the object being referenced. The second argument, s , is a structure array with two fields:

- S.type is a string containing ' ( ) ', '\{ \}', or ' . ' specifying the subscript type. The parentheses represent a numeric array; the curly braces, a cell array; and the dot, a structure array.
- S. subs is a cell array or string containing the actual subscripts. A col on used as a subscript is passed as the string ': '.

For instance, the expression
$A(1: 2,:)$
causes MATLAB to call subsref( $\mathrm{A}, \mathrm{S}$ ), where S is a 1-by-1 structure with
S.type = '()'
S.subs = \{1:2,':'\}

Similarly, the expression
A\{1:2\}
uses
S.type ='\{\}'
S.subs = \{1:2\}

The expression
A.field
calls subsref $(A, S)$ where
S.type = '.'
S.subs = 'field'

These simple calls are combined for more complicated subscripting expressions. In such cases, length (S) is the number of subscripting levels. For example,

$$
A(1,2) . \text { name }(3: 4)
$$

calls subsref $(A, S)$, where $S$ is a 3-by-1 structure array with the values:

```
S(1).type = '()' S(2).type = '.' S(3).type = '()'
S(1).subs = '{1,2}' S(2).subs = 'name' S(3).subs = '{3:4}'
```

## How to W rite subsref

The subsref method must interpret the subscripting expressions passed in by MATLAB. A typical approach is to use the switch statement to determine the type of indexing used and to obtain the actual indices. The following three code fragments illustrate how to interpret the input arguments. In each case, the function must return the value $B$.

```
For an array index:
```

```
switch S.type
```

switch S.type
case '()'
case '()'
B = A(S.subs{:});
B = A(S.subs{:});
end

```
end
```

For a cell array:

```
switch S.type
case '{}'
    B = A(S.subs{:}); % A is a cell array
end
```

For a structure array:

```
switch S.type
case '.'
    switch S.subs
    case 'field1'
        B = A.field1;
    case 'field2'
            B = A.field2;
        end
end
```

## Examples of the subsref Method

See the following sections for examples of the subsref method:

- "The Polynom subsref Method" on page 22-28
- "The Asset subsref Method" on page 22-42
- "The Stock subsref Method" on page 22-49
- "The Portfolio subsref Method" on page 22-64

## Handling Subscripted Assignment

The use of a subscript or field designator with an object on the left-hand side of an assignment statement is known as a subscripted assignment. MATLAB calls a method named subsasgn in these situations. Object subscripted assignment can be of three forms - an array index, a cell array index, and a structure field name.

$$
\begin{aligned}
& A(I)=B \\
& A\{I\}=B \\
& A . f i e l d=B
\end{aligned}
$$

Each of these results in a call to subsasgn of the form

$$
A=\operatorname{subsasgn}(A, S, B)
$$

The first argument, A , is the object being referenced. The second argument, s , has the same fields as those used with subsref. The third argument, $B$, is the new value.

## Examples of the subsasgn Method

See the following sections for examples of the subsasgn method:

- "The Asset subsasgn Method" on page 22-43
- "The Stock subsasgn Method" on page 22-51

## Object Indexing Within Methods

If a subscripted reference is made within a class method, MATLAB uses its built-in subsref function to access data within the method's own class. If the method accesses data from another class, MATLAB calls the overloaded subsref function in that class. The same holds truefor subscripted assignment and subsasgn.

The following example shows a method, testref, that is defined in the class, employee. This method makes a reference to a field, address, in an object of its own class. For this, MATLAB uses the built-in subsref function. It also references the same field in another class, this time using the overloaded subsref of that class.

```
% ---- EMPLOYEE class method: testref.m ----
function testref(myclass,otherclass)
```

```
myclass.address % use built-in subsref
otherclass.address % use overloaded subsref
```

The example creates an employee object and a company object.

```
empl = employee('Johnson','Chicago');
comp = company('The MathWorks','Natick');
```

The employee class method, testref, is called. MATLAB uses an overloaded subsref only to access data outside of the method's own class.

```
testref(empl,comp)
ans = % built-in subsref was called
    Chicago
ans = % @company\subsref was called
Executing @company\subsref ...
    Natick
```

## Defining end Indexing for an Object

When you use end in an object indexing expression, MATLAB calls the object's end class method. If you want to be able to use end in indexing expressions involving objects of your class, you must define an end method for your class.

The end method has the calling sequence

```
end(a,k,n)
```

where a is the user object, k is the index in the expression where the end syntax is used, and n is the total number of indices in the expression.

For example, consider the expression

```
A(end-1,:)
```

MATLAB calls the end method defined for the object A using the arguments

```
end(A, 1,2)
```

That is, the end statement occurs in the first index element and there are two index elements. The class method for end must then return the index value for the last element of the first dimension. When you implement the end method for your class, you must ensure it returns a value appropriate for the object.

## Indexing an Object with Another Object

When MATLAB encounters an object as an index, it calls the subsindex method defined for the object. For example, suppose you have an object a and you want to use this object to index into another object b.

```
c = b(a);
```

A subsindex method might do something as simple as convert the object to double format to be used as an index, as shown in this sample code.

```
function d = subsindex(a)
%SUBSINDEX
% convert the object a to double format to be used
% as an index in an indexing expression
d = double(a);
```

subsindex values are 0-based, not 1-based.

## Converter Methods

A converter method is a class method that has the samename as another class, such as char or double. Converter methods accept an object of one class as input and return an object of another class. Converters enable you to:

- Use methods defined for another class
- Ensure that expressions involving objects of mixed class types execute properly

A converter function call is of the form

```
b = class_name(a)
```

where $a$ is an object of a class other than class_name. In this case, MATLAB looks for a method called class_name in the class directory for object a. If the input object is already of type class_name, then MATLAB calls the constructor, which just returns the input argument.

## Examples of Converter Methods

See the following sections for examples of converter methods:

- "The Polynom to Double Converter" on page 22-25
- "The Polynom to Char Converter" on page 22-26

## Overloading Operators and Functions

In many cases, you may want to change the behavior of MATLAB's operators and functions for cases when the arguments are objects. You can accomplish this by overloading the relevant functions. Overloading enables a function to handle different types and numbers of input arguments and perform whatever operation is appropriate for the highest-precedence object. See "Object Precedence" on page 22-65 for more information on object precedence.

## Overloading Operators

Each built-in MATLAB operator has an associated function name (e.g., the + operator has an associated plus.m function). Y ou can overload any operator by creating an M -file with the appropriate name in the class directory. For example, if either $p$ or $q$ is an object of type class_name, the expression

$$
p+q
$$

generates a call to a function @class_name/plus.m, if it exists. If p and q are both objects of different classes, then MATLAB applies the rules of precedence to determine which method to use.

## Examples of 0 verloaded 0 perators

See the following sections for examples of overloaded operators:

- "Overloading the + Operator" on page 22-29
- "Overloading the - Operator" on page 22-30
- "Overloading the $*$ Operator" on page 22-30

The following table lists the function names for most of MATLAB's operators.

| Operation | M-File | Description |
| :---: | :---: | :---: |
| $\mathrm{a}+\mathrm{b}$ | plus(a,b) | Binary addition |
| a - b | minus(a, b) | Binary subtraction |
| -a | uminus (a) | Unary minus |
| +a | uplus(a) | Unary plus |
| a.*b | times(a, b) | Element-wise multiplication |
| a*b | mtimes ( $\mathrm{a}, \mathrm{b}$ ) | Matrix multiplication |
| a./b | rdivide(a, b) | Right element-wise division |
| a. 1 b | ldivide(a, b) | Left element-wise division |
| $a / b$ | mrdivide (a, b) | Matrix right division |
| $a \backslash b$ | mldivide(a, b) | Matrix left division |
| a.^b | power ( $\mathrm{a}, \mathrm{b}$ ) | Element-wise power |
| $a^{\wedge}{ }^{\text {b }}$ | mpower ( $\mathrm{a}, \mathrm{b}$ ) | Matrix power |
| $\mathrm{a}<\mathrm{b}$ | $l t(a, b)$ | Less than |
| $a>b$ | gt (a, b ) | Greater than |
| $\mathrm{a}<=\mathrm{b}$ | le( $\mathrm{a}, \mathrm{b}$ ) | Less than or equal to |
| $\mathrm{a}>=\mathrm{b}$ | ge( $\mathrm{a}, \mathrm{b}$ ) | Greater than or equal to |
| $\mathrm{a} \sim=\mathrm{b}$ | ne( $\mathrm{a}, \mathrm{b}$ ) | Not equal to |
| $\mathrm{a}==\mathrm{b}$ | eq(a,b) | Equality |
| $a \& b$ | and ( $a, b$ ) | Logical AND |
| a \| b | or ( $\mathrm{a}, \mathrm{b}$ ) | Logical OR |
| $\sim$ a | not(a) | Logical NOT |

