

MEMORANDUM

17th Feb 1987

From: Tamin Bayoumi and John B. Taylor
Department of Economics
Stanford University

To: Ralph Bryant

Subject: Revised Simulations of the Current Account

We attach a revised copy of the tables in our December 17, 1986 memorandum for the conference on the current account. These tables include the reporting and formatting changes agreed to at the conference. (Please note that we have not revised our old Table 4-2, the full simulation of the model. The changes reported there are in percentages, not fractions, as stated in the table).

The data are slightly different from those in our December 17 memorandum. To the export price equation we have added a time trend that improves its historical tracking performance. Because the slope coefficient is approximately the same as before (.9806 rather than .9812), the response of the system to changes in the forcing variables are essentially the same and require no further discussion. (The coefficient on the time trend is .000254).

There is one point concerning historical tracking which Tam mentioned at the conference, but which we would like to emphasize further. Getting good estimates of the size of the shocks to the equations of this model is central to its use in policy evaluation. Stochastic simulation under alternative policy rules is the main technique for policy evaluation, and of course for stochastic simulation we need estimates of the variance covariance matrix. These estimates come from the sample period shocks.

For this reason, close historical tracking for a fixed set of exogenous variables is not a criterion that we have aimed for. For example, there are essentially no dummy variables in the model. We would rather associate such dummy variables with shocks to the equations. The things that dummy variables represent (eg. dock strikes) can not usually be anticipated in the future. As a result an equation with a relatively poor historical tracking may give a better estimate of the shocks for policy purposes than an equation which tracks very well.

Table 1-1. SINGLE EQUATION DYNAMIC SIMULATIONS.
 (Fractional deviation of the simulated path from historical path).
