Abstract. In this paper, we study the statistical limits of deep learning techniques for solving elliptic partial differential equations (PDEs) from random samples using the Deep Ritz Method (DRM) and Physics-Informed Neural Networks (PINNs). To simplify the problem, we focus on a prototype elliptic PDE: the Schrödinger equation on a hypercube with zero Dirichlet boundary condition, which is applied in quantum-mechanical systems. We establish upper and lower bounds for both methods, which improve upon concurrently developed upper bounds for this problem via a fast rate generalization bound. We discover that the current Deep Ritz Method is sub-optimal and propose a modified version of it. We also prove that PINN and the modified version of DRM can achieve minimax optimal bounds over Sobolev spaces. Empirically, following recent work which has shown that the deep model accuracy will improve with growing training sets according to a power law, we supply computational experiments to show similar-behavior of dimension dependent power law for deep PDE solvers.

Key words. Machine Learning, Non-parametric Statistics, Deep Ritz Methods, Physics Informed Neural Networks

1. Introduction. Partial differential equations (PDEs) play a prominent role in many disciplines of science and engineering. The recent deep learning breakthrough and the rapid development of sensors, computational power, and data storage in the past decade has drawn attention to numerically solving PDEs via machine learning methods [45, 44, 58, 26, 68, 38], especially in high dimensions where conventional methods become impractical. The set of applications that motivate this interest is wide-ranging, including computational physics [26, 45, 58], inverse problem [82, 22, 17] and quantitative finance [30, 21]. The numerical methods generated by the use of deep learning techniques are mesh-less methods, see the discussion in [78]. A natural deep learning technique in the problems that are based on a standard feed-forward type of architecture takes advantage (when available) of a variational formulation, whose solution coincides with the solution of the PDE of interest. Despite the success and popularity of adopting neural networks for solving high-dimensional PDEs, the following question still remains poorly answered.

For a given PDE and a data-driven approximation architecture, how large the sample size and how complex the model are needed to reach a prescribed performance level?

In this paper, we aim to establish the numerical analysis of such deep learning based PDE
solvers. Inspired by recent works which showed that the empirical performance of a model is remarkably predictable via a power law of the data number, known as the neural scaling law [37, 31, 65], we aim to explore the neural scaling law for deep PDE solvers and compare its performance to Fourier approximation.

Among the various approaches of using deep learning methods for solving PDEs, in this work, we focus on the Deep Ritz method (DRM) [15, 38] and the Physics-Informed Neural Networks (PINN) approach [68, 58], both of which are based on minimizing neural network parameters according to some loss functional related to the PDEs. To provide theoretical guarantees for DRM and PINN, following [47, 14, 2], we decompose the error into approximation error [80, 70, 66] and generalization error [3, 79, 18, 63, 70]. However, instead of the $O(1/\sqrt{n})$ (n is the number of data sampled) slow rate generalization bounds established in prior work [47, 66, 78, 67], we utilize the strongly convex structure of the DRM and PINN objectives and provide an $O(1/n)$ fast rate generalization bound [3, 79] that leads us to a non-parametric estimation bound. Our theory also suggests an optimal selection of network size with respect to the number of sampled data. Moreover, to illustrate the optimality of our upper bound, we also establish an information-theoretic lower bound which matches our upper bound for PINN and a modified version of DRM.

We also test our theory by numerical experiments. Recent works [31, 37, 62, 51] studying a variety of deep learning algorithms all find the same polynomial scaling relation between the testing error and the number of data. As the number of training data n increases, the population loss $L$ of well-trained and well-tuned models scales with n as a power-law $L \propto \frac{1}{n^\alpha}$ for some $\alpha$. [65] also scans over a large range of $\alpha$ and problem dimension $d$ and finds an approximately $\alpha \propto \frac{1}{d}$ scaling law. In Section 4, we conduct numerical experiments to show that this phenomenon still appears for deep PDE solvers and this neural scaling law tests more idiosyncratic features of the theory.

1.1. Related Works.

**Neural Scaling Law.** The starting point of our work is the recent observation across speech, vision and text [31, 37, 62, 61] that the empirical performance of a model satisfies a power law scales as a power-law with model size and dataset size. [65] further finds out that the power of the scaling law depends on the intrinsic dimension of the dataset. Theoretical works [63, 70, 72, 9, 33, 18, 36] explore the optimal power law under the non-parametric curve estimation setting via a plug-in neural network. Our work extends this line of research to solving PDEs.

**Deep Network Based PDE Solver.** Solving high dimensional partial differential equations (PDEs) has been a long-standing challenge due to the curse of dimensionality. At the same time, deep learning has shown superior flexibility and adaptivity in approximating high dimensional functions, which leads to state-of-the-art performances in a wide range of tasks ranging from computer vision to natural language processing. Recent years, pioneer works [26, 58, 45, 68, 38] try to utilize the deep neural networks to solve different types of PDEs and achieve impressive results in many tasks [46, 42]. Based on the natural idea of representing solutions of PDEs by (deep) neural networks, different loss functions for solving PDEs are proposed. [26, 27] utilize the Feynman-Kac formulation which turns solving PDE to a stochastic control problem and the weak adversarial network [81] solves the weak formulations of PDEs via an adversarial network.
In this paper, we focus on the convergence rate of the Deep Ritz Method (DRM) \cite{15, 38} and Physics-Informed neural network (PINN) \cite{58, 68}. DRM \cite{15, 38} utilizes the variational structure of the PDE, which is similar to the Ritz-Galerkin method in classical numerical analysis of PDEs, and trains a neural network to minimize the variational objective. PINN \cite{58, 68} trains a neural network directly to minimize the residual of the PDE, i.e., using the strong form of the PDE.

**Theoretical Guarantees For Machine Learning Based PDE Solvers.** Theoretical convergence results for deep learning based PDE solvers raises wide interest recently. Specifically, \cite{47, 23, 50, 77, 78, 67, 2} investigate the regularity of PDEs approximated by neural network and \cite{47, 48} further provide a generalization analysis. \cite{54} introduces a prior over the solution of the PDE and considers an equivalent white noise model \cite{6}. \cite{54} provides the rate of convergence of the posterior. Our paper does not need to introduce the prior on the target function and provides a non-asymptotic guarantee for finite number of data. At the same time, \cite{54} can only be applied to linear PDEs while our proof technique can be extend to nonlinear ones. All these papers also fail to answer the question that how to determine the network size corresponding to the sampled data number to achieve a desired statistical convergence rate. \cite{32, 49} consider the similar problem for the optimal transport problem, *i.e.* Monge-Ampere equation. Nevertheless, the variational problem we considered is different from \cite{32, 49} and leads to technical difference. The most related works to ours are two concurrent papers \cite{14, 34, 35}. However, our upper bound is faster than \cite{14, 34, 35}. In this paper, we also show that generalization analysis in \cite{47, 14, 48} are loose due to the lack of a localization technique \cite{12, 3, 39, 79}. With observation of the strong convexity of the loss function, we follow the fast rate results for ERM \cite{63, 79, 18} and provide a near optimal bound for both DRM and PINN.

**1.2. Contribution.** In short, we summarize our contribution as follows

- In this paper, we first considered the statistical limit of learning a PDE solution from sampled observations. The lower bound shows a non-standard exponent different from non-parametric estimation of a function.
- Instead of the $O(1/\sqrt{n})$ slow rate generalization bounds in \cite{47, 14, 34, 36}, we utilized the strongly convex nature of the variational form and provided a fast rate generalization bound via the localization methods \cite{75, 3, 39, 69, 79}. We discovered that the current Deep Ritz Methods is sub-optimal and propose a modified version of it. We showed that PINN and the modified version of DRM can achieve nearly min-max optimal convergence rate. Our result is listed in Table 1.
- We tested the recently discovered neural scaling law \cite{31, 37, 62, 28} for deep PDE solvers numerically. The empirical results verified our theory.

**2. Set-up.** We consider the static Schrödinger equation with zero Dirichlet boundary conditions on the domain $\Omega$, which we assume to be the unit hypercube in $\mathbb{R}^d$. In order to precisely introduce the problem, we recall some standard notions. We consider our domain as $\Omega = [0, 1]^d$ and use $L^2(\Omega)$ to denote the space of square integrable functions on $\Omega$ with respect to the Lebesgue measure. We let $L^\infty(\Omega)$ be the space of essentially bounded (with respect to the Lebesgue measure) functions on $\Omega$ and $C(\partial \Omega)$ denotes the space of continuous functions on $\partial \Omega$.

Let $f \in L^2(\Omega)$, $V \in L^\infty(\Omega)$, and $g \in L^\infty(\Omega)$. Our focus is on the analysis of Deep-
Learning-based numerical methods to solve the elliptic equations

\[-\Delta u + Vu = f \quad \text{in } \Omega,\]
\[u = g \quad \text{on } \partial \Omega.\]

2.1. Loss Functions for Solving PDEs and Induced Evaluation Metric. In this paper, we mainly focus on analyzing Deep Ritz Methods (DRM) and Physics Informed Neural Network (PINN). In this subsection, we first introduce the objective function and algorithm of the two methods.

Deep Ritz Methods. [15, 68] Recall that the equation 2.1 is equivalent to following variational form

\[u^* = \arg \min_{H^1_0(\Omega)} \mathcal{E}^{\text{DRM}}(u) := \frac{1}{2} \int_{\Omega} |\nabla u|^2 + V|u|^2 \, dx - \int_{\Omega} fu \, dx,\]

where \(u\) is minimized over \(H^1_0(\Omega)\) with boundary condition given by \(g\) on \(\partial \Omega\).

This variational form provides the basis for the DRM type method for solving the static Schrödinger equation based on neural network ansatz. More specifically, the energy functional given in equation 2.2 is viewed as the population risk function to train an optimal estimator approximation of the solution to the PDE within a parameterized hypothesis function class \(F \subset H^1(\Omega)\). In this paper, we also rely on the strong convexity of the DRM objective respect to the \(H^1\) norm.

Proposition 2.1. We further assume \(0 < V_{\min} \leq V(x) \leq V_{\max}\), then we have

\[
\frac{2}{\max\{1, V_{\max}\}} \left( \mathcal{E}^{\text{DRM}}(u) - \mathcal{E}^{\text{DRM}}(u^*) \right) \leq \|u - u^*\|_{H^1}^2 \leq \frac{2}{\max\{1, V_{\min}\}} \left( \mathcal{E}^{\text{DRM}}(u) - \mathcal{E}^{\text{DRM}}(u^*) \right)
\]

holds for all \(u \in H^1_0(\Omega)\).

Physics-Informed Neural Network. [58, 68]. PINN solves 2.1 via minimizing the following objective function

\[u^* = \arg \min_{H^1_0(\Omega)} \mathcal{E}^{\text{PINN}}(u) := \arg \min_{H^1_0(\Omega)} \int_{\Omega} |\Delta u(x) - V(x)u(x) + f(x)|^2 \, dx.\]
The objective function $E_{PINN}$ can also be viewed as the population risk function and we can train an optimal estimator approximation of the solution to the PDE within a parameterized hypothesis function class $F \subset H^1_0(\Omega)$. In this paper, we also rely on the strong convexity of the PINN objective with respect to the $H^2$ norm, for which we need some additional assumptions on the potential.

**Proposition 2.2.** For PINN, we further assume $V \in L^\infty(\Omega)$ with $0 < C_{\min} < V^2 - \Delta V, 0 < C_{\min} < V(x) \leq V_{\max}$ and $-\Delta V(x) \leq V_{\max}$, then we have for all $u \in H^1_0(\Omega)$

$$\frac{1}{2} \left( E_{PINN}(u) - E_{PINN}(u^*) \right) \leq \left\| u - u^* \right\|_{H^2}^2 \leq \frac{2}{\max\{1, C_{\min}\}} \left( E_{PINN}(u) - E_{PINN}(u^*) \right).$$

**2.2. Estimator Setting.**

**Empirical Loss Minimization.** In order to access the $d$-dimensional integrals, DRM [15, 38] and PINN[58, 68] employ a Monte-Carlo method for computing the high dimensional integrals, which leads to the so-called empirical risk minimization training for neural networks. To define the empirical loss, let $\{X_j\}_{j=1}^n$ be an i.i.d. sequence of random variables distributed according to the uniform distribution in domain $P_\Omega$. We also have access to $f_j = f(X_j) + \xi_j, j = 1, \cdots, n$ is the noisy observation of the right hand side of the PDE (2.1) and $\xi$ is a bounded random variable with mean zero and independent with $X_j$. Define the empirical losses $E_{n,S}$ by setting

$$E_{DRM}^n(u) = \frac{1}{n} \sum_{j=1}^n \left( |\Omega| \cdot \left( \frac{1}{2} |\nabla u(X_j)|^2 + \frac{1}{2} V(X_j)|u(X_j)|^2 - f_j u(X_j) \right) \right),$$

$$E_{PINN}^n(u) = \frac{1}{n} \sum_{j=1}^n \left[ |\Omega| \cdot \left( \Delta u(X_j) - V(X_j)u(X_j) + f_j \right) \right]^2,$$

where $|\Omega|$ represent the Lebesgue measure of the sets.

Once given an empirical loss $E_n$, we apply the empirical loss minimization to seek the estimation $u_n$, i.e. $u_n = \arg\min_{u \in F} E_n(u)$ where $F$ is the parametrized hypothesis function space we consider. For example, reproducing kernel Hilbert space[10] and tensor training format[60]. In this paper, we consider sparse neural network and truncated fourier basis, which can achieves min-max optimal estimation rate for the non-parametric function estimation[74, 63, 18, 70, 9, 36, 55].

**Sparse Neural Network Function Space.** In this paper, the hypothesis function space $F$ is expressed by the neural network following [63, 70, 18]. Let us denote the ReLU activation by $\eta_3(x) = \max\{x^3, 0\}$ ($x \in \mathbb{R}$) which is used in [15], and for a vector $x$, $\eta(x)$ is operated in an element-wise manner. Define the neural network with height $L$, width $W$, sparsity constraint
S and norm constraint B as
\[
\Phi(L, W, S, B) := \{ (W^{(L)} \eta_{\beta} + b^{(L)}) \circ \cdots \circ (W^{(2)} \eta_{\beta} + b^{(2)}) \circ (W^{(1)} x + b^{(1)}) | \\
W^{(L)} \in \mathbb{R}^{1 \times W}, b^{(L)} \in \mathbb{R}, W^{(1)} \in \mathbb{R}^{W \times d}, b^{(1)} \in \mathbb{R}^W, W^{(l)} \in \mathbb{R}^{W \times W}, b^{(l)} \in \mathbb{R}^W (1 < l < L) \},
\]
(2.5)
\[
\sum_{l=1}^{L} (\|W^{(l)}\|_0 + \|b^{(l)}\|_0) \leq S, \max_l \|W^{(l)}\|_{\infty, \infty} \vee \|b^{(l)}\|_{\infty} \leq B,
\]
where \(\circ\) denotes the function composition, \(\| \cdot \|_0\) is the \(\ell_0\)-norm of the matrix (the number of non-zero elements of the matrix) and \(\| \cdot \|_{\infty, \infty}\) is the \(\ell_\infty\)-norm of the matrix (maximum of the absolute values of the elements).

**Truncated Fourier Basis Estimator.** We also considered the Truncated Fourier basis as our estimator. Suppose the domain we interested \(\Omega \subseteq [0, 1]^d\). For any \(z \in \mathbb{N}^d\), we consider the corresponding Fourier basis function \(\phi_z(x) := e^{2\pi i x \cdot z} \ (x \in \Omega)\). Any function \(f \in L^2(\Omega)\) can be represented as weighted sum of the Fourier basis \(f(x) := \sum_{z \in \mathbb{N}^d} f_z \phi_z(x) \) where \(f_z := \int_\Omega f(x) \phi_z(x) dx \ (\forall z \in \mathbb{N}^d)\) is the Fourier coefficient. This inspired us to use the Fourier Basis whose index lies in a truncated set \(Z_\xi = \{ z \in \mathbb{Z} \|z\|_\infty \leq \xi \}\) to represent the function class \(\mathcal{F}\) as \(\mathcal{F}_\xi = \{ \sum_{\|z\|_\infty \leq \xi} a_z \phi_z | a_z \in \mathbb{R}, \|z\|_\infty \leq \xi \}\).

3. **Lower Bound.** In this section, we aim to consider the statistical limit of learning the solution of a PDE. As discussed in Propositions 2.1 and 2.2, we directly consider the \(H^1\) norm for DRM and \(H^2\) norm for PINN as the evaluation metric. The lower bound shown as follows.

**Theorem 3.1 (Lower bound).** We denote \(u^*(f)\) to be the solution of the PDE 2.1 and we can access randomly sampled data \(\{X_i, f_i\}_{i=1, \ldots, n}\) as described in Section 2.2. We further assume \(u^*(f) \in H^s\) for a given \(s \in \mathbb{Z}^+\), we have the following lower bounds.

**DRM Lower Bound.** For all estimators \(\psi : (\mathbb{R}^d)^{\otimes n} \times \mathbb{R}^{\otimes n} \rightarrow H^s(\Omega)\), we have
\[
(3.1) \quad \inf_{\psi} \sup_{u^* \in H^s(\Omega)} \mathbb{E}\|\psi(\{X_i, f_i\}_{i=1, \ldots, n}) - u^*(f)\|_{H^1}^2 \gtrsim n^{-\frac{2s^2}{d+2s+4}}.
\]

**PINN Lower Bound.** For all estimators \(\psi : (\mathbb{R}^d)^{\otimes n} \times \mathbb{R}^{\otimes n} \rightarrow H^s(\Omega)\), we have
\[
(3.2) \quad \inf_{\psi} \sup_{u^* \in H^s(\Omega)} \mathbb{E}\|\psi(\{X_i, f_i\}_{i=1, \ldots, n}) - u^*(f)\|_{H^2}^2 \gtrsim n^{-\frac{2s^2}{d+2s+4}}.
\]

**Proof.** We construct the following bump function to construct the multiple hypothesis test used for proving the lower bound. Consider a simple \(C^\infty\) bump function supported on \([0, 1]^d\)
\[
g(x) = \prod_{i=1}^{d} \xi(x_i), \quad x = (x_1, \ldots, x_d),
\]
where \(\xi : \mathbb{R} \rightarrow \mathbb{R}\) is a non-zero function in \(C^\infty(\mathbb{R})\) with support contained in \([0, 1]\) and satisfies \(\xi(x) \neq 0, \frac{d}{dx} \xi(x) \neq 0\). Then \(\nabla g(x) \neq 0\) and the support of function \(g\) is \([0, 1]^d\).

Next, we take \(m = \lceil n^{\frac{d}{2(s+1)}} \rceil\) and consider a regular grid \(x^{(j)}, j \in [m]^d\). According to the Varshamov-Gilbert lemma, there exist \(2^{m^d/8}\) \((0, 1)\)-sequences \(\tau^{(1)}, \ldots, \tau^{(2^{m^d/8})} \in \{0, 1\}^m\) such
that $\|\tau^{(k)} - \tau^{(k')}\|^2 \geq \frac{m^d}{8}$ for all $0 < k \neq k' \leq 2^{m^d/8}$. Then we construct the multiple hypothesis as

$$u_k(x) = \sum_{j\in[m]} \tau_j^{(k)} \frac{\omega}{m^{s+2}} g(m(x - x(j))), k = 1, 2, \ldots, 2^{m^d/8},$$

where $\omega$ is a constant to be determined later. It is easy to find out that $u_k \in C^s$.

Then we reduce solving the PDE to a multiple hypothesis testing problem, which considers all mappings from $n$ sampled data to the constructed hypothesis $\Psi : (\mathbb{R}^d)^n \times \mathbb{R}^n \to \mathcal{V} := \{u_i|i = 1, 2, \ldots, 2^{m^d/8}\}$. Then we apply the local Fano method and check that we can obtain a constant lower bound of $\mathcal{P}(\hat{V} \neq V)$ for any estimator $\hat{V}$. From the local Fano method, we know that

$$I(V; X) \leq \frac{1}{|\mathcal{V}|^2} \sum_{z} \sum_{v \neq v'} D_{KL}(P_z|P'_{v'}),$$

where $P_z$ denotes the joint distribution of the sampled data $(x, y)$. In specific, $x$ follows a uniform distribution on $[0, 1]^d$ and $y = f(X) + \epsilon$, where $\epsilon$ is independently sampled from a standard Gaussian distribution $N(0, 1)$. Then we have

$$KL(P_z|P'_{v'}) = \mathbb{E} \log \left(\frac{dP_z}{dP'_{v'}}\right) = \|\Delta u_k + V u_k\|_{L^2}^2 \leq \frac{C\omega}{m^{2s-4}}.$$

Using Fano inequality, if we select $m \propto \lceil n^{\frac{1}{2s-d+3}} \rceil$ then we have the following lower bound when $\omega$ is taken to be sufficiently large:

$$\mathcal{P}(\hat{V} \neq V) \geq 1 - \frac{I(V; X) + \log 2}{\log(|\mathcal{V}|)} \geq 1 - \frac{8C\omega}{m^{2s-4}} \geq 1/2.$$

At the same time, we can estimate the separation of the hypotheses in two different norms:

- Deep Ritz Method:
  $$\int_{[0,1]^d} \|\nabla u_k - \nabla u_{k'}\|^2 dx = \frac{\kappa^2}{m^{2s-2+d}} \sum_{j\in[m]} \|\tau_j^{(k)} - \tau_j^{(k')}\|_1 \int_{\mathbb{R}^d} \|\nabla g(x)\|^2 dx \geq \frac{1}{m^{2s-2}}.$$

- Physic Informed Neural Network:
  $$\int_{[0,1]^d} \|\Delta u_k - \Delta u_{k'}\|^2 dx = \frac{\kappa^2}{m^{2s-4+d}} \sum_{j\in[m]} \|\tau_j^{(k)} - \tau_j^{(k')}\|_1 \int_{\mathbb{R}^d} \Delta g(x)^2 dx \geq \frac{1}{m^{2s-4}}.$$

Plugging in $m \propto \lceil n^{\frac{1}{2s-d+3}} \rceil$, we know that with constant probability we have

$$\inf_{\psi} \sup_{u^* \in H^s(\Omega)} \mathbb{E} \|\psi(\{X_i, Y_i\}_{i=1,\ldots,n}) - u^*(f)\|_{H^1}^2 \geq n^{-\frac{2s-2}{d+2s-4}}, \tag{3.3}$$

$$\inf_{\psi} \sup_{u^* \in H^s(\Omega)} \mathbb{E} \|\psi(\{X_i, Y_i\}_{i=1,\ldots,n}) - u^*(f)\|_{H^2}^2 \geq n^{-\frac{2s-4}{d+2s-4}}. \tag{3.4}$$
Given that $n^{-2(\beta-k)/(\beta+2\alpha)}$ is the minimax rate of estimation of the $k$-th derivative of a $\beta$-smooth density in $L_2$ [43, 57, 53], the lower bound obtained here is the rate of estimating the right hand side function $f$ in terms of the $H^{-1}$ norm. Given the $H^{-1}$ norm error estimate on $f$, we can achieve estimate of $u$, which provides an alternative way to understand our upper bound.

4. Upper Bound. To theoretically understand the empirical success of Physics Informed Neural Networks and the Deep Ritz solver, in this section, we aim to prove that the excess risk $\Delta E_n := E(u_n) - E(u^*)$ of a well-trained neural networks on the PINN/DRM loss function will follow a precise power-law scaling relations with the size of the training dataset. Similar to [78, 47, 14, 34, 35], we decompose the excess risk into approximation error and generalization error. Different from the concurrent bound [14, 34], we provided a fast rate $O(1/n)$ by utilizing the strong convexity of the objective function established in Section 2.1 and achieved a faster and near optimal upper bound. We showed that the generalization error can be bounded by the fixed point of the local Rademacher complexity

$$\psi(r) = R_n(\{I(u)||u-u^*||_A^2 \leq r\}),$$

where $R_n$ is the Rademacher complexity, $I(u) = \Delta u + V u, ||u||_A = ||\cdot||_{H^2}$ for PINN and $I(u) = ||\nabla u||^2 + V u, ||\cdot||_A = ||\cdot||_{H^1}$ for DRM.

4.1. Bounding the Approximation Error.

4.1.1. Approximation using Truncated Fourier Basis.

Lemma 4.1. Given $\alpha > 0$ and a fixed integer $\xi \in \mathbb{Z}^+$. For any function $f \in H^\alpha(\Omega)$, we let $f_\xi = \sum ||z||_\infty \leq \xi f_z \phi_z$ be the best approximation of $f$ in the space $F_\xi(\Omega)$. Then for any $0 < \beta \leq \alpha$, we have the following inequality:

$$\|f - f_\xi\|^2_{H^\beta(\Omega)} \leq \xi^{-2(\alpha-\beta)}\|f\|^2_{H^\alpha}.$$  

Proof. For $f \in H^\alpha(\Omega)$, we know the Fourier coefficient satisfies

$$\sum ||z||_\infty \geq \xi |f_z|^2 ||z||^{2\alpha} \lesssim \|f\|^2_{H^\alpha}.$$  

We directly construct $f_\xi = \sum ||z||_\infty \leq \xi f_z \phi_z$ to be the truncated Fourier series of the function $f$, then we have

$$\|f - f_\xi\|^2_{H^\beta(\Omega)} \lesssim \sum ||z||_\infty \geq \xi |f_z|^2 ||z||^{2\beta} \leq \xi^{-2(\alpha-\beta)} \sum ||z||_\infty \geq \xi |f_z|^2 ||z||^{2\alpha} \leq \xi^{-2(\alpha-\beta)}\|f\|^2_{H^\alpha}.$$  

4.1.2. Approximation using Neural Network. In this section, we aim to provide approximation bound for deep neural network. Our proof of the approximation upper bound is based on the observation that the B-spline approximation[12, 64] can be formulated as a ReLU3 neural network efficiently[70, 25, 14, 34]. Although the proof of the approximation of the neural network to the Sobolev spaces is a standard approach, we still demonstrate the proof sketch here.
Definition 4.2. (Univariate and Multivariate B-splines) Fix an arbitrary integer \( l \in \mathbb{Z}^+ \). Consider a corresponding uniform partition \( \pi_l \) of \([0, 1]\):

\[
\pi_l : 0 = t_i^{(l)} < t_i^{(l)} < \cdots < t_i^{(l)} < t_i^{(l)} = 1,
\]

where \( t_i^{(l)} = \frac{i}{l} \) (\( 0 \leq i \leq l \)). Now for any \( k \in \mathbb{Z}^+ \), we can define an extended partition \( \pi_{l,k} \) as:

\[
\pi_{l,k} : t_{-k+1}^{(l)} = \cdots t_{-1}^{(l)} = 0 = t_0^{(l)} \leq t_1^{(l)} \leq \cdots < t_{l-1}^{(l)} \leq t_l^{(l)} = 1 = t_{l+1}^{(l)} = \cdots = t_{l+k-1}^{(l)}
\]

Based on the extended partition \( \pi_{l,k} \), the univariate B-splines of order \( k \) with respect to partition \( \pi_l \) are defined by:

\[
N_{l,i}^{(k)}(x) := (-1)^k (t_{i+k}^{(l)} - t_i^{(l)}) \cdot \left[ t_i^{(l)}, \ldots, t_{i+k}^{(l)} \right] \max\{(x-t), 0\}^{k-1}, \ x \in [0, 1], \ i \in I_{l,k}
\]

where \( I_{l,k} = \{ -k+1, -k+2, \ldots, l-1 \} \) and \( \left[ t_i^{(l)}, \ldots, t_{i+k}^{(l)} \right] \) denotes the divided difference operator.