| Operation | M-File | Description |
| :---: | :---: | :---: |
| $\begin{aligned} & a: d: b \\ & a: b \end{aligned}$ | $\begin{aligned} & \text { colon }(a, d, b) \\ & \text { colon }(a, b) \end{aligned}$ | Colon operator |
| $\mathrm{a}^{\prime}$ | ctranspose(a) | Complex conjugate transpose |
| a. ${ }^{\prime}$ | transpose(a) | M atrix transpose |
| command window output | display(a) | Display method |
| [ a b] | horz- $\operatorname{cat}(a, b, \ldots)$ | Horizontal concatenation |
| [a; b] | vert- <br> cat (a,b,...) | Vertical concatenation |
| $a(s 1, s 2, \ldots s n)$ | subsref( $\mathrm{a}, \mathrm{s}$ ) | Subscripted reference |
| $a(s 1, \ldots, s n)=b$ | subsasgn(a, s, b) | Subscripted assignment |
| b (a) | subsindex(a) | Subscript index |

## Overloading Functions

You can overload any function by creating a function of the same name in the class directory. When a function is invoked on an object, MATLAB al ways looks in the class directory before any other location on the search path. To overload the plot function for a class of objects, for example, simply place your version of plot.m in the appropriate class directory.

## Examples of 0 verloaded Functions

See the following sections for examples of overloaded functions:

- "Overloading Functions for the Polynom Class" on page 22-31
- "The Portfolio pie3 Method" on page 22-57

## Example - A Polynomial Class

This example implements a MATLAB data type for polynomials by defining a new class called polynom. The class definition specifies a structure for data storage and defines a directory (@polynom) of methods that operate on polynom objects.

## Polynom Data Structure

The polynom class represents a polynomial with a row vector containing the coefficients of powers of the variable, in decreasing order. Therefore, a polynom object p is a structure with a single field, p.c, containing the coefficients. This field is accessible only within the methods in the @polynom directory.

## Polynom Methods

To create a class that is well behaved within the MATLAB environment and provides useful functionality for a polynomial data type, the polynom class implements the following methods:

- A constructor method polynom.m
- A polynom to double converter
- A polynom to char converter
- A display method
- A subsref method
- Overloaded +, -, and * operators
- Overloaded roots, polyval, plot, and diff functions

## The Polynom Constructor Method

Here is the polynom class constructor, @polynom/polynom.m.

```
function p = polynom(a)
%POLYNOM Polynomial class constructor.
% p = POLYNOM(v) creates a polynomial object from the vector v,
% containing the coefficients of descending powers of x.
if nargin == 0
    p.c = [];
    p = class(p,'polynom');
```

```
elseif isa(a,'polynom')
    p = a;
else
    p.c = a(:).';
    p = class(p,'polynom');
end
```

## Constructor Calling Syntax

You can call the polynom constructor method with one of three different arguments:

- Nol nput Argument - If you call the constructor function with no arguments, it returns a polynom object with empty fields.
- Input Argument is an Object - If you call the constructor function with an input argument that is already a polynom object, MATLAB returns theinput argument. The isa function (pronounced "is a") checks for this situation.
- Input Argument is a coefficient vector - If the input argument is a variable that is not a polynom object, reshape it to be a row vector and assign it to the .c field of the object's structure. The class function creates the polynom object, which is then returned by the constructor.

An example use of the polynom constructor is the statement

```
p = polynom([1 0 -2 -5])
```

This creates a polynomial with the specified coefficients.

## Converter Methods for the Polynom Class

A converter method converts an object of one class to an object of another class. Two of the most important converter methods contained in MATLAB classes are double and char. Conversion to double produces MATLAB's traditional matrix, although this may not be appropriate for some classes. Conversion to char is useful for producing printed output.

## The Polynom to Double Converter

The double converter method for the polynom class is a very simple M-file, @polynom/double.m, which merely retrieves the coefficient vector.

```
function c = double(p)
% POLYNOM/DOUBLE Convert polynom object to coefficient vector.
% c = DOUBLE(p) converts a polynomial object to the vector c
% containing the coefficients of descending powers of x.
c = p.c;
```

On the object $p$,

```
p = polynom([[1 0 -2 -5])
```

the statement

```
double(p)
```

returns
ans $=$
$\begin{array}{llll}1 & 0 & -2 & -5\end{array}$

## The Polynom to Char Converter

The converter to char is a key method because it produces a character string involving the powers of an independent variable, $x$. Therefore, once you have specified x , the string returned is a syntactically correct MATLAB expression, which you can then evaluate.

Here is @polynom/char.m.

```
function s = char(p)
% POLYNOM/CHAR
% CHAR(p) is the string representation of p.c
if all(p.c == 0)
    s = '0';
else
        d = length(p.c) - 1;
        s = [];
        for a = p.c;
            if a ~= 0;
                    if ~isempty(s)
                            if a > 0
                        s = [s ' + '];
                        else
                        s = [s ' - '];
                        a = -a;
```

```
            end
            end
        if a ~= 1 | d == 0
        s = [s num2str(a)];
        if d > 0
            s = [s '*'];
            end
        end
        if d >= 2
            s = [s 'x^' int2str(d)];
        elseif d == 1
            s = [s 'x'];
            end
            end
        d = d - 1;
    end
end
```

## Evaluating the Output

If you create the polynom object p

```
p = polynom([1 0 -2 -5]);
```

and then call the char method on $p$

```
    char(p)
```

MATLAB produces the result
ans $=$
$x^{\wedge} 3-2 * x-5$

The value returned by char is a string that you can pass to eval once you have defined a scalar value for $x$. For example,

```
x = 3;
eval(char(p))
ans =
    1 6
```

See "The Polynom subsref Method" on page 22-28 for a better method to evaluate the polynomial.

## The Polynom display Method

Here is @polynom/display.m. This method relies on the char method to produce a string representation of the polynomial, which is then displayed on the screen. This method produces output that is the same as standard MATLAB output. That is, the variable name is displayed followed by an equal sign, then a blank line, then a new line with the value.

```
function display(p)
% POLYNOM/DISPLAY Command window display of a polynom
disp(' ');
disp([inputname(1),' = '])
disp(' ');
disp([' ' char(p)])
disp(' ');
```

The statement

```
p = polynom([1 0 -2 -5])
```

creates a polynom object. Since the statement is not terminated with a semicol on, the resulting output is

```
p =
    x^3 - 2*x - 5
```

## The Polynom subsref Method

Suppose the design of the polynom class specifies that a subscripted reference to a polynom object causes the polynomial to be evaluated with the value of the independent variable equal to the subscript. That is, for a polynom object $p$,

```
p = polynom([1 0 -2 -5]);
```

the following subscripted expression returns the value of the polynomial at $x=3$ and $x=4$.

```
p([3 4])
```

ans $=$
$16 \quad 51$

## subsref Implementation Details

This implementation takes advantage of the char method already defined in the polynom class to produce an expression that can then be evaluated.

```
function b = subsref(a,s)
% SUBSREF
switch s.type
case '()'
    ind = s.subs{:};
    for k = 1:length(ind)
        b(k) = eval(strrep(char(a),'x',num2str(ind(k))));
    end
otherwise
    error('Specify value for x as p(x)')
end
```

Once the polynomial expression has been generated by the char method, the strrep function is used to swap the passed in value for the character $x$. The eval function then evaluates the expression and returns the value in the output argument.

## Overloading Arithmetic Operators for polynom

Several arithmetic operations are meaningful on polynomials and should be implemented for the polynom class. When overloading arithmetic operators, keep in mind what data types you want to operate on. In this section, the plus, minus, and mtimes methods are defined for the polynom class to handle addition, subtraction, and multiplication on polynom/polynom and polynom/ double combinations of operands.

