subgroup is the best stimulus for evoking spontaneous speech. And the general configurations of the culture change rapidly even though the value system remains intact: a teacher raised in Harlem in the 1950's, returning to the streets today, would find it difficult to understand how and why gang fighting is no longer in style.

We propose that a cultural intermediary be introduced into the classroom in the person of a young black man,11 16 to 25 years old, with high-school-level reading skills, but not a college graduate. We propose the creation of a special license to allow this young man to carry out the following functions:

1. To acquaint the teacher with the specific interests of members of the class and help design reading materials centering on these interests.
2. To provide effective rewards and punishments that will motivate members of street culture for whom normal school sanctions are irrelevant.
3. To lead group discussion on topics of immediate concern to members of the class.
4. To lead boys in sports and other recreational activities in school time.
5. To maintain contact with boys outside of school, on the streets, and help organize extracurricular activities.

We are well aware of the difficulties that any school system will have in absorbing such outside elements. The situation in most ghetto schools is plainly desperate enough so that many educators will be willing to endorse a proposal that may create such difficulties. Our proposal is not equivalent to the usual program for para-professionals, who are usually parents or upward-bound youth already removed from the vernacular culture. The difference between such isolated individuals and members is the main topic of the next chapter. Part III of this volume will describe some of the skills and understandings that make up the vernacular culture. These chapters will document the distance between the socialized adult and the members who are now effectively shut out of the educational system.

11. We specifically designate a male for this role, in contrast to a number of proposals for para-professionals in the schools which utilize women from the community or from college training courses. We cannot elaborate on the importance of sex differentiation here, except to indicate that we believe it is a matter of prime importance.
This volume for grammatical analysis were obtained from this setting; in recent work on Hawaiian Creole this was also the major focus (Labov 1971b, Day to appear). We have followed the same policy in exploratory work on sound change in various regions of the United States, England, Ireland, and France (Labov, Yaeger, and Steiner 1972). As we enter any city we look for preadolescent and adolescent peer groups engaged in sports or hanging out; we encounter family groups at tea or after dinner; we join groups of old men at bowls, in pubs, or sitting at pensioner's benches.

In this approach we are departing more and more from the earlier tradition of sociolinguistic studies which depended upon face-to-face interviews with single individuals drawn from judgment samples (Kurath 1949; Sociolinguistic Patterns, chapter 1) or from random samples (Social Stratification; Shuy, Wolfram and Riley 1967; Levine and Crockett 1966; Anschen 1969; Trudgill 1971); and we are following the more ethnographic approach that was first outlined by Gumperz in his work in Norway (1964). Random sampling is of course an essential procedure if we want to describe the overall sociolinguistic structure of the community, and our work in south-central Harlem relied heavily on a stratified random sample of 100 adults. But severe problems of explanation and interpretation are created when we extract single speakers from their social network and limit ourselves to records of their speech in one-to-one interaction with the interviewer. It seems most likely that a random sample will be used in future sociolinguistic studies to select individuals for study in the context of the social groups in which they normally operate.

We focus upon natural groups as the best possible solution to the observer's paradox: the problem of observing how people speak when they are not being observed (Sociolinguistic Patterns, chapter 8). The natural interaction of peers can overshadow the effects of observation and helps us approach the goal of capturing the vernacular of everyday life in which the minimum amount of attention is paid to speech: this is the most systematic level of linguistic behavior and of greatest interest to the linguist who wants to explain the structure and evolution of language.

But there is a second even more compelling reason for us to select natural groups of speakers rather than isolated individuals. The vernacular is the property of the group, not the individual. Its consistency and well-formed, systematic character is the result of a vast number of interactions; the group exerts its control over the vernacular in a supervision so close that a single slip may be condemned and remembered for years. The overt norms of the dominant social class can operate to produce a consistent superordinate dialect, if class is reasonably cohesive and protected from large-scale invasions from below. Thus the Received Pronunciation described by H. G. Wyld was a class dialect rigorously controlled in the British public (private) schools (1936:3). At the other end of the social spectrum, the covert norms of the street culture operate to produce the consistent vernacular of the urban working class. The lower-class culture differs from upper-class culture in that its base in the population becomes progressively narrower with age. In the early adolescent years, the focal concerns of lower-class culture (Miller 1958) involve all but the upper-middle and upper class in America. But individuals are gradually split away from involvement in these concerns, so that only a small percentage of "lower-lower-class" adults retain this orientation wholeheartedly as they grow older.

We usually find that the most consistent vernacular is spoken by those between the ages of 9 and 18. It is well known that in most cities peer-group membership reaches a peak at the ages of 15 to 18 (Wilmott 1966); as the young adult is detached from the teenage hang-out group he inevitably acquires a greater ability to shift towards the standard language and more occasions to do so. In some sharply differentiated subsystems, a consistent vernacular can be obtained only from children and adolescents: the grammars of adults seem to be permanently changed by their use of standard rules. This is the case with both Hawaiian Creole English ("Hawaiian Pidgin") and black vernacular. In general, working adults will use a sharper degree of style shifting than adolescents in their careful speech with outside observers, and only under the most favorable circumstances.

1. A classic case, reported in Whyte 1955, is that of the Cornerville group known as the Cream Puffs for many years, because someone had heard one member say "Aw shucks!" when a store was out of something he wanted to buy.

2. In any survey, we run across a few lower-class subjects who openly and defiantly endorse lower-class values. A woman of 55 answered all of the questions in the Lower East Side survey (Labov 1966a) in this style. She told me that when asked by a previous interviewer about her job aspirations, she had answered, "To be a prostitute"; and claimed that she would curse and swear to anyone, it didn't matter who. But one of her married daughters disagreed, "Not when you answer the phone, Ma!"
will their vernacular system emerge. In old age, much of this superposed variation disappears. But it is still an open question how much the basic vernacular system changes in the course of a lifetime.  

2. Members and Lames

In our work on sound change, we are concerned with the working-class vernacular rather than an upper-class dialect because it forms the main stream in the history of the language. The vernacular affects a much larger number of speakers in a more intimate way than the standard and the transmission of linguistic tradition through successive peer groups takes place in the subculture dominated by the vernacular (which we refer to as the vernacular culture). But even in the most solid working-class areas, there are many isolated children who grow up without being members of any vernacular peer group and a steadily increasing number of individuals split away from the vernacular culture in their adolescent years.

The black English vernacular currently refers to such isolated individuals as lames. They are not hip, since they do not hang out. It is only by virtue of being available and on the street every day that anyone can acquire the deep familiarity with local doings and the sure command of local slang that are needed to participate in vernacular culture. To be lame means to be outside of the central group and its culture; it is a negative characterization and does not imply any single set of social characteristics. Some lames can't or won't fight—they are cowards or weaklings; some are "good" in that they do not steal, smoke, shoot up dope, or make out, but others may be just as tough or just as "bad" as peer-group members; they may merely be distant, going their own way with their own concerns.