Equivalently, for any \( x \in [0, 1] \), we can rewrite the univariate B-splines \( N_{l,i}^{(k)}(x) \) in an explicit form:

\[
N_{l,i}^{(k)}(x) = \begin{cases} \frac{k!}{(k-1)!} \cdot \sum_{j=0}^{k-1} (-1)^j \binom{k}{j} \max\left\{ x - \frac{i+j}{l}, 0 \right\}^{k-1} & (0 \leq i \leq l - k + 1) \\ \sum_{j=0}^{l-k+1} a_{ij} \max\left\{ x - \frac{i+j}{l}, 0 \right\}^{k-1} + \sum_{n=1}^{k-2} b_{in} x^n + b_{0n} & (-k + 1 \leq i \leq 0) \\ \sum_{j=l-k+1}^{l} c_{ij} \max\left\{ x - \frac{i+j}{l}, 0 \right\}^{k-1} & (l - k + 1 \leq i \leq l - 1) \end{cases}
\]

where \( \{a_{ij} \mid -k+1 \leq i \leq 0, 0 \leq j \leq k-1\}, \{b_{in} \mid -k+1 \leq i \leq 0, 1 \leq n \leq k-2\} \) and \( \{c_{ij} \mid l - k + 1 \leq i \leq l - 1, l - k + 1 \leq j \leq l - 1\} \) are some fixed constants.

For any index vector \( i = (i_1, i_2, \ldots, i_d) \in I_{l,k}^d \), we can define a corresponding multivariate B-spline as a product of univariate B-splines:

\[
N_{l,i}^{(k)}(x) := \Pi_{j=1}^d N_{l,i_j}^{(k)}(x_j).
\]

Definition 4.3. (Interpolation Operator[64]) Take some domain \( \Omega \subset [0, 1]^d \) and two arbitrary integers \( k, l \in \mathbb{Z}^+ \). Consider the extended partition \( \pi_{l,k} \) and the corresponding set of multivariate B-splines \( \{N_{l,i}^{(k)}(x)\}_{i \in I_{l,k}^d} \) defined in Definition 4.2. For any \( i \in I_{l,k}^d \), we define the domain \( \Omega_{l,i} := \{ x \in \Omega : x_j \in [t_{i_j}, t_{i_j+k}], 1 \leq j \leq d \} \). There exists a set of linear functionals \( \{\lambda_i\}_{i \in I_{l,k}^d} \), where \( \lambda_i : L^1(\Omega) \to \mathbb{R} \) (\( \forall \ i \in I_{l,k}^d \)), such that for any \( i \in I_{l,k}^d \) and \( p \in [1, \infty] \), we have:

\[
\lambda_i(N_{l,i}^{(k)}) = \delta_{i,j} \text{ and } |\lambda_i(f)| \leq g^d(k-1)(2k+1)d \left( \frac{k}{l} \right)^{\frac{d}{p}} \|f\|_{L^p(\Omega_{l,i})}, \ \forall \ f \in L^p(\Omega).
\]

The corresponding interpolation operator \( Q_{k,l}f \) is defined as:

\[
Q_{k,l}f := \sum_{i \in I_{l,k}^d} \lambda_i(f)N_{l,i}^{(k)}, \ \forall \ f \in L^1(\Omega).
\]
Theorem 4.4. ([64]) Fix $f \in W^s(\Omega)$ with $\Omega \subseteq [0,1]^d$, $s \in \mathbb{Z}^+$ and $p \in [1,\infty)$. Then for any $k,l,r \in \mathbb{Z}^+$ with $k \geq s$ and $0 \leq r \leq s$, we have that there exists some constant $C = C(k,s,r,p,d)$, such that:

$$
\|f - Q_{k,l}f\|_{H^r(\Omega)} \leq C\left(\frac{1}{L}\right)^{s-r}\|f\|_{H^s(\Omega)}.
$$

Theorem 4.5. (Approximation result of Deep Neural Network) Fix some dimension $d \in \mathbb{Z}^+$, some domain $\Omega \subseteq [0,1]^d$. We pick some $l = N^\frac{1}{2} \geq 2$, for any $s,r \in \mathbb{Z}^+$ with $0 \leq r \leq s$ and any function $u^* \in H^s(\Omega)$, there exists some sparse Deep Neural Network $u_{DNN} \in \Phi(L,W,S,B)$ with $L = O(1), W = O(N), S = O(N), B = O(N)$, such that:

$$
\|u_{DNN} - u^*\|_{H^r(\Omega)} \lesssim N^{-\frac{r}{d-r}}\|u^*\|_{H^s(\Omega)}.
$$

**Proof.** We firstly show that the given function $u^*$ can be approximated well by some linear combination of multivariate splines, which is denoted by $u_{sp}$. Note that $N$ is assumed to be sufficiently large. Hence, we may pick $l = \lceil N^\frac{1}{2} \rceil = \Theta(N^\frac{1}{2}) \in \mathbb{Z}^+$ to be the partition size of the B-splines. Moreover, by picking $k = 4$ and $p = 2$ in Theorem 4.4, we have that the linear combination $u_{sp} := Q_{4,4}u^* = \sum_{i \in I_{4,4}^l} \lambda_i(u^*)N_{i,4}^{(4)}$ satisfies:

$$
\|u^* - u_{sp}\|_{H^r(\Omega)} = \|u^* - Q_{4,4}u^*\|_{H^r(\Omega)} \leq C\left(\frac{1}{L}\right)^{s-r}\|u^*\|_{H^s(\Omega)} = CN^{-\frac{r}{d-r}}\|u^*\|_{H^s(\Omega)}.
$$

We will then show that the linear combination $u_{sp} = \sum_{i \in I_{4,4}^l} \lambda_i(f)N_{i,4}^{(4)}$ can be implemented by some Deep Neural Network $u_{DNN} \in \Phi(L,W,S,B)$ with $L = O(1), W = O(N), S = O(N)$ and $B = O(\log N)$. Firstly, note that for $x \geq 0$, both $x$ and $x^2$ can be expressed in terms of the ReLU3 activation function $\eta_3$ with no error:

$$
x = -\frac{1}{12}[\eta_3(x) + 3 - 5\eta_3(x + 2) + 7\eta_3(x + 1) - 3\eta_3(x) + 6],
$$

$$
x^2 = -\frac{1}{6}[\eta_3(x + 2) - 4\eta_3(x + 1) + 3\eta_3(x) - 4].
$$

Applying the explicit formula listed in equation 4.2 implies that for any $-3 \leq i \leq l - 1$, the univariate B-spline function $N_{i,4}^{(4)}(x)$ ($x \in [0,1]$) can be implemented by some ReLU3 Deep Neural Network $v_{DNN}$ with both scalar input and scalar output. We have that for $v_{DNN}$, the depth $L_v$ is 2 and the maximum width $W_v$ is upper bounded by 11. Secondly, for any $x, y \geq 0$, we have that the product operation $x \cdot y$ can be expressed in terms of the ReLU3 activation function $\eta_3$ with no error:

$$
x \cdot y = \frac{1}{2}[(x + y)^2 - x^2 - y^2]
$$

$$
= -\frac{1}{12}[\eta_3(x + y + 2) - 4\eta_3(x + y + 1) + 3\eta_3(x + y)
\quad - \eta_3(x + 2) + 4\eta_3(x + 1) - 3\eta_3(x) - \eta_3(y + 2) + 4\eta_3(y + 1) - 3\eta_3(y) + 4].
$$
In [64], it has been proved that the B-splines are always non-negative, i.e. $N_{i,k}^{(4)}(x) \geq 0$, $\forall x \in [0,1]$. Therefore, by multiplying the non-negative univariate B-splines, we can implement any multivariate B-spline $N_{l,i}^{(4)} = \Pi_{j=1}^{d} N_{i_{j},1}^{(4)} (x_{j})$ with some ReLU3 Deep Neural Network $p_{\text{DNN}}$. We have that for $p_{\text{DNN}}$, the depth $L_{p} = \lceil \log_{2} d \rceil + 2$ and the maximum width $W_{p} = \max\{11d, \frac{9d}{2}\}$. Hence, we can further claim that $u^{*} = \sum_{i \in I_{k,i}^{d}} \lambda_{i} (u^{*}) N_{l,i}^{(4)}$, which is a linear combination of the multivariate B-splines $N_{l,i}^{(4)}$, can be implemented by some ReLU3 Deep Neural Network $u_{\text{DNN}}$. Therefore, by multiplying the non-negative univariate B-splines, we can implement any multivariate B-spline $N_{l,i}^{(4)}$, which completes our proof.

For the norm constraint $B$ of $u_{\text{DNN}}$, starting from the third layer, the number of activated neurons is half of the number of activated neurons at previous layer. This yields the following upper bound on $S$: 

$$S \leq 2(W + W + \sum_{j=0}^{L-2} \frac{W}{2^{j}}) \leq 8W \Rightarrow S = O(W) = O(N)$$

For the sparsity constraint $S$ of $u_{\text{DNN}}$, we have that $W \leq |I_{k,i}^{d}| W_{p}$, where $W_{p}$ denotes the width of the ReLU3 Deep Neural Network $p_{\text{DNN}}$. This implies: 

$$W \leq |I_{k,i}^{d}| \times 11d = 11d(l + k)d = 11d(l + 4)d = O(l^{d}) \Rightarrow W = O(N)$$

For the sparsity constraint $S$ of $u_{\text{DNN}}$, starting from the third layer, the number of activated neurons is half of the number of activated neurons at previous layer. This yields the following upper bound on $S$: 

$$S \leq 2(W + W + \sum_{j=0}^{L-2} \frac{W}{2^{j}}) \leq 8W \Rightarrow S = O(W) = O(N)$$

For the norm constraint $B$ of $u_{\text{DNN}}$, we have the following upper bound on $B$ from equation 4.2 and equation 4.4:

$$B = O(\max\{l^{k-1}, \sup_{i \in I_{k,i}^{d}} \lambda_{i}(u^{*})\}) = O(\max\{l^{3}, l^{d}\}) = O(N)$$

Now we have shown that parameters $L, W, S, B$ of the Deep Neural Network $u_{\text{DNN}}$ are of the desired magnitude, which completes our proof.

4.2. Bounding the Local Rademacher Complexity.

4.2.1. Local Rademacher Complexity of Truncated Fourier Basis. In this subsection, we aim to bound the local Rademacher complexity of the Truncated Fourier Basis estimator. The proof is standard and we put the proof in the appendix.

**Lemma 4.6. (Local Rademacher Complexity of Localized Truncated Fourier Series)** For a fixed $\xi \in \mathbb{Z}^{+}$, we consider a localized class of functions $\mathcal{F}_{p,\xi}(\Omega) = \left\{ f \in F_{\xi}(\Omega) \mid \|f\|_{H^{1}(\Omega)}^{2} \leq \rho \right\}$, where $\rho > 0$ is fixed. Then we have the following upper bound on the local Rademacher complexity:

$$R_{n}(\mathcal{F}_{p,\xi}(\Omega)) = \mathbb{E}_{X} \left[ \sup_{f \in \mathcal{F}_{p,\xi}(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_{i} f (X_{i}) \left| X_{1}, \cdots, X_{n} \right\} \leq \sqrt{\frac{\rho}{n}} \right].$$
Lemma 4.7. (Local Rademacher Complexity of Localized Truncated Fourier Series’ Gradient) For a fixed $\xi \in \mathbb{Z}^+$, we consider a localized class of functions $\mathcal{G}_{\rho,\xi}(\Omega) = \{\| \nabla f \| \neq f \in F_{\rho,\xi}(\Omega)\}$, where $\rho > 0$ is fixed. Then for any sample $\{X_i\}_{i=1}^n \subset \Omega$, we have the following upper bound on the local Rademacher complexity:

$$R_n(\mathcal{G}_{\rho,\xi}(\Omega)) = \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \sup_{f \in \mathcal{G}_{\rho,\xi}(\Omega)} \frac{1}{n} \sum_{i=1}^n \sigma_i \| \nabla f(X_i) \| \mid X_1, \cdots, X_n \right] \right] \lesssim \sqrt{\frac{\rho \xi^4}{n}}.
$$

Lemma 4.8. (Local Rademacher Complexity of Localized Truncated Fourier Series’ Laplacian) For a fixed $\xi \in \mathbb{Z}^+$, we consider a localized class of functions $\mathcal{J}_{\rho,\xi}(\Omega) := \{ f \in F_{\xi}(\Omega) \mid \| f \|_{H^2(\Omega)} \leq \rho \}$, where $\rho > 0$ is fixed. Correspondingly, we define a localized class of Laplacians $\mathcal{K}_{\rho,\xi}(\Omega) := \{ \Delta f \mid f \in \mathcal{J}_{\rho,\xi}(\Omega)\}$. Then for any sample $\{X_i\}_{i=1}^n \subset \Omega$, we have the following upper bound on the local Rademacher complexity:

$$R_n(\mathcal{K}_{\rho,\xi}(\Omega)) = \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \sup_{f \in \mathcal{K}_{\rho,\xi}(\Omega)} \frac{1}{n} \sum_{i=1}^n \sigma_i \Delta f(X_i) \mid X_1, \cdots, X_n \right] \right] \lesssim \sqrt{\frac{\rho \xi^4}{n}}.
$$

4.2.2. Local Rademacher Complexity of Deep Neural Networks. In this subsection, we aim to bound the local Rademacher complexity of the Neural Network estimator. Informally, we showed that the local Rademacher complexity is at the scale of $\sqrt{\frac{\xi}{n}}$, where $N$ is the number of neuron of a neural network. For simplicity, we put the proof in the appendix.

Lemma 4.9 (Local Rademacher Complexity Bound for Deep Ritz Method). Consider a Deep Neural Network space $\mathcal{F}(\Omega) = \Phi(L,W,S,B)$ with $L = O(1), W = O(N), S = O(N)$ and $B = O(N)$, where $N \in \mathbb{Z}^+$ is fixed to be sufficiently large. Moreover, assume that the gradients and function value of $\mathcal{F}(\Omega)$, $V$ and $f$ are uniformly bounded

$$\max \left\{ \sup_{u \in \mathcal{F}(\Omega)} \| u \|_{L^\infty(\Omega)}, \sup_{u \in \mathcal{F}(\Omega)} \| \nabla u \|_{L^\infty(\Omega)}, \| u^* \|_{L^\infty(\Omega)}, \| \nabla u^* \|_{L^\infty(\Omega)}, V_{\text{max}}, \| f \|_{L^\infty(\Omega)} \right\} \leq C.
$$

For any $\rho > 0$, we consider a localized set $L_\rho$ defined by:

$$L_\rho(\Omega) := \{ u : u \in \mathcal{F}(\Omega), \| u - u^* \|_{H^1} \leq \rho \}.
$$

Then for any $\rho \gtrsim n^{-2}$, the Rademacher complexity of a localized function space $\mathcal{S}_\rho(\Omega) := \{ h := |\Omega| \cdot \left[ \frac{1}{2} \left( \| \nabla u \|^2 - \| \nabla u^* \|^2 \right) + \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*) \right] \mid u \in L_\rho(\Omega) \}$ can be upper bounded by a sub-root function

$$\phi(\rho) := O \left( \sqrt{\frac{S^3 L \rho}{n} \log (BWn)} \right).
$$

i.e. we have

$$\phi(4\rho) \leq 2\phi(\rho) \text{ and } R_n(\mathcal{S}_\rho(\Omega)) \leq \phi(\rho).
$$

holds for all $\rho \gtrsim n^{-2}$. 

$$\sqrt{\frac{\xi}{n}}$$
Lemma 4.10 (Local Rademacher Complexity Bound for Physics Informed Neural Network). Consider a Deep Neural Network space $F(\Omega) = \Phi(L, W, S, B)$ with $L = O(1)$, $W = O(N)$, $S = O(N)$ and $B = O(N)$, where $N \in \mathbb{Z}^+$ is fixed to be sufficiently large. Moreover, assume that the gradients and function value of $F(\Omega), V$ and $f$ are uniformly bounded
\begin{equation}
\max \left\{ \sup_{u \in F(\Omega)} \|u\|_{L^\infty(\Omega)}, \sup_{u \in F(\Omega)} \|\Delta u\|_{L^\infty(\Omega)}, \|u^*\|_{L^\infty(\Omega)}, \|\Delta u^*\|_{L^\infty(\Omega)}, V_{\text{max}}, \|f\|_{L^\infty(\Omega)} \right\} \leq C.
\end{equation}

For any $\rho > 0$, we consider a localized set $M_\rho$ defined by:
\begin{equation}
M_\rho(\Omega) := \{ u : u \in F(\Omega), \|u - u^*\|_{H^2} \leq \rho \}.
\end{equation}
Then for any $\rho \gtrsim n^{-2}$, the Rademacher complexity of a localized function space $T_\rho(\Omega) := \{ h := |\Omega| \cdot [(\Delta u - Vu + f)^2 - (\Delta u^* - Vu^* + f)^2] \mid u \in M_\rho(\Omega) \}$ can be upper bounded by a sub-root function
\begin{equation}
\phi(\rho) := O \left( \sqrt{\frac{3L^3 \rho}{n \log (BWn)}} \right).
\end{equation}
i.e. we have
\begin{equation}
\phi(4\rho) \leq 2\phi(\rho) \quad \text{and} \quad R_n(T_\rho(\Omega)) \leq \phi(\rho).
\end{equation}
holds for all $\rho \gtrsim n^{-2}$.

4.3. Final Upper Bound.

Deep Ritz Methods. In this subsection, we provide the proof of upper bounds for DRM. We first provide a meta-theorem to illustrate the approximation and generalization decomposition with a $O(1/n)$ fast rate generalization bound\cite{3, 78}. Then we use truncated fourier basis estimator and neural network estimator as example to obtain the final rate.

Theorem 4.11 (Meta-theorem for Upper Bounds of Deep Ritz Methods). Let $u^* \in H^s(\Omega)$ denote the true solution to the PDE model with Dirichlet boundary condition:
\begin{equation}
-\Delta u + Vu = f \quad \text{on} \ \Omega,
\end{equation}
\begin{equation}
u = 0 \quad \text{on} \ \partial \Omega,
\end{equation}
where $f \in L^2(\Omega)$ and $V \in L^\infty(\Omega)$ with $0 < V_{\text{min}} \leq V(x) \leq V_{\text{max}} > 0$. For a fixed function space $F(\Omega)$, consider the empirical loss induced by the Deep Ritz Method:
\begin{equation}
E_n(u) = \frac{1}{n} \sum_{j=1}^{n} \left[ |\Omega| \cdot \left( \frac{1}{2} \nabla u(X_j)^2 + \frac{1}{2} V(X_j)|u(X_j)|^2 - f(X_j)u(X_j) \right) \right],
\end{equation}
where $\{X_j\}_{j=1}^{n}$ are datapoints uniformly sampled from the domain $\Omega$. Then the Deep Ritz estimator associated with function space $F(\Omega)$ is defined as the minimizer of $E_n(u)$ over the function space $F(\Omega)$:
\begin{equation}
\hat{u}_{DRM} = \min_{u \in F(\Omega)} E_n(u)
\end{equation}
Moreover, we assume that there exists some constant $C > 0$ such that all function $u$ in the function space $F(\Omega)$, the real solution $u^*$ and $f,V$ satisfy the following two conditions.
• The gradients and function value are uniformly bounded
  \[
  \max \left\{ \sup_{u \in F(\Omega)} \|u\|_{L^\infty(\Omega)}, \sup_{u \in F(\Omega)} \|\nabla u\|_{L^\infty(\Omega)}, \|u^*\|_{L^\infty(\Omega)}, \|\nabla u^*\|_{L^\infty(\Omega)}, V_{\text{max}}, \|f\|_{L^\infty(\Omega)} \right\} \leq C. \]

• All the functions in the function space \( F(\Omega) \) satisfy the boundary condition
  \[ u = 0 \quad \text{on} \quad \partial \Omega. \]

At the same time, for any \( \rho > 0 \), we assume the Rademacher complexity of a localized function space \( S_\rho(\Omega) := \{ h = |\Omega| \cdot \left[ \frac{1}{2} (|\nabla u|^2 - |\nabla u^*|^2) + \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*) \right] \mid \|u - u^*\|^2 \leq \rho \} \) can be upper bounded by a sub-root function \( \phi = \phi(\rho) : [0, \infty) \rightarrow [0, \infty), \) i.e.
  \[
  (4.16) \quad \phi(4\rho) \leq 2\phi(\rho) \quad \text{and} \quad R_n(S_\rho(\Omega)) \leq \phi(\rho) \quad (\forall \rho > 0). \]

For all constant \( t > 0 \). We denote \( r^* \) to be the solution of the fix point equation of local Rademacher complexity \( r = \phi(r) \). There exists a constant \( C_p \) such that for probability \( 1 - C_p \exp(-t) \), we have the following upper bound for the Deep Ritz Estimator
  \[
  \|\hat{u}_{\text{DRM}} - u^*\|^2_{L^2} \leq \inf_{u \in F(\Omega)} \left( \mathcal{E}(u_F) - \mathcal{E}(u^*) \right) + \max \{ r^*, \frac{t}{n} \}. \]

**Proof.** To upper bound the excess risk \( \Delta \mathcal{E}^{(n)} := \mathcal{E}(\hat{u}_{\text{DRM}}) - \mathcal{E}(u^*) \), following [78, 47, 14], we decompose the excess risk into approximation error and generalization error with probability \( 1 - e^{-t} \):
  \[
  (4.17) \quad \Delta \mathcal{E}^{(n)}(\hat{u}_{\text{DRM}}) = \mathcal{E}(\hat{u}_{\text{DRM}}) - \mathcal{E}(u^*) = \left[ \mathcal{E}(\hat{u}_{\text{DRM}}) - \mathcal{E}(\hat{u}_{\text{DRM}}) \right] + \left[ \mathcal{E}(\hat{u}_{\text{DRM}}) - \mathcal{E}(u_F) \right] + \left[ \mathcal{E}(u_F) - \mathcal{E}(u^*) \right] \]
  \[
  \leq \left[ \mathcal{E}(\hat{u}_{\text{DRM}}) - \mathcal{E}(u^*) \right] + \left[ \mathcal{E}(u_F) - \mathcal{E}(u^*) \right] + \left[ \mathcal{E}(u^*) - \mathcal{E}(u^*) \right] \]
  \[
  \leq \left[ \mathcal{E}(\hat{u}_{\text{DRM}}) - \mathcal{E}(u^*) \right] + \left[ \mathcal{E}(u_F) - \mathcal{E}(u^*) \right] + \left[ \mathcal{E}(u^*) - \mathcal{E}(u^*) \right] \]
  \[
  + \frac{3}{2} \left[ \mathcal{E}(u_F) - \mathcal{E}(u^*) \right] + \frac{t}{2n}, \]

where the expectation is on all sampled data. The inequality of the third line is because the \( u \) is the minimizer of the empirical loss \( \mathcal{E}_n \) in the solution set \( F(\Omega) \), so we have \( \mathcal{E}_n(u) \leq \mathcal{E}_n(u_F). \) The last inequality is based on the Bernstein inequality. The variance of \( h = |\Omega| \cdot \left[ \frac{1}{2} (|\nabla u|^2 - |\nabla u^*|^2) + \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*) \right] \) can be bounded by \( \mathcal{E}(u_F) - \mathcal{E}(u^*) \) due to the strong convexity of the variation objective (4.19). According to the Bernstein inequality, we know with probability \( 1 - e^{-t} \) we have
  \[
  \mathcal{E}_n(u_F) - \mathcal{E}_n(u^*) - \mathcal{E}(u_F) + \mathcal{E}(u^*) \leq \sqrt{\frac{t[\mathcal{E}(u_F) - \mathcal{E}(u^*)]}{n}} \leq \frac{1}{2} \left[ \mathcal{E}(u_F) - \mathcal{E}(u^*) \right] + \frac{t}{2n}. \]
Note that 4.17 holds for all function lies in the function space $F$. Thus, we can take $u_F := \arg\min_{u_0 \in F(\Omega)} (E(u_0) - E(u^*))$ and finally get

$$\Delta E(n) \leq \frac{3}{2} \inf_{u_F \in F(\Omega)} \left( E(u_F) - E(u^*) \right) + \frac{t}{2n}.$$

This inequality decompose the excess risk to the generalization error $\Delta E_{\text{gen}} := E(\hat{u}_{\text{DRM}}) - E(u^*) + E_n(u^*) - E_n(\hat{u}_{\text{DRM}})$ and the approximation error $\Delta E_{\text{app}} = \inf_{u_F \in F(\Omega)} \left( E(u_F) - E(u^*) \right)$. We’ll focus on providing fast rate upper bounds of the generalization error for the two estimators using the localization technique[3, 78]. To achieve the fast generalization bound, we focus on the following normalized empirical process

$$\hat{S}_r(\Omega) := \{ \hat{h}(x) := \frac{E[h] - h(x)}{E[h] + r} \mid h \in S(\Omega) \} \quad (r > 0).$$

First, we try to bound the expectation of the normalized empirical process. Applying the Symmetrization Lemma A.3, we can first bound the expectation as

$$\sup_{\hat{h} \in \hat{S}_r(\Omega)} \mathbb{E}_x \left[ \frac{1}{n} \sum_{i=1}^n \hat{h}(x'_i) \right] \leq \mathbb{E}_x \left[ \sup_{h \in S(\Omega)} \left| \frac{1}{n} \sum_{i=1}^n h(x'_i) - \mathbb{E}[h] \right| - \mathbb{E}[h] + r \right] \leq 2R_n(\hat{S}_r(\Omega)).$$

where the function class $\hat{S}_r(\Omega)$ is defined as:

$$\hat{S}_r(\Omega) := \{ \hat{h}(x) := \frac{h(x)}{E[h] + r} \mid h \in S(\Omega) \},$$

where $S(\Omega) = \{ h := \frac{1}{2} \left( |\nabla u|^2 - |\nabla u^*|^2 \right) + \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*) \}$. Then applying the Peeling Lemma to any function $h \in S(\Omega)$ helps us upper bound the local Rademacher complexity $R_n(\hat{S}_r(\Omega))$ with the function $\phi$ defined in equation 4.16:

$$R_n(\hat{S}_r(\Omega)) = \mathbb{E}_x \left[ \mathbb{E}_x \left[ \sup_{h \in S(\Omega)} \frac{1}{n} \sum_{i=1}^n \sigma_i h(x_i) \right] \right] \leq \frac{4\phi(r)}{r}.$$