## 0 verloading the +0 perator

If either $p$ or $q$ is a polynom, the expression
$p+q$
generates a call to a function @polynom/plus.m, if it exists (unless por q is an object of a higher precedence, as described in "Object Precedence" on page 22-65).

The following M-file redefines the + operator for the polynom class.

```
function r = plus(p,q)
% POLYNOM/PLUS Implement p + q for polynoms.
p = polynom(p);
q = polynom(q);
k = length(q.c) - length(p.c);
r = polynom([zeros(1,k) p.c] + [zeros(1,-k) q.c]);
```

The function first makes sure that both input arguments are polynomials. This ensures that expressions such as

```
p + 1
```

that involve both a polynom and a double, work correctly. The function then accesses the two coefficient vectors and, if necessary, pads one of them with zeros to make them the same length. The actual addition is simply the vector sum of the two coefficient vectors. Finally, the function calls the polynom constructor a third time to create the properly typed result.

## $O$ verloading the -0 perator

You can implement the overloaded minus operator (-) using the same approach as the plus (+) operator. MATLAB calls @polynom/minus.m to compute p-q.

```
function r = minus(p,q)
% POLYNOM/MINUS Implement p - q for polynoms.
p = polynom(p);
q = polynom(q);
k = length(q.c) - length(p.c);
r = polynom([zeros(1,k) p.c] - [zeros(1,-k) q.c]);
```

## $O$ verloading the $* O$ perator

MATLAB calls the method @polynom/mtimes.m to compute the product $p * q$. The letter $m$ at the beginning of the function name comes from the fact that it is overloading MATLAB's matrix multiplication. Multiplication of two polynomials is simply the convolution of their coefficient vectors.

```
function r = mtimes(p,q)
% POLYNOM/MTIMES Implement p * q for polynoms.
p = polynom(p);
q = polynom(q);
r = polynom(conv(p.c,q.c));
```

## Using the $\mathbf{O}$ verloaded $\mathbf{O}$ perators

Given the polynom object

$$
p=\operatorname{polynom([\begin{array} {llll}
{1}&{0}&{-2}&{-5}
\end{array} ])}
$$

MATLAB calls these two functions @polynom/plus.m and @polynom/mtimes.m when you issue the statements

$$
\begin{aligned}
& q=p+1 \\
& r=p^{*} q
\end{aligned}
$$

to produce
$\mathrm{q}=$
$x^{\wedge} 3-2^{*} x-4$
$r=$
$x^{\wedge} 6-4 * x^{\wedge} 4-9 * x^{\wedge} 3+4 * x^{\wedge} 2+18 * x+20$

## Overloading Functions for the Polynom Class

MATLAB already has several functions for working with polynomials represented by coefficient vectors. They should be overloaded to al so work with the new polynom object. In many cases, the overloading methods can simply apply the original function to the coefficient field.

## O verloading roots for the Polynom Class

The method @polynom/roots.m finds the roots of polynom objects.

```
function r = roots(p)
% POLYNOM/ROOTS. ROOTS(p) is a vector containing the roots of p.
r = roots(p.c);
```

The statement
roots (p)
results in
ans $=$

```
2.0946
    -1.0473 + 1.1359i
    -1.0473 - 1.1359i
```

## Overloading polyval for the Polynom Class

The function polyval evaluates a polynomial at a given set of points.
@polynom/polyval.m uses nested multiplication, or Horner's method to reduce the number of multiplication operations used to compute the various powers of x .

```
function y = polyval(p,x)
% POLYNOM/POLYVAL POLYVAL(p,x) evaluates p at the points x.
y = 0;
for a = p.c
    y = y.*x + a;
end
```

## Overloading plot for the Polynom Class

The overloaded plot function uses both root and polyval. Thefunction selects the domain of the independent variable to be slightly larger than an interval containing all real roots. Then polyval is used to evaluate the polynomial at a few hundred points in the domain.

```
function plot(p)
% POLYNOM/PLOT PLOT(p) plots the polynom p.
r = max(abs(roots(p)));
x = (-1.1:0.01:1.1)*r;
y = polyval(p,x);
plot(x,y);
title(char(p))
grid on
```

## O verloading diff for the Polynom Class

The method @polynom/diff.m differentiates a polynomial by reducing the degree by 1 and multiplying each coefficient by its original degree.

```
function q = diff(p)
% POLYNOM/DIFF DIFF(p) is the derivative of the polynom p.
c = p.c;
d = length(c) - 1; % degree
q = polynom(p.c(1:d).*(d:-1:1));
```

## Listing Class Methods

The function call

```
    methods('class_name')
```

or its command form

```
methods class_name
```

shows all the methods available for a particular class. For the polynom example, the output is

```
methods polynom
Methods for class polynom:
char display minus plot polynom roots
diff double mtimes plus polyval subsref
```

Plotting the two polynom objects $x$ and $p$ calls most of these methods.

```
x = polynom([1 0]);
p = polynom([1 0 -2 -5]);
plot(diff(p*p + 10*p + 20*x) - 20)
```

## Building on Other Classes

A MATLAB object can inherit properties and behavior from another MATLAB object. When one object (the child) inherits from another (the parent), the child object includes all the fields of the parent object and can call the parent's methods. The parent methods can access those fields that a child object inherited from the parent class, but not fields new to the child class.

Inheritance is a key feature of object-oriented programming. It makes it easy to reuse code by allowing child objects to take advantage of code that exists for parent objects. Inheritance enables a child object to behave exactly like a parent object, which facilitates the development of related classes that behave similarly, but are implemented differently.
There are two kinds of inheritance:

- Simple inheritance, in which a child object inherits characteristics from one parent class.
- Multiple inheritance, in which a child object inherits characteristics from more than one parent class.

This section also discusses a related topic, aggregation. Aggregation allows one object to contain another object as one of its fields.

## Simple Inheritance

A class that inherits attributes from a single parent class, and adds new attributes of its own, uses simple inheritance. Inheritance implies that objects bel onging to the child class have the same fields as the parent class, as well as additional fields. Therefore, methods associated with the parent class can operate on objects belonging to the child class. Themethods associated with the child class, however, cannot operate on objects belonging to the parent class. Y ou cannot access the parent's fields directly from the child class; you must use access methods defined for the parent.

The constructor function for a class that inherits the behavior of another has two special characteristics:

- It calls the constructor function for the parent class to create the inherited fields.
- The calling syntax for the class function is slightly different, reflecting both the child class and the parent class.

The general syntax for establishing a simpleinheritance relationship using the class function is

```
child_obj = class(child_obj,'child_class',parent_obj);
```

Simple inheritance can span more than one generation. If a parent class is itself an inherited class, the child object will automatically inherit from the grandparent class.

## Visibility of Class Properties and Methods

The parent class does not have knowledge of the child properties or methods. The child class cannot access the parent properties directly, but must use parent access methods (e.g., get or subsref method) to access the parent properties. From the child class methods, this access is accomplished via the parent field in the child structure. F or example, when a constructor creates a child object c,

```
c = class(c,'child_class_name',parent_object);
```

MATLAB automatically creates a field, c.parent_class_name, in the object's structure that contains the parent object. You could then have a statement in the child's display method that calls the parent's display method.
display(c.parent_class_name)
See "Designing the Stock Class" on page 22-45 for examples that use simple inheritance.

## Multiple Inheritance

In the multipleinheritance case, a class of objects inherits attributes from more than one parent class. The child object gets fields from all the parent classes, as well as fields of its own.

Multiple inheritance can encompass more than one generation. For example, each of the parent objects could have inherited fields from multiple grandparent objects, and so on. Multiple inheritance is implemented in the constructors by calling class with more than three arguments.

```
obj = class(structure,'class_name',parent1,parent2,...)
```

You can append as many parent arguments as desired to the class input list.
Multiple parent classes can have associated methods of the same name. In this case, MATLAB calls the method associated with the parent that appears first in the class function call in the constructor function. There is no way to access subsequent parent function of this name.

## Aggregation

In addition to standard inheritance, MATLAB objects support containment or aggregation. That is, one object can contain (embed) another object as one of its fields. F or example, a rational object might usetwo polynom objects, onefor the numerator and one for the denominator.