What all lames have in common is that they lack the knowledge which is necessary to run any kind of a game in the vernacular culture. The term lame can carry a great deal of contempt especially where someone pretends to knowledge he doesn't have. One of the epic statements of vernacular culture, "The Fall," begins on this note as shown in the epigraph to this chapter. Again we find that in "Mexicali Rose", the protagonist puts down his main man, Smitty, because he hit on a girl and failed.

Smitty dipped easy and from behind
"Lame, you think your game is stronger than mine?"
Sam said, "Not only is my game stronger, but my spiel is tougher,
So move over, Jake, and watch me work."  

There are many reasons for someone to be lame. Separation from the peer group may take place under the influence of parents, or of school, or of the individual's own perception of the advantages of the dominant culture for him; on the other hand, he may be too sick or too weak to participate in the peer-group vernacular activities, or he may be rejected by the peer-groups as mentally or morally defective (a punk). In our work in south-central Harlem, we encountered many examples of all these factors; one of the most important is the active intervention of parents. For example, a swimming team at Millbank recreation center is said to have been broken up when the mother of Ricky S. objected to his "hanging around with Stanley an 'em."

A high concentration of lames will be found in any selective social institution or activity which requires the active participation of parents, such as the Vacation Day Camps mentioned in the previous chapter. Since parents had to enroll boys in the program, and it was run in schools by adults, this "VDC" series contrasts as a whole with data provided by the Thunderbirds, jet, and Cobra peer groups, formed apart from and in spite of the influence of parents and schools.

4. From the version of Big Brown, recorded in New York City in 1960.
3. Although the selection of Vacation Day Camps was done on a geographically random basis, the individual subjects in the camps were not chosen randomly. They were boys who were not engaged in sports or any other social activity at the time, and the bias of the VDC selection was therefore increased in the direction of isolates or lames.
Social institutions like the early grades of the public schools will of course include both lames and members of the vernacular culture (hereafter referred to as members). Teachers, testers, educational psychologists, and linguists who work or hang out only in schools have no way of distinguishing these categories. Only by working outside of these institutions can we obtain an overall view of students' status and estimate the relative size of the vernacular component. The importance of this knowledge for an analysis of educational problems cannot be overstated. Chapter 6 showed that lames in Harlem schools read only one or two grades behind the national norms and generally follow an upward curve of reading achievement; but the large body of peer-group members show a very much lower pattern with a ceiling at the fourth grade reading level. The ability to distinguish lames from members is even more important for linguists trying to study the vernacular, for as we shall see, lames and members differ systematically in their grammars as well as in their school performance.

What are the percentages of members and lames in any inner city population? One answer to this question appears in our study of the peer groups located in a 13-story apartment building in a low-income project, 1390 Fifth Avenue. With help from the boys themselves, we carried out an enumeration of all youth living in this building. Table 7.1 shows the distribution of boys from 6 to 19 years old. The 17 Thunderbirds range from 9 to 13 years, and make up 45 percent of the 39 boys in this range. The 7 Oscar Brothers, a related older group, make up 33 percent of the boys in the 16-to-18 age range.8 Table 7.1 also indicates some of the reasons that boys are not members. Some have different family backgrounds—West Indian or Puerto Rican. At least one is kept at home by his parents. Some go to Catholic schools. In any case, it is evident that the Thunderbirds are the only self-organized peer-group in their age range, and the rest are isolated individuals, who are lames by definition. We interviewed four of these boys individually; we will refer to them as the "1390 Lames".

Membership is demonstrated by actual participation in group activities, but it appears quite clearly in answers to the hang-out question in individual interviews. We can plot answers to "Who are all the cats you hang out with?" on sociometric diagrams such as Fig. 7.1, which shows members of the Thunderbirds from 10 to 13.7 The double lines show symmetrical naming; the lighter lines with arrow heads indicate a naming by someone who is not named in return. The leaders Boot and Roger and central members Money, David, Ricky, Junior, Calvin are bound by a network of mutual namings. A younger subgroup is formed by Billy, Gary, and Robbie. The isolated position of James Del, Lesley, and Curtis is apparent.

6. The Oscar Brothers are not in fact a named group like the Thunderbirds. They are an informal hang-out group of older boys, including several older brothers of the Thunderbirds, who have helped them out once or twice in fights with other groups in the neighborhood. No one is sure how the name "Oscar Brothers" originated; it probably refers to the Big O (Oscar Robertson). The Oscar Brothers themselves say the name is used only by the younger boys. In accounts of great fights in the history of the Thunderbirds, the leader Boot is quoted as saying: "Go get the Oscar Brotheral"

7. There are several nine-year-olds involved who were not interviewed. The verbal leader Boot has many connections with outsiders, while the nonverbal leader, Roger, is located entirely within the Thunderbirds.
3. Linguistic Differentiation of Preadolescent Members and Lames

We can make the most precise comparison of lames and peer-group members by pairing the 1390 Lames with the Thunderbirds. The Aces, who were located in the neighboring project building, are a peer group which we can expect to match the Thunderbirds. On the other hand, the Vacation Day Camp series should be intermediate, since it includes some local boys we know as members as well as a good many lames. The VDC series also covers a much wider area than the Jet, Cobra, and Thunderbird territory, and some boys reported membership in named groups that we were not familiar with. In the following analysis we will then present four groups of preadolescent speakers: The Thunderbirds, the Aces, 10 boys from the VDC series, and the 1390 Lames. It must be remembered that all of these boys appear to speak the black vernacular at first hearing. None of them are middle-class or standard speakers who would stand out from the others as obviously speaking a different dialect; the linguistic differences we will show here emerge only on close analysis. All groups use the same linguistic variables and the differences in the system are internal variations in the organization of similar rules: differential weightings of variable constraints.

To illustrate this general point, consider the following fight story from Lesley C., one of the 1390 Lames:

See, Book pushed the door and Calvin pushed it back on him an' then they start pushing each other an' then they started to fight... Book was holding Calvin by the neck and Calvin had his han' up at his face... Book was almost crying and then Book got a cut right down his nose. (Who won that fight?) I say it was Calvin 'cause he ain't cry or bleed.

There are no grammatical items here which distinguish Lesley's speech from BEV; it has the characteristic syntax of a BEV fight narrative and ends with one of the most marked BEV forms, ain't for didn't. But Lesley is a lame, and his language reflects this fact. To see how it does so, we will have to look more closely at the Lame use of BEV variable rules.

Table 7.2 shows some of the phonological indices that differentiate these four groups. The variables presented here are the same as those which operate in the white community and have been extensively studied in New York City (Social Stratification) and in Detroit (Shuy, Wolfram, and Riley 1967). A detailed description of the first four variables in the adult white community is given in chapter 3 of Sociolinguistic Patterns. For a description of the variables of Table 7.2 in the black community see CRR 3288: Vol. 1 and chapters 1–4 of this volume.