Combining all inequalities derived above yields:

$$\sup_{\hat{h} \in \hat{S}_r(\Omega)} \mathbb{E}_x \left[ \frac{1}{n} \sum_{i=1}^n \hat{h}(x'_i) \right] \leq 2R_n(\hat{S}_r(\Omega)) \leq \frac{8\phi(r)}{r} \quad (r > 0).$$

Secondly we’ll apply the Talagrand concentration inequality, which requires us to verify the condition needed. We will first check that the expectation value $\mathbb{E}[h]$ is always non-negative for
any \( h \in S(\Omega) \):

\[
\mathbb{E}[h] = \frac{1}{|\Omega|} \int_{\Omega} |\Omega| \cdot \left( \frac{1}{2} |\nabla u(x)|^2 + \frac{1}{2} V(x)|u(x)|^2 - f(x)u(x) \right) dx
- \frac{1}{|\Omega|} \int_{\Omega} |\Omega| \cdot \left( \frac{1}{2} |\nabla u^*(x)|^2 + \frac{1}{2} V(x)|u^*(x)|^2 - f(x)u^*(x) \right) dx
= \mathcal{E}(u) - \mathcal{E}(u^*) \geq 0 \Rightarrow \mathbb{E}[h] \geq 0.
\]

We will proceed to verify that any \( \hat{h} = \frac{\mathbb{E}[h] - h}{\mathbb{E}[h] + r} \in \hat{S}_r(\Omega) \) is of bounded inf-norm. We need to prove that any \( h \in S(\Omega) \) is of bounded inf-norm beforehand. Using boundedness condition listed in equation \ref{4.15} implies:

\[
\|h\|_{\infty} = |\Omega| \left( \frac{1}{2} \left( |\nabla u|^2 - |\nabla u^*|^2 \right) + \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*) \right)_{\infty}
\leq \frac{|\Omega|}{2} \left( |\nabla u|_{\infty}^2 + |\nabla u^*|_{\infty}^2 \right) + \frac{|\Omega|}{2} V_{\max} \left( |u|_{\infty}^2 + |u^*|_{\infty}^2 \right) + |\Omega| \|f\|_{\infty} \left( |u|_{\infty} + |u^*|_{\infty} \right)
\leq \frac{|\Omega|}{2} \times 2C^2 + \frac{|\Omega|}{2} V_{\max} \times 2C^2 + 2|\Omega|C^2 = |\Omega|(V_{\max} + 3)C^2
\]

By taking \( M := |\Omega|(V_{\max} + 3)C^2 \), we then have \( \|h\|_{\infty} \leq M \) for all \( h \in S(\Omega) \). Note that the denominator can be lower bounded by \( |\mathbb{E}[h] + r| \geq r > 0 \). Combining these two inequalities help us upper bound the inf-norm \( \|h\|_{\infty} = \sup_{x \in \Omega} |\hat{h}(x)| \) as follows:

\[
\|\tilde{h}\|_{\infty} = \left\| \frac{\mathbb{E}[h] - h}{|\mathbb{E}[h] + r|} \right\|_{\infty} \leq \frac{2\|h\|_{\infty}}{r} \leq \frac{2M}{r} =: \beta.
\]

We will then check the normalized functions \( \frac{\mathbb{E}[h] - h}{|\mathbb{E}[h] + r|} \) in \( \hat{S}_r(\Omega) \) have bounded second moment, which is satisfied because of the regularity results of the PDE. We aim to show that there exist some constants \( \alpha, \alpha' > 0 \), such that for any \( h \in S(\Omega) \), the following inequality holds:

\[
(\ref{4.19}) \quad \alpha\mathbb{E}[h^2] \leq \|u - u^*\|_{H^1(\Omega)}^2 \leq \alpha'\mathbb{E}[h].
\]

The RHS of the inequality follows from strong convexity of the DRM objective function proved in Theorem A.1:

\[
\mathbb{E}[h] = \mathcal{E}(u) - \mathcal{E}(u^*) \geq \min\{1, V_{\min}\} \frac{1}{4}\|u - u^*\|_{H^1(\Omega)}^2
\]

The LHS of the inequality follows from boundedness condition listed in equation \ref{4.15} and the QM-AM inequality:

\[
\mathbb{E}[h^2] = \int_{\Omega} \left( \frac{1}{2} \left( |\nabla u|^2 - |\nabla u^*|^2 \right) + \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*) \right)^2 dx
\leq \frac{3}{4} \int_{\Omega} \left( |\nabla u|^2 - |\nabla u^*|^2 \right)^2 dx + \frac{3}{4} \int_{\Omega} V^2(|u|^2 - |u^*|^2)^2 dx + 3 \int_{\Omega} f^2(u - u^*) dx
\leq \frac{3}{4} \int_{\Omega} |\nabla u| - |\nabla u^*| \right)^2 (|\nabla u| + |\nabla u^*|)^2 dx + \frac{3}{4} V_{\max} \int_{\Omega} |u| - |u^*| \right)^2 (|u| + |u^*|)^2 dx
+ 3C^2 \int_{\Omega} (u - u^*)^2 dx \leq 3C^2 \int_{\Omega} |\nabla u - \nabla u^*|^2 dx + 3C^2(1 + V_{\max}) \int_{\Omega} |u - u^*|^2 dx
\leq 3C^2(1 + V_{\max}) \|u - u^*\|_{H^1(\Omega)}^2
\]
By picking $\alpha' = \frac{4}{\min(1, V_{\text{min}})}$ and $\alpha = \frac{1}{3C^2(1+V_{\text{max}}^2)}$, we have finished proving inequality 4.19. Then we can upper bound the expectation $E[\tilde{h}^2]$ as:

$$E[\tilde{h}^2] = \frac{\mathbb{E}[(h - E[h])^2]}{|E[h] + r|^2} = \frac{\mathbb{E}[h^2] - E[h]^2}{|E[h] + r|^2} \leq \frac{\mathbb{E}[h^2]}{|E[h] + r|^2}.$$  

Using the fact that $E[h] \geq 0$ and inequality 4.19, we can lower bound the denominator $|E[h] + r|^2$ as follows:

$$|E[h] + r|^2 \geq 2E[h]r \geq \frac{2r\alpha}{\alpha'} \mathbb{E}[h^2].$$

Therefore, we can deduce that:

$$E[\tilde{h}^2] \leq \frac{\mathbb{E}[h^2]}{|E[h] + r|^2} \leq \frac{\mathbb{E}[h^2]}{2r\alpha \mathbb{E}[h^2]} = \frac{\alpha'}{2r\alpha} =: \sigma^2.$$  

Hence, any function in the localized class $\tilde{S}_r(\Omega)$ is of bounded second moment.

It is easy to check that for any $\tilde{h} \in \tilde{S}_r(\Omega)$, we have

$$E[\tilde{h}] = \frac{E[h] - E[h]}{E[h] + r} = 0,$$

i.e. any function in the localized class $\tilde{S}_r(\Omega)$ is of zero mean.

Now we have verified that any function $\tilde{h} \in \tilde{S}_r(\Omega)$ satisfies all the required conditions. By taking $\mu$ to be the uniform distribution on the domain $\Omega$ and applying Talagrand’s Concentration inequality given in Lemma A.6, we have:

$$\mathbb{P}_x \left[ \sup_{\tilde{h} \in \tilde{S}_r(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \tilde{h}(x_i) \geq 2 \sup_{\tilde{h} \in \tilde{S}_r(\Omega)} \mathbb{E}_x' \left[ \frac{1}{n} \sum_{i=1}^{n} \tilde{h}(x'_i) \right] + \sqrt{\frac{2t\sigma^2}{n} + \frac{2t\beta}{n}} \right] \leq e^{-t}.$$  

By using the upper bound deduced above and plugging in the expressions of $\beta$ and $\sigma$, we can rewrite Talagrand’s Concentration Inequality in the following way. With probability at least $1 - e^{-t}$, the inequality below holds:

$$\frac{1}{n} \sum_{i=1}^{n} \tilde{h}(x_i) \leq \sup_{\tilde{h} \in \tilde{S}_r(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \tilde{h}(x_i) \leq 2 \sup_{\tilde{h} \in \tilde{S}_r(\Omega)} \mathbb{E}_x' \left[ \frac{1}{n} \sum_{i=1}^{n} \tilde{h}(x'_i) \right] + \sqrt{\frac{2t\sigma^2}{n} + \frac{2t\beta}{n}}$$

$$\leq \frac{16\phi(r)}{r} + \sqrt{\frac{4\alpha'}{n\alpha r} + \frac{4Mt}{nr}} =: \psi(r).$$

Let’s pick the critical radius $r_0$ to be:

$$(4.20) \quad r_0 = \max \{ 2^{14}r^*, \frac{24Mt}{n}, \frac{36\alpha't}{\alpha n} \}.$$
Note that concavity of the function $\phi$ implies that $\phi(r) \leq r$ for any $r \geq r^*$. Combining this with the first inequality listed in 4.16 yields:

$$\frac{16\phi(r)}{r} \leq \frac{\phi(r)}{r} = \frac{1}{8} \times \frac{\phi(\frac{r}{r^*})}{\frac{r}{r^*}} \leq \frac{1}{8}.$$  

On the other hand, applying equation 4.20 yields:

$$\sqrt{\frac{\alpha't}{nar_0}} \leq \sqrt{\frac{\alpha'n}{36\alpha't}} = \frac{1}{6},$$

$$\frac{4Mt}{nr_0} \leq \frac{4M}{n} \times \frac{n}{24Mt} = \frac{1}{6}.$$

Summing the three inequalities above implies:

$$\psi(r_0) = \frac{16\phi(r_0)}{r_0} + \sqrt{\frac{\alpha't}{nar_0}} + \frac{4Mt}{nr_0} \leq \frac{1}{8} + \frac{1}{6} + \frac{1}{6} < \frac{1}{2}.$$  

By picking $r = r_0$, we can further deduce that for any function $u \in F(\Omega)$, the following inequality holds with probability $1 - e^{-t}$:

$$\frac{\mathcal{E}(u) - \mathcal{E}(u^*) - \mathcal{E}_n(u) + \mathcal{E}_n(u^*)}{\mathcal{E}(u) - \mathcal{E}(u^*) + r_0} = \frac{1}{n} \sum_{i=1}^{n} \hat{h}(x_i) \leq \psi(r_0) < \frac{1}{2}.$$  

Multiplying the denominator on both sides indicates:

$$\Delta\mathcal{E}_{\text{gen}} = \mathcal{E}(u) - \mathcal{E}(u^*) - \mathcal{E}_n(u) + \mathcal{E}_n(u^*) \leq \frac{1}{2} \left[ \mathcal{E}(u) - \mathcal{E}(u^*) \right] + \frac{1}{2} r_0 = \frac{1}{2} \Delta\mathcal{E}^{(n)} + \frac{1}{2} r_0.$$  

Substituting the upper bound above into the decomposition $\Delta\mathcal{E}^{(n)} \leq \Delta\mathcal{E}_{\text{gen}} + \frac{3}{2} \Delta\mathcal{E}_{\text{app}} + \frac{t}{2n}$ yields that with probability $1 - e^{-t}$, we have:

$$\Delta\mathcal{E}^{(n)} \leq \Delta\mathcal{E}_{\text{gen}} + \frac{3}{2} \Delta\mathcal{E}_{\text{app}} + \frac{t}{2n} \leq \frac{1}{2} \Delta\mathcal{E}^{(n)} + \frac{1}{2} r_0 + \frac{3}{2} \Delta\mathcal{E}_{\text{app}} + \frac{t}{2n}.$$  

Simplifying the inequality above yields that with probability $1 - e^{-t}$, we have:

$$\Delta\mathcal{E}^{(n)} \leq r_0 + 3 \Delta\mathcal{E}_{\text{app}} + \frac{t}{n} = 3 \inf_{u \in F(\Omega)} \left( \mathcal{E}(u) - \mathcal{E}(u^*) \right) + \max \left\{ 24 \frac{\alpha^*}{n}, 24 \frac{\alpha^*}{n} \right\} + \frac{t}{n}.$$  

Moreover, using strong convexity of the DRM objective function proved in Theorem A.1 implies:

$$\Delta\mathcal{E}^{(n)} = \mathcal{E}(\hat{u}_{\text{DRM}}) - \mathcal{E}(u^*) \geq \frac{\min \{ 1, V_{\text{min}} \} \| \hat{u}_{\text{DRM}} - u^* \|^2_{H^1(\Omega)}}{4}.$$  

Combining the two bounds above yields that with probability $1 - e^{-t}$, we have:

$$\| \hat{u}_{\text{DRM}} - u^* \|^2_{H^1(\Omega)} \lesssim \inf_{u \in F(\Omega)} \left( \mathcal{E}(u) - \mathcal{E}(u^*) \right) + \max \left\{ r^*, \frac{t}{n} \right\}.$$
Theorem 4.12. (Final Upper Bound of DRM with Deep Neural Network Estimator) With proper assumptions, consider the sparse Deep Neural Network function space $\Phi(L,W,S,B)$ with parameters $L = O(1)$, $W = O(n^{\frac{d}{\pi^2 + 7}})$, $S = O(n^{\frac{d}{\pi^2 + 7}})$, $B = O(1)$, then the Deep ritz estimator $\hat{u}_{\text{DRM}}^{\text{DNN}} = \min_{u \in \Phi(L,W,S,B)} \mathcal{E}_n^{\text{DRM}}(u)$ satisfies the following upper bound with high probability:

$$\|\hat{u}_{\text{DRM}}^{\text{DNN}} - u^*\|_{H^1}^2 \lesssim n^{-\frac{2s-2}{s+2s-2}} \log n.$$  

Proof. On the one hand, by taking $s = 1$ and $p = 2$ in Theorem 4.5 proved above, we have that there exists some Deep Neural Network $u_{\text{DNN}} \in \Phi(L,W,S,B)$ with $L = O(1), W = O(N), S = O(N), B = O(N)$, such that.

$$\|u_{\text{DNN}} - u^*\|_{H^1(\Omega)}^2 \lesssim N^{-\frac{2s-2}{s}} \|u^*\|_{H^s(\Omega)}.$$  

Applying strong convexity of the DRM objective function proved in Section 2.1 further implies:

$$\Delta \mathcal{E}_{\text{app}} \lesssim \|u_{\text{DNN}} - u^*\|_{H^1(\Omega)}^2 \lesssim N^{-\frac{2s-2}{s}}.$$  

On the other hand, from Lemma 4.9 proved above, we know that the function $\phi(\rho)$ that upper bounds the local Rademacher complexity of the Deep Neural Network space is of the same magnitude as $\sqrt{\frac{1}{n^{\frac{d}{\pi^2 + 7}}} \log (BWn)}$. By plugging in the magnitudes of $L, W, S, B$, we can determine the critical radius $r^*$:

$$\sqrt{\frac{r^* 3LS}{n} \log (BWn)} \simeq \sqrt{\frac{r^* N}{n} (2 \log N + \log n)} \simeq r^* \Rightarrow r^* \simeq \frac{N(\log N + \log n)}{n}.$$  

Combining the two bounds above with Theorem 4.11 yields that with high probability, we have:

$$\|\hat{u}_{\text{DRM}}^{\text{DNN}} - u^*\|_{H^1}^2 \lesssim \Delta \mathcal{E}_{\text{app}} + \hat{r} \lesssim N^{-\frac{2(s-1)}{s}} + \frac{N(\log N + \log n)}{n}.$$  

By equating the two terms above, we can solve for the optimal $N$ that yields the desired bound:

$$N^{-\frac{2(s-1)}{s}} \simeq \frac{N}{n} \Rightarrow N \simeq n^{\frac{1}{2s-2}}.$$  

Plugging in the optimal $N$ gives us the magnitudes of the four parameters $L = O(1)$, $W = O(n^{\frac{d}{\pi^2 + 7}})$, $S = O(n^{\frac{d}{\pi^2 + 7}})$, $B = O(n^{\frac{d}{\pi^2 + 7}})$, as well as the final rate:

$$\|\hat{u}_{\text{DRM}}^{\text{DNN}} - u^*\|_{H^1}^2 \lesssim N^{-\frac{2(s-1)}{s}} + \frac{N \log N}{n} \lesssim n^{-\frac{2(s-1)}{s+2s-2}} \log n.$$  

Theorem 4.13. (Final Upper Bound of DRM with Truncated Fourier Series Estimator) With proper assumptions, consider the Deep Ritz objective with a plug in Fourier Series estimator $\hat{u}_{\text{DRM}}^{\text{Fourier}} = \min_{\xi \in \mathcal{F}_{\xi}(\Omega)} \mathcal{E}_n^{\text{DRM}}(u)$ with $\xi = \Theta(n^{\frac{d}{\pi^2 + 7}})$, then with high probability we have

$$\|\hat{u}_{\text{DRM}}^{\text{Fourier}} - u^*\|_{H^1}^2 \lesssim n^{-\frac{2s-2}{s+2s-2}}.$$  

Proof. On the one hand, from Lemma 4.6 and Lemma 4.7 proved above, we know that the function $\phi(\rho)$ that upper bounds the local Rademacher complexity for Truncated Fourier Series can be dominated by the term

\begin{equation}
\begin{aligned}
(4.21) \\
R_n(S_\rho(\Omega)) \leq R_n \left( \left\{ u - u^* : u \in \mathcal{F}_{\rho,\xi}(\Omega), \|u - u^*\|_{L^2(\Omega)} \leq \sqrt{\rho} \right\} \right) \\
+ R_n \left( \left\{ \|\nabla u - \nabla u^*\| : u \in \mathcal{F}_{\rho,\xi}(\Omega), \left\|\nabla u - \nabla u^*\right\|_{L^2(\Omega)} \leq \sqrt{\rho} \right\} \right)
\end{aligned}
\end{equation}

\begin{align*}
\leq \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \sup_{f \in \mathcal{F}_{\rho,\xi}(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i (u(X_i) - u^*(X_i)) \right] \|u - \Pi_x u^*\|_{H^1(\Omega)}^2 \leq \rho \right] \\
+ \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \sup_{f \in \mathcal{F}_{\rho,\xi}(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i \|\nabla u(X_i) - \nabla u^*(X_i)\| \right] \left\|\Pi_x u^*\|_{H^1(\Omega)}^2 \leq \rho \right] \\
+ \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \frac{1}{n} \sum_{i=1}^{n} \sigma_i \|\nabla f(X_i)\| \right] \left\|f\right\|_{H^1(\Omega)}^2 \leq \rho \right] \\
+ \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \frac{1}{n} \sum_{i=1}^{n} \sigma_i \|\nabla \Pi_x u^*(X_i)\| \right] + \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \frac{1}{n} \sum_{i=1}^{n} \sigma_i \Pi_x u^*(X_i) \right] \right] \right] \\
\leq \sqrt{\frac{\rho}{n} \frac{\xi^d}{n}} + \sqrt{\frac{\|\Pi_x f\|_{H^1(\Omega)}^2}{n}} \leq \sqrt{\frac{\rho}{n} \frac{\xi^d}{n}} + \sqrt{\frac{\xi^{-2(s-1)}}{n}} \leq \sqrt{\frac{\rho}{n} \frac{\xi^d}{n}} + \frac{1}{n} + \xi^{-2(s-1)},
\end{align*}

where $\Pi_x u := \sum_{\|\Omega\|_{\infty} \leq \xi} u_{\Omega} \phi_{\xi}(x)$ is the projection to the Fourier basis whose frequency is smaller than $\xi$ and $\Pi_x u := \sum_{\|\Omega\|_{\infty} \geq \xi} u_{\Omega} \phi_{\xi}(x)$ is the projection to the Fourier basis whose frequency is larger than $\xi$. Then, the critical radius $\hat{\rho}$ can be determined as follows:

$$\sqrt{\frac{\rho}{n} \frac{\xi^d}{n}} + \frac{1}{n} + \xi^{-2(s-1)} \cong \rho \Rightarrow \hat{\rho} \cong \frac{\xi^d}{n} + \frac{1}{n} + \xi^{-2(s-1)},$$

On the other hand, by taking $\alpha = s$ and $\beta = 1$ in Lemma 4.1 and applying strong convexity of the DRM objective function proved in Theorem A.1, we can upper bound the approximation error $\Delta \mathcal{E}_{\text{app}}$ as below:

$$\Delta \mathcal{E}_{\text{app}} \lesssim \xi^{-2(s-1)},$$

By equating the two terms above, we can solve for $\xi$ that yields the desired bound:

$$\frac{\xi^d}{n} \cong \xi^{-2(s-1)} \Rightarrow \xi \cong n^{\frac{1}{2d + 2s - 2}},$$
Plugging in the expression of $\xi$ gives the final upper bound:

$$E_{x \sim \mu} [\Delta E_n] \lesssim \bar{\epsilon} + \Delta \varepsilon_{\text{app}} \lesssim \frac{e_d}{n} + \xi^{-2(s-1)} \simeq n^{-2s-2}.$$  

**Physics Informed Neural Network.** Then we aim to provide the upper bound for the Physics Informed Neural Network with a similar meta-theorem followed by upper bounds of DNN and truncated Fourier Estimators. For simplicity, we drop the proof of the meta-theorem to appendix for all the proof follows the similar idea of the DRM one.

**Theorem 4.14 (Meta-theorem for Upper Bounds of Physics Informed Neural Network).** Let $u^* \in H_s(\Omega)$ denote the true solution to the PDE model with Dirichlet boundary condition:

$$\begin{align*}
-\Delta u + Vu &= f \text{ on } \Omega, \\
u &= 0 \text{ on } \partial \Omega,
\end{align*}$$

where $f \in L^2(\Omega)$ and $V \in L^\infty(\Omega)$ with $0 < V_{\text{min}} \leq V(x) \leq V_{\text{max}} > 0$. For a fixed function space $\mathcal{F}(\Omega)$, consider the empirical loss induced by the Physics Informed Neural Network:

$$(4.23) \quad \mathcal{E}_n(u) = \frac{1}{n} \sum_{j=1}^{n} \left[ \frac{|\Omega|}{n} \cdot \left( \Delta u(X_j) - V(X_j)u(X_j) + f(X_j) \right)^2 \right],$$

where $\{X_j\}_{j=1}^{n}$ are datapoints uniformly sampled from the domain $\Omega$. Then the Physics Informed Neural Network estimator associated with function space $\mathcal{F}(\Omega)$ is defined as the minimizer of $\mathcal{E}_n(u)$ over the function space $\mathcal{F}(\Omega)$:

$$\hat{u}_{\text{PINN}} = \min_{u \in \mathcal{F}(\Omega)} \mathcal{E}_n(u).$$

Moreover, we assume that there exists some constant $C > 0$ such that all functions $u$ in the function space $\mathcal{F}(\Omega)$, the real solution $u^*$ and $f, V$ satisfy the following two conditions.

- The gradients and function value are uniformly bounded

$$\max \left\{ \sup_{u \in \mathcal{F}(\Omega)} \|u\|_{L^\infty(\Omega)}, \sup_{u \in \mathcal{F}(\Omega)} \|\nabla u\|_{L^\infty(\Omega)}, \sup_{u \in \mathcal{F}(\Omega)} \|\Delta u\|_{L^\infty(\Omega)}, \|u^*\|_{L^\infty(\Omega)}, \|\nabla u^*\|_{L^\infty(\Omega)}, \|\Delta u^*\|_{L^\infty(\Omega)}, V_{\text{max}}, \|f\|_{L^\infty(\Omega)} \right\} \leq C. \quad (4.24)$$

- All the functions in the function space $\mathcal{F}(\Omega)$ satisfy the boundary condition

$$u = 0 \text{ on } \partial \Omega.$$ 

At the the same time, for any $\rho > 0$, we assume the Rademacher complexity of a localized function space $T_\rho(\Omega) := \left\{ h := |\Omega| \cdot \left[ (\Delta u - Vu + f)^2 - (\Delta u^* - Vu^* + f)^2 \right] \right\}$ can be upper bounded by a sub-root function $\phi = \phi(\rho) : [0, \infty) \to [0, \infty)$, i.e.

$$\phi(4\rho) \leq 2\phi(\rho) \text{ and } R_n(T_\rho(\Omega)) \leq \phi(\rho) \quad (\forall \rho > 0). \quad (4.25)$$
For all constant $t > 0$. We denote $r^*$ to be the solution of the fix point equation of local Rademacher complexity $r = \phi(r)$. There exists a constant $C_p$ such that for probability $1 - C_p \exp(-t)$, we have the following upper bound for the Physics Informed Neural Network Estimator

$$ \| \hat{u}_{\text{PINN}} - u^* \|_{H^2}^2 \lesssim \inf_{u_F \in \mathcal{F}(\Omega)} \left( \mathcal{E}(u_F) - \mathcal{E}(u^*) \right) + \max \left\{ r^*, \frac{t}{n} \right\}. $$

Then we aim to calculate the final upper bound for DNN and truncated Fourier series based PINN estimator.