You can call a method for the contained object only from within a method for the outer object. When determining which version of a function to call, MATLAB considers only the outermost containing class of the objects passed as arguments; the classes of any contained objects are ignored.
See "Example - The Portfolio Container" on page 22-54 for an example of aggregation.

## Example - Assets and Asset Subclasses

As an example of simple inheritance, consider a general asset class that can be used to represent any item that has monetary value. Some examples of an asset are: stocks, bonds, savings accounts, and any other piece of property. In designing this collection of classes, the asset class holds the data that is common to all of the specialized asset subclasses. The individual asset subclasses, such as the stock class, inherit the asset properties and contribute additional properties. The subclasses are "kinds of" assets.

## Inheritance Model for the Asset Class

An example of a simple inheritance relationship using an asset parent class is shown in this diagram.

As shown in the diagram, the stock, bond, and savings classes inherit structure fields from the asset class. In this example, the asset class is used to provide storage for data common to all subclasses and to share asset methods with these subclasses. This example shows how to implement the
asset and stock classes. The bond and savings classes can be implemented in a way that is very similar to the stock class, as would other types of asset subclasses.

## Asset Class Design

The asset class provides storage and access for information common to all asset children. It is not intended to be instantiated directly, so it does not require an extensive set of methods. To serve its purpose, the class needs to contain the following methods:

- Constructor
- get and set
- subsref and subsasgn
- display

## Other Asset Methods

The asset class provides inherited data storage for its child classes, but is not instanced directly. The set, get, and display methods provide access to the stored data. It is not necessary to implement the full complement of methods for asset objects (such as converters, end, and subsindex) since only the child classes access the data.

## The Asset Constructor Method

The asset class is based on a structure array with four fields:

- descriptor - Identifier of the particular asset (e.g., stock name, savings account number, etc.)
- date - The date the object was created (calculated by the date command)
- type - The type of asset (e.g., savings, bond, stock)
- current_value - The current value of the asset (calculated from subclass data)

This information is common to asset child objects (stock, bond, and savings), so it is handled from the parent object to avoid having to define the same fiel ds in each child class. This is particularly hel pful as the number of child classes increases.

```
function a = asset(varargin)
% ASSET Constructor function for asset object
% a = asset(descriptor, current_value)
switch nargin
case 0
% if no input arguments, create a default object
    a.descriptor = 'none';
    a.date = date;
    a.type = 'none';
    a.current_value = 0;
    a = class(a,'asset');
case 1
% if single argument of class asset, return it
        if (isa(varargin{1},'asset'))
            a = varargin{1};
        else
            error('Wrong argument type')
        end
case 2
% create object using specified values
        a.descriptor = varargin{1};
        a.date = date;
        a.type = varargin{2};
        a.current_value = varargin{3};
        a = class(a,'asset');
otherwise
        error('Wrong number of input arguments')
end
```

The function uses a switch statement to accommodate three possible scenarios:

- Called with no arguments, the constructor returns a default asset object.
- Called with one argument that is an asset object, the object is simply returned.
- Called with two arguments (subclass descriptor, and current value), the constructor returns a new asset object.

The asset constructor method is not intended to be called directly; it is called from the child constructors since its purpose is to provide storage for common data.

## The Asset get Method

The asset class needs methods to access the data contained in asset objects. The following function implements a get method for the class. It uses capitalized property names rather than literal field names to provide an interface similar to other MATLAB objects.

```
function val = get(a,prop_name)
% GET Get asset properties from the specified object
% and return the value
switch prop_name
case 'Descriptor'
    val = a.descriptor;
case 'Date'
    val = a.date;
case 'CurrentValue'
    val = a.current_value;
otherwise
    error([prop_name,' Is not a valid asset property'])
end
```

This function accepts an object and a property name and uses a switch statement to determine which field to access. This method is called by the subclass get methods when accessing the data in the inherited properties. See "The Stock get Method" on page 22-48 for an example.

## The Asset set Method

The asset class set method is called by subclass set methods. This method accepts an asset object and variable length argument list of property name/ property value pairs and returns the modified object.

```
function a = set(a,varargin)
% SET Set asset properties and return the updated object
property_argin = varargin;
while length(property_argin) >= 2,
    prop = property_argin{1};
    val = property_argin{2};
```

```
    property_argin = property_argin(3:end);
switch prop
case 'Descriptor'
    a.descriptor = val;
case 'Date'
    a.date = val;
case 'CurrentValue'
    a.current_value = val;
otherwise
    error('Asset properties: Descriptor, Date, CurrentValue')
end
end
```

Subclass set methods call the asset set method and require the capability to return the modified object since MATLAB does not support passing arguments by reference. See "The Stock set Method" on page 22-48 for an example.

## The Asset subsref Method

The subsref method provides access to the data contained in an asset object using one-based numeric indexing and structure field name indexing. The outer switch statement determines if the index is a numeric or field name syntax. The inner switch statements map the index to the appropriate value.

MATLAB calls subsref whenever you make a subscripted reference to an object (e.g., A(i), A\{i\}, or A.fieldname).

```
function b = subsref(a,index)
%SUBSREF Define field name indexing for asset objects
switch index.type
case '()'
    switch index.subs{:}
    case 1
        b = a.descriptor;
    case 2
        b = a.date;
    case 3
        b = a.current_value;
    otherwise
        error('Index out of range')
    end
```

```
case '.'
    switch index.subs
    case 'descriptor'
        b = a.descriptor;
    case 'date'
        b = a.date;
    case 'current_value'
        b = a.current_value;
    otherwise
        error('Invalid field name')
    end
case '{}'
    error('Cell array indexing not supported by asset objects')
end
```

See the "The Stock subsref Method" on page 22-49 for an example of how the child subsref method calls the parent subsref method.

## The Asset subsasgn Method

The subsasgn method is the assignment equivalent of the subsref method. This version enables you to change the data contained in an object using one-based numeric indexing and structure field name indexing. The outer switch statement determines if the index is a numeric or field name syntax. The inner switch statements map the index value to the appropriate value in the stock structure.

MATLAB calls subsasgn whenever you execute an assignment statement (e.g., A(i) = val, A\{i\} = val, or A.fieldname = val).

```
function a = subsasgn(a,index,val)
% SUBSASGN Define index assignment for asset objects
switch index.type
case '()'
    switch index.subs{:}
    case 1
        a.descriptor = val;
    case 2
            a.date = val;
    case 3
            a.current_value = val;
```

```
    otherwise
        error('Index out of range')
    end
case '.'
    switch index.subs
    case 'descriptor'
        a.descriptor = val;
    case 'date'
        a.date = val;
    case 'current_value'
        a.current_value = val;
    otherwise
        error('Invalid field name')
    end
end
```

The subsasgn method enables you to assign values to the asset object data structure using two techniques. For example, suppose you have a child stock object s.

```
s = stock('XYZ',100,25);
```

Within stock class methods, you could change the descriptor field with either of the following statements

```
s.asset(1) = 'ABC';
```

```
s.asset.descriptor = 'ABC';
```

```
s.asset.descriptor = 'ABC';
```

or

See the "The Stock subsasgn Method" on page 22-51 for an example of how the child subsasgn method calls the parent subsasgn method.

## The Asset display Method

The asset display method is designed to be called from child-class display methods. Its purpose is to display the data it stores for the child object. The method simply formats the data for display in a way that is consistent with the formatting of the child's display method.

```
function display(a)
% DISPLAY(a) Display an asset object
```

```
stg = sprintf(...
    'Descriptor: %s\nDate: %s\nType: %s\nCurrent Value:%9.2f',...
    a.descriptor,a.date,a.current_value);
disp(stg)
```

The stock class display method can now call this method to display the data stored in the parent class. This approach isolates the stock display method from changes to the asset class. See "The Stock display Method" on page 22-52 for an example of how this method is called.

## The Asset fieldcount Method

The asset fieldcount method returns the number of fields in the asset object data structure. fieldcount enables asset child methods to determine the number of fields in the asset object during execution, rather than requiring the child methods to have knowledge of the asset class. This allows you to make changes to the number of fields in the asset class data structure without having to change child-class methods.

```
function num_fields = fieldcount(asset_obj)
% Determines the number of fields in an asset object
% Used by asset child class methods
num_fields = length(fieldnames(asset_obj));
```

The struct function converts an object to its equivalent data structure, enabling access to the structure's contents.