The comparisons of Table 7.2 do not give data on Style A, the

8. Lesley is far enough outside of the group that he has gotten Boot's name wrong. It is usually pronounced without any final consonant [b], and for a long time we ourselves thought his name was Boo, but one day he visited us with sneakers labelled across the toes BOO. Lesley has reconstructed a [k] for the final consonant, a common form of hypercorrection in a dialect where don has become dent.
groups all show a low figure from 4 to 7 percent. Only the 1390 Lames use a sizeable percentage of constricted [r], at (r# # V)-21.

The general r variable is (r), the percentage of constricted [r] in postvocalic position where the next word does not begin with a vowel; in car, card, fear, heard. This always operates at lower levels than (r# # V), and in Table 7.2 the peer groups are at 00, just as in BEV. Only the Lames show any sign of [r] in speech. But in more formal styles, we see a regular slope of upward shifting. Figure 7.2 shows that the slope of style shifting for the 1390 Lames is twice that of the other groups, so that in Style D, the Lames use [r] half of the time.

The (dh) index represents a stigmatized feature, the frequency of stops and affricates for the initial consonant of /bd/ in this and then. (Unlike the other indices, it does not run from 0–100, but 0–200.) It does not form as regular a pattern as the r variables among adolescents, but Table 7.2 clearly shows that the 1390 Lames are lower than the Aces and T-Birds in their use of this feature. The VDC series is lower than the others only in reading style, but as a whole resembles the peer groups more than the Lames.

The Linguistic Consequences of Being a Lame

![Graph](image)

**Fig. 7.2.** Use of the variable (r) by preadolescent groups.
Perhaps the most sensitive sociolinguistic variable for BEV groups is \( \text{ing} \)—the percentage of [ɪŋ] variants for unstressed /ɪŋ/. It is typical of BEV speakers to go from \( \text{ing} \)-00 in causal speech to \( \text{ing} \)-100 in reading. All of these preadolescent speakers show an \( \text{ing} \) index of 100 or close to it in their reading styles C and D, and Table 7.2 therefore shows only Style B. The T-Birds and Aces adhere closely to the vernacular level, but the VDC speakers and the 1390 Lames use the prestige variant almost one quarter of the time.

The last five lines of Table 7.2 concern the deletion of -t,d in final consonant clusters. As we saw in chapter 2, this (KD) variable is subdivided into four subvariables, depending on the values of two environmental features: the absence or presence of a grammatical boundary before the final /t/ or /d/ (passed vs. post) and the absence or presence of a following vowel (passed me vs. passed over). The combination of these gives us the four subcategories shown in Table 7.2:

\[
\begin{align*}
(KD_m) & \rightarrow K \quad \text{post me} \\
(KD_m) & \rightarrow V \quad \text{passed us} \\
(KD_p) & \rightarrow K \quad \text{passed me} \\
(KD_p) & \rightarrow V \quad \text{passed us}
\end{align*}
\]

The index numbers represent the average frequency of deletion of /t/ or /d/ in these contexts. All follow the regular rule by showing lower figures before a vowel than before a consonant, and lower figures for KDp than KDm. The overall level of t,d deletion is also remarkably similar. But a very important difference between the 1390 Lames and the others appears in the crossproducts—that is, the cases where one factor favors the operation of the rule and the other does not. In these intermediate cases, we can see which of the two constraints on the variable rule is more important. It is plainly the phonological constraint for the T-Birds, the Aces, and the VDC series, and the effect of the grammatical boundary is much less by comparison. But for the 1390 Lames, the presence of a grammatical boundary is much more important, and KDp \( \rightarrow K \) is much lower than KDm \( \rightarrow V \). In this respect, the 1390 Lames show the same pattern as the white nonstandard vernacular of New York City.

We see a characteristic difference in the weighting of the variable constraints on the t,d deletion rule:

1. BEV rule of Aces, Thunderbirds and VDC:
   \( t,d \rightarrow \langle \theta \rangle / [+\text{cons}]^p \langle \theta \rangle \rightarrow ^p \langle \text{syll} \rangle \)

2. General rule of 1390 Lames, adults, and white groups:
   \( t,d \rightarrow \langle \theta \rangle / [+\text{cons}]^n \langle \theta \rangle \rightarrow ^n \langle \text{syll} \rangle \)

This qualitative difference in the organization of the deletion rule emerges from a quantitative study of natural speech. It represents a regular development with age as well as a difference among social groups, since even the peer-group members shift to rule 2 when they become adults. The predominant standard English pattern is heavily against deletion in past tense forms, and its influence is thus felt in the internal reorganization of the vernacular rule; since the 1390 Lames are isolated from the black vernacular and are most sensitive to SE influence, they are aligned in the SE direction from the outset.

In the overall pattern of Table 7.2, the VDC series is closer to the BEV peer groups than to the 1390 Lames. There are, however, four measures where the VDC subjects are shifted in the direction of the Lames and away from the peer groups. For all these variables, the T-Birds and the Aces are remarkably similar.

We next consider a more complex phenomenon: the operation of rules for contraction and deletion of is as a realization of the copula and auxiliary be. Here the comparison will be confined to two groups—the Thunderbirds and the 1390 Lames, who are directly opposed in their relation to the BEV subculture. The upper half of Table 7.3 shows the actual number of full forms (F), contracted forms (C), and deleted forms (D) for both the Thunderbirds and 1390 Lames, subclassified in a variety of grammatical environments. We follow the analysis of chapter 3 in subdividing the cases into those which begin with a full noun phrase (NP—) and those which begin with a pronoun (pro—). Within each of these, we consider three possibilities: that the following element is a noun phrase or sentence (—NP, S), a predicate adjective or locative (—PA, Loc), or a verb

9. Studies of other white nonstandard dialects (south-central Texas, Atlanta, Columbus, Detroit) show that the grammatical constraint is regularly predominant over the phonological constraint, just as with the white control group in the New York City studies.

10. The influence on the 1390 Lames may come from several directions: parents, the mass media, teachers, or other adolescents outside of the BEV influence. The fact that their pattern matches that of the white nonstandard speakers in many details does not necessarily show any direct influence, since they are moving towards SE along the same axes from a greater distance.
with -ing or gonna (—Vn, gn). Our general study of contraction and deletion of the copula in chapter 3 showed that there is progressively more contraction and deletion in these three environments, and more after pronouns than after full noun phrases. The form of the rule in the analysis of contraction and deletion presented in chapter 3 shows that the rule which deletes is is dependent upon the contraction rule and operates only upon auxiliaries with single consonants produced by contraction. The contraction rule is essentially the same as that which operates in the white dialects; the deletion rule is found only in BEV and appears to be uniform throughout the various vernacular communities. The differences which we will now examine have to do with the level of use of the two rules, rather than their specific forms.

The probabilities which govern the use of variable rules can be expressed by the quantity \( \phi \), ranging between 0 and 1; the lower half of Table 7.3 gives overall values of \( \phi \) for the contraction rule, operating upon F to give C, and for the deletion rule, operating upon C to give D.