**Theorem 4.15.** *(Informal Upper Bound of PINN with Deep Neural Network Estimator)* With proper assumptions, consider the sparse Deep Neural Network function space $\Phi(L, W, S, B)$ with parameters $L = O(1), W = O(n^{\frac{d}{d+1}}), S = O(n^{\frac{d}{d+1}}), B = O(1)$, then the Physics Informed estimator $\hat{u}_{\text{PINN}}^{\text{DNN}} = \min_{u \in \Phi(L, W, S, B)} \mathcal{E}_{\text{PINN}}(u)$ satisfies the following upper bound with high probability:

$$ \| \hat{u}_{\text{PINN}}^{\text{DNN}} - u^* \|_{H^2}^2 \lesssim n^{-\frac{2s-4}{d}} \log n. $$

**Proof.** On the one hand, by taking $s = 2$ and $p = 2$ in Theorem 4.5 proved above, we have that there exists some Deep Neural Network $u_{\text{DNN}} \in \Phi(L, W, S, B)$ with $L = O(1), W = O(N), S = O(N), B = O(1)$, such that.

$$ \| u_{\text{DNN}} - u^* \|_{H^2(\Omega)} \leq N^{-\frac{2s-4}{d}} \| u \|_{H^s(\Omega)}. $$

Applying strong convexity of the DRM objective function proved in Section 2.1 further implies:

$$ \Delta \mathcal{E}_{\text{app}} \lesssim \| u_{\text{DNN}} - u^* \|_{H^2(\Omega)}^2 \leq N^{-\frac{2s-4}{d}}. $$

On the other hand, from lemma 4.10 proved above, we know that the function $\phi(\rho)$ that upper bounds the local Rademacher complexity of the Deep Neural Networks $u_{\text{DNN}}$ is dominated by the term $\sqrt{\frac{\rho^L S}{n}} \log(W(B \lor 1)n)$. By plugging in the magnitudes of $L, W, S, B$, we can determine the critical radius $\hat{r}$:

$$ \sqrt{\frac{\rho^L S}{n}} \log(W(B \lor 1)n) \simeq \sqrt{\frac{\rho N}{n} \left( \log N + \log n \right)} \simeq \hat{r} \Rightarrow \hat{r} \simeq \frac{N(\log N + \log n)}{n}. $$

Combining the two bounds above gives us:

$$ \mathbb{E}_{x \sim \mu}[\Delta \mathcal{E}_n] \lesssim \Delta \mathcal{E}_{\text{app}} + \hat{r} \lesssim N^{-\frac{2(s-2)}{d}} + \frac{N(\log N + \log n)}{n}. $$

By equating the two terms above, we can solve for the optimal $N$ that yields the desired bound:

$$ N^{-\frac{2(s-2)}{d}} \simeq \frac{N}{n} \Rightarrow N \simeq n^{\frac{d}{2(s-2)}}. $$

Plugging in the optimal $N$ gives us the magnitudes of the four parameters $L = O(1), W = O(n^{\frac{d}{d+1}}), S = O(n^{\frac{d}{d+1}}), B = O(1)$, as well as the final rate:

$$ \mathbb{E}_{x \sim \mu}[\Delta \mathcal{E}_n] \lesssim N^{-\frac{2(s-2)}{d}} + \frac{N \log N}{n} \lesssim n^{-\frac{2(s-2)}{d}} \log n. $$
Theorem 4.16. (Informal Upper Bound of PINN with Truncated Fourier Series Estimator)
With proper assumptions, consider the Physics Informed Neural Network objective with a plug-in Fourier Series estimator 
\( \hat{u}_{\text{PINN}}^{\text{Fourier}} = \min_{u \in F} \mathbb{E}_{\xi} \left[ 2 \right] \) 
then with high probability we have 
\[ \| \hat{u}_{\text{PINN}}^{\text{Fourier}} - u^* \|_2^2 \lesssim n^{-\frac{2s-4}{4+2s-4}}. \]

Proof. On the one hand, from Lemma 4.6 and Lemma 4.7 proved above, we know that the function \( \phi(\rho) \) that upper bounds the local Rademacher complexity for Truncated Fourier Series is dominated by 
\[ R_n(S_{\rho}(\Omega)) \lesssim R_n \left( \left\{ |\Delta u - \Delta u^*| : u \in F_{\rho,\xi}(\Omega), |\Delta u - \Delta u^*|_{L^2(\Omega)} \leq \sqrt{\rho} \right\} \right) \]
\[ \lesssim \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \sup_{f \in F_{\rho,\xi}(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i |\Delta u(X_i) - \Delta u^*(X_i)| \left\| u - \Pi_\xi u^* \right\|_H^2 \leq \rho \right] \right] \]
\[ + \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \frac{1}{n} \sum_{i=1}^{n} \sigma_i |\Pi_\xi u^*(X_i)| \right] \right] \]
\[ \leq \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \sup_{f \in F_{\rho,\xi}(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i |\Delta f(X_i)| \left\| f \right\|_H^2 \leq \rho \right] \right] \]
\[ + \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \frac{1}{n} \sum_{i=1}^{n} \sigma_i \left\| \Pi_\xi u^*(X_i) \right\| \right] \right] \]
\[ \leq \sqrt{\frac{\rho \xi^d}{n}} + \sqrt{\frac{|\Pi_\xi f|^2}{n}} \leq \sqrt{\frac{\rho \xi^d}{n}} + \sqrt{\frac{\xi^{-2(s-1)}}{n}} \lesssim \sqrt{\frac{\rho \xi^d}{n}} + \frac{1}{n} + \xi^{-2(s-2)}, \]

Thus, the localization radius \( \hat{r} \) can be determined as follows:
\[ \sqrt{\frac{\rho \xi^d}{n}} + \frac{1}{n} + \xi^{-2(s-2)} \simeq \rho \Rightarrow \hat{r} \simeq \frac{\xi^d}{n} + \frac{1}{n} + \xi^{-2(s-2)}, \]

On the other hand, by taking \( \alpha = s \) and \( \beta = 1 \) in Lemma 4.1 and applying strong convexity of the DRM objective function proved in Theorem A.1, we can upper bound the approximation error \( \Delta \mathcal{E}_{\text{app}} \) as below:
\[ \Delta \mathcal{E}_{\text{app}} \lesssim \xi^{-2(s-2)}, \]

By equating the two terms above, we can solve for \( \xi \) that yields the desired bound:
\[ \frac{\xi^d}{n} \simeq \xi^{-2(s-2)} \Rightarrow \xi \simeq n^{\frac{1}{4+2s-4}}, \]
Plugging in the expression of $\xi$ gives the final upper bound:

$$E_{x \sim \mu} [\Delta E_n] \lesssim \hat{r} + \Delta E_{\text{app}} \lesssim \frac{\xi^d}{n} + \xi^{-2(s-2)} \simeq n^{-\frac{2s-4}{\alpha + 2s-4}}.$$  

\textbf{Remark.}

- There is a common belief that Machine learning based PDE solvers can break the curse of dimensionality [15, 24, 40]. However we obtained an $n^{-\frac{2s-4}{\alpha + 2s-4}}$ convergence rate which can become super slow in high dimension. Our analysis showed that it is essential to constrain the function space to break the curse of dimensionality. [47] considered the DRM in Barron spaces. [56] showed that functions in the Barron space enjoy a smoothness $s$ at the same magnitude as $d$, which will also leads to convergence rate independent of the dimension using our upper bound. Neural network can also approximate mixed sparse grid spaces [52, 70], function on manifold [55, 9] without curse of dimensionality. Combined with these approximation bounds, we can also achieve a bound that breaks the curse of dimensionality using Theorem 4.14 and 4.11. In this paper, we aim to consider the statistical power of the loss function in common function spaces and leave the curse of dimensionality as a separate topic.

- Our bound is faster than the concurrent bound [14, 34] for we provided a fast rate $O(1/n)$ by utilizing the strong convexity of the objective function and improves the convergence rate from $n^{-\frac{2s-4}{\alpha + 2s-4}}$ to $n^{-\frac{2s-4}{\alpha + 2s-4}}$ for Deep Ritz and from $n^{-\frac{2s-4}{\alpha + 2s-4}}$ to $n^{-\frac{2s-4}{\alpha + 2s-4}}$ for PINN. Comparing to the lower bound provided in Section 3, we show that our bound for PINN is near optimal and we’ll let our bound for DRM become near optimal in the next section.

- For upper bound of DRM, due to a technical issue, we assume the observation we access is clean, i.e $f_i = f(X_i)$. We conjecture that add noising on observation will not effect the rate and leave this to future work.

5. Modified Deep Ritz Methods. Comparing the lower bound in Section 3 and the upper bound in Section 4, we find out that the Physics Informed Neural Network achieved min-max optimality while the Deep Ritz Method does not. In this section, we proposed a modified version of deep Ritz which can be statistically optimal.

As discussed in Appendix B, the reason behind the suboptimality of DRM comes from the high complexity introduced via the uniform concentration bound of the gradient term in the variational form. At the same time, we further observed that the $\int ||\nabla u||^2 dx$ does not require any query from the right hand side function $f$, which means that we can easily make another splitted sample to approximate the $\int ||\nabla u||^2 dx$ term more precisely.

\begin{equation}
\mathcal{E}_{N,n}(u) = \frac{1}{N} \sum_{j=1}^{N} \left[ ||\Omega|| \cdot \frac{1}{2} ||\nabla u(X_j')||^2 \right] + \frac{1}{n} \sum_{j=1}^{n} \left[ ||\Omega|| \cdot \left( \frac{1}{2} V(X_j)|u(X_j)|^2 - f_j u(X_j) \right) \right]
\end{equation}

Once we sampled more data for approximating $\int ||\nabla u||^2 dx$, we can achieve an near optimal bound for the Truncated Fourier Estimator when $\frac{N}{n} \gtrsim n^{\frac{2}{\alpha + 2s-4}}$. The proof is based on a similar meta-theorem as following.
We denote the true solution to the PDE model with Dirichlet boundary condition:

\begin{equation}
-\Delta u + Vu = f \quad \text{on } \Omega,
\end{equation}

\begin{equation}
u = 0 \quad \text{on } \partial \Omega,
\end{equation}
where \( f \in L^2(\Omega) \) and \( V \in L^\infty(\Omega) \) with \( 0 < V_{\min} \leq V(x) \leq V_{\max} > 0 \). For a fixed function space \( F(\Omega) \), consider the empirical loss induced by the Modified Deep Ritz Method \( (N \geq n) \):

\begin{equation}
\mathcal{E}_{N,n}(u) = \frac{1}{N} \sum_{i=1}^{N} \left[ |\Omega| \cdot \frac{1}{2} |\nabla u(X_i')|^2 \right] + \frac{1}{n} \sum_{j=1}^{n} \left[ |\Omega| \cdot \left( \frac{1}{2} V(X_j)|u(X_j)|^2 - f(X_j)u(X_j) \right) \right],
\end{equation}

where \( \{X_i'\}_{i=1}^{N} \) and \( \{X_j\}_{j=1}^{n} \) are datapoints uniformly and independently sampled from the domain \( \Omega \). Then the Modified Deep Ritz estimator associated with function space \( F(\Omega) \) is defined as the minimizer of \( \mathcal{E}_{N,n}(u) \) over the function space \( F(\Omega) \):

\[ \hat{u}_{MDRM} = \min_{u \in F(\Omega)} \mathcal{E}_{N,n}(u) \]

Moreover, we assume that there exists some constant \( C > 0 \) such that all function \( u \) in the function space \( F(\Omega) \), the real solution \( u^* \) and \( f, V \) satisfy the following two conditions.

- The gradients and function value are uniformly bounded

\begin{equation}
\max \left\{ \sup_{u \in F(\Omega)} \|u\|_{L^\infty(\Omega)}, \sup_{u \in F(\Omega)} \|\nabla u\|_{L^\infty(\Omega)}, \|u^*\|_{L^\infty(\Omega)}, \|\nabla u^*\|_{L^\infty(\Omega)}, V_{\max}, \|f\|_{L^\infty(\Omega)} \right\} \leq C,
\end{equation}

- All the functions in the function space \( F(\Omega) \) satisfy the boundary condition

\[ u = 0 \quad \text{on } \partial \Omega. \]

At the same time, for any \( \rho > 0 \), we assume the Rademacher complexity of two localized function spaces

\[ S_{\rho}(\Omega) := \{ (h_1, h_2) | h_1 := |\Omega|, \frac{1}{2} \left[ |\nabla u|^2 - |\nabla u^*|^2 \right], h_2 := |\Omega|, \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*) \}, \|u - u^*\|_{H^1} \leq \rho \}
\]

can be upper bounded by a sub-root function \( \phi = \phi(\rho) : [0, \infty) \to [0, \infty), \) i.e.

\begin{equation}
\phi(4\rho) \leq 2\phi(\rho) \text{ and } R_{N,n}(S_{\rho}(\Omega)) \leq \phi(\rho) \text{ (\forall } \rho > 0),
\end{equation}

where \( R_{N,n}(S) := R_{N}(\{h_1 | (h_1, h_2) \in S\}) + R_{n}(\{h_2 | (h_1, h_2) \in S\}) \). For all constant \( t > 0 \), we denote \( r^* \) to be the solution of the fix point equation of local Rademacher complexity \( r = \phi(r) \). There exist a constant \( C_p \) such that for probability \( 1 - C_p \exp(-t) \), we have the following upper bound for the Modified Deep Ritz Estimator

\[ \|\hat{u}_{MDRM} - u^\star\|_{H^1} \leq \inf_{u \in F(\Omega)} \left( \mathcal{E}(u) - \mathcal{E}(u^\star) \right) + \max \left\{ r^*, \frac{t}{n} \right\}. \]
**Theorem 5.2.** *(Informal Upper Bound of DRM with Truncated Fourier Series Estimator)* With proper assumptions, consider the Deep Ritz objective with a plug in Fourier Series estimator \( \hat{u}_{\text{Fourier}}^{\text{DRM}} = \min_{u \in \mathcal{F}_\xi(\Omega)} E_n^{\text{DRM}}(u) \) with \( \xi = \Theta(n^{\frac{d-2}{2s-4}+2}) \) and \( \frac{N}{n} \gtrsim n^{\frac{2d-2}{2s-4}} \), then we have

\[
\| \hat{u}_{\text{Fourier}}^{\text{DRM}} - u^* \|^2_{H^1} \lesssim n^{-\frac{2d-2}{2s-4}}.
\]

**Proof.** On the one hand, from Lemma 4.6 and Lemma 4.7 proved above, we know that the function \( \phi(\rho) \) that upper bounds the local Rademacher complexity is dominated by the term \( \sqrt{\frac{\rho \xi d}{n}} \) for Truncated Fourier Series in \( \mathcal{F}_\xi(\Omega) \). Following the same proof as shown for DRM upper bound, the localization radius \( \hat{r} \) can be determined as follows:

\[
\sqrt{\frac{\rho \xi d}{n}} + \sqrt{\frac{\rho \xi d}{N}} + \frac{1}{n} + \frac{1}{N} + \xi^{-2(s-1)} \simeq \rho.
\]

For we have assumed \( \frac{\rho d}{N} < \frac{\rho d-2}{n} \), the solution of the fixed point equation is \( \hat{r} \simeq \frac{\xi d}{n} \). On the other hand, by taking \( \alpha = s \) and \( \beta = 1 \) in Lemma 4.1 and applying strong convexity of the DRM objective function proved in Theorem A.1, we can upper bound the approximation error \( \Delta E_{\text{app}} \) as below:

\[
\Delta E_{\text{app}} \lesssim \xi^{-2(s-1)},
\]

By equating the two terms above, we can solve for \( \xi \) that yields the desired bound:

\[
\frac{\xi d-2}{n} + \xi^{-2(s-1)} \simeq \xi^{-2(s-1)} \Rightarrow \xi \simeq n^{\frac{1}{2s-4}} + \xi^{-2(s-1)},
\]

Plugging in the expression of \( \xi \) gives the final upper bound:

\[
\text{E}_{\mu}[\Delta E_n] \lesssim \hat{r} + \Delta E_{\text{app}} \lesssim \frac{\xi d-2}{n} + \xi^{-2(s-2)} \simeq n^{-\frac{2d-2}{2s-4}}.
\]

**Remark.** We still cannot achieve optimal rate for neural network even with modified DRM methods. The reason is because the number of neuron is not a good complexity measure for the gradient of the function thus the bound for \( \psi(r) = R_n(\{I(u)||u-u^*||^2_{H^1} \leq r\}) \) is not enough for achieving optimal convergence rate. However, following [63, 70, 33, 9, 18] using deep networks for estimating functions, we optimize the best neural network with constrained sparsity in our paper. Here we conjecture that there exists a computable complexity measure can make DRM statistical optimal and leave finding the right complexity of the neural network’s gradient to be future work.

**6. Experiments.** In this section, we conduct several numerical experiments to verify our theory. We follow the neural network and hyper-parameter setting in [7]. Due to the page limit, we only put the experiments for Deep Ritz Methods here.
6.1. The Modified Deep Ritz Methods. In this section, we conduct experiments which substantiate our theoretical results for modified Deep Ritz methods. For simplicity, we take $V(x) = 1$ in our experiment. We conduct experiment in 2-dimension and select the solution of the PDE as $u^* = \sum_\phi \|z\|^{-s} \phi_z(x) \in H^s$. We show the log-log plot of the $H^1$ loss against the number of sampled data for $s = 4$ in Figure 1. We use an OLS estimator to fit the log-log plot and put the estimated slope and corresponding $R^2$ score in Figure 1. As our theory predicts, the modified Deep Ritz Method converges faster than the original one. All the derivation of the two estimators is listed in Appendix B.

6.2. Dimension Dependent Scaling Law. We conduct experiments to illustrate that the population loss of well-trained and well-tuned Deep Ritz method will scale with the $d$-dimensional training data number $N$ as a power-law $L \sim \frac{1}{N^\alpha}$. We also scan over a range of $d$ and $\alpha$ and verify an approximately $\alpha \sim \frac{1}{d}$ scaling law as our theory suggests. We use the same test function in Section 6.1 as the solution of our PDE. For simplicity, we take $V(x) = 1$ in our experiment. We train the deep Ritz method on $20, 80, 320, 1280, 10240$ sampled data points for $5, 6, 7, 8, 9, 10$ dimensional problems and we plot our results on the log-log scale. Results are shown in Figure 2. We discover the $L \sim \frac{1}{n^{\frac{1}{2}}} \approx \frac{1}{\sqrt{n}}$ scaling law in practical situations.

6.3. Adaptation To The Simpler Functions. [65] showed that the neural scaling law will adapt to the structure that the target function enjoys. This adaptivity enables the neural network to break the cure of the dimensionality for simple functions in high dimension. [72, 8] also observed this theoretically. For solving PDEs, we also observed this adaptivity in practice. Here we tested the following two hypothesis:

- **Random Neural Network Teacher.** Following [65], we also tested random neural network using He initialization [29] as the ground truth solution $u^*$. [13] showed that random deep neural networks are biased towards simple functions and in practice we
observed a scaling law at the parametric rate. Specifically, we obtained a linear estimate with slope $\alpha = -0.50679429$ and a $R^2$ score = 0.96 in the log-log plot. See Figure 3(a).

- **Simple Polynomials.** Neural network can approximate simple polynomials exponentially fast [76]. Thus, we select the ground truth solution to be the following simple polynomial in 10 dimensional spaces $u^*(x) = x_1x_2 + \cdots + x_9x_{10}$. In this example, we obtained a linear estimate with slope $\alpha = -0.49755418$ and a $R^2$ score = 0.99 in the log-log plot. See Figure 3(b).

7. Conclusion and Discussion.

**Conclusion.** In this paper, we considered the statistical min-max optimality of solving a PDE from random samples. We improved the previous bounds [78, 47, 14, 34] by providing the first fast rate generalization bound for learning PDE solutions via the strongly convex nature of the two objective functions. We achieved the optimal rate via the PINN and a modified Deep Ritz method. We verified our theory via numerical experiments and explored the dimension dependent scaling laws of Deep PDE solvers.

**Discussion and Future Work.** Here we discuss several drawbacks of our theory

- We restricted our target function and estimators in $W^{1,\infty}$ instead of $H^1$ due to boundedness assumption made in the local Rademacher complexity arguments. However, typical functional used in physics is always unbounded, such as the Newtonian potential $1/\|x-y\|^{d-2}$, which limits the application of our theory.

- This paper did not discuss any optimization aspect of the deep PDE solvers and always assumed achieves global optimum. However, it is important to investigate whether the optimization error [71, 11] will finally dominate.

- Instead of solving a single PDE, recent works [45, 44, 42, 40, 4, 17, 19] considered the so-called "operator learning", which aims to learn a family of PDE/inverse problems using a single network. It is interesting to investigate the generalization bound and neural scaling law there.

- We find out that the sparsity of the neural network is not a good complexity measure of neural network’s gradient. We conjecture that there exists an oracle complexity measure, whose approximation and generalization bounds can lead Modified DRM to achieve the optimal convergence rate.

[27] J. Han, J. Lu, and M. Zhou, Solving high-dimensional eigenvalue problems using deep neural networks:

Appendix A. Proof of the Upper Bounds.

A.1. Notations. In this section, we provide all the notations we need in the proof. Let $\Omega \subset \mathbb{R}^d$ be some open set. We denote $C(\Omega)$ the space of continuous functions on $\Omega$ and $C^k(\Omega)$ the space of all functions that are $k$ times continuously differentiable on $\Omega$ ($\forall k \in \mathbb{Z}^+$). For any $n \in \mathbb{N}_0$ ($\mathbb{N}_0 := \mathbb{Z}^+ \cup \{0\}$ is the set of all non-negative integers) and $1 \leq p \leq \infty$, we define the Sobolev space $W^{n,p}(\Omega)$ by

$$W^{n,p}(\Omega) := \{ f \in L^p(\Omega) : D^\alpha f \in L^p(\Omega), \forall \alpha \in \mathbb{N}_0^d \text{ with } |\alpha| \leq n \}.$$ 

In particular, when $p = 2$, we define $H^n(\Omega) := W^{n,2}(\Omega)$ for any $n \in \mathbb{N}_0$. Moreover, for any $f \in W^{n,p}(\Omega)$ with $1 \leq p < \infty$, we define the Sobolev norm by:

$$\|f\|_{W^{n,p}(\Omega)} := \left( \sum_{0 \leq |\alpha| \leq n} \|D^\alpha f\|_{L^p(\Omega)}^p \right)^{1/p}.$$ 

In particular, when $p = \infty$, we have:

$$\|f\|_{W^{n,\infty}(\Omega)} := \max_{0 \leq |\alpha| \leq n} \|D^\alpha f\|_{L^\infty(\Omega)}.$$ 

Consider the Fourier expansion $f := \sum_{z \in \mathbb{N}^d} f_z \phi_z(x)$ of the function $f \in W^{n,p}(\Omega)$. We can equivalently express the Sobolev norm as:

$$\|f\|_{W^{n,p}(\Omega)} = \left( \sum_z \|z^\alpha f_z\|^p \right)^{1/p},$$ 

where $f_z = \int_{\Omega} f(x) \phi_z(x) dx = \int_{\Omega} f(x) e^{-2\pi i (\xi \cdot x)} dx \ (x \in \Omega)$ is the $z$-th Fourier coefficient of $f$. Moreover, we use $W^{1,p}_0(\Omega)$ to denote the closure of $C_c^1(\Omega)$ in $W^{1,p}(\Omega)$. In particular, when $p = 2$, we define $H_0^1(\Omega) := W^{1,2}_0(\Omega)$.

Furthermore, we use $\| \cdot \|$ to present the vector 2 norm and, given a data sample \{X_i\}_{i=1}^n \subset \Omega, $\| \cdot \|_{n,p} = (\mathbb{E}_n \| \cdot \|^p)^{1/p}$ denote the empirical $p$ norm, where $\mathbb{E}_n : L^2(\Omega) \to \mathbb{R}$ is the corresponding empirical average operator defined as $\mathbb{E}_n f := \frac{1}{n} \sum_{i=1}^n f(X_i), \forall f \in L^2(\Omega)$. Given two quantities $X$ and $Y$, we write $X \lesssim Y$ when the inequality $X \leq CY$ holds, where $C$ is some constant. For two functions $f$ and $g$ mapping from $\mathbb{R}^+$ to $\mathbb{R}$, we write $f = O(g)$ when there exist two constants $C'$ and $x_0$ independent of $f$ and $g$, such that the inequality $f(x) \leq C'g(x)$ holds for any $x \geq x_0$. We use $X \simeq Y$ to denote $X \lesssim Y$ and $Y \lesssim X$.

A.2. Regularity Result For the PDE model.

Regularity Results of the DRM Objective Function.

Theorem A.1. We consider the static Schrödinger equation on the unit hypercube on $\mathbb{R}^d$ with the zero Dirichlet boundary condition:

$$-\Delta u + Vu = f \text{ on } \Omega,$$

$$u = 0 \text{ on } \partial \Omega. \tag{A.1}$$
where \( f \in L^2(\Omega) \) and \( V \in L^\infty(\Omega) \) with \( 0 < V_{\text{min}} \leq V(x) \leq V_{\text{max}} > 0 \). There exists a unique weak solution \( u_S^* \) to the equivalent variational problem [16]:

\[
(A.2) \quad u_S^* = \arg\min_{u \in H^1_0(\Omega)} \mathcal{E}^{\text{DRM}}_S(u) := \arg\min_{u \in H^1_0(\Omega)} \left\{ \frac{1}{2} \int_\Omega \|\nabla u\|^2 + V|u|^2 \, dx - \int_\Omega f u \, dx \right\}.
\]

Then for any \( u \in H^1(\Omega) \), we have:

\[
(A.3) \quad \frac{\min(1, V_{\text{min}})}{2} \| u - u_S^* \|^2_{H^1(\Omega)} \leq \mathcal{E}^{\text{DRM}}(u) - \mathcal{E}^{\text{DRM}}(u_S^*) \leq \frac{\max(1, V_{\text{max}})}{2} \| u - u_S^* \|^2_{H^1(\Omega)}.
\]

**Proof.** To show that \( u_S^* \) satisfies estimate \( A.3 \), we first claim that for any \( u \in H^1(\Omega) \),

\[
(A.4) \quad \mathcal{E}^{\text{DRM}}(u) - \mathcal{E}^{\text{DRM}}(u_S^*) = \frac{1}{2} \int_\Omega \|\nabla u - \nabla u_S^*\|^2 \, dx + \frac{1}{2} \int_\Omega V(u_S^* - u)^2 \, dx.
\]

In fact, by plugging in the first equation of \( A.1 \), one has that

\[
\mathcal{E}^{\text{DRM}}(u_S^*) = \frac{1}{2} \int_\Omega \|\nabla u_S^*\|^2 \, dx + \frac{1}{2} \int_\Omega V|u_S^*|^2 \, dx - \int_\Omega f u_S^* \, dx
\]

\[
= \frac{1}{2} \int_\Omega \|\nabla u_S^*\|^2 \, dx + \frac{1}{2} \int_\Omega V|u_S^*|^2 \, dx + \int_\Omega (\Delta u_S^* - V u_S^*) u_S^* \, dx
\]

\[
= \frac{1}{2} \int_\Omega \|\nabla u_S^*\|^2 \, dx + \int_\Omega (\Delta u_S^*) u_S^* \, dx - \frac{1}{2} \int_\Omega V|u_S^*|^2 \, dx.
\]

Furthermore, applying Green’s formula to the true solution \( u_S^* \) yields:

\[
\mathcal{E}^{\text{DRM}}(u_S^*) = \frac{1}{2} \int_\Omega \|\nabla u_S^*\|^2 \, dx + \int_\partial \Omega \frac{\partial u_S^*}{\partial n} u_S^* \, dx - \frac{1}{2} \int_\Omega V|u_S^*|^2 \, dx
\]

\[
= -\frac{1}{2} \int_\Omega \|\nabla u_S^*\|^2 \, dx - \frac{1}{2} \int_\Omega V|u_S^*|^2 \, dx,
\]

where the last identity above follows from the second equality in \( A.1 \). Now for any \( u \in H^1(\Omega) \), applying Green’s formula to \( u \) and the true solution \( u_S^* \) implies:

\[
\mathcal{E}^{\text{DRM}}(u) - \mathcal{E}^{\text{DRM}}(u_S^*) = \frac{1}{2} \int_\Omega \|\nabla u\|^2 \, dx + \frac{1}{2} \int_\Omega V|u|^2 \, dx - \int_\Omega f u \, dx + \frac{1}{2} \int_\Omega \|\nabla u_S^*\|^2 \, dx + \frac{1}{2} \int_\Omega V|u_S^*|^2 \, dx
\]

\[
= \frac{1}{2} \int_\Omega \|\nabla u\|^2 \, dx + \frac{1}{2} \int_\Omega V|u|^2 \, dx + \int_\Omega (\Delta u_S^* - V u_S^*) u \, dx + \frac{1}{2} \int_\Omega \|\nabla u_S^*\|^2 \, dx + \frac{1}{2} \int_\Omega V|u_S^*|^2 \, dx
\]

\[
= \frac{1}{2} \int_\Omega \|\nabla u\|^2 \, dx + \int_\Omega (\Delta u_S^*) u \, dx - \frac{1}{2} \int_\Omega \|\nabla u_S^*\|^2 \, dx + \frac{1}{2} \int_\Omega V(u_S^* - u)^2 \, dx
\]

\[
= \frac{1}{2} \int_\Omega \|\nabla u - \nabla u_S^*\|^2 \, dx + \frac{1}{2} \int_\Omega V(u_S^* - u)^2 \, dx.
\]
Then for any \( u \) the Neumann boundary condition:

\[
\mathcal{E}_S^{\text{DRM}}(u) - \mathcal{E}_S^{\text{DRM}}(u^*_S) \leq \frac{\max(1, V_{\text{max}})}{2} \left[ \int_\Omega \| \nabla u - \nabla u^*_S \|^2 \, dx + \int_\Omega (u^*_S - u)^2 \, dx \right]
\]

\[
= \frac{\max(1, V_{\text{max}})}{2} \| u - u^*_S \|^2_{L^1(\Omega)},
\]

\[
\mathcal{E}_S^{\text{DRM}}(u) - \mathcal{E}_S^{\text{DRM}}(u^*_S) \geq \frac{\max(1, V_{\text{min}})}{2} \left[ \int_\Omega \| \nabla u - \nabla u^*_S \|^2 \, dx + \int_\Omega (u^*_S - u)^2 \, dx \right]
\]

\[
= \frac{\max(1, V_{\text{min}})}{2} \| u - u^*_S \|^2_{L^2(\Omega)}.
\]