## Designing the Stock Class

A stock object is designed to represent one particular asset in a person's investment portfolio. This object contains two properties of its own and inherits three properties from its parent asset object.
Stock properties:

- NumberShares - The number of shares for the particular stock object.
- SharePrice - The value of each share.

Asset properties:

- Descriptor - The identifier of the particular asset (e.g., stock name, savings account number, etc.).
- Date - The date the object was created (calculated by the date command).
- CurrentValue - The current value of the asset.

Note that the property names are not actually the same as the field names of the structure array used internally by stock and asset objects. The property name interface is controlled by the stock and asset set and get methods and is designed to resemble the interface of other MATLAB object properties.

The asset field in the stock object structure contains the parent asset object and is used to access the inherited fields in the parent structure.

## Stock Class Methods

The stock class implements the following methods:

- Constructor
- get and set
- subsref and subsasgn
- display

## The Stock Constructor Method

The stock constructor creates a stock object from three input arguments:

- The stock name
- The number of shares
- The share price

The constructor must create an asset object from within the stock constructor to be able to specify it as a parent to the stock object. The stock constructor must, therefore, call the asset constructor. The class function, which is called to create the stock object, defines the asset object as the parent.
Keep in mind that the asset object is created in thetemporary workspace of the stock constructor function and is stored as a field (.asset) in the stock structure. The stock object inherits the asset fields, but the asset object is not returned to the base workspace.

```
function s = stock(varargin)
% STOCK Stock class constructor.
% s = stock(descriptor, num_shares, share_price)
switch nargin
```

```
case 0
% if no input arguments, create a default object
    s.num_shares = 0;
    s.share_price = 0;
    a = asset('none',0);
    s = class(s, 'stock',a);
case 1
% if single argument of class stock, return it
    if (isa(varargin{1},'stock'))
        s = varargin{1};
    else
            error('Input argument is not a stock object')
    end
case 3
% create object using specified values
    s.num_shares = varargin{2};
    s.share_price = varargin{3};
    a = asset(varargin{1},'stock',varargin{2} * varargin{3});
    s = class(s,'stock',a);
otherwise
    error('Wrong number of input arguments')
end
```

## Constructor Calling Syntax

The stock constructor method can be called in one of three ways:

- Nol nput Argument - If called with no arguments, the constructor returns a default object with empty fields.
- Input Argument is a Stock Object - If called with a single input argument that is a stock object, the constructor returns the input argument. A single argument that is not a stock object generates an error.
- Three Input Arguments - If therearethreeinput arguments, the constructor uses them to define the stock object.

Otherwise, if none of the above three conditions are met, return an error.
For example, this statement creates a stock object to record the ownership of 100 shares of XYZ corporation stocks with a price per share of 25 dollars.

```
XYZ_stock = stock('XYZ',100,25);
```

## The Stock get Method

The get method provides a way to access the data in the stock object using a "property name" style interface, similar to Handle Graphics. While in this example the property names are similar to the structure field name, they can be quite different. Y ou could also choose to exclude certain fields from access via the get method or return the data from the same field for a variety of property names, if such behavior suits your design.

```
function val = get(s,prop_name)
% GET Get stock property from the specified object
% and return the value. Property names are: NumberShares
% SharePrice, Descriptor, Date, CurrentValue
switch prop_name
case 'NumberShares'
    val = s.num_shares;
case 'SharePrice'
    val = s.share_price;
case 'Descriptor'
    val = get(s.asset,'Descriptor'); % call asset get method
case 'Date'
    val = get(s.asset,'Date');
case 'CurrentValue'
    val = get(s.asset,'CurrentValue');
otherwise
    error([prop_name ,'Is not a valid stock property'])
end
```

Notethat the asset object is accessed via the stock object's asset field (s. asset). MATLAB automatically creates this field when the class function is called with the parent argument.

## The Stock set Method

The set method provides a "property name" interface likethe get method. It is designed to update the number of shares, the share value, and the descriptor. The current value and the date are automatically updated.

```
function s = set(s,varargin)
% SET Set stock properties to the specified values
% and return the updated object
property_argin = varargin;
```

```
while length(property_argin) >= 2,
    prop = property_argin{1};
    val = property_argin{2};
    property_argin = property_argin(3:end);
    switch prop
    case 'NumberShares'
        s.num_shares = val;
    case 'SharePrice'
        s.share_price = val;
    case 'Descriptor'
        s.asset = set(s.asset,'Descriptor',val);
    otherwise
        error('Invalid property')
    end
end
s.asset = set(s.asset,'CurrentValue',...
    s.num_shares * s.share_price,'Date',date);
```

Note that this function creates and returns a new stock object with the new values, which you then copy over the old value. F or example, given the stock object,

```
s = stock('XYZ',100,25);
```

the following set command updates the share price.

```
s = set(s,'SharePrice',36);
```

It is necessary to copy over the original stock object (i.e., assign the output to s) because MATLAB does not support passing arguments by reference. Hence the set method actually operates on a copy of the object.

## The Stock subsref Method

The subsref method defines subscripted indexing for the stock class. In this example, subsref is implemented to enable numeric and structure field name indexing of stock objects.

```
function b = subsref(s,index)
% SUBSREF Define field name indexing for stock objects
fc = fieldcount(s.asset);
switch index.type
```

```
case '()'
    if (index.subs{:} <= fc)
        b = subsref(s.asset,index);
    else
            switch index.subs{:} - fc
            case 1
                b = s.num_shares;
            case 2
                    b = s.share_price;
            otherwise
            error(['Index must be in the range 1 to ',num2str(fc + 2)])
            end
    end
case '.'
    switch index.subs
    case 'num_shares'
        b = s.num_shares;
    case 'share_price'
        b = s.share_price;
    otherwise
        b = subsref(s.asset,index);
    end
end
```

The outer switch statement determines if the index is a numeric or field name syntax.

The fieldcount asset method determines how many fields there are in the asset structure, and the if statement calls the asset subsref method for indices 1 to fieldcount. See "The Asset fieldcount Method" on page 22-45 and "The Asset subsref Method" on page 22-42 for a description of these methods.
Numericindices greater than the number returned by fieldcount are handled by the inner switch statement, which maps the index value to the appropriate field in the stock structure.

Field-name indexing assumes field names other than num_shares and share_price are asset fields, which eliminates the need for knowledge of asset fields by child methods. The asset subsref method performs field-name error checking.

See the subsref help entry for general information on implementing this method.

## The Stock subsasgn Method

The subsasgn method enables you to change the data contained in a stock object using numeric indexing and structure field name indexing. MATLAB calls subsasgn whenever you execute an assignment statement (e.g., $A(i)=$ val, $A\{i\}=$ val, or A.fieldname $=$ val).

```
function s = subsasgn(s,index,val)
% SUBSASGN Define index assignment for stock objects
fc = fieldcount(s.asset);
switch index.type
case '()'
    if (index.subs{:} <= fc)
        s.asset = subsasgn(s.asset,index,val);
    else
            switch index.subs{:}-fc
            case 1
                s.num_shares = val;
            case 2
                    s.share_price = val;
            otherwise
            error(['Index must be in the range 1 to ',num2str(fc + 2)])
            end
    end
case '.'
    switch index.subs
    case 'num_shares'
        s.num_shares = val;
    case 'share_price'
        s.share_price = val;
    otherwise
        s.asset = subsasgn(s.asset,index,val);
    end
end
```

The outer switch statement determines if the index is a numeric or field name syntax.

The fieldcount asset method determines how many fields there are in the asset structure and the if statement calls the asset subsasgn method for indices 1 to fieldcount. See "The Asset fieldcount Method" on page 22-45 and "The Asset subsasgn Method" on page 22-43 for a description of these methods.
Numeric indices greater than the number returned by fieldcount are handled by the inner switch statement, which maps the index value to the appropriate field in the stock structure.