The data on contraction for the 1390 Lames is limited, but it is sufficient to show that they use this rule in the same way as the Thunderbirds. The overall probability of contraction rule for the Thunderbirds is .73, and for the Lames .65; furthermore, they follow the same pattern throughout the six subcases. But the Thunderbirds and Lames are diametrically opposed in their use of the deletion rule: .52 for the Thunderbirds and only .12 for the Lames. And where the Thunderbirds follow the regular pattern of variable constraints that we find in all other BEV speakers, the 1390 Lames do not. Figure 7.3 contrasts the use of the deletion rule for the Lames and T-Birds for the six subcases and adds a comparison on the absence of are. The Lames' use of the rule is minimal: they delete the copula often enough so that it is evident that the rule is present in their system, but it is plainly being suppressed. In this respect, as in the case of -ld deletion, the 1390 Lames have brought their rule system into alignment with that of the dominant white society.

There are also a number of grammatical features of BEV which demonstrate the linguistic differentiation of the Lames. For these
grammatical variables we can contrast 12 of the Thunderbirds with four 1390 Lames.

1. BEV uses the dummy subject it where standard English uses there, as in It's a difference or It's a policeman at the door. This is not a categorical rule, but it rises to a very high frequency in the vernacular. The T-Birds use 79 percent it and only 21 percent there; the 1390 Lames use 91 percent there and only 9 percent it.

2. In BEV, the rule of negative concord operates regularly to indefinites any and ever within the clause, so that Nobody knows nothing about it is expected in place of Nobody knows anything (chapter 4). In all white nonstandard dialects, this is an optional rule. The T-Birds apply the negative concord rule in 98 percent of these cases, the 1390 Lames only 76 percent of the time. We have here a qualitative contrast between a semicategorical use of the rule and a variable one.

3. One of the characteristic features of informal southern syntax is the use of inverted word order in embedded questions: I asked him could be do it instead of the northern form I asked him if he could do it. This is the normal use in BEV but is heard only rarely in northern white dialects. The Thunderbirds use the inverted order without if 80 percent of the time, the 1390 Lames only 20 percent. We saw in chapter 2 that this feature was quite compelling for many members, but it is not so for Lames.

There are many more such indicators which we might select from our grammatical studies of BEV, but by now the overall pattern should be apparent. Categorical or semicategorical rules of BEV are weakened to variable rules by the Lames; rules that are in strong use in BEV are reduced to a low level by the Lames. Whenever there is a contrast between SE and BEV, the language of the Lames is shifted dramatically towards SE. In many cases, this leads to a close alignment between the Lames and white nonstandard vernaculars. This does not necessarily imply that the Lames are modeling their behavior directly on the white nonstandard speakers, but rather that their interaction with SE patterns brings them from a point farther away from SE to roughly the same distance as members of the white vernacular culture.

If we now return to the speech of Lesley C. on page 283, his distance from the vernacular becomes more apparent. Lesley uses the [in] version three times in a row in connected speech, which is simply not done by members. He preserves consonant clusters in the second pushed (the first is neutralized), and in almost crying, though he deletes the -d in and hand. The use of the preterit ain't shows that Lesley is within the BEV system, but his use of that system is lame.

4. Verbal Agreement and Disagreement for Members and Lames

For a broader view of the contrast between the language of members and lames, we can turn to a series of measures which are very sensitive to distance from the vernacular culture. In general, we can say that the black vernacular has no agreement between subject and verb. There is one exception: some agreement is clearly registered in the finite forms of be. Here the 1st person singular regularly has contracted 'm, 3rd person singular has is or 's when realized, and other persons when realized mostly have are, sometimes is. Aside from this, we have invariant verb forms with no relation to the person and number of the subject. Forms in -s are rarely found for have, do, don't, want, or say. The invariant form for be in the past is was, not were. These facts are illustrated by Tables 7.4 and 7.5,
THE VERNACULAR IN ITS SOCIAL SETTING

The Linguistic Consequences of Being a Lame

beginning to modify their speech in the direction characteristic of adults. They show 22 -s forms altogether in Table 7.4, though the predominant use is still the zero form in all cases except want. In Table 7.5, they show a clear tendency towards the use of were with the plural and 2nd person singular.

The third line of Tables 7.4 and 7.5 shows the figures for 10 lames, drawn from the T-Bird, Cobra, and Jet areas. There is a clear reversal of the BEV pattern for have and want, where has and wants are preferred in 3rd person singular contexts. There is also a pronounced shift towards doesn’t. In Table 7.4, only do and say keep their vernacular forms. In Table 7.5, the Lames have clearly adopted subject-verb agreement. They show almost no were with 1st and 3rd person singular and use mainly were forms elsewhere.

The last line of Tables 7.4 and 7.5 gives us a comparison with the white Inwood groups, speakers of the nonstandard New York City vernacular. There is no deviation from the standard pattern of agreement for have, do, or say. A few anomalies appear for want and was/were. The only place where there is any sizeable lack of agreement is with the predominant use of don’t for doesn’t with third person singular subjects. Note that the Lames match the Inwood group closely on this verb and differ from the Inwood group only on do and say.

The pattern of agreement and disagreement can be summed up in Table 7.6, which shows the use of the standard marker of agreement for the five auxiliaries studied in Tables 7.4 and 7.5. The club

members use these forms with very low frequency. The Lames use has and were and show some use of doesn't. The white Inwood group uses all of them except doesn't, where its use is about that of the Lames.

We can therefore conclude that the use of has, were, and doesn't is a clear sign of shifting away from the black vernacular which distinguishes lames from members.

5. Analysis of the Jet Membership

Having determined that the lames are indeed marked linguistically by their distance from the vernacular culture, we can ask whether the same principle may not operate within the central peer groups as well. If peer-group pressures are important in maintaining the vernacular in its present uniform state and in resisting the pressures of other dialects, then those who are most bound by the norms of the group should show the most consistent form of the vernacular. It is the leaders of vernacular peer groups who are most closely governed by group norms, as Whyte (1955) and others have shown. We might therefore ask what linguistic consequences follow if we decompose the group into leaders and followers, core and periphery, and see if peer-group pressures can make such fine discriminations.

The largest of the groups that we studied in south-central Harlem was the Jets, the adolescent club which dominated West 112th Street between Eighth Avenue and St. Nicholas Avenue. Figure 7.4 shows the distribution of the Jet membership in that area; altogether, 36 persons were interviewed. There are plainly two centers from a geographic point of view: one is concentrated on the short block between Seventh and St. Nicholas Avenues—the 100’s block—and the other at the far end of the 200’s block, near Eighth Avenue. These areas also represent two separate subgroups in social organization.

The Linguistic Consequences of Being a Lame

The Jets are a street club, organized by the members, without adult initiation, supervision, or guidance. As a named club, the Jets have the following features:

1. Leaders: a president, vice-president, war-lord, and prime minister.
2. Members.
3. A name.
4. A history and mythology.
5. A song.
6. Initiation ceremonies.
7. An associated junior club.