This completes our proof of identity A.4. Using the assumptions on the potential function \( V \) then implies:

\[
\mathcal{E}_S^{\text{DRM}}(u) - \mathcal{E}_S^{\text{DRM}}(u^*_S) \leq \max(1, V_{\text{max}}) \int_\Omega \| \nabla u - \nabla u^*_S \|^2 \, dx + \int_\Omega (u^*_S - u)^2 \, dx
\]

\[
= \max(1, V_{\text{max}}) \| u - u^*_S \|^2_{L^1(\Omega)}.
\]

This completes our proof of identity A.4. Using the assumptions on the potential function \( V \) then implies:

\[
\mathcal{E}_S^{\text{DRM}}(u) - \mathcal{E}_S^{\text{DRM}}(u^*_S) \geq \max(1, V_{\text{min}}) \int_\Omega \| \nabla u - \nabla u^*_S \|^2 \, dx + \int_\Omega (u^*_S - u)^2 \, dx
\]

\[
= \max(1, V_{\text{min}}) \| u - u^*_S \|^2_{L^2(\Omega)}.
\]

**Regularity Results of the PINN Objective Function.**

**Theorem A.2.** We consider the static Schrödinger equation on the unit hypercube on \( \mathbb{R}^d \) with the Neumann boundary condition:

\[
-\Delta u + Vu = f \quad \text{on } \Omega,
\]

\[
u = 0 \quad \text{on } \partial \Omega,
\]

where \( f \in L^2(\Omega) \) and \( V \in L^\infty(\Omega) \) with \( V - \frac{1}{2} \Delta V > C_{\text{min}}, 0 < C_{\text{min}} < V(x) \leq V_{\text{max}} \) and \( -\Delta V(x) \leq V_{\text{max}} \). Then there exists a unique solution \( u^*_S \in H_0^1(\Omega) \) to the following minimization problem [5]:

\[
u^*_S = \arg \min_{u \in H_0^1(\Omega)} \mathcal{E}_S^{\text{PINN}}(u) := \arg \min_{u \in H_0^1(\Omega)} \left\{ \int_\Omega |\Delta u - Vu + f|^2 \, dx \right\}.
\]

Then for any \( u \in H_0^1(\Omega) \), we have:

\[
\mathcal{E}_S^{\text{PINN}}(u) - \mathcal{E}_S^{\text{PINN}}(u^*_S) \leq 2(1+V_{\text{max}}+V_{\text{max}}^2) \| u - u^*_S \|^2_{H^2(\Omega)}.
\]

**Proof.** For any \( u \in H_0^1(\Omega) \), we let \( \tilde{u} = u - u^* \), then we have \( \tilde{u} \in H_0^1(\Omega) \).

\[
\mathcal{E}_S^{\text{PINN}}(u) - \mathcal{E}_S^{\text{PINN}}(u^*_S) = \int_\Omega |\Delta u - Vu - \Delta u^* + Vu^*|^2 \, dx = \int_\Omega |\Delta \tilde{u} - V\tilde{u}|^2 \, dx
\]

\[
= \int_\Omega (\Delta \tilde{u})^2 \, dx + \int_\Omega V^2 \tilde{u}^2 \, dx - 2 \int_\Omega V\tilde{u}\Delta \tilde{u} \, dx.
\]

Using Green’s formula, we have:

\[
\int_\Omega V\tilde{u}\Delta \tilde{u} \, dx + \int_\Omega \nabla (V\tilde{u}) \cdot \nabla \tilde{u} \, dx = \int_{\partial \Omega} \frac{\partial \tilde{u}}{\partial n} V\tilde{u} \, ds = 0,
\]

where the last equality above follows from the fact that \( \tilde{u} \in H_0^1(\Omega) \). This further implies:

\[
\mathcal{E}_S^{\text{PINN}}(u) - \mathcal{E}_S^{\text{PINN}}(u^*_S) = \int_\Omega (\Delta \tilde{u})^2 \, dx + \int_\Omega V^2 \tilde{u}^2 \, dx + 2 \int_\Omega \nabla (V\tilde{u}) \cdot \nabla \tilde{u} \, dx
\]

\[
= \int_\Omega (\Delta \tilde{u})^2 \, dx + \int_\Omega V^2 \tilde{u}^2 \, dx + 2 \int_\Omega V\|\nabla \tilde{u}\|^2 \, dx + 2 \int_\Omega \tilde{u} \nabla V \cdot \nabla \tilde{u} \, dx.
\]
Then we can further deduce that:
\[ (A.9) \quad M \text{ is the minimal number of balls such that} \]
\[ \{u^*_S \} \subset T \] for any \( L \)-Lipschitz with \( C_{\min} \leq V < V(x) \leq V_{\max} \) and \( -\Delta V(x) \leq V_{\max} \), thus we have
\[ \min \{1, C_{\min}\} \|u - u^*_S\|_{H^2(\Omega)} \leq E_S^{\text{PINN}}(u) - E_S^{\text{PINN}}(u^*_S) \leq 2(1 + V_{\max} + V_{\max}^2)\|u - u^*_S\|_{H^2(\Omega)} \]

A.3. Auxiliary definitions and lemmata On Generalization Error. To bound the generalization error, we use the localized Rademacher complexity [3]. Recall that the Rademacher complexity of a function class \( G \) is defined by
\[ R_n(G) = \mathbb{E}_Z \mathbb{E}_{\sigma} \left[ \sup_{g \in G} \frac{1}{n} \sum_{j=1}^n \sigma_j g(Z_j) \middle| Z_1, \ldots, Z_n \right], \]
where \( Z_i \) are i.i.d samples according to the data distributions and \( \sigma_j \) are i.i.d Rademacher random variables which take the value 1 with probability \( \frac{1}{2} \) and value \(-1\) with probability \( \frac{1}{2} \).

The following important symmetrization lemma makes the connection between the uniform law of large numbers and the Rademacher complexity.

**Lemma A.3 (Symmetrization Lemma).** Let \( \mathcal{F} \) be a set of functions. Then
\[ \mathbb{E} \sup_{u \in \mathcal{F}} \left| \frac{1}{n} \sum_{j=1}^n u(X_j) - \mathbb{E}_{X \sim \mathcal{P}_\Omega} u(X) \right| \leq 2R_n(\mathcal{F}). \]

**Lemma A.4 (Ledoux-Talagrand contraction [41, Theorem 4.12]).** Assume that \( \phi : \mathbb{R} \to \mathbb{R} \) is \( L \)-Lipschitz with \( \phi(0) = 0 \). Let \( \{\sigma_i\}_{i=1}^N \) be independent Rademacher random variables. Then for any \( T \subset \mathbb{R}^n \)
\[ \mathbb{E}_{\sigma} \left[ \sup_{(t_1, \ldots, t_N) \in T} \sum_{i=1}^N \sigma_i \phi(t_i) \right] \leq 2L \cdot \mathbb{E}_{\sigma} \left[ \sup_{(t_1, \ldots, t_N) \in T} \sum_{i=1}^N \sigma_i t_i \right]. \]

Let \((E, \rho)\) be a metric space with metric \( \rho \). A \( \delta \)-cover of a set \( A \subset E \) with respect to \( \rho \) is a collection of points \( \{x_1, \ldots, x_n \} \subset A \) such that for every \( x \in A \), there exists \( i \in \{1, \ldots, n \} \) such that \( \rho(x, x_i) \leq \delta \). The \( \delta \)-covering number \( N(\delta, A, \rho) \) is the cardinality of the smallest \( \delta \)-cover of the set \( A \) with respect to the metric \( \rho \). Equivalently, the \( \delta \)-covering number \( N(\delta, A, \rho) \) is the minimal number of balls \( B_\rho(x, \delta) \) of radius \( \delta \) needed to cover the set \( A \).

**Theorem A.5 (Dudley’s Integral theorem).** Let \( \mathcal{F} \) be a function class such that \( \sup_{f \in \mathcal{F}} \|f\|_{n,2} \leq M \). Then the Rademacher complexity \( R_n(\mathcal{F}) \) satisfies that
\[ R_n(\mathcal{F}) \leq \inf_{0 \leq \delta \leq M} \left\{ 4\delta + \frac{12}{\sqrt{n}} \int_{\delta}^M \sqrt{\log N(\varepsilon, \mathcal{F}, \| \cdot \|_{n,2})} \, d\varepsilon \right\}. \]
Then we have
\[ \mathbb{P}_{z_1, \ldots, z_n \sim \mu} \left( \sup_{f \in \mathcal{F}} \frac{1}{n} \sum_{i=1}^{n} f(z_i) \geq 2 \sup_{f \in \mathcal{E}} \mathbb{E}_{z_1, \ldots, z_n \sim \mu} \frac{1}{n} \sum_{i=1}^{n} f(z_i') + \sqrt{\frac{2t\sigma^2}{n}} + \frac{2t\beta}{n} \right) \leq e^{-t}. \]

**Lemma A.6 (Talagrand Concentration Inequality).** Consider a function class \( \mathcal{F} \) defined on a probability measure \( \mu \) such that for all \( f \in \mathcal{F} \), we have \( \|f\|_{\infty} \leq \beta, \mathbb{E}_{\mu}[f] = 0, \mathbb{E}_{\mu}[f^2] \leq \sigma^2 \). Then for any \( t > 0 \), we can have the following concentration results.

\[ \mathbb{P}_{z_1, \ldots, z_n \sim \mu} \left( \sup_{f \in \mathcal{F}} \frac{1}{n} \sum_{i=1}^{n} f(z_i) \geq \sup_{f \in \mathcal{E}} \mathbb{E}_{z_1, \ldots, z_n \sim \mu} \frac{1}{n} \sum_{i=1}^{n} f(z_i') + \sqrt{\frac{2t\sigma^2}{n}} + 2t\beta \right) \leq e^{-t}. \]

**Lemma A.7 (Peeling Lemma [3]).** Consider some measurable function class \( \mathcal{F} \). Assume that there exists a sub-root function \( \phi(r) \) satisfying

\[ R_n(\{f \in \mathcal{F} \mid \mathbb{E}[f] \leq r\}) \leq \phi(r) \quad (\forall r > 0). \]

Then we have

\[ \mathbb{E}_{\sigma_1, z_1} \left[ \sup_{f \in \mathcal{F}} \frac{1}{n} \sum_{i=1}^{n} \sigma_i f(z_i) \right] \leq 4 \phi(r). \]

**Proof.** Denote \( \mathcal{F}(r) = \{f \in \mathcal{F} \mid \mathbb{E}[f] \leq r\} \) to be the localized set with radius \( r \). Then for a fixed set of datapoints \( \{z_i\}_{i=1}^{n} \) and a fixed set of Rademacher random variables \( \{\sigma_i\}_{i=1}^{n} \), we have:

\[ \mathbb{E}_{\sigma_1, z_1} \left[ \sup_{f \in \mathcal{F}} \frac{1}{n} \sum_{i=1}^{n} \sigma_i f(z_i) \right] \leq \mathbb{E}_{\sigma_1, z_1} \left[ \sup_{f \in \mathcal{F}(r)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i f(z_i) \right] \leq \frac{4 \phi(r)}{r}. \]

We also modify the peeling lemma above, as we aim to apply it to derive the upper bound for the Modified Deep Ritz Method (MDRM).

**Lemma A.8 (Peeling Lemma For MDRM).** Given some measurable function class \( \mathcal{F} \) and two continuous mappings \( g, h : \mathcal{F} \to \mathbb{R} \), we define a set \( \mathcal{F} \) of vector functions by:

\[ \mathcal{F} := \{(g \circ f, h \circ f) \mid f \in \mathcal{F}\}. \]

For any \( r > 0 \), the localized set \( \mathcal{F}_r \) is defined by:

\[ \mathcal{F}_r = \{(g_f, h_f) \in \mathcal{F} \mid \mathbb{E}_x[g_f(x)] + \mathbb{E}_y[h_f(y)] \leq r\}. \]

Moreover, the modified Rademacher Complexity of \( \mathcal{F}_r \) is defined by:

\[ R_{n,m}(\mathcal{F}_r) := R_n \left( \{g_f | (g_f, h_f) \in \mathcal{F}_r\} \right) + R_m \left( \{h_f | (g_f, h_f) \in \mathcal{F}_r\} \right). \]

Assume that there exists some function \( \phi : [0, \infty) \to [0, \infty) \) and some \( r^* > 0 \), such that for any \( r > r^* \), we have:

\[ \phi(4r) \leq 2 \phi(r) \text{ and } R_{n,m}(\mathcal{F}_r) \leq \phi(r). \]
Then for any $r > r^*$, we have:
\[
\mathbb{E}_{\sigma, r} \left[ \mathbb{E}_{x,y} \left[ \sup_{f \in F} \frac{1}{n} \sum_{i=1}^{n} \sigma_i g_f(x_i) + \frac{1}{m} \sum_{j=1}^{m} \tau_j h_f(y_j) \right] \right] \leq 4\phi(r) / r.
\]

**Proof.** The proof is the same as the original peeling lemma, thus we omit the detailed proof here. \[ \blacksquare \]

### A.3.1. Local Rademacher Complexity of Truncated Fourier Basis.

**Definition A.9.** (Fourier Series) Given a domain $\Omega \subseteq [0,1]^d$, for any $z \in \mathbb{N}^d$, we consider the corresponding Fourier basis function $\phi_z(x) := e^{2\pi i (z, x)}$ ($x \in \Omega$). With respect to the Fourier basis, any function $f \in L^2(\Omega)$ can be decomposed as the following sum:

\[ f(x) := \sum_{z \in \mathbb{N}^d} f_z \phi_z(x). \tag{A.11} \]

where for any $z \in \mathbb{N}^d$, the Fourier coefficient $f_z = \int_\Omega f(x) \overline{\phi_z(x)} dx$.

**Definition A.10.** (Truncated Fourier Series) For a fixed positive integer $\xi \in \mathbb{Z}^+$, we define the space $F_{\xi}(\Omega)$ of truncated Fourier series as follows:

\[ F_{\xi}(\Omega) := \left\{ f = \sum_{z \in \mathbb{N}^d} f_z \phi_z \mid f_z = 0, \quad \forall \|z\|_\infty > \xi \right\}. \tag{A.12} \]

Equivalently, we can decompose any $f \in F_{\xi}(\Omega)$ as $f := \sum_{\|z\|_\infty \leq \xi} f_z \phi_z$.

**Lemma A.11.** (Local Rademacher Complexity of Localized Truncated Fourier Series) For a fixed $\xi \in \mathbb{Z}^+$, we consider a localized class of functions $\mathcal{F}_{\rho, \xi}(\Omega) = \left\{ f \in F_{\xi}(\Omega) \mid \|f\|_{H^1(\Omega)} \leq \rho \right\}$, where $\rho > 0$ is fixed. Then we have the following upper bound on the local Rademacher complexity:

\[ R_n(\mathcal{F}_{\rho, \xi}(\Omega)) = \mathbb{E}_X \left[ \mathbb{E}_{\sigma} \left[ \sup_{f \in \mathcal{F}_{\rho, \xi}(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i f(X_i) \mid X_1, \ldots, X_n \right] \right] \lesssim \sqrt{\frac{\rho \xi d z^2}{n}}. \tag{A.13} \]

**Proof.** Take an arbitrary function $f \in \mathcal{F}_{\rho, \xi}(\Omega)$. Let $f = \sum_{\|z\|_\infty \leq \xi} f_z \phi_z$ be the Fourier basis expansion of $f$. $\rho \geq \|f\|_{H^1(\Omega)}^2$ implies constraint $\sum_{\|z\|_\infty \leq \xi} |f_z|^2 \|z\|^2 \lesssim \rho$ on the Fourier coefficients.$^\dagger$

On the other hand, substituting the Fourier expansion into the average sum $\frac{1}{n} \sum_{i=1}^{n} \sigma_i f(X_i)$ and using Cauchy-Schwarz inequality imply:

\[
\frac{1}{n} \sum_{i=1}^{n} \sigma_i f(X_i) = \frac{1}{n} \sum_{i=1}^{n} \sigma_i \sum_{\|z\|_\infty \leq \xi} f_z \phi_z(X_i) = \frac{1}{n} \sum_{\|z\|_\infty \leq \xi} \sum_{i=1}^{n} \sigma_i f_z \phi_z(X_i) \\
\leq \frac{1}{n} \left( \sum_{\|z\|_\infty \leq \xi} |f_z|^2 \|z\|^2 \right)^{\frac{1}{2}} \left( \sum_{\|z\|_\infty \leq \xi} \left( \sum_{i=1}^{n} |\sigma_i| \phi_z(X_i) \right)^2 \right)^{\frac{1}{2}} \\
\lesssim \sqrt{\frac{\rho}{n}} \left( \sum_{\|z\|_\infty \leq \xi} \left( \sum_{i=1}^{n} |\sigma_i| \phi_z(X_i) \right)^2 \right)^{\frac{1}{2}}.
\]
where we have used the constraint \( \sum_{\|z\|\leq \xi} |f_z|^2 \|z\|^2 \lesssim \rho \) in the last step above. Moreover, by taking expectation with respect to the i.i.d Rademacher random variables \( \sigma_i \) (1 \( \leq i \leq n \)) and the uniformly sampled data points \( \{X_i\}_{i=1}^n \) on both sides and applying Jensen’s inequality, we can deduce that:

\[
\mathbb{E}_X \mathbb{E}_\sigma \left[ \frac{1}{n} \sum_{i=1}^n \sigma_i f(X_i) \right] \lesssim \sqrt{\frac{\rho}{n}} \mathbb{E}_X,\sigma \left[ \left( \sum_{\|z\|\leq \xi} \left| \sum_{i=1}^n \frac{\sigma_i}{\|z\|} \phi_z(X_i) \right|^2 \right)^{\frac{1}{2}} \right]
\]

\[
\leq \sqrt{\frac{\rho}{n}} \left( \mathbb{E}_X,\sigma \left[ \sum_{\|z\|\leq \xi} \left( \sum_{i=1}^n \frac{\sigma_i}{\|z\|} \phi_z(X_i) \right)^2 \right] \right)^{\frac{1}{2}}.
\]

Using independence between the random variables \( \sigma_i \) (1 \( \leq i \leq n \)), we can further simplify the expectation inside the square root above as below:

\[
\mathbb{E}_X,\sigma \left[ \sum_{\|z\|\leq \xi} \left| \sum_{i=1}^n \frac{\sigma_i}{\|z\|} \phi_z(X_i) \right|^2 \right] = \sum_{\|z\|\leq \xi} \mathbb{E}_X,\sigma \left[ \left( \sum_{i=1}^n \frac{\sigma_i}{\|z\|} \phi_z(X_i) \right)^2 \right]
\]

\[
\leq \sum_{\|z\|\leq \xi} \sum_{i=1}^n \mathbb{E}_X,\sigma \left[ \frac{\sigma_i^2}{\|z\|^2} \right] \lesssim n \sum_{\|z\|\leq \xi} \sum_{\|z\|\leq \xi} \frac{1}{\|z\|^2} \lesssim n \xi^d = n \xi^{d-2}.
\]

Combining the two bounds above yields the desired upper bound:

\[
\mathbb{E}_X \left[ \sup_{f \in \mathcal{F}_{\rho,\xi}(\Omega)} \frac{1}{n} \sum_{i=1}^n \sigma_i f(X_i) \mid X_1, \ldots, X_n \right] \lesssim \sqrt{\frac{\rho}{n}} \sqrt{n \xi^{d-2}} = \sqrt{\frac{\rho \xi^{d-2}}{n}}.
\]

**Lemma A.12.** *(Local Rademacher Complexity of Localized Truncated Fourier Series’ Gradient)* For a fixed \( \xi \in \mathbb{Z}^+ \), we consider a localized class of functions \( \mathcal{G}_{\rho,\xi}(\Omega) = \{ \|\nabla f\| \mid f \in \mathcal{F}_{\rho,\xi}(\Omega) \} \), where \( \rho > 0 \) is fixed. Then for any sample \( \{X_i\}_{i=1}^n \subset \Omega \), we have the following upper bound on the local Rademacher complexity:

\[
R_n(\mathcal{G}_{\rho,\xi}(\Omega)) = \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \sup_{f \in \mathcal{F}_{\rho,\xi}(\Omega)} \frac{1}{n} \sum_{i=1}^n \sigma_i \|\nabla f(X_i)\| \mid X_1, \ldots, X_n \right] \right] \lesssim \sqrt{\frac{\rho}{n}} \xi^{\frac{d-2}{2}}.
\]

**Proof.** Take an arbitrary function \( f \in \mathcal{F}_{\rho,\xi}(\Omega) \). Let \( f = \sum_{\|z\|\leq \xi} f_z \phi_z \) be the Fourier basis expansion of \( f \). Similarly, the norm restriction condition \( \|f\|^2_{L^2(\Omega)} \leq \rho \) can be reduced to the following condition about Fourier coefficients:

\[
\sum_{\|z\|\leq \xi} |f_z|^2 \|z\|^2 \lesssim \rho.
\]
Moreover, substituting the Fourier expansion into the average sum $\frac{1}{n} \sum_{i=1}^{n} \sigma_i \|\nabla f(X_i)\|$ and using Cauchy-Schwarz inequality imply:

$$\frac{1}{n} \sum_{i=1}^{n} \sigma_i \|\nabla f(X_i)\| = \frac{1}{n} \sum_{i=1}^{n} \sigma_i \left| \sum_{\|z\| \leq \xi} f_z \nabla \phi_z(X_i) \right| \leq \frac{1}{n} \sum_{i=1}^{n} \|f_z \nabla \phi_z(X_i)\|$$

$$\leq \frac{1}{n} \left( \sum_{\|z\| \leq \xi} |f_z|^2 \|z\|^2 \right)^{\frac{1}{2}} \left( \sum_{\|z\| \leq \xi} \left| \sum_{i=1}^{n} \sigma_i \|\nabla \phi_z(X_i)\| \right|^2 \right)^{\frac{1}{2}}$$

$$\lesssim \frac{\sqrt{\rho}}{n} \left( \sum_{\|z\| \leq \xi} \left| \sum_{i=1}^{n} \sigma_i \|\nabla \phi_z(X_i)\| \right|^2 \right)^{\frac{1}{2}}.$$ 

where we have used the constraint $\sum_{\|z\| \leq \xi} |f_z|^2 \|z\|^2 \lesssim \rho$ in the last step above. Moreover, by taking expectation with respect to the i.i.d Rademacher random variables $\sigma_i$ ($1 \leq i \leq n$) and the uniformly sampled data points $\{X_i\}_{i=1}^{n}$ on both sides and applying Jensen’s inequality, we can deduce that:

$$\mathbb{E}_{X} \mathbb{E}_{\sigma} \left[ \frac{1}{n} \sum_{i=1}^{n} \sigma_i \|\nabla f(X_i)\| \right] \leq \frac{\sqrt{\rho}}{n} \mathbb{E}_{X,\sigma} \left[ \left( \sum_{\|z\| \leq \xi} \left| \sum_{i=1}^{n} \sigma_i \|\nabla \phi_z(X_i)\| \right|^2 \right)^{\frac{1}{2}} \right]$$

$$\leq \frac{\sqrt{\rho}}{n} \mathbb{E}_{X,\sigma} \left[ \sum_{\|z\| \leq \xi} \left| \sum_{i=1}^{n} \sigma_i \|\nabla \phi_z(X_i)\| \right|^2 \right]^{\frac{1}{2}}.$$ 

Using independence between the random variables $\sigma_i$ ($1 \leq i \leq n$), we can further simplify the expectation inside the square root above as below:

$$\mathbb{E}_{X,\sigma} \left[ \sum_{\|z\| \leq \xi} \left| \sum_{i=1}^{n} \sigma_i \|\nabla \phi_z(X_i)\| \right|^2 \right] = \sum_{\|z\| \leq \xi} \mathbb{E}_{X,\sigma} \left[ \sum_{i=1}^{n} \sigma_i \|\nabla \phi_z(X_i)\|^2 \right]$$

$$= \sum_{\|z\| \leq \xi} \sum_{i=1}^{n} \mathbb{E}_{X,\sigma} \left[ \frac{\sigma_i^2}{\|z\|^2} \|\nabla \phi_z(X_i)\|^2 \right]$$

$$= \sum_{\|z\| \leq \xi} \sum_{i=1}^{n} |\Omega| \frac{4\pi^2 \|z\|^2}{\|z\|^2} \lesssim n \sum_{\|z\| \leq \xi} 1 \lesssim n \xi^d.$$ 

Combining the two bounds above yields the desired upper bound:

$$\mathbb{E}_{X} \left[ \mathbb{E}_{\sigma} \left[ \sup_{f \in \mathcal{F}_{\rho,\xi}(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i \|\nabla f(X_i)\| \mid X_1, \ldots, X_n \right] \right] \lesssim \frac{\sqrt{\rho}}{n} \sqrt{n \xi^d} = \sqrt{\frac{\rho}{n}} \xi^d.$$ 

**Lemma A.13.** (Local Rademacher Complexity of Localized Truncated Fourier Series’ Laplacian) For a fixed $\xi \in \mathbb{Z}^+$, we consider a localized class of functions $\mathcal{J}_{\rho,\xi}(\Omega) := \{ f \in F_{\xi}(\Omega) \mid \|f\|^2_{H^2(\Omega)} \leq \rho \}$, where $\rho > 0$ is fixed. Correspondingly, we define a localized class of
Laplacians $K_{\rho, \xi}(\Omega) := \{ \Delta f \mid f \in J_{\rho, \xi}(\Omega) \}$. Then for any sample $\{X_i\}_{i=1}^n \subset \Omega$, we have the following upper bound on the local Rademacher complexity:

(A.15) \[ R_n(K_{\rho, \xi}(\Omega)) = \mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \sup_{f \in \mathcal{F}_{\rho, \xi}(\Omega)} \frac{1}{n} \sum_{i=1}^n \sigma_i \Delta f(X_i) \mid X_1, \ldots, X_n \right] \right] \lesssim \sqrt{\frac{\rho \xi^d}{n}}.