Field-name indexing assumes field names other than num_shares and share_price are asset fields, which eliminates the need for knowledge of asset fields by child methods. The asset subsasgn method performs field-name error checking.
The subsasgn method enables you to assign values to stock object data structure using two techniques. For example, suppose you have a stock object

```
s = stock('XYZ',100,25)
```

You could change the descriptor field with either of the following statements

```
s(1) = 'ABC';
```

or

```
s.descriptor = 'ABC';
```

See the subsasgn help entry for general information on assignment statements in MATLAB.

## The Stock display Method

When you issue the statement (without terminating with a semicolon)

```
XYZStock = stock('XYZ',100,25)
```

MATLAB looks for a method in the @stock directory called display. The display method for the stock class produces this output.

Descriptor: XYZ
Date: 17-Nov-1998
Type: stock
Current Value: 2500.00
Number of shares: 100
Share price: 25.00

Here is the stock display method.

```
function display(s)
% DISPLAY(s) Display a stock object
display(s.asset)
stg = sprintf('Number of shares: %g\nShare price: %3.2f\n',...
    s.num_shares,s.share_price);
disp(stg)
```

First, the parent asset object is passed to the asset display method to display its fields (MATLAB calls the asset display method because the input argument is an asset object). The stock object's fields are displayed in a similar way using a formatted text string.

Note that if you did not implement a stock class display method, MATLAB would call the asset display method. This would work, but would display only the descriptor, date, type, and current value.

## Example - The Portfolio Container

Aggregation is the containment of one class by another class. The basic relationship is: each contained class "is a part of" the container class.
For example, consider a financial portfolio class as a container for a set of assets (stocks, bonds, savings, etc.). Once the individual assets are grouped, they can be analyzed, and useful information can be returned. The contained objects are not accessible directly, but only via the portfolio class methods.

See "E xample - Assets and Asset Subclasses" on page 22-38 for information about the assets collected by this portfolio class.

## Designing the Portfolio Class

The portfolio class is designed to contain the various assets owned by a given individual and provide information about the status of his or her investment portfolio. This example implements a somewhat over-simplified portfolio class that:

- Contains an individual's assets
- Displays information about the portfolio contents
- Displays a 3-D pie chart showing the relative mix of asset types in the portfolio

## Required Portfolio Methods

The portfolio class implements only three methods:

- portfolio - The portfolio constructor.
- display - Displays information about the portfolio contents.
- pie3- Overloaded version of pie3 function designed totakea single portfolio object as an argument.
Since a portfolio object contains other objects, the portfolio class methods can use the methods of the contained objects. F or example, the portfolio display method calls the stock class display method, and so on.

## The Portfolio Constructor Method

The portfolio constructor method takes as input arguments a client's name and a variable length list of asset subclass objects (stock, bond, and savings objects in this example). The portfolio object uses a structure array with the following fields:

- name - The client's name.
- ind_assets - The array of asset subclass objects (stock, bond, savings).
- total_value - The total value of all assets. The constructor calculates this value from the objects passed in as arguments.
- account_number - The account number. This field is assigned a value only when you save a portfolio object (see "Saving and Loading Objects" on page 22-60).

```
function p = portfolio(name,varargin)
% PORTFOLIO Create a portfolio object containing the
% client's name and a list of assets
switch nargin
case 0
    % if no input arguments, create a default object
    p.name = 'none';
    p.total_value = 0;
    p.ind_assets = {};
    p.account_number = '';
    p = class(p,'portfolio');
case 1
    % if single argument of class portfolio, return it
    if isa(name,'portfolio')
            p = name;
        else
            disp([inputname(1) ' is not a portfolio object'])
            return
        end
otherwise
    % create object using specified arguments
    p.name = name;
    p.total_value = 0;
    for k = 1:length(varargin)
```

```
            p.ind_assets(k) = {varargin{k}};
            asset_value = get(p.ind_assets{k},'CurrentValue');
            p.total_value = p.total_value + asset_value;
        end
        p.account_number = '';
        p = class(p,'portfolio');
end
```

## Constructor Calling Syntax

The portfolio constructor method can be called in one of three different ways:

- No input arguments - If called with no arguments, it returns an object with empty fields.
- Input argument is an object - If the input argument is already a portfolio object, MATLAB returns the input argument. The isa function checks for this case.
- More than two input arguments - If there are more than two input arguments, the constructor assumes the first is the client's name and the rest are asset subclass objects. A more thorough implementation would perform more careful input argument checking, for example, using the isa function to determine if the arguments are the correct class of objects.

## The Portfolio display Method

The portfolio display method lists the contents of each contained object by calling the object's display method. It then lists the client name and total asset value.

```
function display(p)
% DISPLAY Display a portfolio object
for k = 1:length(p.ind_assets)
    display(p.ind_assets{k})
end
stg = sprintf('\nAssets for Client: %s\nTotal Value: %9.2f\n',...
p.name,p.total_value);
disp(stg)
```

## The Portfolio pie3 Method

The portfolio class overloads the MATLAB pie3 function to accept a portfolio object and display a 3-D pie chart illustrating the relative asset mix of the client's portfolio. MATLAB calls the @portfolio/pie3.m version of pie3 whenever the input argument is a single portfolio object.

```
function pie3(p)
% PIE3 Create a 3-D pie chart of a portfolio
stock_amt = 0; bond_amt = 0; savings_amt = 0;
for k = 1:length(p.ind_assets)
    if isa(p.ind_assets{k},'stock')
        stock_amt = stock_amt + ...
                get(p.ind_assets{k},'CurrentValue');
    elseif isa(p.ind_assets{k},'bond')
            bond_amt = bond_amt + ...
                get(p.ind_assets{k},'CurrentValue');
    elseif isa(p.ind_assets{k},'savings')
            savings_amt = savings_amt + ...
                get(p.ind_assets{k},'CurrentValue');
    end
end
i = 1;
if stock_amt ~= 0
    label(i) = {'Stocks'};
    pie_vector(i) = stock_amt;
    i = i +1;
end
if bond_amt ~= 0
    label(i) = {'Bonds'};
    pie_vector(i) = bond_amt;
    i = i +1;
end
if savings_amt ~= 0
    label(i) = {'Savings'};
    pie_vector(i) = savings_amt;
end
pie3(pie_vector,label)
set(gcf,'Renderer','zbuffer')
set(findobj(gca,'Type','Text'),'FontSize',14)
cm = gray(64);
```

```
colormap(cm(48:end,:))
stg(1) = {['Portfolio Composition for ',p.name]};
stg(2) = {['Total Value of Assets: $',num2str(p.total_value)]};
title(stg,'FontSize',12)
```

There are three parts in the overloaded pie3 method.

- The first uses the asset subclass get methods to access the CurrentValue property of each contained object. The total value of each class is summed.
- The second part creates the pie chart labels and builds a vector of graph data, depending on which objects are present.
- The third part calls the MATLAB pie3 function, makes some font and colormap adjustments, and adds a title.

## Creating a Portfolio

Suppose you have implemented a collection of asset subclasses in a manner similar to the stock class. You can then use a portfolio object to present the individual's financial portfolio. For example, given the following assets

```
XYZStock = stock('XYZ',200,12);
SaveAccount = savings('Acc # 1234',2000,3.2);
Bonds = bond('U.S. Treasury',1600,12);
```

Create a portfolio object.

```
p = portfolio('Gilbert Bates',XYZStock,SaveAccount,Bonds)
```

The portfolio display method summarizes the portfol io contents (because this statement is not terminated by a semicolon).

```
Descriptor: XYZ
Date: 24-Nov-1998
Current Value: 2400.00
Type: stock
Number of shares: 200
Share price: 12.00
Descriptor: Acc # 1234
Date: 24-Nov-1998
Current Value: 2000.00
Type: savings
Interest Rate: 3.2%
```

```
Descriptor: U.S. Treasury
Date: 24-Nov-1998
Current Value: 1600.00
Type: bond
Interest Rate: 12%
Assets for Client: Gilbert Bates
Total Value: 6000.00
```

The portfolio pie3 method displays the relative mix of assets using a pie chart.
pie3(p)

Portfolio Composition for Gilbert Bates Total Value of Assets: $\$ 6000$

## Saving and Loading Objects

You can use the MATLAB save and load commands to save and retrieve user-defined objects to and from .mat files, just like any other variables.

When you load objects, MATLAB calls the object's class constructor to register the object in the workspace. The constructor function for the object class you are loading must be able to be called with no input arguments and return a default object. See "Guidelines for Writing a Constructor" on page 22-10 for more information.