The history of the Jets goes back to 1958. It was formed as a junior club to the Red Devils, which was then headed by Mickey Collins. Mickey’s younger brother Stanley became the president of the junior club and has continued to be the number one man in all the various changes that the group has been through. The Little Red Devils, with about 16 members, were renamed the Little Diamonds in 1960; in 1962 became in rapid succession the Jets, the Cobrastetas, the Horsemen, and again the Jets. Shortly before we contacted them in 1965, the numbers of the Jets were doubled by the joining up of the 200’s block, giving a total membership of 35 to 40.

The internal structure of the Jets is much more complex than we first realized: it is a product of geography, local interests, and primary group alliances. The club is actually a superordinate organization, the largest unit of social structure in the vernacular culture, called

---

13. The analyses of the social structure of the Jets and the conceptual framework used here are the work of Teresa Labov, to whom I am greatly indebted. For further analysis of peer terminology, club names, the associative plural and ‘em, and the relations of hang-out groups to the club, see T. Labov 1969.
14. There are also one or two scattered members to the north, including the president, Stanley, but this is a result of recent relocation by his family. The apartment rented by John Lewis (club house) is located in the middle of the 100’s block.
15. The Cobras, located on 115th–116th Streets, was at one time a brother club but at the time of the study was in conflict with the Jets. In 1962, the Cobras were known as the Jets for a time, which explains the rapid shifting of names.
into existence only on ritual occasions or at moments of crisis in conflict with another group. Members normally associate in hang-out groups, smaller aggregates who are involved in a range of daily transactions quite distinct from the Jet activities. As we will see below, the primary influence and major control on linguistic behavior is exercised by these hang-out groups.

Our most systematic information on the structure of the hang-out groups is derived from two questions: "Is there a bunch of cats you hang out with?" and "Of all the cats you hang with, who's the leader?" These data yield sociometric diagrams such as Fig. 7.5, which shows the hang-out groups in the 100's block. Again, the main social links are the reciprocal namings, shown as heavy dark lines. Connections with the 200's block are quite weak: there are no such reciprocal namings between the 100's and 200's. Fig. 7.5 shows that the leader, Stanley, is a pivotal member of two distinct hang-out groups of core members. One is the "six best fighters:" Deuce, Vaughn, Larry, Jesse, Ronald, and Stanley. The other is a group of five that owns and flies pigeons on the roof-tops: Stanley, Hop, Rednall, Doug, and Rel. At the lower end of Fig. 7.5 is a group of younger members, from 12 to 14; the core members at the upper end are 15 to 16 years old. The complete pattern of namings is shown in Table 7.7, in which the Jets are broken down into core, secondary, and peripheral members. Core members are clearly marked in the number of reciprocal namings, with at least two, and as many as eight; secondary and peripheral members have only one or two. The secondary members of the Jets are located entirely within the structure where they hold an inferior status; this is their primary "social address." Peripheral members, on the other hand, are partially detached from the group because they are older, live at a distance, or have other interests, but not because they have lower status.16 They are less under the control of the group, and we may therefore expect them to be less dominated by it in their linguistic patterns.

On the outer edge of the networks in Fig. 7.5 we see a few lames who name some Jets in the hang-out question, but are not normally mentioned in turn by anyone (with one exception, by a peripheral member). These are definitely not considered members by anyone,

16. Senior members such as Deuce are actually peripheral in this sense. Other members of the Jet age range who are under pressure from parents to break away, but resist this pressure, may also hold a respected position, as with Ricky S.

Fig. 7.5. Hang-out pattern for the Jets 100's block. F = six best fighters, P = pigeon flyers.
of the group in the 100's core show the highest use of this rule, the
200's core slightly lower, and both sets of secondary members again
considerably lower use. The most striking fact is that the peripheral
members and lames use the deletion rule less than half as much as
core members.

If we now compare Table 7.8 with Tables 7.4 and 7.5, it is evident
that the Oscar Brothers and the peripheral members of the Jets are
in the same relative position. These are older, somewhat wiser
members who have begun to emerge from their total immersion in
the vernacular culture. They are not lames—they have not lost their
knowledge of local ways and doings; but they have begun to show
the effects of a greater awareness of the larger cultural matrix in
which the black English vernacular is embedded. They would nor-
mally be considered "bidialectal," and they would give outside
observers the strong impression that they were capable of switching
abruptly between the vernacular and a more standard dialect. But
even the most casual style in group sessions among these older
members shows a distinct shift away from the vernacular. In general,
we do not find bidialectalism in this simple sense of switching from
a new to an older dialect. Learning a new set of closely related rules
inevitably influences the form of the old rules. Turning to the lames,
we observe the same kind of shift away from the vernacular—but
at a younger age, with different consequences. The lames have not
passed through the same period of adolescent immersion in the
vernacular culture. Though they arrive at a similar grammatical
stance, the lames do not have the deep experience of the subculture
which peripheral members have absorbed. How much of this early
knowledge can be retrieved from older members who have shifted
away from the vernacular in their own personal use of the BEV
rules? We will return to this important question in section 6.

Not all of the features of the vernacular show a regular gradation
from the core members of the Jets outward. Some vernacular rules
are intact for everyone. One such case is negative concord within the
clause, which operates categorically in BEV to yield Nobody never
saw nothin' like that instead of Nobody ever saw anything like that
(see chapter 4 in this volume). Thirty-one of the 37 individuals
interviewed in the Jet area showed 100 percent use of this rule; the
remaining six are all individual cases and do not show any kind of
pattern.

There are also some markers of BEV which are common to all
members, but their use differentiates the lames sharply, giving the
kind of pattern that we saw in section 3. For example, all members
of the Jets use dummy it much more than dummy there in such
sentences as It's a difference. The members range from 60 to 84
percent use of dummy it; but the lames use it only 23 percent of
the time.

If the primary mechanism of social control is the hang-out group,
we should find local differentiation of clubs and of units within the
club. It is not difficult to locate examples of specific linguistic fea-
tures which are generalized throughout a primary group. The Cobras,
for example, may be differentiated from the Jets in their tendency
to use skr- for str- (as in skreet)—a coastal South Carolina feature
which has been adopted by members, including those with no family
background in that area. In general, we find no correlation between
linguistic features used by members and the geographic background
of their family; whatever regional influence appears is quickly gen-
eralized throughout the group.

A more specific highly localized feature is the pronunciation
an'sh-ith [anʃjθ] for the common tag an'shith. A small tightly-knit
subgroup within the six best fighters of the Jets core members uses
this form regularly—Larry, Jesse, and Vaughn. There are also a
number of intonational features and vocabulary items which differ-
entiate the two major groups and subgroups within them. Such small
tokens of group identification bear witness to the powerful group
pressures exerted on language.