Proof. Take an arbitrary function $f \in J_{\rho, \xi}(\Omega)$. Let $f = \sum_{\|z\| \leq \xi} f_z \phi_z$ be the Fourier basis expansion of $f$. Similarly, the norm restriction condition $\|f\|_{H^2(\Omega)} \leq \rho$ can be reduced to the following condition about Fourier coefficients:

$$\sum_{\|z\| \leq \xi} |f_z|^2 \|z\|^4 \lesssim \rho.$$ 

Moreover, substituting the Fourier expansion into the average sum $\frac{1}{n} \sum_{i=1}^n \sigma_i \Delta f(X_i)$ and using Cauchy-Schwarz inequality imply:

$$\frac{1}{n} \sum_{i=1}^n \sigma_i \Delta f(X_i) = \frac{1}{n} \sum_{i=1}^n \sigma_i \sum_{\|z\| \leq \xi} f_z \Delta \phi_z(X_i) = \frac{1}{n} \sum_{\|z\| \leq \xi} \sum_{i=1}^n \sigma_i f_z \Delta \phi_z(X_i) \leq \frac{1}{n} \left( \sum_{\|z\| \leq \xi} \|f_z\| \|z\|^4 \right)^{1/2} \left( \sum_{\|z\| \leq \xi} \left| \sum_{i=1}^n \sigma_i \Delta \phi_z(X_i) \right|^2 \right)^{1/2} \leq \sqrt{\frac{\rho}{n}} \left( \sum_{\|z\| \leq \xi} \left| \sum_{i=1}^n \sigma_i \Delta \phi_z(X_i) \right|^2 \right)^{1/2}.$$

where we have used the constraint $\sum_{\|z\| \leq \xi} |f_z|^2 \|z\|^4 \lesssim \rho$ in the last step above. Moreover, by taking expectation with respect to the i.i.d Rademacher random variables $\sigma_i (1 \leq i \leq n)$ and the uniformly sampled data points $\{X_i\}_{i=1}^n$ on both sides and applying Jensen’s inequality, we can deduce that:

$$\mathbb{E}_X \mathbb{E}_\sigma \left[ \frac{1}{n} \sum_{i=1}^n \sigma_i \Delta f(X_i) \right] \leq \frac{\sqrt{\rho}}{n} \mathbb{E}_X \mathbb{E}_\sigma \left[ \left( \sum_{\|z\| \leq \xi} \left| \sum_{i=1}^n \sigma_i \Delta \phi_z(X_i) \right|^2 \right)^{1/2} \right] \leq \frac{\sqrt{\rho}}{n} \left( \mathbb{E}_X \mathbb{E}_\sigma \left[ \sum_{\|z\| \leq \xi} \left| \sum_{i=1}^n \sigma_i \Delta \phi_z(X_i) \right|^2 \right] \right)^{1/2}.$$

Using independence between the random variables $\sigma_i (1 \leq i \leq n)$, we can further simplify the expectation inside the square root above as below:

$$\mathbb{E}_X \mathbb{E}_\sigma \left[ \sum_{\|z\| \leq \xi} \left| \sum_{i=1}^n \sigma_i \Delta \phi_z(X_i) \right|^2 \right] = \sum_{\|z\| \leq \xi} \mathbb{E}_X \mathbb{E}_\sigma \left[ \left| \sum_{i=1}^n \sigma_i \Delta \phi_z(X_i) \right|^2 \right] \leq \sum_{\|z\| \leq \xi} \sum_{i=1}^n \mathbb{E}_X \mathbb{E}_\sigma \left[ \frac{\sigma_i^2}{\|z\|^4} \left| \Delta \phi_z(X_i) \right|^2 \right] \leq \sum_{\|z\| \leq \xi} \sum_{i=1}^n \frac{16 \pi^4 \|z\|^4}{\|\psi_i\|^4} \lesssim n \sum_{\|z\| \leq \xi} 1 \lesssim n \xi^d.$$
Combining the two bounds above yields the desired upper bound:

$$
\mathbb{E}_X \left[ \mathbb{E}_\sigma \left[ \sup_{f \in \mathcal{F}_F, \xi(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i \Delta f(X_i) \mid X_1, \cdots, X_n \right] \right] \lesssim \frac{\sqrt{p}}{n} \sqrt{n \xi^d} = \frac{p^{\frac{d}{4}}}{n^{\frac{3}{4}}}. 
$$

**A.3.2. Local Rademacher Complexity of the Deep Neural Network Model.** In this section we aim to bound the local Rademacher Complexity of a Deep Neural Network. We first bound the covering number of the function space composed by the gradient of all possible neural networks and then apply a Duley Integral to achieve the final bound.

**Definition A.14.** Let $\eta_l$ denote the $l$-ReLU activation function. Here we use $\eta_\beta := \max \{0, x\}^3$ as the activation function to ensure smoothness. We can define the space consisting of all neural network models with depth $L$, width $W$, sparsity constraint $S$ and norm constraint $B$ as follows:

(A.16) \quad \Phi(L, W, S, B) := \left\{ (W^{(L)}_{\beta}(\cdot) + b^{(L)}_{\beta}) \cdots (W^{(1)}_{\beta}(x) + b^{(1)}_{\beta}) \mid W^{(L)} \in \mathbb{R}^{1\times W}, b^{(L)} \in \mathbb{R}, \right. \\
(A.17) \quad W^{(l)} \in \mathbb{R}^{W \times d}, b^{(l)} \in \mathbb{R}^W, (1 < l < L), \\
(A.18) \quad \sum_{l=1}^{L} (\|W^{(l)}\|_0 + \|b^{(l)}\|_0) \leq S, \max_{i} \|W^{(i)}\|_{\infty, \infty} \vee \|b^{(i)}\|_{\infty} \leq B \bigg\}.

where $\| \cdot \|_0$ measures the number of nonzero entries in a matrix and $\| \cdot \|_{\infty, \infty}$ measures the maximum of the absolute values of the entries in a matrix.

For any $d \in \mathbb{Z}^+$, we refer to an arbitrary element in $\Phi(L, W, S, B)$ as a ReLU3 Deep Neural Network. Then for any index $1 \leq k \leq L$, we use $F_k$ to denote the $k$–ReLU3 Deep Neural Network composed by the first $k$ layers, i.e:

$$F_k(x) := (W^{(k)}_{\beta}(\cdot) + b^{(k)}_{\beta}) \cdots (W^{(1)}_{\beta}(x) + b^{(1)}_{\beta}).$$

Also, we use $\Phi_k(L, W, S, B)$ to denote the space consisting of all $F_k$. In particular, when $k = L$, we have:

$$F(x) := F_L(x) = (W^{(L)}_{\beta}(\cdot) + b^{(L)}_{\beta}) \cdots (W^{(1)}_{\beta}(x) + b^{(1)}_{\beta}), \quad and \quad \Phi_L(L, W, S, B) = \Phi(L, W, S, B).$$

Furthermore, given that the domain $\Omega \subset [0, 1]^d$ is bounded, we have $\sup_{x \in \Omega} \|x\|_{\infty} = 1$.

**Lemma A.15.** (Upper bound on $\infty$-norm of functions in DNN space) For any $1 \leq k \leq L$, the following inequality holds:

$$\sup_{x \in \Omega, \; F_k \in \Phi_k(L, W, S, B)} \|F_k(x)\|_{\infty} \leq W^{\frac{k-1}{2}}(B \vee d) + dW^{\frac{k-1}{2}}B^{\frac{k-1}{2}}. 
$$

**Proof.** We use induction to prove this claim.

Base cases: When $k = 1$, we have that for any $x \in \Omega$ and any $F_1 \in \Phi_1(L, W, S, B)$, the following holds:

(A.19) \quad \|F_1(x)\|_{\infty} = \|W^{(1)}_{\beta}(x) + b^{(1)}_{\beta}\|_{\infty} \leq \|W^{(1)}_{\beta}\|_{\infty} \|x\|_{\infty} + \|b^{(1)}_{\beta}\|_{\infty} \\
\quad \leq d\|W^{(1)}_{\beta}\|_{\infty} + B \leq dB + B \leq 2(B \vee d)^2.
When \( k = 2 \), we have that for any \( x \in \Omega \) and any \( f_2 \in \Phi_2(L, W, S, B) \), the following holds:
\[
\|f_2(x)\|_\infty = \|W_F^{(2)} \eta_3(f_1(x)) + b_F^{(2)}\|_\infty \leq \|W_F^{(2)}\|_\infty \|\eta_3(f_1(x))\|_\infty + \|b_F^{(2)}\|_\infty \leq W\|W_F^{(2)}\|_\infty,\infty \|f_1(x)\|_\infty^3 + B.
\]

By applying the bound proved in the case when \( k = 1 \), we have:
\[
\|f_2(x)\|_\infty \leq WB(dB + B)^3 + B = WB^4(d + 1)^3 + B = WB^4(d^3 + 3d^2 + 3d + 1) + B \leq 8W(B \triangledown d)^7.
\]

where the last inequality follows from the assumption that \( W \geq 2 \).

Inductive Step: Now we assume that the claim has been proved for \( k - 1 \), where \( 3 \leq k \leq L \).

Similarly, for any \( x \in \Omega \) and any \( f_k \in \Phi_k(L, W, S, B) \), we have:
\[
\|f_k(x)\|_\infty = \|W_F^{(k)} \eta_3(f_{k-1}(x)) + b_F^{(k)}\|_\infty \leq \|W_F^{(k)}\|_\infty \|\eta_3(f_{k-1}(x))\|_\infty + \|b_F^{(k)}\|_\infty \leq W\|W_F^{(k)}\|_\infty,\infty \|f_{k-1}(x)\|_\infty^3 + B \leq WB\|f_{k-1}(x)\|_\infty^3 + B.
\]

Using inductive hypothesis, we can further deduce that:
\[
\|f_k(x)\|_\infty \leq WB \times W^{\frac{k-1}{2}}(B \triangledown d)^{\frac{3^{k-1} - 3}{2}} \times 2^{\frac{3^k - 3k + 6}{2}} + B \\
\leq W^{\frac{k-1}{2}}(B \triangledown d)^{\frac{3^{k-1} - 3}{2}} \times 2^{\frac{3^k - 3k + 6}{2}} + B \triangledown d \\
\leq W^{\frac{k-1}{2}}(B \triangledown d)^{\frac{3^{k-1} - 3}{2}} \times [2^{\frac{3^k - 3k + 6}{2}} + 1] \\
\leq W^{\frac{k-1}{2}}(B \triangledown d)^{\frac{3^{k-1} - 3}{2}} \times 2^{\frac{3^k - 3k + 6}{2} + k} \quad (k \geq 3) \\
= W^{\frac{k-1}{2}}(B \triangledown d)^{\frac{3^{k-1} - 3}{2}} \times 2^{\frac{3^k - 3k + 6}{2} + k}.
\]

Taking supremum with respect to \( x \in \Omega \) and \( f_k \in \Phi_k(L, W, S, B) \) on the LHS implies that the given upper bound also holds for \( k \). By induction, the claim is proved.

We also need to show that the ReLU3 activation function is a Lipschitzness functions over a bounded domain.

**Lemma A.16.** For any \( k \in \mathbb{Z}^+ \), consider the \( k \)-ReLU activation function \( \eta_k \) defined on some bounded domain \( D \subset \mathbb{R}^d \) (i.e., \( \sup_{x \in D} \|x\|_\infty \leq C \) for some \( C > 0 \)). Then we have that for any \( x, y \in D \), the following inequalities hold:
\[
\|\eta_1(x) - \eta_1(y)\|_\infty \leq \|x - y\|_\infty,
\|\eta_2(x) - \eta_2(y)\|_\infty \leq 2C\|x - y\|_\infty,
\|\eta_3(x) - \eta_3(y)\|_\infty \leq 3C^2\|x - y\|_\infty.
\]

**Proof.** This is because \( |\nabla \eta_1(x)| = |\max\{1, 0\}| = 1 \), \( |\nabla \eta_2(x)| = 2\max\{x, 0\} \leq 2C \) and \( |\nabla \eta_3(x)| = 3\max\{x, 0\}^2 \leq 3C^2 \).
Lemma A.17. (Relation between the covering number of DNN space and parameter space)

For any $1 \leq k \leq L$, suppose that a pair of different two networks $F_k, G_k \in \Phi_k(L, W, S, B)$ are given by:

$$
F_k(x) := (W^{(k)}_F \eta_3(\cdot) + b^{(k)}_F) \cdots (W^{(1)}_F x + b^{(1)}_F),
$$

$$
G_k(x) := (W^{(k)}_G \eta_3(\cdot) + b^{(k)}_G) \cdots (W^{(1)}_G x + b^{(1)}_G).
$$

Furthermore, assume that the $\| \cdot \|_\infty$ norm of the distance between the parameter spaces of $F_k$ and $G_k$ is uniformly upper bounded by $\delta$, i.e.

$$
\|W_F^{(l)} - W_G^{(l)}\|_{\infty, \infty} \leq \delta, \quad \|b_F^{(l)} - b_G^{(l)}\|_\infty \leq \delta, \quad (\forall \ 1 \leq l \leq k).
$$

Then we have:

$$
sup_{x \in \Omega} \|F_k(x) - G_k(x)\|_\infty \leq \delta W \frac{d^{k-1} - 1}{2} (B \lor d) \frac{d^{k-1} - 1}{2} \frac{d^{k-1}}{2} - k + 1 \cdot 3^{k-1}.
$$

Proof. Let’s prove the claim by using induction on $k$.

Base Case: When $k = 1$, we have that for any $x \in \Omega$ and any $F_1, G_1 \in \Phi_1(L, W, S, B)$ satisfying constraint A.20, the following holds:

$$
\|F_1(x) - G_1(x)\|_\infty = \|W^{(1)}_F x + b^{(1)}_F - W^{(1)}_G x - b^{(1)}_G\|_\infty
$$

$$
\leq \|W^{(1)}_F - W^{(1)}_G\|_\infty \|x\|_\infty + \|b^{(1)}_F - b^{(1)}_G\|_\infty
$$

$$
\leq \delta d + \delta = \delta(d + 1) \leq 2\delta(B \lor d) \leq 2\delta(B \lor d)^2.
$$

When $k = 2$, we have that for any $x \in \Omega$ and any $F_2, G_2 \in \Phi_2(L, W, S, B)$ satisfying constraint A.20, the following inequality holds:

$$
\|F_2(x) - G_2(x)\|_\infty = \|W^{(2)}_F \eta_3(F_1(x)) + b^{(2)}_F - W^{(2)}_G \eta_3(G_1(x)) - b^{(2)}_G\|_\infty
$$

$$
\leq \|W^{(2)}_F \eta_3(F_1(x)) - W^{(2)}_G \eta_3(G_1(x))\|_\infty + \|b^{(2)}_F - b^{(2)}_G\|_\infty
$$

$$
\leq \|W^{(2)}_F \eta_3(F_1(x)) - W^{(2)}_G \eta_3(F_1(x))\|_\infty + \|W^{(2)}_G \eta_3(F_1(x)) - W^{(2)}_G \eta_3(G_1(x))\|_\infty + \delta.
$$

By applying the upper bound proved in equation A.19, we can upper bound the first part $\|W^{(2)}_F \eta_3(F_1(x)) - W^{(2)}_G \eta_3(F_1(x))\|_\infty$ by:

$$
\|W^{(2)}_F \eta_3(F_1(x)) - W^{(2)}_G \eta_3(F_1(x))\|_\infty \leq \|W^{(2)}_F - W^{(2)}_G\|_\infty \|\eta_3(F_1(x))\|_\infty
$$

$$
\leq W\delta\|F_1(x)\|_\infty^3 \leq \delta W[2(B \lor d)^2]^3.
$$

By applying the Lipschitz condition proved in Lemma A.16 and the bound proved in equation A.22, we can further upper bound the second part $\|W^{(2)}_G \eta_3(F_1(x)) - W^{(2)}_G \eta_3(G_1(x))\|_\infty$ by:

$$
\|W^{(2)}_G \eta_3(F_1(x)) - W^{(2)}_G \eta_3(G_1(x))\|_\infty \leq \|W^{(2)}_G\|_\infty \|\eta_3(F_1(x)) - \eta_3(G_1(x))\|_\infty
$$

$$
\leq WB \times 3 sup_{F_1 \in \Phi_1(L, W, S, B)} \|F_1(x)\|_\infty^2 \times \|F_1(x) - G_1(x)\|_\infty
$$

$$
\leq WB \times 3[2(B \lor d)^2]^2 \times 2\delta(B \lor d)
$$

$$
\leq 24\delta W(B \lor d)^6.
$$
Applying triangle inequality helps us upper bound the first term above as follows:

\[
\|F_k(x) - G_k(x)\|_\infty \leq 8\delta W(B \vee d)^6 + 24\delta W(B \vee d)^6 \leq 24\delta W(B \vee d)^7.
\]

where we again use the assumption \( d \geq 2 \) in the last step.

Inductive Step: Now we assume that the claim has been proved for \( k - 1 \), where \( k \geq 3 \). For any \( x \in \Omega \) and \( F_k \in \Phi_k(L,W,S,B) \), we have that:

\[
\|F_k(x) - G_k(x)\|_\infty = \|W_F^{(k)} \eta_3(F_{k-1}(x)) + b_F^{(k)} - W_G^{(k)} \eta_3(G_{k-1}(x)) - b_G^{(k)}\|_\infty \\
\leq \|W_F^{(k)} \eta_3(F_{k-1}(x)) - W_G^{(k)} \eta_3(G_{k-1}(x))\|_\infty + \|b_F^{(k)} - b_G^{(k)}\|_\infty \\
\leq \|W_F^{(k)} \eta_3(F_{k-1}(x)) - W_G^{(k)} \eta_3(G_{k-1}(x))\|_\infty + \delta.
\]

Applying triangle inequality helps us upper bound the first term above as follows:

\[
\|W_F^{(k)} \eta_3(F_{k-1}(x)) - W_G^{(k)} \eta_3(G_{k-1}(x))\|_\infty \\
\leq \|W_F^{(k)} \eta_3(F_{k-1}(x)) - W_G^{(k)} \eta_3(F_{k-1}(x))\|_\infty + \|W_G^{(k)} \eta_3(F_{k-1}(x)) - W_G^{(k)} \eta_3(G_{k-1}(x))\|_\infty \\
\leq \|W_F^{(k)} - W_G^{(k)}\|_\infty \|\eta_3(F_{k-1}(x))\|_\infty + \|W_G^{(k)}\|_\infty \|\eta_3(F_{k-1}(x)) - \eta_3(G_{k-1}(x))\|_\infty \\
\leq \delta W \|F_{k-1}(x)\|_\infty^3 + BW \|\eta_3(F_{k-1}(x)) - \eta_3(G_{k-1}(x))\|_\infty.
\]

From Lemma A.15, we can upper bound the first term \( \delta W \|F_{k-1}(x)\|_\infty^3 \) by:

\[
\delta W \|F_{k-1}(x)\|_\infty^3 \leq \delta W^{3k-2} (B \vee d)^{3k-3} 2^{-3k+6}.
\]

Moreover, applying Lemma A.16 and the inductive hypothesis let us upper bound the second term \( BW \|\eta_3(F_{k-1}(x)) - \eta_3(G_{k-1}(x))\|_\infty \) as follows:

\[
BW \|\eta_3(F_{k-1}(x)) - \eta_3(G_{k-1}(x))\|_\infty \\
\leq BW \times 3 \sup_{x \in \Omega, F_{k-1} \in \Phi_{k-1}(L,W,S,B)} \|F_{k-1}(x)\|_\infty^2 \times \|F_{k-1}(x) - G_{k-1}(x)\|_\infty \\
\leq 3BW \times W^{3k-2} (B \vee d)^{5k-3} 2^{-3k-1-2k+4} \|F_{k-1}(x) - G_{k-1}(x)\|_\infty \\
\leq 3BW \times W^{3k-2} (B \vee d)^{5k-3} 2^{-3k-1-2k+4} \times \delta W^{3k-2} (B \vee d)^{5k-3} 2^{-3k+2-2} 2^{-3k+2} 3^{-k-2} \\
\leq 3^{-k-1} \delta W^{3k-1} (B \vee d)^{5k-3} 2^{-3k+2} 2^{-3k+2} 3^{-k+5}.
\]

Combining the two upper bounds derived above yields:

\[
\|F_k(x) - G_k(x)\|_\infty \leq \delta W^{3k-1} (B \vee d)^{5k-3} 2^{-3k+2} 3^{-k+5} + 3^{-k-1} \delta W^{3k-1} (B \vee d)^{5k-3} 2^{-3k+2} 3^{-k+5} + \delta \\
\leq 3^{k-1} W^{3k-1} (B \vee d)^{5k-3} 2^{-3k+2} 3^{-k+5} + \delta.
\]

where the last inequality above follows from \( k \geq 3 \). Taking supremum with respect to \( x \in \Omega \) on the LHS implies the given upper bound also holds for \( k \). By induction, the claim is proved.
Theorem A.18. (Bounding the DNN space covering number) Fix some sufficiently large \( N \in \mathbb{Z}^+ \). Consider a Deep Neural Network space \( \Phi(L, W, S, B) \) with \( L = O(1), W = O(N), S = O(N) \) and \( B = O(N) \). Then the log value of the covering number of this DNN space with respect to the inf-norm \( \|F(x)\|_\infty := \sup_{x \in \Omega} |F(x)| \), which is denoted by \( \mathcal{N}(\delta, \Phi(L, W, S, B), \| \cdot \|_\infty) \), can be upper bounded by:

\[
\log \mathcal{N}(\delta, \Phi(L, W, S, B), \| \cdot \|_\infty) = O \left( S \left[ \log(\delta^{-1}) + 3^L \log(WB) \right] \right). \tag{A.23}
\]

**Proof.** We firstly fix a sparsity pattern (i.e, the locations of the non-zero entries are fixed). By picking \( k = L \) in Lemma A.17, we get the following upper bound on the covering number with respect to \( \| \cdot \|_\infty \):

\[
\left( \frac{\delta}{3^L - 1 W \frac{3^L - 1}{2}(B \lor d) \frac{5 \times 3^L - 1}{2} 2^{\frac{3L - 1}{2} - L + 1}} \right)^{-S}.
\]

Furthermore, note that the number of feasible configurations is upper bounded by \( \binom{W + 1}{S} \leq (W + 1)^L \).\cite{63, 18} Plug in the previous inequality and yields:

\[
\log \mathcal{N}(\delta, \Phi(L, W, S, B), \| \cdot \|_\infty) \leq \log \left( (W + 1)^LS \left( \frac{\delta}{3^L - 1 W \frac{3^L - 1}{2}(B \lor d) \frac{5 \times 3^L - 1}{2} 2^{\frac{3L - 1}{2} - L + 1}} \right)^{-S} \right)
\]

\[
\leq S \log \left( \delta^{-1} (W + 1)^L 3^L - 1 W \frac{3^L - 1}{2}(B \lor d) \frac{5 \times 3^L - 1}{2} 2^{\frac{3L - 1}{2} - L + 1} \right)
\]

\[
\lesssim S \left[ \log(\delta^{-1}) + L \log(3W) + 3^L \log(W(B \lor d)) + 3^L \log 2 \right].
\]

Note that here the dimension \( d \) is some constant. Thus, by plugging in the given magnitudes \( L = O(1), W = O(N), S = O(N) \) and \( B = O(N) \), we can further deduce that:

\[
\log \mathcal{N}(\delta, \Phi(L, W, S, B), \| \cdot \|_\infty) \lesssim S \left[ \log(\delta^{-1}) + 3^L \log(WB) \right].
\]

This finishes our proof. \( \square \)

Now let’s consider upper bounding the covering number of the \( l_2 \) norm of the sparse Deep Neural Networks’ gradients. Note that for any \( 1 \leq k \leq L - 1 \), any \( k \)-ReLU3 Deep Neural Network \( F_k \in \Phi_k(L, W, S, B) \) is a map from \( \mathbb{R}^d \) to \( \mathbb{R}^W \). For any \( 1 \leq l \leq W \), we use \( F_{k,l}(x) \) to denote the \( l \)-th component of the map \( F_k \). This helps us write the map \( F_k(x) \) and its Jacobian \( J[F_k](x) \) explicitly as:

\[
F_k(x) = [F_{k,1}(x), F_{k,2}(x), \ldots, F_{k,W}(x)]^T \in \mathbb{R}^W.
\]

\[
J[F_k](x) = \begin{bmatrix}
\frac{\partial}{\partial x_1} F_{k,1}(x) & \frac{\partial}{\partial x_2} F_{k,1}(x) & \cdots & \frac{\partial}{\partial x_d} F_{k,1}(x) \\
\frac{\partial}{\partial x_1} F_{k,2}(x) & \frac{\partial}{\partial x_2} F_{k,2}(x) & \cdots & \frac{\partial}{\partial x_d} F_{k,2}(x) \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\partial}{\partial x_1} F_{k,W}(x) & \frac{\partial}{\partial x_2} F_{k,W}(x) & \cdots & \frac{\partial}{\partial x_d} F_{k,W}(x)
\end{bmatrix} \in \mathbb{R}^{W \times d}.
\]
In particular, when \( k = L \), we have that any \( F_L \in \Phi_L(L, W, S, B) = \Phi(L, W, S, B) \) is a map from \( \mathbb{R}^d \) to \( \mathbb{R} \). Thus, its Jacobian can be explicitly written as the following row vector:

\[
J[F_L](x) = \left[ \frac{\partial}{\partial x_1} F_L(x), \frac{\partial}{\partial x_2} F_L(x), \cdots \frac{\partial}{\partial x_d} F_L(x) \right] \in \mathbb{R}^{1 \times d}.
\]

**Lemma A.19.** (Upper bound on \( \infty \)-norm of Jacobian/Gradient of elements in the DNN space) For any \( 1 \leq k \leq L \), the following inequality holds:

\[
\sup_{x \in \Omega, F_k \in \Phi_k(L, W, S, B)} \| J[F_k](x) \|_\infty \leq W \frac{3^{k-1} - 1}{2} (B \vee d) 3^{k-1} - 1 - 2k + 4 \times W^{1/2} (B \vee d) 2^{3k-2} - 3k + 53k-1.
\]

**Proof.** We use induction on \( k \) to prove the claim.

Base case: \( k = 1 \). By the definition of Jacobian matrix, we have that for any \( x \in \Omega \) and any \( F_1 \in \Phi_1(L, W, S, B) \), the following holds:

\[
\| J[F_1](x) \|_\infty = \| W_F^{(1)} \|_\infty \leq dB \leq 2(B \vee d)^2.
\]

Inductive Step: Assume that the claim has been proved for \( k - 1 \), where \( 2 \leq k \leq L \). For any \( x \in \Omega \) and any \( F_k \in \Phi_k(L, W, S, B) \), by applying the Chain Rule, we can write the Jacobian matrix \( J[F_k](x) \) as \( J[F_k](x) = W_F^{(k)} J[\eta_3 \circ F_{k-1}](x) \), where the ReLU3 activation function \( \eta_3 \) is applied to each component \( F_{k-1,l} \) \((1 \leq l \leq W)\) of the map \( F_k \). Then we have the following upper bound:

\[
\| J[F_k](x) \|_\infty \leq \| W_F^{(k)} \|_\infty \| J[\eta_3 \circ F_{k-1}](x) \|_\infty \leq WB \| J[\eta_3 \circ F_{k-1}](x) \|_\infty.
\]

Note that the composition \( \eta_3 \circ F_{k-1} \) is a map from \( \mathbb{R}^d \) to \( \mathbb{R}^W \). Hence, the Jacobian matrix \( J[\eta_3 \circ F_{k-1}](x) \) is of shape \( \mathbb{R}^{W \times d} \). Applying the Chain Rule again implies:

\[
\| J[\eta_3 \circ F_{k-1}](x) \|_\infty = \sup_{1 \leq l \leq W} \left( \sum_{j=1}^{d} \left| 3\eta_2(F_{k-1,l}(x)) \frac{\partial F_{k-1,l}(x)}{\partial x_j} \right| \right).
\]

Furthermore, for any \( 1 \leq l \leq W \), the summation on the RHS above can be upper bounded by:

\[
\sum_{j=1}^{d} \left| \eta_2(F_{k-1,l}(x)) \frac{\partial F_{k-1,l}(x)}{\partial x_j} \right| \leq 3 \| F_{k-1}(x) \|_\infty^2 \sum_{j=1}^{d} \left| \frac{\partial F_{k-1,l}(x)}{\partial x_j} \right| \leq 3 \| F_{k-1}(x) \|_\infty^2 \| J[F_{k-1}](x) \|_\infty.
\]

Now let’s take supremum with respect to \( l \) and apply the inductive hypothesis and Lemma A.15. This yields:

\[
\| J[\eta_3 \circ F_{k-1}](x) \|_\infty \leq 3W 3^{k-2} - 1 (B \vee d) 3^{k-1} - 1 - 2k + 4 \times W^{1/2} (B \vee d) 2^{3k-2} - 3k + 53k-1.
\]

By substituting equation A.25 into equation A.24, we can derive the final bound:

\[
\| J[F_k](x) \|_\infty \leq WB \| J[\eta_3 \circ F_{k-1}](x) \|_\infty \leq W \frac{3^{k-1} - 1}{2} (B \vee d) 3^{k-1} - 1 - 2k + 4 \times W^{1/2} (B \vee d) 2^{3k-2} - 3k + 53k-1 \leq W \frac{3^{k-1} - 1}{2} (B \vee d) 2^{3k-2} - 3k + 53k-1.
\]
where the last inequality above follows from \( k \geq 2 \). Taking supremum with respect to \( x \in \Omega \) and \( F_k \in \Phi_k(L, W, S, B) \) on the LHS implies that the given upper bound also holds for \( k \). By induction, the claim is proved.