## Modifying Objects During Save or Load

When you issue a save or load command on objects, MATLAB looks for class methods called saveobj and loadobj in the class directory. You can overload these methods to modify the object before the save or load operation. For example, you could definea saveobj method that saves related data al ong with the object or you could write a loadobj method that updates objects to a newer version when this type of object is loaded into the MATLAB workspace.

## Example - Defining saveobj and loadobj for Portfolio

In the section "Example - The Portfolio Container" on page 22-54, portfolio objects are used to collect information about a client's investment portfolio. Now suppose you decideto add an account number to each portfol io object that is saved. You can define a portfolio saveobj method to carry out this task automatically during the save operation.

Suppose further that you have already saved a number of portfolio objects without the account number. Y ou want to update these objects during the load operation so that they are still valid portfolio objects. Y ou can do this by defining a loadobj method for the portfolio class.

## Summary of Code Changes

To implement the account number scenario, you need to add or change the following functions:

- portfolio - The portfolio constructor method needs to be modified to create a new field, account_number, which is initialized to the empty string when an object is created.
- saveobj - A new portfolio method designed to add an account number to a portfolio object during the save operation, only if the object does not already have one.
- loadobj - A new portfolio method designed to update older versions of portfolio objects that were saved before the account number structure field was added.
- subsref - A new portfolio method that enables subscripted reference to portfolio objects outside of a portfolio method.
- getAccountNumber - a MATLAB function that returns an account number that consists of the first three letters of the client's name.

## New Portfolio Class Behavior

With the additions and changes made in this example, the portfolio class now:

- Includes a field for an account number
- Adds the account number when a portfolio object is saved for the first time
- Automatically updates the older version of portfolio objects when you load them into the MATLAB workspace

## The saveobj Method

MATLAB looks for the portfolio saveobj method whenever the save command is passed a portfolio object. If @portfolio/saveobj exists, MATLAB passes the portfolio object to saveobj, which must then return the modified object as an output argument. The following implementation of saveobj determines if the object has already been assigned an account number from a previous save operation. If not, saveobj calls getAccountNumber to obtain the number and assigns it to the account_number field.

```
function b = saveobj(a)
if isempty(a.account_number)
    a.account_number = getAccountNumber(a);
end
b = a;
```

## The Ioadobj Method

MATLAB looks for the portfolio loadobj method whenever the load command detects portfolio objects in the .mat file being loaded. If loadobj exists, MATLAB passes the portfolio object to loadobj, which must then return the modified object as an output argument. The output argument is then loaded into the workspace.

If the input object does not match the current definition as specified by the constructor function, then MATLAB converts it to a structure containing the same fields and the object's structure with all the values intact (that is, you now have a structure, not an object).
The following implementation of loadobj first uses is a to determine whether the input argument is a portfolio object or a structure. If the input is an object, it is simply returned since no modifications are necessary. If the input argument has been converted to a structure by MATLAB, then the new account_number field is added to the structure and is used to create an updated portfolio object.

```
function b = loadobj(a)
% loadobj for portfolio class
if isa(a,'portfolio')
```

```
    b = a;
else % a is an old version
    a.account_number = getAccountNumber(a);
    b = class(a,'portfolio');
end
```

## Changing the Portfolio Constructor

The portfolio structure array needs an additional field to accommodate the account number. To create this field, add the line

```
p.account_number = '';
```

to @portfolio/portfolio.m in both the zero argument and variable argument sections.

## The getA ccountN umber Function

In this example, getAccountNumber is a MATLAB function that returns an account number composed of the first three letters of the client name prepended to a series of digits. To illustrate implementation techniques, getAccountNumber is not a portfolio method so it cannot access the portfolio object data directly. Therefore, it is necessary to define a portfolio subsref method that enables access to the name field in a portfolio object's structure.

For this example, getAccountNumber simply generates a random number, which is formatted and concatenated with elements 1 to 3 from the portfolio name field.

```
function n = getAccountNumber(p)
% provides a account number for object p
n = [upper(p.name(1:3)) strcat(num2str(round(rand(1,7)*10))')'];
```

Note that the portfolio object is indexed by field name, and then by numerical subscript to extract thefirst three letters. The subsref method must be written to support this form of subscripted reference.

## The Portfolio subsref Method

When MATLAB encounters a subscripted reference, such as that made in the getAccountNumber function

```
p.name(1:3)
```

MATLAB calls the portfolio subsref method to interpret the reference. If you do not define a subsref method, the above statement is undefined for portfolio objects (recall that here p is an object, not just a structure).

The portfolio subsref method must support field-name and numeric indexing for the getAccountNumber function to access the portfolio name field.

```
function b = subsref(p,index)
% SUBSREF Define field name indexing for portfolio objects
switch index(1).type
case '.'
    switch index(1).subs
    case 'name'
        if length(index)== 1
            b = p.name;
            else
                    switch index(2).type
            case '()'
                b = p.name(index(2).subs{:});
            end
        end
    end
end
```

Notethat the portfolio implementation of subsref is designed to provide access to specific elements of the name field; it is not a general implementation that provides access to all structure data, such as the stock class implementation of subsref.

See the subsref help entry for more information about indexing and objects.

## Object Precedence

Object precedence is a means to resolve the question of which of possibly many versions of an operator or function to call in a given situation. Object precedence enables you to control the behavior of expressions containing different classes of objects. F or example, consider the expression

```
objectA + objectB
```

Ordinarily, MATLAB assumes that the objects have equal precedence and calls the method associated with the leftmost object. However, there are two exceptions:

- User-defined classes have precedence over MATLAB built-in classes.
- User-defined classes can specify their relative precedence with respect to other user-defined classes using the inferiorto and superiorto functions.

For example, in the section "Example - A Polynomial Class" on page 22-24 the polynom class defines a plus method that enables addition of polynom objects. Given the polynom object p

```
p = polynom([[1 0 -2 -5])
p =
    x^3-2*x-5
```

The expression,
$1+p$
ans $=$

$$
x^{\wedge} 3-2^{*} x-4
$$

calls the polynom plus method (which converts the double, 1, to a polynom object, and then adds it to $p$ ). The user-defined polynom class has precedence over the MATLAB double class.

## Specifying Precedence of User-Defined Classes

You can specify the relative precedence of user-defined classes by calling the inferiorto or superiorto function in the class constructor.

The inferiorto function places a class below other classes in the precedence hierarchy. The calling syntax for the inferiorto function is

```
inferiorto('class1','class2',...)
```

You can specify multiple classes in the argument list, placing the class below many other classes in the hierarchy.
Similarly, the superiorto function places a class above other classes in the precedence hierarchy. The calling syntax for the superiorto function is

```
superiorto('class1','class2',...)
```

## Location in the Hierarchy

If objectA is above objectB in the precedence hierarchy, then the expression

```
objectA + objectB
```

calls @classA/plus.m. Conversely, if objectB is above objectA in the precedence hierarchy, then MATLAB calls @classB/plus.m.
See "How MATLAB Determines Which Method to Call" on page 22-67 for related information.

## How MATLAB Determines Which Method to Call

In MATLAB, functions exist in directories in the computer's file system. A directory may contain many functions ( M -files). Function names are unique only within a single directory (e.g., more than one directory many contain a function called pie3). When you type a function name on the command line, MATLAB must search all the directories it is aware of to determine which function to call. This list of directories is called the MATLAB path.

When looking for a function, MATLAB searches the directories in the order they are listed in the path, and calls the first function whose name matches the name of the specified function.
If you write an M-file called pie3.m and put it in a directory that is searched before the specgraph directory that contains MATLAB's pie3 function, then MATLAB uses your pie3 function instead (note that this is not truefor built-in functions like plot, which are always found first).

Object-oriented programming allows you to have many methods (MATLAB functions located in class directories) with the same name and enables MATLAB to determine which method to use based on the type or class of the variables passed to the function. For example, if $p$ is a portfolio object, then

```
pie3(p)
```

calls @portfolio/pie3.m because the argument is a portfolio object.