The social organization known as the Jets has persisted for many
years with extraordinary stability, in spite of opposition from all of
the other social groups in the community. The adults in the Jet area
consider them "hoodlums"; the schools have suspended their leading
members; the courts have sent several to correctional institutions;
and the neighboring groups of their own age are even more hostile.
What then explains the success of the Jets as a stable social institu-
ction?

First of all, it is clear that there are socioeconomic factors, not
analyzed here, which operate upon inner-city communities to pro-
duce similar patterns of social organization. Table 7.9 shows some
of the social characteristics of the Jets and Cobras. They are remark-

18. Larry and Jesse are brothers; a third brother is Peaches, a central figure among
the younger members of the 200's block.

do not fight with the Jets, do not participate in any of the hang-out groups, and are plainly not members of the vernacular culture. In addition, we interviewed a number of lames in the Jet area who do not appear in Fig. 7.5 at all and have no connection with the Jets though they knew of them. We thus have eight lames in the Jet area to contrast linguistically with the members.

We can dispense with a diagram of the sociometric diagram for the 200's block, whose naming pattern is included in Table 7.7. The same principles apply to the division of the 200's membership.

In section 3, we found that the frequencies of the contraction and deletion of is were among the most sensitive indicators of the speaker's relation to the vernacular and the vernacular subculture. The use of the contraction rules was similar for members and lames, but there was a qualitative difference in the use of the deletion rule. We are now in a position to use that index to look for finer linguistic correlates of peer-group membership.

Table 7.8 shows the use of contraction and deletion by the six subcategories of Jet membership developed in Table 7.7. Again, we note no significant differences in the use of the contraction rule, which is the common property of all dialects. But the deletion rule is tightly correlated with subdivisions of Jet membership. The leaders

17. Ed and Donald are connected with the pattern only in that they name others but are not named by anyone in return. Kenneth, 10, forms one of two exceptions, since he hangs out with the secondary member Sammy. It should be emphasized that these sociometric patterns are not the only defining characteristics of the members: more substantive accounts of their activity are essential elements in this assignment.
Champ’s answer illustrates the jet values of mutual support and gain of status in fighting and the sense of belonging to a neighborhood. There are also gains in support against the perceived oppression of the surrounding society, the prestige of close association, and the inside knowledge proceeding from that association. In chapter 6, Vaughn R. gives us the clearest view of what the Jets can provide for someone who could follow the upward path of social mobility through education, but refuses. Vaughn moved into the area from Washington Heights the year before. He had demonstrated the ability to use the school culture for his personal advantage, but he deliberately selected the Jets’ culture instead. In Vaughn’s statement (page 250), we saw that the inside knowledge proceeding from the association with the peer group is a major factor in supporting the group. For Vaughn, the covert values of the vernacular culture have become overt: he sees the Jets as a force directly opposed to the dominant white value system which claimed his allegiance but which he has rejected.

We have already seen that Vaughn is an integral member of the “six best fighters” and has some superficial linguistic markers in common with Larry and Jessie H. But since Vaughn has come into the jet orbit only in the past year, one would not expect him to have absorbed the whole range of grammatical and phonological patterns of the Jets. Vaughn implies that he was more or less a lama in Washington Heights and it is inevitable that his grammar will reflect this. Whereas other Jets show the usual 100 percent negative concord within the clause, Vaughn is variable: he shows only 30 of 35 cases of transfer of the negative to a following indefinite. He uses dummy if for there in only two out of seven cases. Whereas other Jets show 17 out of 18 or 21 out of 22 monomorphic clusters simplified before a consonant (as in just me) Vaughn simplifies only 4 out of 17. We would therefore be justified in removing Vaughn’s records from the mean values for the Jets, which would explain some of the slight irregularities noted in the tables above. Vaughn is able to give us an excellent and explicit statement of the value of belonging to the jets; but his linguistic system cannot adjust as quickly as his value system or his style of life. The remarkably consistent grammar of the Jets is the result of ten years of their continuous interaction with each other and with other groups in the BEV system.

If we see the primary group as the main agent in the social control of language, we then have to explain the great uniformity of the black English vernacular throughout the major cities of the North and
South and even in most rural areas. It has now been well-established that the grammar we are dealing with is essentially the same in New York, Detroit, Washington, Philadelphia, and San Francisco, and such uniformity may very well reflect the presence of a widespread Creole grammar used throughout the southern United States in the 18th and 19th centuries. Yet if the primary group can exert such influence on language, what prevents various subgroups from drifting off in different directions? This is a question which cannot be settled in the light of our present knowledge. But it should be noted that it is not merely the grammar which is uniform. The vernacular culture itself is equally constant from one urban area to another; the grammar is just one of the many elements of the social pattern which is transmitted. This uniformity cannot be maintained by adolescents, since the great majority of the members who travel from one city to another are adults. We should therefore be hesitant in saying that the late teens are the upper limit for the consistent use of the black English vernacular. It is true that the adults recorded in interviews with Clarence Robins have as a whole shifted away from the vernacular on all the variables that discriminate members and lames. In their use of (t), (dh), and (ing), working-class adults resemble the lames rather than members. Negative concord is variable in adults and in lames, but obligatory for members. In consonant cluster simplification, adults show the grammatical constraint as more important than the phonological one, again resembling lames more than members. The most sensitive index of the black English vernacular is the use of the deletion rule for is: working-class adults are at an even lower level than the lames, e = .21 as against .60–.70 for members and .36 for lames. We also find that adults show subject-verb agreement with 3rd person singular -s; while this inflection is present only zero to 40 percent of the time among members, it is found from 70 to 100 percent of the time among adults; furthermore, the adults show a phonological rule operating in that they show more -s before a following vowel, while members show the inflection less often in this context. Adults rarely use dummy it for there, seldom use ain't for didn't, and rarely use the habitual be.

But before we conclude that the entire adult population is lame, it must be remembered that we did not record adults in social interaction with their own friends and neighbors. Even in casual speech, adults fall short of the mark set by the group sessions with members; but the sections of casual speech which we drew from

the interview are less valid approximations to the vernacular than the group sessions of the Jets and Cobras. Instead of concluding that the basic grammar of adults has shifted we might say that adults have greater practice in shifting the use of the variables towards the standard in semi-formal contexts. Until we have carried out long-term participant observation with adult groups, it is impossible to make any firm statements about adult grammars. If we do finally conclude that adult grammars have shifted away from the vernacular, the problem of explaining the uniformity of the BEV grammar throughout the country will become formidable. If adults are not the ultimate model upon which the vernacular is based, what would prevent the adolescent peer groups from gradually dispersing in 100 different directions?

6. The Prevalence of Lames

The term ‘lame’ carries the negative connotation that was originally intended by the BEV culture who applied it to the isolated individuals around them. But it is evident that the lames are better off than members in many ways. They are more open to the influence of the standard culture, and they can take advantage of the path of upward mobility through education, if they are so inclined or so driven (see chapter 6). They are less open to social pressures to fight, to steal, or take drugs. Of course some lames steal, shoot up, and drop out; but as a group, they have a better record.