For the convenience of the following proof, we first prove this lemma for vector 2 norm and \( \infty \) norm.

**Lemma A.20.** Given any two row vectors \( u, v \in \mathbb{R}^{1 \times d} \), we have:

\[
\left\| u - v \right\|_\infty \leq \left\| u \right\| - \left\| v \right\|.
\]

**Proof.** Assume that the two vectors \( u, v \in \mathbb{R}^d \) can be explicitly written as \( u = [u_1, u_2, \ldots, u_d] \) and \( v = [v_1, v_2, \ldots, v_d] \), respectively. By applying Cauchy-Schwarz inequality, we have:

\[
\left\| u - v \right\|_\infty^2 = \left( \sum_{i=1}^d |u_i - v_i| \right)^2 \leq \left( \sum_{i=1}^d |u_i|^2 + \sum_{i=1}^d |v_i|^2 \right) - 2 \left( \sum_{i=1}^d u_i v_i \right).
\]

Taking the square root on both sides yields the desired inequality.

Then we upper bound the Lipschitz constant of the gradient of the neural network. Given a DNN space \( \Phi(L, W, S, B) \), we define a corresponding DNN Gradient space \( \nabla \Phi(L, W, S, B) \) as:

\[
(A.26) \quad \nabla \Phi(L, W, S, B) := \{ \left\| \nabla F \right\| \mid F \in \Phi(L, W, S, B) \}.
\]

**Lemma A.21.** (Relation between the covering number of the DNN Gradient space and parameter space) For any \( 1 \leq k \leq L \), suppose that a pair of different two networks \( F_k, G_k \in \Phi_k(L, W, S, B) \) are given by:

\[
F_k(x) := (W_F^{(k)} \eta_3(\cdot) + b_F^{(k)}) \cdots (W_F^{(1)} x + b_F^{(1)}),
\]

\[
G_k(x) := (W_G^{(k)} \eta_3(\cdot) + b_G^{(k)}) \cdots (W_G^{(1)} x + b_G^{(1)}).
\]

Furthermore, assume that the \( \| \|_\infty \) norm of the distance between the parameter spaces is uniformly upper bounded by \( \delta \), i.e

\[
(A.27) \quad \| W_F^{(l)} - W_G^{(l)} \|_{\infty, \infty} \leq \delta, \quad \| b_F^{(l)} - b_G^{(l)} \|_{\infty} \leq \delta, \quad (\forall 1 \leq l \leq k).
\]

Then we have:

\[
(A.28) \quad \sup_{x \in \Omega} \| J[F_k](x) - J[G_k](x) \|_{\infty} \leq \delta W^{k-1} (B \lor d) 2^{k-1} 13^{2k-2} B^{k-1}.\]
In particular, when \( k = L \), we have:

\[
\sup_{x \in \Omega} \left| \left\| \nabla F_L(x) \right\| - \left\| \nabla G_L(x) \right\| \right| \leq \delta W \frac{3^{L-1}}{2} (B \vee d)^{\frac{5 \cdot 3^{L-1}}{2} - \frac{3^{L-1}-1}{2} - L + 3} 2^{L-2}.
\]

**Proof.** We use induction on \( k \) to prove the claim.

Base case: When \( k = 1 \), we have that for any \( x \in \Omega \) and any \( F_1, G_1 \in \Phi_1(L, W, S, B) \), the following holds:

\[
\left\| J[F_1](x) - J[G_1](x) \right\|_{\infty} = \left\| \mathcal{W}^{(1)}_F - \mathcal{W}^{(1)}_G \right\|_{\infty} \leq \delta d \leq 2\delta(B \vee d)^2.
\]

Inductive Step: assume that the claim has been proved for \( k - 1 \), where \( 2 \leq k \leq L \). Then for any \( x \in \Omega \) and \( F_k, G_k \in \Phi_k(L, W, S, B) \) satisfying constraint A.27, applying the Chain Rule and triangle inequality help us upper bound the inf-norm \( \left\| J[F_k](x) - J[G_k](x) \right\|_{\infty} \) by:

\[
\left\| J[F_k](x) - J[G_k](x) \right\|_{\infty} = \left\| \mathcal{W}^{(k)}_F - \mathcal{W}^{(k)}_G \right\|_{\infty} \leq \delta W \left\| J[\eta_{3} \circ F_{k-1}](x) - J[\eta_{3} \circ G_{k-1}](x) \right\|_{\infty}.
\]

Using equation A.25 helps us upper bound the first term by:

\[
\delta W \left\| J[\eta_{3} \circ F_{k-1}](x) \right\|_{\infty} \leq \delta W \frac{4^{k-1}}{2} (B \vee d)^{\frac{5 \cdot 4^{k-1}}{2} - \frac{4^{k-1}-1}{2} - 3k + 5} 3^{k-1}.
\]

Note that the two compositions \( \eta_{3} \circ F_{k-1} \) and \( \eta_{3} \circ G_{k-1} \) both map from \( \mathbb{R}^d \) to \( \mathbb{R}^W \). Hence, the two Jacobian matrices \( J[\eta_{3} \circ F_{k-1}](x) \) and \( J[\eta_{3} \circ G_{k-1}](x) \) are of shape \( \mathbb{R}^W \times d \). Applying the Chain Rule again implies:

\[
\left\| J[\eta_{3} \circ F_{k-1}](x) - J[\eta_{3} \circ G_{k-1}](x) \right\|_{\infty} = \sup_{1 \leq l \leq W} \left( \sum_{j=1}^{d} |3\eta_2(F_{k-1,l}(x)) \frac{\partial F_{k-1,l}(x)}{\partial x_j} - 3\eta_2(G_{k-1,l}(x)) \frac{\partial G_{k-1,l}(x)}{\partial x_j}| \right)
\]

For any \( 1 \leq l \leq W \), the summation on the RHS above can be upper bounded by:

\[
\sum_{j=1}^{d} |3\eta_2(F_{k-1,l}(x)) \frac{\partial F_{k-1,l}(x)}{\partial x_j} - 3\eta_2(G_{k-1,l}(x)) \frac{\partial G_{k-1,l}(x)}{\partial x_j}|
\]

\[
\leq \sum_{j=1}^{d} |3\eta_2(F_{k-1,l}(x)) \frac{\partial F_{k-1,l}(x)}{\partial x_j} - 3\eta_2(G_{k-1,l}(x)) \frac{\partial F_{k-1,l}(x)}{\partial x_j}|
\]

\[
+ \sum_{j=1}^{d} |3\eta_2(G_{k-1,l}(x)) \frac{\partial F_{k-1,l}(x)}{\partial x_j} - 3\eta_2(G_{k-1,l}(x)) \frac{\partial G_{k-1,l}(x)}{\partial x_j}|
\]

\[
\leq \sum_{j=1}^{d} |3\eta_2(F_{k-1,l}(x)) - 3\eta_2(G_{k-1,l}(x))| \left| \frac{\partial F_{k-1,l}(x)}{\partial x_j} \right| + \sum_{j=1}^{d} |3\eta_2(G_{k-1,l}(x))| \left| \frac{\partial F_{k-1,l}(x)}{\partial x_j} - \frac{\partial G_{k-1,l}(x)}{\partial x_j} \right|.
\]
We denote the two summations above by $T_1$ and $T_2$, respectively:

$$T_1 := \sum_{j=1}^{d} \left| 3\eta_2(F_{k-1,l}(x)) - 3\eta_2(G_{k-1,l}(x))\right| \left| \frac{\partial F_{k-1,l}(x)}{\partial x_j} - \frac{\partial G_{k-1,l}(x)}{\partial x_j} \right|,$$

$$T_2 := \sum_{j=1}^{d} \left| 3\eta_2(G_{k-1,l}(x))\right| \left| \frac{\partial F_{k-1,l}(x)}{\partial x_j} - \frac{\partial G_{k-1,l}(x)}{\partial x_j} \right|.$$ 

For the first sum $T_1$, applying Lemma A.15, Lemma A.16, Lemma A.17 and Lemma A.19 yields the following upper bound:

$$T_1 \leq 6 \left( \sup_{x \in \Omega, \; F_{k-1} \in \Phi_{k-1}(L,W,S,B)} \| F_{k-1}(x) \|_{\infty} \right) \left\| F_{k-1}(x) - G_{k-1}(x) \right\|_{\infty} \sum_{j=1}^{d} \left| \frac{\partial F_{k-1,l}(x)}{\partial x_j} \right|$$

$$\leq 6 \left( \sup_{x \in \Omega, \; F_{k-1} \in \Phi_{k-1}(L,W,S,B)} \| F_{k-1}(x) \|_{\infty} \right) \left\| F_{k-1}(x) - G_{k-1}(x) \right\|_{\infty} \left\| J[F_{k-1}(x)] \right\|_{\infty}$$

$$\leq 3 \times W^{\frac{k-2}{2}} (B \vee d)^{\frac{k-2}{2}} \left( \frac{k-2}{2} - k + 2 \right) \times \delta W^{\frac{k-2}{2}} (B \vee d)^{\frac{k-2}{2}} \left( 2^{k-2} - k + 2 \right) 3^{k-2}$$

$$\times W^{\frac{k-2}{2}} (B \vee d)^{\frac{k-2}{2}} \left( \frac{k-2}{2} - k + 2 \right) 3^{k-2} = \delta W^{\frac{k-1}{3}} (B \vee d)^{\frac{k-1}{3}} 3^{k-3}.$$ 

For the second sum $T_2$, applying Lemma A.15 and inductive hypothesis yields:

$$T_2 \leq 3 \left( \sup_{x \in \Omega, \; G_{k-1} \in \Phi_{k-1}(L,W,S,B)} \| G_{k-1}(x) \|_{\infty} \right)^2 \left\| J[F_{k-1}(x)] - J[G_{k-1}(x)] \right\|_{\infty}$$

$$\leq 3 \times W^{3k-2} (B \vee d)^{\frac{3k-2}{2}} \left( \frac{3k-2}{2} - 2k + 1 \right) \times \delta W^{\frac{k-2}{2}} (B \vee d)^{\frac{k-2}{2}} \left( 2^{k-2} - k + 2 \right) 3^{2k-4}$$

$$= \delta W^{\frac{k-1}{3}} (B \vee d)^{\frac{k-1}{3}} 3^{k-3}.$$ 

Combining the two upper bounds on $T_1$ and $T_2$ yields:

$$\sum_{j=1}^{d} \left| 3\eta_2(F_{k-1,l}(x))\left( \frac{\partial F_{k-1,l}(x)}{\partial x_j} - \frac{\partial G_{k-1,l}(x)}{\partial x_j} \right) \right| \leq T_1 + T_2 \leq 2 \times \delta W^{\frac{k-1}{2}} (B \vee d)^{\frac{k-1}{2}} \left( \frac{k-1}{2} - 3k + 6 \right) 3^{2k-3}.$$ 

By taking supremum with respect to $1 \leq l \leq W$ on the LHS yields:

(32)

$$BW \left\| J[\eta_3 \circ F_{k-1}](x) - J[\eta_3 \circ G_{k-1}](x) \right\|_{\infty} \leq \delta W^{\frac{k-1}{2}} (B \vee d)^{\frac{k-1}{2}} \left( \frac{k-1}{2} - 3k + 6 \right) 3^{2k-3}.$$ 

By adding the two upper bounds in A.31 and A.32, we can deduce that:

$$\left\| J[F_k](x) - J[G_k](x) \right\|_{\infty} \leq \delta W^{\frac{k-1}{2}} (B \vee d)^{\frac{k-1}{2}} \left( \frac{k-1}{2} - 3k + 5 \right) 3^{k-1}$$

$$+ \delta W^{\frac{k-1}{2}} (B \vee d)^{\frac{k-1}{2}} \left( \frac{k-1}{2} - 3k + 6 \right) 3^{k-3}$$

$$\leq \delta W^{\frac{k-1}{2}} (B \vee d)^{\frac{k-1}{2}} \left( \frac{k-1}{2} - k + 1 \right) 3^{2k-2}.$$
where the last inequality above follows from $k \geq 2$. Taking supremum with respect to $x \in \Omega$ on the LHS implies the given upper bound also holds for $k$. By induction, the claim is proved. In particular, when $k = L$, we have $\nabla F_L(x) = J[F_L](x)^T$ for any $x \in \Omega$. Applying Lemma A.20 then yields:

$$
\sup_{x \in \Omega} \left| \left| \nabla F_L(x) \right|\right| - \left| \left| \nabla G_L(x) \right|\right| = \sup_{x \in \Omega} \left| \left| \nabla J[F_L](x)^T \right|\right| - \left| \left| \nabla J[G_L](x)^T \right|\right| \\
\leq \sup_{x \in \Omega} \left| \left| J[F_L](x) - J[G_L](x) \right|\right| \infty \\
\leq \delta W \frac{5^{L-1}}{2} (B \vee d) \frac{5^{L-1}}{2^{L-2} - L+1} 3^{2L-2} - k + 132L-2. 
$$

This finishes our proof of the Lemma. 

**Theorem A.22.** (Bounding the DNN Gradient space covering number) Fix some sufficiently large $N \in \mathbb{Z}^+$. Consider a Deep Neural Network space $\Phi(L, W, S, B)$ with $L = O(1), W = O(N), S = O(N)$ and $B = O(N)$. Then the log value of the covering number of the DNN Gradient space with respect to the $\| \cdot \| \infty$ norm $\| F(x) \| \infty := \sup_{x \in \Omega} |F(x)|$, which is denoted by $\mathcal{N}(\delta, \nabla \Phi(L, W, S, B), \| \cdot \| \infty)$, can be upper bounded by:

$$
(A.33) \quad \log \mathcal{N}(\delta, \nabla \Phi(L, W, S, B), \| \cdot \| \infty) = O\left( S \left( \log(\delta^{-1}) + 3^L \log(WB) \right) \right).
$$

**Proof.** We firstly fix a sparsity pattern (i.e., the locations of the non-zero entries are fixed). Using equation A.29 in Lemma A.21, yields the following upper bound on the covering number with respect to $\| \cdot \| \infty$:

$$
\left( \frac{\delta}{W \frac{5^{L-1}}{2} (B \vee d) \frac{5^{L-1}}{2^{L-2} - L+1} 3^{2L-2}} \right)^{-S}.
$$

Furthermore, note that the number of feasible configurations is upper bounded by: $\left( \frac{(W+1)^L}{S} \right) \leq (W + 1)^{L S}. [63, 18]$. Plug this inequality into the previous estimation then yields:

$$
\log \mathcal{N}(\delta, \Phi(L, W, S, B), \| \cdot \| \infty) \leq \log \left[ (W + 1)^{L S} \left( \frac{\delta}{W \frac{5^{L-1}}{2} (B \vee d) \frac{5^{L-1}}{2^{L-2} - L+1} 3^{2L-2}} \right)^{-S} \right] \\
\leq S \log \left[ \delta^{-1} (W + 1)^L 3^{2L-2} W \frac{5^{L-1}}{2^{L-2} - L+1} (B \vee d) \frac{5^{L-1}}{2^{L-2} - L+1} 3^{2L-2} - k + 132L-2 \right] \\
\lesssim S \left[ \log(\delta^{-1}) + 2L \log(3W) + 3^L \log(W (B \vee d)) + 3^L \log 2 \right].
$$

Note that here the dimension $d$ is some constant. Thus, by plugging in the given magnitudes $L = O(1), W = O(N), S = O(N)$ and $B = O(N)$, we can further deduce that:

$$
\log \mathcal{N}(\delta, \Phi(L, W, S, B), \| \cdot \| \infty) \lesssim S \left[ \log(\delta^{-1}) + 3^L \log(WB) \right].
$$

This finishes our proof.
Now let’s consider upper bounding the covering number of the Laplacian of the sparse Deep Neural Networks. Note that for any $1 \leq k \leq L - 1$, any $k-$ReLU3 Deep Neural Network $F_k \in \Phi_k(L, W, S, B)$ is a vector-valued function mapping from $\mathbb{R}^d$ to $\mathbb{R}^W$. Moreover, we define the Laplacian of $F_k(x)$, which is denoted by $\Delta[F_k](x)$, as follows:

$$\Delta[F_k](x) = [\Delta F_{k,1}(x), \Delta F_{k,2}(x), \ldots, \Delta F_{k,W}(x)]^T \in \mathbb{R}^W,$$

where for any $1 \leq l \leq W$, we have:

$$\Delta F_{k,l}(x) = \sum_{j=1}^{d} \frac{\partial^2}{\partial x_j^2} F_{k,l}(x).$$

In particular, when $k = L$, we have that any $F_L \in \Phi_L(L, W, S, B) = \Phi(L, W, S, B)$ is a scalar-valued function mapping from $\mathbb{R}^d$ to $\mathbb{R}$. Thus, its Laplacian can be explicitly written as:

$$\Delta[F_L](x) = \Delta F_L(x) = \sum_{j=1}^{d} \frac{\partial^2}{\partial x_j^2} F_L(x).$$

For both Lemma A.23 and Lemma A.24 below, we consider a fixed Deep Neural Network space $\Phi(L, W, S, B)$ with $L = O(1), W = O(N), S = O(N)$ and $B = O(N)$, where $N \in \mathbb{Z}^+$ is fixed and sufficiently large.

**Lemma A.23.** (Upper bound on $\infty$-norm of Laplacian of elements in the DNN space) For any $1 \leq k \leq L$, we have the following upper bound:

$$\sup_{x \in \Omega, F_k \in \Phi_k(L, W, S, B)} \|\Delta[F_k](x)\|_\infty = O\left(W^{\frac{k-1}{2}} (B \lor d)^{\frac{5}{2}k-\frac{1}{2}}\right).$$

**Proof.** We use induction on $k$ to prove the claim.

Base case: $k = 1$. Note that any $F_1 \in \Phi_1(L, W, S, B)$ is a linear transform, so the Laplacian $\Delta[F_1](x)$ must be the zero vector for any $x \in \Omega$. This implies:

$$\|\Delta[F_1](x)\|_\infty = 0 \lesssim (B \lor d)^2.$$

Inductive Step: Assume that the claim has been proved for $k - 1$, where $2 \leq k \leq L$. For any $x \in \Omega$ and any $F_k \in \Phi_k(L, W, S, B)$, using linearity of the Laplacian operator implies:

$$\Delta[F_k](x) = W_F^{(k)} \Delta[\eta_3 \circ F_{k-1}](x).$$

Taking the inf-norm on both sides of the identity above implies:

$$\|\Delta[F_k](x)\|_\infty \leq \|W_F^{(k)}\|_\infty \|\Delta[\eta_3 \circ F_{k-1}](x)\|_\infty \leq WB \|\Delta[\eta_3 \circ F_{k-1}](x)\|_\infty.$$

It now remains to upper bound the term $\|\Delta[\eta_3 \circ F_{k-1}](x)\|_\infty$. For any $1 \leq l \leq W$, we will use the Chain Rule to write the $l$-th component $\left(\Delta[\eta_3 \circ F_{k-1}](x)\right)_l$ in an explicit form. For any $1 \leq j \leq d$, we have:

$$\frac{\partial}{\partial x_j} \eta_3[F_{k-1,l}(x)] = 3\eta_2[F_{k-1,l}(x)] \frac{\partial}{\partial x_j} F_{k-1,l}(x).$$
Differentiating with respect to \( x_j \) on both sides above yields:

\[
(A.34) \quad \frac{\partial^2}{\partial x_j^2} \eta_3[F_{k-1,l}(x)] = 6\eta_1[F_{k-1,l}(x)] \left( \frac{\partial}{\partial x_j} F_{k-1,l}(x) \right)^2 + 3\eta_2[F_{k-1,l}(x)] \frac{\partial^2}{\partial x_j^2} F_{k-1,l}(x).
\]

Summing the expression above from \( j = 1 \) to \( j = d \) implies:

\[
\left| \left( \Delta [\eta_3 \circ F_{k-1}] (x) \right) \right| = \left| \sum_{j=1}^d \frac{\partial^2}{\partial x_j^2} \eta_3[F_{k-1,l}(x)] \right| = \left| 6\eta_1[F_{k-1,l}(x)] \sum_{j=1}^d \left( \frac{\partial}{\partial x_j} F_{k-1,l}(x) \right)^2 + 3\eta_2[F_{k-1,l}(x)] \sum_{j=1}^d \frac{\partial^2}{\partial x_j^2} F_{k-1,l}(x) \right| \\
\leq 6 \left| \eta_1[F_{k-1,l}(x)] \right| \left( \sum_{j=1}^d \left| \frac{\partial}{\partial x_j} F_{k-1,l}(x) \right| \right)^2 + 3 \left| \eta_2[F_{k-1,l}(x)] \right| \left| \sum_{j=1}^d \frac{\partial^2}{\partial x_j^2} F_{k-1,l}(x) \right|.
\]

We denote the two summations above by \( U_1 \) and \( U_2 \), respectively:

\[
U_1 := 6 \left| \eta_1[F_{k-1,l}(x)] \right| \left( \sum_{j=1}^d \left| \frac{\partial}{\partial x_j} F_{k-1,l}(x) \right| \right)^2,
\]

\[
U_2 := 3 \left| \eta_2[F_{k-1,l}(x)] \right| \left| \sum_{j=1}^d \frac{\partial^2}{\partial x_j^2} F_{k-1,l}(x) \right|.
\]

On the one hand, by applying Lemma A.15 and Lemma A.19, we can upper bound \( U_1 \) by:

\[
U_1 \leq 6 \left( \sup_{x \in \Omega, \; F_{k-1} \in \Phi_{k-1}(L,W,S,B)} \| F_{k-1}(x) \|_\infty \right) \left( \sup_{x \in \Omega, \; F_{k-1} \in \Phi_{k-1}(L,W,S,B)} \| J[F_{k-1}](x) \|_\infty \right)^2 \\
\leq 6 \times W^{\frac{k^2-2}{2}} (B \lor d) 5^{\frac{k^2-2}{2}} 2^{\frac{k^2}{2} - 1 - k + 2} \times W^{3k^2 - 2 - 1} (B \lor d) 5^{3k^2 - 2} 2^{3k^2 - 1 - 2k + 4} 3^{2k - 4} \\
\lesssim W^{\frac{k^2-1}{2}} (B \lor d) 5^{\frac{k^2-1}{2}} 2^{\frac{k^2}{2} - 1 - k + 2},
\]

where the last step above follows from \( k \leq L \) and \( L = O(1) \).

On the other hand, by applying Lemma A.15 and the inductive hypothesis, we have:

\[
U_2 \leq 3 \left( \sup_{x \in \Omega, \; F_{k-1} \in \Phi_{k-1}(L,W,S,B)} \| F_{k-1}(x) \|_\infty \right)^2 \| \Delta [F_{k-1}](x) \|_\infty \\
\lesssim 3 \times W^{3k^2 - 2 - 1} (B \lor d) 5^{3k^2 - 2 - 1} 2^{3k^2 - 1 - 2k + 4} \times W^{\frac{k^2-1}{2}} (B \lor d) 5^{\frac{k^2-1}{2}} 2^{\frac{k^2}{2} - 1} \\
\lesssim W^{\frac{k^2-1}{2}} (B \lor d) 5^{\frac{k^2-1}{2}} 2^{\frac{k^2}{2} - 1} ,
\]

where the last step above follows from \( k \leq L \) and \( L = O(1) \).

Summing the two bounds on \( U_1 \) and \( U_2 \) implies that for any \( 1 \leq l \leq W \), we have:

\[
(A.35) \quad \left| \left( \Delta [\eta_3 \circ F_{k-1}] (x) \right) \right| \leq U_1 + U_2 \lesssim W^{\frac{k^2-1}{2}} (B \lor d) 5^{\frac{k^2-1}{2}} 2^{\frac{k^2}{2} - 1}.
\]
Taking supremum with respect to $1 \leq l \leq W$ then yields:
\[
\|\Delta[F_k](x)\|_{\infty} \leq WB\|\Delta[\eta_3 \circ F_{k-1}](x)\|_{\infty} \lesssim W^{\frac{k-1}{2}}(B \vee d)^{\frac{5}{2}k-1-1}.
\]

Taking supremum with respect to $x \in \Omega$ and $F_k \in \Phi_k(L, W, S, B)$ on the LHS implies that the given upper bound also holds for $k$. By induction, the claim is proved. 