## Selecting a Method

When you call a method for which there are multiple versions with the same name, MATLAB determines the method to call by:

- Looking at the classes of the objects in the argument list to determine which argument has the highest object precedence; the class of this object controls the method selection and is called the dispatch type
- Applying the function precedence order to determine which of possibly several implementations of a method to call. This order is determined by the location and type of function.

## Determining the Dispatch Type

MATLAB first determines which argument controls the method selection. The class type of this argument then determines the class in which MATLAB searches for the method. The controlling argument is either:

- The argument with the highest precedence, or
- The leftmost of arguments having equal precedence

User-defined objects take precedence over MATLAB's built-in classes such as double or char. Y ou can set therelative precedence of user-defined objects with the inferiorto and superiorto functions, as described in "Object Precedence" on page 22-65.

MATLAB searches for functions by name. When you call a function, MATLAB knows the name, number of arguments, and the type of each argument. MATLAB uses the dispatch type to choose among multiple functions of the same name, but does not consider the number of arguments.

## Function Precedence Order

The function precedence order determines the precedence of one function over another based on the type of function and its location on the MATLAB path. From the perspective of method selection, MATLAB contains two types of functions: those built into MATLAB, and those written as M-files. MATLAB treats these types differently when determining the function precedence order.

MATLAB selects the correct function for a given context by applying the following function precedence rules, in the order given.

## For built-in functions:

1 Overloaded Methods
If there is a method in the class directory of the dispatching argument that has the same name as a MATLAB built-in function, then this method is called instead of the built-in function.

2 Nonoverloaded MATLAB Functions
If there is no overloaded method, then the MATLAB built-in function is called.

MATLAB built-in functions take precedence over both subfunctions and private functions. Therefore, subfunctions or private functions with the same name as MATLAB built-in functions can never be called.

## For nonbuilt-in functions:

## 1 Subfunctions

Subfunctions take precedence over all other M-filefunctions and overloaded methods that are on the path and have the same name. Even if the function is called with an argument of type matching that of an overloaded method, MATLAB uses the subfunction and ignores the overloaded method.

2 Private Functions
Private functions are called if there is no subfunction of the same name within the current scope. As with subfunctions, even if the function is called with an argument of type matching that of an overloaded method, MATLAB uses the private function and ignores the overloaded method.

## 3 Class Constructor Functions

Constructor functions (functions having names that are the same as the @ directory, for example @polynom/polynom.m) take precedence over other MATLAB functions. Therefore, if you create an M-file called polynom.m and put it on your path before the constructor @polynom/polynom.m version, MATLAB will always call the constructor version.

4 Overloaded Methods
MATLAB calls an overloaded method if it is not masked by a subfunction or private function.

## 5 Current Directory

A function in the current working directory is selected before one elsewhere on the path.

6 Elsewhere On Path
Finally, a function anywhere else on the path is selected.

## Selecting Methods from Multiple Directories

There may be a number of directories on the path that contain methods with the same name. MATLAB stops searching when it finds the first implementation of the method on the path, regardless of the implementation type (MEX-file, P-code, M-file).

## Selecting Methods from Multiple Implementation Types

There are four file precedence types. MATLAB uses file precedence to select between identically named functions in the same directory. The order of precedence for file types is:

1 MEX-files
2 MDL-file (Simulink model)
3 P-code
4 M-file

For example, if MATLAB finds a P-code and an M-file version of a method in a class directory, then the P-code version is used. It is, therefore, important to regenerate the P -code version whenever you edit the M -file.

## Querying Which Method MATLAB Will Call

You can determine which method MATLAB will call using thewhich command. For example,
which pie3
your_matlab_path/toolbox/matlab/specgraph/pie3.m
However, if $p$ is a portfolio object,
which pie3(p)
dir_on_your_path/@portfolio/pie3.m \% portfolio method
The which command determines which version of pie3 MATLAB will call if you passed a portfol io object as the input argument. To see a list of all versions of a particular function that are on your MATLAB path, use the -all option. See the which reference page for more information on this command.

## External Interfaces and the MATLAB API

Finding the Documentation in Online Help<br>A-2

Reference Documentation . . . . . . . . . . . . . . A-4

## Finding the Documentation in Online Help

MATLAB provides interface capabilities that allow you to communicate between MATLAB and the following programs and devices:

- External C and Fortran programs
- Object-oriented technol ogies likeJ ava and ActiveX
- Hardware devices on your computer's serial port

You can also import and export data to and from MATLAB.
These interfaces, also referred to as the MATLAB Application Program Interface (API), are documented in full in the online help. Use the following path to locate the help sections listed below.

```
MATLAB -> Using MATLAB -> External Interfaces/API
```

## Calling C and Fortran Programs from MATLAB

MATLAB provides an interface to external programs written in the $C$ and Fortran Ianguages that enables you to interact with data and programs external to the MATLAB environment. This section explains how to call your own C or F ortran subroutines from MATLAB as if they were built-in functions.

## Creating C Language MEX-Files

MATLAB callable C and Fortran programs are referred to as MEX-files. This section explains how to create and work with C MEX-files.

## Creating Fortran MEX-Files

This section explains how to create and work with Fortran MEX-files.

## Calling MATLAB from C and Fortran Programs

You can employ MATLAB as a computational engine that responds to calls from your C and Fortran programs. This section describes the MATLAB functions that allow you to:

- Start and end a MATLAB process
- Send commands to and exchange data with MATLAB
- Compile and link MATLAB engine programs

## Calling Java from MATLAB

This section describes how to use the MATLAB interface to J ava classes and objects. This MATLAB capability enables you to:

- BringJ ava classes into the MATLAB environment
- Construct objects from those classes
- Work with J ava arrays in MATLAB
- Call methods on J ava objects, passing MATLAB or J ava data types

## Importing and Exporting Data

This section describes how to use MAT-files to import data to and export data from the MATLAB environment. MAT-files provide a convenient mechanism for moving your MATLAB data between different platforms in a highly portable manner. In addition, they provide a means to import and export your data to other stand-alone MATLAB applications.

## ActiveX and DDE Support

MATLAB has interfaces that allow you to interact with ActiveX and Dynamic Data Exchange, (DDE). This section explains how to:

- IntegrateActiveX control components into an ActiveX control container such as a MATLAB figure window
- Use ActiveX Automation components to control or be controlled by MATLAB
- Enable access between MATLAB and other Windows applications using DDE

## Serial Port I/ 0

This section describes the MATLAB serial port interface which provides direct access to peripheral devices such as modems, printers, and scientific instruments that you connect to your computer's serial port. This interface is established through a serial port object that allows you to:

- Configure serial port communications
- Use serial port control pins
- Write data to and read data from the device
- Execute an action when a particular event occurs
- Create a record of your serial port session

## Reference Documentation

The onlineHelp Reference section provides a detailed description of each of the MATLAB functions available in the MATLAB external interfaces. You can find this documentation in the online Help Contents by following the path shown here. Click on the page called External Interfaces/API Reference to see links to the sections listed below.

```
MATLAB -> Reference -> External Interfaces/API Reference
```

## API Notes

An introduction to using the mex script, the MATLAB mxArray and other data types, and passing pointers in Fortran.

## C Engine Routines

Functions that allow you to call MATLAB from your own C programs.

## C MAT-File Routines

Functions that allow you to incorporate and use MATLAB data in your own C programs.

## C MEX-F unctions

Functions that you use in your $C$ files to perform operations in the MATLAB environment.

## C MX-F unctions

Array access and creation functions that you use in your C files to manipulate MATLAB arrays.

## Fortran Engine Routines

Functions that allow you to call MATLAB from your own F ortran programs.

## Fortran MAT-File Routines

Functions that allow you to incorporate and use MATLAB data in your own Fortran programs.

## Fortran MEX-F unctions

Functions that you use in your F ortran files to perform operations in the MATLAB environment.

## Fortran MX-F unctions

Array access and creation functions that you use in your Fortran files to manipulate MATLAB arrays.

## J ava Interface Functions

Functions that enable you to create and interact with J ava classes and objects from MATLAB.

## ActiveX Functions

Functions that create ActiveX objects and manipulate their interfaces.

## DDE Functions

Dynamic Data Exchange functions that enable MATLAB to access other Windows applications and vice versa.

## Serial Port I/O Functions

Functions that enable you to interact with devices connected to your computer's serial port.

A External Interfaces and the M ATLAB API