In a study of 37 addict and nonaddict sibling pairs, Claser et al. 1971 found that 22 of the addicts said that they had hung out in gangs as kids, and only seven of the nonaddicts. In 16 of the cases, it was agreed that the nonaddict had stayed home most as a teenager, and in only seven was this said of the addict. There are any number of positive terms that I might have applied to lames which would reflect this side of the matter, contrasting them with the members of the lower-class peer groups: nondelinquents, culture-free as against culture-bound, upwardly mobile as against downwardly mobile. Even a neutral term such as isolates would have avoided the pejorative sense of lame which must inevitably irritate readers who realize that lames are better individuals from the standpoint of middle-class society—and even more importantly, that it is to the personal advantage of any individual to be a lame. Even if he does not go to college, he has a better chance
of making money, staying out of jail and off of drugs, and raising children in an intact family. Given hindsight or a little foresight, who would not rather be a lame?

The term lame serves to remind us that it is the normal, intelligent, well-coordinated youth who is a member of the BEV culture and who is suffering from the social and educational depression of the ghetto. The lames are exceptional in one way or another. Some unusually intelligent and some unusually stupid boys are lames; some lames are courageous and self-reliant individuals who go their own way with no need of group support, and some are weak or fearful types who are protected from the street culture by their mothers, their teachers, and their television set. Some lames gain safety or success through isolation, but in exchange they give up the satisfaction of a full social life and any first-hand knowledge of the vernacular culture. Other lames have gained nothing through their isolation; they are the victims of a disorganized and demoralized sub-section of the community. Many descriptions of the poor and disadvantaged are explicitly about lame areas and lame children. The study by Pavenstedt et al. of deprived children in the North Point Project of Boston was concerned with disorganized families exhibiting "social and/or psychological pathology".

They do not belong to a "culture," having neither traditions nor institutions. No ethnic ties nor active religious affiliations hold them together. In fact we speak of them as a group only because of certain common patterns of family life and a form of peripheral social existence (Pavenstedt 1967:10).

The descriptions of the language of these children matches the picture of "verbal deprivation" which we find in educational psychologists who have developed the "deficit hypothesis" (Sociolinguistic Patterns, chapter 8; Ginsburg 1971). We have not studied children of this type, but many of the apparently unrealistic descriptions of the language behavior of lower-class black children may be based on such specially selected populations.19 It should also be noted that "verbal deprivation" may occur in isolated upper-working-class families where both parents work, and preschool children are kept at home, forbidden to play with others on the street.

In other discussions of the vernacular we have indicated that the lames have suffered a loss of some magnitude in their isolation from its rich verbal culture.20 The members themselves, who have responded to the definition of man as a social animal, see most clearly the overwhelming disadvantages of being a lame. For those who are trying to understand the structure and evolution of social behavior, the disadvantages of dealing with lames will eventually appear just as clearly. At first glance, lames appear to be members of the community; they are much more accessible to the outsider than members are; and the limitations of their knowledge are not immediately evident. But the result as we have seen may be an inaccurate or misleading account of the vernacular culture.

Many of the informants used by linguists and anthropologists are lames—marginal men who are detached from their own society far enough to be interested and accessible to the language, the problems and preoccupations of the investigator.21 It is even more common for the linguist to work with captive populations—classes of students who are tested as a whole without regard to their group membership or participation in the culture being studied. Subjects selected with the assistance of teachers, psychologists, or parents are even more heavily biased towards the lame population and unfortunately, the number of studies of black English vernacular made in schools far outnumber the studies done by direct contact with members in a vernacular context.22 If

19. Note that some such projects explicitly concentrate on subjects with histories of psychological pathology or work in areas with high concentrations of mental retardation. This was the case with the study of Heber, Dever, and Conry 1968, discussed in chapter 8.

20. See Abrahms (1964), chapters 7 and 8 in this volume and section 4.2 of CRR 3288 for evidence that BEV culture is the most verbal subculture within the United States. As a whole, the lames have lost out on this, although many have managed to transfer their verbal skills into a superbly elaborated version of the Bernsteinian elaborated code.

21. The classic case is the work of Loflin (1967) whose descriptions of the grammar of black English vernacular are explicitly based on data obtained over a period of approximately a year from one 14-year-old boy. Data supplied by an isolated individual in response to direct questions may be skewed from the vernacular in the direction of the standard, as in the data given above. But if the informant understands that the linguist is interested primarily in those features which are most different from the standard he will produce a stereotyped version in the opposite direction. A comparison of Loflin's descriptions with the spontaneous group data from the same community collected in Loman (1967) shows that this kind of distortion is most common: as for example, reporting that there is no prefer it—ed or have -en in the dialect.

22. For school-based studies see Lohman 1966, Henrie 1968, Entwisle and Greenberger 1969, Baratz 1968, Casden 1968, Carney and McFarlane 1968 and many others. For secular studies, see Wolfram 1969, Mitchell 1969; those cited in this study, and not many others.
the vernacular culture is the main stream of linguistic and social evolution as we have argued elsewhere then this is a serious matter. Let us consider for a moment some of the ways in which lames fall short as informants.

We have already seen in section 2 that Lesley and the other 1390 Lames used a kind of black vernacular that was much closer to some of the other nonstandard vernaculars than to BEV. They show subject-verb agreement, variable negative concord, contraction of is but very little deletion, and so on. If we begin to explore broader aspects of the vernacular culture, the data are even more skewed. One of the most important regulations in peer-group society are the rules for fair fighting and the violations of those rules that make up street fighting. The information we can get from Curtis is only hearsay. He has been in no major fights of his own, and his accounts of T-Bird fights are those of a bystander who never understands how they started. One of our basic questions in the "Fight" section of our interview schedule is, "What was the best fight you ever saw?" To get the same message across to lames, we have to translate this into "What was the worst fight you ever saw?" A great many lames actually deny the fights they were in—partly because they lost, and partly because they have been trained to think of fighting as a bad thing to do. As a result, lame narratives of personal experience are lame, too.

If we are interested in toasts, jokes, sounds, the dozens, rifing, or capping, we cannot turn to the lames. They have heard sounding from a distance, but proficiency at these verbal skills is achieved only by daily practice and constant immersion in the flow of speech. Lames do not know "Signifying Monkey," "Shine," "The Fall," or any of the other great toasts of the oral literature. But away from home, some lames look back on the vernacular culture and try to claim it as their own; the result can be a very confused report for the outsider who relies on such data.

