Linear systems and additive noise

Linear systems, e.g., filters, can easily separate additive noise from useful information when we know the frequency range of the noise and information

$$y[n] = x[n] + w[n]$$

In vector notation

$$Hy = Hx + Hw$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Multiplicative or convolutive noise

This is harder if the signal and noise are convoluted, e.g., in speech processing

$$y[n] = x[n] \ast w[n]$$

- w[n] is the flowing air (noise source)
- ▶ *h*[*n*] is the vocal tract (filter)

We can develop an operator that can separate convoluted components by **transforming convolution into addition**

Cepstrum

Developed to separate convoluted signals

$$y[n] = x[n] \ast w[n]$$

Discrete Fourier Domain:

$$Y[k] = X[k]W[k]$$

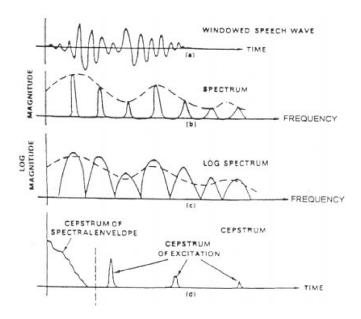

Take logarithms

$$\log[Y[k]] = \log X[k] + \log W[k]$$

• we can apply a linear filter to $\log Y[k]$ to separate

• equivalently we can take DFT of $\log Y[k]$ and process in frequency domain

cepstrum is the DFT (or DCT) of the log spectrum

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 - のへで

$$\mathsf{MF}[r] = \sum_{k} |V_r[k]X[k]|^2$$

Mel Frequency Cepstral Coefficient (MFCC)

$$\mathsf{MFCC}[m] = \sum_{r=1}^{R} \log(\mathsf{MF}[r]) \cos\left[\frac{2\pi}{R}\left(r + \frac{1}{2}\right)m\right] \quad (1)$$

• i.e., inner-product with cosines $MFCC[m] = \langle \log MF[r], c_m[r] \rangle$

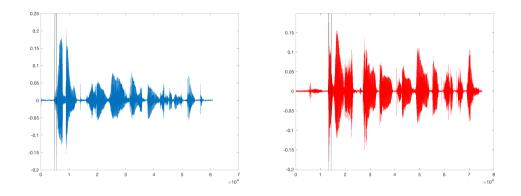

train a k-Nearest Neighbor classifier to classify frames

▲□▶ ▲□▶ ▲三▶ ▲三▶ ● 三 - のへで

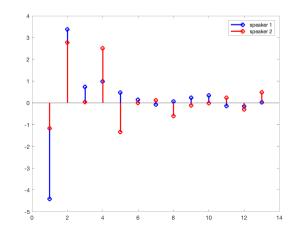

- AN4 dataset (CMU): 5 male and 5 female subjects speaking words and numbers
- collect the training samples into frames of 30 ms with an overlap of 75%
- calculate MFCC
- train a k-Nearest Neighbor classifier on the frames
- for a given test signal, predictions are made every frame
- most frequently occurring label is declared as the speaker

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ の < @

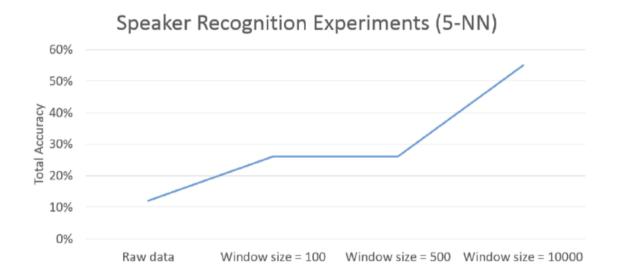

Application: Speaker Identification speaker 1 (blue) and speaker 2 (red) time domain signals

frame based MFCC features