At recent scholarly meetings on black studies, there have been violent objections from black students and professionals to the use of the term black English, with repeated demands for a definition which could not be satisfied. Some educated black speakers argue that black English should be used for the language that they themselves use, since they are black, and deny that they use many of the words or grammatical forms quoted by the linguist as "black English." This objection seems to be valid. It seems much more appro-

The Linguistic Consequences of Being a Lame

propriate to use the term black English vernacular, BE vernacular, or BEV to identify the consistent grammar of the peer group members that has been analyzed by linguists. We will then avoid the improper opposition of "Standard English" to "black English," implying that this is the major axis dividing the English language. Instead, we should oppose the standard language to all nonstandard dialects or vernaculars. One of these is the black English vernacular.

Most of the black professors and students that I have met in the universities are intent on absorbing whatever the "high culture" of Western literature, European literature, art, and scholarship has to offer, but without losing what they feel are the essential values of their own background. But at the same time, many condemn "ghetto English" as an inferior means of communication and claim that black people can improve their social and economic position only if they acquire the formal means of expression used by this high culture. There is a division of opinion on the place for the vernacular, usually referred to as "our own language," "home language" or "soul language." Most college students will claim to have a deep and intimate knowledge of it and insert into their basically standard grammar quotations from the "language of the street." But very few are willing to examine the grammar of this dialect.

But the findings presented here indicate that unless these speakers were raised within the majority peer group culture and broke away from their group only in late adolescence, their grammar will be peripheral to the black English vernacular. They may be at a greater disadvantage than they realize in dealing with complex rules such as those involved in negative concord since their own grammars may be influenced by other dialects in a number of subtle and indirect ways. In any case, black students are not yet making the major contribution to linguistics and the investigation of the black English vernacular that we hope for. 23 This is a serious problem, for it is hard to imagine the study of the BE vernacular making good progress without black linguists carrying the major share of the field work and analysis. Given our present social situations, most black graduate students will be lames; but even with the limitations shown here,

23. There are a number of graduate students from black communities in the U.S. who are now working on problems of black English in various research groups throughout the country; there is a good possibility that the statement made here will be obsolete by the time this book appears.
it should be clear that they are much closer to the black vernacular than any white student will be. More importantly, they have the background and credentials to become as close as they want to. To do this it is only necessary that they achieve a firm understanding of what the vernacular is, who speaks it, and how they stand in relation to it.

The position of the black graduate student in linguistics is no different from that of any linguist in his removal from the vernacular. If a black student should take seriously Chomsky’s claim that the primary data of linguistics is the intuition of the theorist and begin to write an introspective BEV grammar, the results would be bad—but no worse than other grammars now being written on the same basis. The problem we are dealing with here is one of the greatest generality, for it must be realized that most linguists are lames.

7. The Linguist as Lame

There are communities where the basic vernacular is a prestige dialect which is preserved without radical changes as the adolescent becomes an adult. The class dialect used in British public schools had that well-formed character, and presumably a British linguist raised as a speaker of Received Pronunciation can serve as an accurate informant on it. There are middle-class French and Spanish children who may be in the same favorable position in relation to their prestige dialect. To a lesser extent, this may be said about a few Americans who grow up in upper middle-class communities where 90 percent of the high-school graduates go on to college. On the surface, they seem to continue using the dialect that was the main vehicle of communication by peer groups in their preadolescent years and are able to represent that group in speech as well as intuition.

The great majority of linguists are probably not in that position. They were already detached from the main peer group activity in early adolescence as they pursued their own interests, and by the time they enter graduate studies in linguistics are at some distance from the majority of vernacular speakers in their community. I was a lame myself in my adolescent years; my knowledge of the nonstandard vernacular of the working-class majority in Fort Lee, New Jersey, is as indirect as the lames’ knowledge of black vernacular described above. The knowledge I now have of how to deal with the vernacular culture of adolescent and adult groups was gained in contacts since then—in factories, in the service, and in many field trips to urban and rural areas—always with a full recognition of this initial distance. Fortunately for linguists interested in the study of language in its social context, the problem of gaining access to peer groups and of observing natural interaction does not require that the full distance be crossed in each encounter. The linguist can learn principles of social organization which are very much the same in regions as distant as Hawaii, Chicago, Kingston, Glasgow, and Paris.

Even if the linguist is raised in a community of peers, fully immersed in the mainstream of social life in his high school years, he inevitably broadens his horizon when he pursues college and graduate training and weakens his command of the vernacular. Our studies of sound change in progress in cities throughout England and America shows that college students are in general a very poor source of data. The sharp, clear patterns shown in the working-class speakers are blurred, limited, and mixed in the speech of the college student. The principle seems to hold that learning closely-related dialect rules affects the form of the original ones. The linguist who is alert to the widest range of dialect differences, who may construct the broadest pan-dialectal grammar, is often the worst informant on his own local dialect. There are of course exceptions—some speakers show an extraordinarily tenacious hold on their original dialect. But we do not know who the exceptions are until we have studied the vernacular in the intact speech community itself.

I do not believe that it is natural or inevitable that the linguist be a lame, or that only lames go to college. I am not convinced that linguistic analysis—or a future linguistic science—must be carried out in the grammar of the high culture. Nor is it inevitable that black students who go to college and graduate school be lames. In our present social system, the best way for a lower-class youth to achieve upward social mobility, money and security is by breaking away from his group. The social and psychological price for this move is well-known. But there is some reason to think that the group can
move as a whole, and a few signs that this might indeed happen in our society. If this should happen, the gains would be very great for everyone concerned, including the linguist who has more to learn from members than lames.

When we now hear linguists speaking at every hand about "my dialect" and "dialect variation" we are bound to wonder what basis they have for their claims. The only data usually provided is that some other linguist has disagreed with their intuitive judgments on certain sentences, and it is therefore decided that the critic is speaking a different dialect. "My dialect" turns out to be characterized by all the sentence types that have been objected to by others. Although it has been claimed that some speakers differ from each other repeatedly and reliably, no correlation is claimed with geography, peer group, family, or fraternity. Such idiolectal variations are said to be correlated with the systematic development of syntactic rules in particular directions, a product of the language-learning faculty in its most subtle and efficient form. If so, it will undoubtedly appear that no two linguists have the same dialect, unless they are colleagues jointly responsible for the same theory. These are lame dialects, and it is appropriate that they be conceived, developed and analyzed in isolation.

It is difficult for us, caught up in current linguistic practice, to evaluate the overwhelming reliance of our field on the theorist's own intuitions as data. Scholars of the future who must eventually review and explain our behavior may find it hard to understand our casual acceptance of confused and questionable data, the proliferation of ad hoc dialects, and the abandonment of the search for intersubjective agreement. They may point out that most scholars will do whatever they have been told is right and proper by other scholars. But their analysis may also indicate that our current trend is supported by more than local ideology: a theoretical stance can become a congenial way of life. To refine the intricate structure of one's own thoughts, to ask oneself what one would say in an imaginary world where one's own dialect is the only reality, to dispute only with those few colleagues who share the greatest part of this private world—these academic pleasures will not easily be abandoned by those who were early detached from the secular life. The student of his own intuitions, producing both data and theory in a language abstracted from every social context, is the ultimate lame.