**Lemma A.24.** (Relation between the covering number of the DNN Laplacian space and parameter space) For any $1 \leq k \leq L$, suppose that a pair of different two networks $F_k, G_k \in \Phi_k(L, W, S, B)$ are given by:
\[
F_k(x) := (W^{(k)}_F \eta_3(\cdot) + b^{(k)}_F) \cdots (W^{(1)}_F x + b^{(1)}_F),
\]
\[
G_k(x) := (W^{(k)}_G \eta_3(\cdot) + b^{(k)}_G) \cdots (W^{(1)}_G x + b^{(1)}_G).
\]

Furthermore, assume that the $\| \cdot \|_{\infty}$ norm of the distance between the parameter spaces is uniformly upper bounded by $\delta$, i.e.
\[
\|W^{(l)}_F - W^{(l)}_G\|_{\infty, \infty} \leq \delta, \quad \|b^{(l)}_F - b^{(l)}_G\|_{\infty} \leq \delta, \quad (\forall 1 \leq l \leq k).
\]

Then we have:
\[
\sup_{x \in \Omega} \|\Delta[F_k](x) - \Delta[G_k](x)\|_{\infty} = O\left(\delta W^{\frac{k-1}{2}}(B \vee d)^{\frac{5}{2}k-1-1}\right).
\]

**Proof.** We use induction on $k$ to prove the claim.

Base case: $k = 1$. Note that any $F_1 \in \Phi_1(L, W, S, B)$ is a linear transform, so the Laplacian $\Delta[F_1](x)$ must be the zero vector for any $x \in \Omega$. Hence, for any $x \in \Omega$ and any $F_1, G_1 \in \Phi_1(L, W, S, B)$, we have:
\[
\|\Delta[F_1](x) - \Delta[G_1](x)\|_{\infty} = 0 \lesssim \delta(B \vee d)^2.
\]

Inductive Step: assume that the claim has been proved for $k - 1$, where $2 \leq k \leq L$. Then for any $x \in \Omega$ and $F_k, G_k \in \Phi_k(L, W, S, B)$ satisfying constraint A.36, applying linearity of the Laplacian operator indicates:
\[
\|\Delta[F_k](x) - \Delta[G_k](x)\|_{\infty} = \|W^{(k)}_F \Delta[\eta_3 \circ F_{k-1}](x) - W^{(k)}_G \Delta[\eta_3 \circ G_{k-1}](x)\|_{\infty}
\]
\[
= \left\| \left( W^{(k)}_F - W^{(k)}_G \right) \Delta[\eta_3 \circ F_{k-1}](x) \right\|_{\infty}
\]
\[
+ \left\| \left( W^{(k)}_G \right) \left( \Delta[\eta_3 \circ F_{k-1}](x) - \Delta[\eta_3 \circ G_{k-1}](x) \right) \right\|_{\infty}
\]
\[
\leq \|W^{(k)}_F - W^{(k)}_G\|_{\infty} \|\Delta[\eta_3 \circ F_{k-1}](x)\|_{\infty}
\]
\[
+ \|W^{(k)}_G\|_{\infty} \|\Delta[\eta_3 \circ G_{k-1}](x)\|_{\infty}.
\]

For the first term $\|W^{(k)}_F - W^{(k)}_G\|_{\infty} \|\Delta[\eta_3 \circ F_{k-1}](x)\|_{\infty}$, applying the bound in equation A.35 and equation A.36 yields:
\[
\|W^{(k)}_F - W^{(k)}_G\|_{\infty} \|\Delta[\eta_3 \circ F_{k-1}](x)\|_{\infty} \lesssim \delta W \times W^{\frac{k-1}{2}}(B \vee d)^{\frac{5}{2}k-1-3}
\]
\[
= \delta W^{\frac{k-1}{2}}(B \vee d)^{\frac{5}{2}k-1-3}.
\]
For the second term \( \| W_{k}^{(k)} \|_{\infty} \| \Delta[\eta_{3} \circ F_{k-1}] - \Delta[\eta_{3} \circ G_{k-1}] \|_{\infty} \), we need to upper bound the norm \( \| \Delta[\eta_{3} \circ F_{k-1}] - \Delta[\eta_{3} \circ G_{k-1}] \|_{\infty} \) at first. Note that for any \( 1 \leq l \leq W \), we can use equation A.34 to write the \( l \)-th component of \( \Delta[\eta_{3} \circ F_{k-1}] - \Delta[\eta_{3} \circ G_{k-1}] \) as:

\[
\left( \Delta[\eta_{3} \circ F_{k-1}] - \Delta[\eta_{3} \circ G_{k-1}] \right)_{l} = \sum_{j=1}^{d} \frac{\partial^{2}}{\partial x_{j}^{2}} \eta_{3}[F_{k-1,l}(x)] - \sum_{j=1}^{d} \frac{\partial^{2}}{\partial x_{j}^{2}} \eta_{3}[G_{k-1,l}(x)]
\]

\[
= 6\eta_{1}[F_{k-1,l}(x)] \sum_{j=1}^{d} \left( \frac{\partial}{\partial x_{j}} F_{k-1,l}(x) \right)^{2} - 6\eta_{1}[G_{k-1,l}(x)] \sum_{j=1}^{d} \left( \frac{\partial}{\partial x_{j}} G_{k-1,l}(x) \right)^{2}
\]

\[
+ 3\eta_{2}[F_{k-1,l}(x)] \sum_{j=1}^{d} \frac{\partial^{2}}{\partial x_{j}^{2}} F_{k-1,l}(x) - 3\eta_{2}[G_{k-1,l}(x)] \sum_{j=1}^{d} \frac{\partial^{2}}{\partial x_{j}^{2}} G_{k-1,l}(x)
\]

We denote the four summations above by \( V_{1}, V_{2}, V_{3} \) and \( V_{4} \), respectively:

\[
V_{1} := 6\eta_{1}[F_{k-1,l}(x)] \sum_{j=1}^{d} \left( \frac{\partial}{\partial x_{j}} F_{k-1,l}(x) \right)^{2} - 6\eta_{1}[G_{k-1,l}(x)] \sum_{j=1}^{d} \left( \frac{\partial}{\partial x_{j}} G_{k-1,l}(x) \right)^{2},
\]

\[
V_{2} := 6\eta_{1}[G_{k-1,l}(x)] \sum_{j=1}^{d} \left( \frac{\partial}{\partial x_{j}} F_{k-1,l}(x) \right)^{2} - 6\eta_{1}[G_{k-1,l}(x)] \sum_{j=1}^{d} \left( \frac{\partial}{\partial x_{j}} G_{k-1,l}(x) \right)^{2},
\]

\[
V_{3} := 3\eta_{2}[F_{k-1,l}(x)] \sum_{j=1}^{d} \frac{\partial^{2}}{\partial x_{j}^{2}} F_{k-1,l}(x) - 3\eta_{2}[G_{k-1,l}(x)] \sum_{j=1}^{d} \frac{\partial^{2}}{\partial x_{j}^{2}} G_{k-1,l}(x),
\]

\[
V_{4} := 3\eta_{2}[G_{k-1,l}(x)] \sum_{j=1}^{d} \frac{\partial^{2}}{\partial x_{j}^{2}} F_{k-1,l}(x) - 3\eta_{2}[G_{k-1,l}(x)] \sum_{j=1}^{d} \frac{\partial^{2}}{\partial x_{j}^{2}} G_{k-1,l}(x).
\]

By applying Lemma A.15, Lemma A.16, Lemma A.17 and Lemma A.19, we can upper bound
where the last step above follows from

\[
(\text{Lemma A.19 and Lemma A.21 helps us upper bound})
\]

\[
|V| \leq 6|F_{k-1,l}(x) - G_{k-1,l}(x)|^2 \leq 6\|F_{k-1} - G_{k-1}\|_\infty^2\|J[F_{k-1}]\|_\infty^2
\]

\[
\lesssim \delta W^{\frac{3k-2}{2}} (B \vee d)^{5. \frac{3k-2}{2} - 1} \lesssim \delta W^{\frac{3k-2}{2}} (B \vee d)^{5. \frac{3k-2}{2} - 1 - 2k + 4}\]

where the last step above follows from \(k \leq L\) and \(L = O(1)\).

Furthermore, note that for any \(1 \leq j \leq d\), we can upper bound the difference \(\left(\frac{\partial}{\partial x_j} F_{k-1,l}(x)\right)^2 - \left(\frac{\partial}{\partial x_j} G_{k-1,l}(x)\right)^2\) as follows:

\[
\left(\frac{\partial}{\partial x_j} F_{k-1,l}(x)\right)^2 - \left(\frac{\partial}{\partial x_j} G_{k-1,l}(x)\right)^2 \leq \left|\left(\frac{\partial}{\partial x_j} F_{k-1,l}(x)\right)^2 - \left(\frac{\partial}{\partial x_j} G_{k-1,l}(x)\right)^2\right|
\]

\[
= \left|\frac{\partial}{\partial x_j} F_{k-1,l}(x) + \frac{\partial}{\partial x_j} G_{k-1,l}(x)\right| \left|\frac{\partial}{\partial x_j} F_{k-1,l}(x) - \frac{\partial}{\partial x_j} G_{k-1,l}(x)\right|
\]

\[
\leq \left(\left|\frac{\partial}{\partial x_j} F_{k-1,l}(x)\right| + \left|\frac{\partial}{\partial x_j} G_{k-1,l}(x)\right|\right) \left|\frac{\partial}{\partial x_j} F_{k-1,l}(x) - \frac{\partial}{\partial x_j} G_{k-1,l}(x)\right|
\]

Note that \(\eta_l(G_{k-1,l}(x)) \geq 0\). Combining the non-negativity with equation A.39, Lemma A.15, Lemma A.19 and Lemma A.21 helps us upper bound \(V_2\) by:

\[
V_2 = 6\eta_l[G_{k-1,l}(x)] \sum_{j=1}^{d} \left[\left(\frac{\partial}{\partial x_j} F_{k-1,l}(x)\right)^2 - \left(\frac{\partial}{\partial x_j} G_{k-1,l}(x)\right)^2\right]
\]

\[
\leq 6\|G_{k-1}(x)\|_\infty \sum_{j=1}^{d} \left|\frac{\partial}{\partial x_j} F_{k-1,l}(x)\right| \left|\frac{\partial}{\partial x_j} F_{k-1,l}(x) - \frac{\partial}{\partial x_j} G_{k-1,l}(x)\right|
\]

\[
\leq 6\|G_{k-1}(x)\|_\infty \left(\sum_{j=1}^{d} \left|\frac{\partial}{\partial x_j} F_{k-1,l}(x)\right| + \sum_{j=1}^{d} \left|\frac{\partial}{\partial x_j} G_{k-1,l}(x)\right|\right) \left(\sum_{j=1}^{d} \left|\frac{\partial}{\partial x_j} F_{k-1,l}(x) - \frac{\partial}{\partial x_j} G_{k-1,l}(x)\right|\right)
\]

\[
\leq 6\|G_{k-1}(x)\|_\infty \left(\|J[F_{k-1}]\|_\infty + \|J[G_{k-1}]\|_\infty\right) \left\|J[F_{k-1}](x) - J[G_{k-1}](x)\right\|_\infty
\]

\[
\leq 6W^{\frac{3k-2}{2}} (B \vee d)^{5. \frac{3k-2}{2} - 1} \lesssim \delta W^{\frac{3k-2}{2}} (B \vee d)^{5. \frac{3k-2}{2} - 1 + 4}\]

where the last step above follows from \(k \leq L\) and \(L = O(1)\).
Moreover, using Lemma A.15, Lemma A.16 and Lemma A.23 helps us upper bound $V_3$ by:

$$ V_3 = \left( 3\eta_2[F_{k-1,l}(x)] - 3\eta_2[G_{k-1,l}(x)] \right) \sum_{j=1}^{d} \frac{\partial^2}{\partial x_j^2} F_{k-1,l}(x) $$

$$ \leq \left| 3\eta_2[F_{k-1,l}(x)] - 3\eta_2[G_{k-1,l}(x)] \right| \left| \sum_{j=1}^{d} \frac{\partial^2}{\partial x_j^2} F_{k-1,l}(x) \right| $$

$$ \leq 6 \left( \sup_{x \in \Omega, F_{k-1} \in \Phi_{k-1}(L,W,S,B)} \| F_{k-1}(x) \|_\infty \right) \| F_{k-1}(x) - G_{k-1}(x) \|_\infty \| \Delta [F_{k-1}] (x) \|_\infty $$

$$ \lesssim 6W^{\frac{k-2}{2}} (B \vee d)^{\frac{5}{2}k-2-1} 2^{\frac{k-1}{2}} 2^{k+2} \times \delta W \frac{3k-2-1}{2} (B \vee d)^{\frac{5}{2}k-2-1} 2^{\frac{k-1}{2}} - k^2 3k-2 $$

$$ \times W^{\frac{k-2-1}{2}} (B \vee d)^{\frac{5}{2}k-2-1} \lesssim \delta W^{\frac{k-1-3}{2}} (B \vee d)^{\frac{5}{2}k-1-3} $$

where the last step above follows from $k \leq L$ and $L = O(1)$.

Finally, applying Lemma A.15 and inductive hypothesis helps us upper bound $V_4$ by:

$$ V_4 = 3\eta_2[G_{k-1,l}(x)] \left( \sum_{j=1}^{d} \frac{\partial^2}{\partial x_j^2} F_{k-1,l}(x) - \sum_{j=1}^{d} \frac{\partial^2}{\partial x_j^2} G_{k-1,l}(x) \right) $$

$$ \leq 3 \| G_{k-1}(x) \|_\infty^2 \| \Delta [F_{k-1}] (x) - \Delta [G_{k-1}] (x) \|_\infty $$

$$ \lesssim 3W^{\frac{k-2}{2}} (B \vee d)^{\frac{5}{2}k-2-1} 2^{\frac{k-1}{2}} 2^{3k-1-1-2k+4} \times \delta W^{\frac{3k-2-1}{2}} (B \vee d)^{\frac{5}{2}k-2-1} $$

$$ \lesssim \delta W^{\frac{k-1-3}{2}} (B \vee d)^{\frac{5}{2}k-1-3} $$

where the last step above follows from $k \leq L$ and $L = O(1)$.

Combining the four bounds on $V_1, V_2, V_3$ and $V_4$ implies:

$$ \left( \Delta [\eta_3 \circ F_{k-1}] (x) - \Delta [\eta_3 \circ G_{k-1}] (x) \right) \mid_l = \sum_{i=1}^{4} V_i \lesssim \delta W^{\frac{1-k-1}{2}} (B \vee d)^{\frac{5}{2}k-1-3} $$

Taking supremum with respect to $1 \leq l \leq W$ gives us an upper bound on the second term $\| W_G^{(k)} \|_\infty \Delta [\eta_3 \circ F_{k-1}] (x) - \Delta [\eta_3 \circ G_{k-1}] (x) \|_\infty$:

$$ \| W_G^{(k)} \|_\infty \| \Delta [\eta_3 \circ F_{k-1}] (x) - \Delta [\eta_3 \circ G_{k-1}] (x) \|_\infty \lesssim W B \times \delta W^{\frac{3k-1-1}{2}} (B \vee d)^{\frac{5}{2}k-1-3} $$

$$ = \delta W^{\frac{3k-1-1}{2}} (B \vee d)^{\frac{5}{2}k-1-3} $$

Combining the two bounds derived in equation A.38 and equation A.40 then implies:

$$ \| \Delta [F_k] (x) - \Delta [G_k] (x) \|_\infty \lesssim \delta W^{\frac{3k-1-1}{2}} (B \vee d)^{\frac{5}{2}k-1-1} + \delta W^{\frac{3k-1-1}{2}} (B \vee d)^{\frac{5}{2}k-1-1} $$

$$ \lesssim \delta W^{\frac{3k-1-1}{2}} (B \vee d)^{\frac{5}{2}k-1-1} $$

Taking supremum with respect to $x \in \Omega$ on the LHS implies that the given upper bound also holds for $k$. By induction, the claim is proved.
Given a Neural Network function space $\Phi(L, W, S, B)$, we define a corresponding Neural Network Laplacian space $\Delta \Phi(L, W, S, B)$ as:

\[
\Delta \Phi(L, W, S, B) := \{\Delta F \mid F \in \Phi(L, W, S, B)\}. \tag{A.41}
\]

**Theorem A.25.** (Bounding the Neural Network Laplacian space covering number) Fix some sufficiently large $N \in \mathbb{Z}^+$. Consider a Deep Neural Network space $\Phi(L, W, S, B)$ with $L = O(1), W = O(N), S = O(N)$ and $B = O(N)$. Then the log value of the covering number of the DNN Laplacian space with respect to the $\| \cdot \|_\infty$ norm $\|F(x)\|_\infty := \sup_{x \in \Omega}|F(x)|$, which is denoted by $N(\delta, \Delta \Phi(L, W, S, B), \| \cdot \|_\infty)$, can be upper bounded by:

\[
\log N(\delta, \Delta \Phi(L, W, S, B), \| \cdot \|_\infty) = O \left( S \left[ \log(\delta^{-1}) + 3L \log(WB) \right] \right) \tag{A.42}
\]

**Proof.** We firstly fix a sparsity pattern (i.e, the locations of the non-zero entries are fixed). Applying Lemma A.24 yields that there exists some constant $C = O(1)$, such that the covering number with respect to $\| \cdot \|_\infty$ can be upper bounded by:

\[
\left( \frac{\delta}{CW^\frac{3L-1}{2} (B \lor d)^\frac{5L-1}{2}} \right)^{-S}
\]

Furthermore, note that the number of feasible configurations is upper bounded by $(\binom{W+1}{S}^L) \leq (W + 1)^{L S}[63, 18]$. Then we plug this into the pervious estimation and yields:

\[
\log N(\delta, \Phi(L, W, S, B), \| \cdot \|_\infty) \leq \log \left( (W + 1)^{LS} \left( \frac{\delta}{CW^\frac{3L-1}{2} (B \lor d)^\frac{5L-1}{2}} \right)^{-S} \right)
\]

\[
\leq S \log \left( \delta^{-1}(W + 1)^{L} W^{-\frac{3L-1}{2}} (B \lor d)^{\frac{5L-1}{2}} \right)
\]

\[
\lesssim S \left[ \log(\delta^{-1}) + L \log(W) + 3L \log(W(B \lor d)) \right]
\]

Note that here the dimension $d$ is some constant. Thus, by plugging in the given magnitudes $L = O(1), W = O(N), S = O(N)$ and $B = O(N)$, we can further deduce that:

\[
\log N(\delta, \Delta \Phi(L, W, S, B), \| \cdot \|_\infty) \lesssim S \left[ \log(\delta^{-1}) + 3L \log(WB) \right]
\]

This finishes our proof. \[ \]

**Lemma A.26 (Local Rademacher Complexity Bound for Deep Ritz Method).**

Consider a Deep Neural Network space $\mathcal{F}(\Omega) = \Phi(L, W, S, B)$ with $L = O(1), W = O(N), S = O(N)$ and $B = O(N)$, where $N \in \mathbb{Z}^+$ is fixed to be sufficiently large. Moreover, assume that the gradients and function value of $\mathcal{F}(\Omega), V$ and $f$ are uniformly bounded

\[
\max \left\{ \sup_{u \in \mathcal{F}} \| u \|_{L^\infty(\Omega)}, \sup_{u \in \mathcal{F}} \| \nabla u \|_{L^\infty(\Omega)}, \| u^* \|_{L^\infty(\Omega)}, \| \nabla u^* \|_{L^\infty(\Omega)}, \| f \|_{L^\infty(\Omega)} \right\} \leq C. \tag{A.43}
\]
For any \( \rho > 0 \), we consider a localized set \( L_\rho \) defined by:
\[
L_\rho(\Omega) := \{ u : u \in F(\Omega), \| u - u^* \|_{H^1} \leq \rho \}.
\]

Then for any \( \rho \gtrsim n^{-2} \), the Rademacher complexity of a localized function space \( S_\rho(\Omega) := \left\{ h := |\Omega| \cdot \left[ \frac{1}{2} \left( \| \nabla u \|^2 - \| \nabla u^* \|^2 \right) + \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*) \right] \quad u \in L_\rho(\Omega) \right\} \) can be upper bounded by a sub-root function
\[
\phi(\rho) := O \left( \sqrt{\frac{3L^4 \rho}{n \log(BWn)}} \right).
\]
i.e. we have
\[
(A.44) \quad \phi(4\rho) \leq 2\phi(\rho) \text{ and } R_n(S_\rho(\Omega)) \leq \phi(\rho).
\]

holds for all \( \rho \gtrsim n^{-2} \).

**Proof.** Firstly, we will check that for any \( u \in L_\rho(\Omega) \), the corresponding function \( h \) in \( S_\rho(\Omega) \) is Lipschitz with respect to \( u - u^* \) and \( \| \nabla u \| - \| \nabla u^* \| \). Note that for any \( u_1, u_2 \in L_\rho(\Omega) \) with corresponding functions \( h_1, h_2 \in S_\rho(\Omega) \), applying boundedness condition 4.9 yields:
\[
|h_1(x) - h_2(x)| \leq \frac{1}{2} \| \nabla u_1(x) \|^2 - \| \nabla u_2(x) \|^2 \right) + \frac{1}{2} V(|u_1(x)|^2 - |u_2(x)|^2) + |f(x)||u_1(x) - u_2(x)|
\leq C \| \nabla u_1(x) \| - \| \nabla u_2(x) \| \right) + (C^2 + C)|u_1(x) - u_2(x)|
= C \left( \| \nabla u_1(x) \| - \| \nabla u^*(x) \| \right) - \left( \| \nabla u_2(x) \| - \| \nabla u^*(x) \| \right)
+ (C^2 + C)|u_1(x) - u^*(x)) - (u_2(x) - u^*(x))|.\]

Let’s pick \( L = C^2 + C > C \). Applying the Talagrand Contraction Lemma A.4 helps us upper bound the local Rademacher complexity \( R_n(S_\rho(\Omega)) \) by
\[
R_n(S_\rho(\Omega)) = \mathbb{E}_x \mathbb{E}_\sigma \left[ \sup_{u \in L_\rho(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i \left[ \frac{1}{2} \left( \| \nabla u \|^2 - \| \nabla u^* \|^2 \right) + \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*) \right] \right]
\leq 2\mathbb{E}_x \mathbb{E}_\sigma \left[ \sup_{u \in L_\rho(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i \left( u(x_i) - u^*(x_i) \right) \right]
+ 2\mathbb{E}_x \mathbb{E}_\sigma \left[ \sup_{u \in L_\rho(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i' \left( \| \nabla u(x_i) \| - \| \nabla u^*(x_i) \| \right) \right]
\lesssim R_n \left( \left\{ u - u^* : u \in L_\rho \right\} \right) + \mathbb{E}_u \left( \left\| \nabla u - \nabla u^* \| : u \in L_\rho \right\| \right)
\]
From the localization constraint \( \rho \geq \| u - u^* \|^2_{H^1(\Omega)} = \| u - u^* \|^2_{L^2(\Omega)} + \| \nabla u - \nabla u^* \|^2_{L^2(\Omega)} \), we can deduce that
\[
(A.45) \quad \| u - u^* \|_{L^2(\Omega)} \leq \sqrt{\rho} \quad \text{and} \quad \| \nabla u - \nabla u^* \|_{L^2(\Omega)} \leq \sqrt{\rho}
\]
Moreover, note that $\Omega \subset [0, 1]^d$. Applying triangle inequality yields:

\begin{equation}
\tag{A.46}
\left\| \nabla u - \nabla u^* \right\|_{L^2(\Omega)}^2 = \int_\Omega \left| \nabla u(x) - \nabla u^*(x) \right|^2 \, dx \leq \int_\Omega \left| \nabla u(x) - \nabla u^*(x) \right|^2 \, dx
\end{equation}

Using inequality A.45 and inequality A.46, we have:

\[
R_n(S_\rho(\Omega)) \lesssim R_n \left( \left\{ u - u_* : u \in L_\rho \right\} \right) + R_n \left( \left\{ \nabla u - \nabla u^* : u \in L_\rho \right\} \right)
\]

\[
\leq R_n \left( \left\{ u - u_* : u \in \Phi(L, W, S, B), \| u - u^* \|_{L^2(\Omega)} \leq \sqrt{\delta} \right\} \right)
\]

\[
+ R_n \left( \left\{ \nabla u - \nabla u^* : u \in \Phi(L, W, S, B), \left\| \nabla u - \nabla u^* \right\|_{L^2(\Omega)} \leq \sqrt{\delta} \right\} \right)
\]

\[
\lesssim \inf_{0 < \alpha < 2\sqrt{\delta}} \left\{ 4\alpha + \frac{12}{\sqrt{n}} \int_0^{2\sqrt{\delta}} \sqrt{\log N(\delta, \Phi(L, W, S, B), \| \cdot \|_{n, 2})} \, d\delta \right\}
\]

\[
+ \inf_{0 < \alpha < 2\sqrt{\delta}} \left\{ 4\alpha + \frac{12}{\sqrt{n}} \int_0^{2\sqrt{\delta}} \sqrt{\log N(\delta, \nabla \Phi(L, W, S, B), \| \cdot \|_{n, 2})} \, d\delta \right\}
\]

\[
\lesssim \inf_{0 < \alpha < 2\sqrt{\delta}} \left\{ 4\alpha + \frac{12}{\sqrt{n}} \int_0^{2\sqrt{\delta}} \sqrt{\log N(\delta, \Phi(L, W, S, B), \| \cdot \|_{L^2})} \, d\delta \right\}
\]

\[
+ \inf_{0 < \alpha < 2\sqrt{\delta}} \left\{ 4\alpha + \frac{12}{\sqrt{n}} \int_0^{2\sqrt{\delta}} \sqrt{\log N(\delta, \nabla \Phi(L, W, S, B), \| \cdot \|_{L^2})} \, d\delta \right\}
\]

For any $\rho \gtrsim \frac{1}{n}$, we pick $\alpha = \frac{1}{n} \lesssim \sqrt{\delta}$ and plug in the upper bounds proved in Theorem A.18 and Theorem A.22, which implies:

\[
R_n(S_\rho(\Omega)) \lesssim \frac{1}{n} + \frac{1}{\sqrt{n}} \int_{\frac{1}{n}}^{2\sqrt{\delta}} \sqrt{S \left[ \log(\delta^{-1}) + 3L \log(WB) \right]} \, d\delta + \frac{1}{\sqrt{n}} \int_{\frac{1}{n}}^{2\sqrt{\delta}} \sqrt{S \left[ \log(\delta^{-1}) + 3L \log(WB) \right]} \, d\delta
\]

\[
\lesssim \sqrt{S^3} \frac{1}{n} \rho \log(BWn)
\]

\[
\]
Lemma A.27 (Local Rademacher Complexity Bound for Physics Informed Neural Network).

Consider a Deep Neural Network space \( \mathcal{F}(\Omega) = \Phi(L,W,S,B) \) with \( L = O(1), W = O(N), S = O(N) \) and \( B = O(N) \), where \( N \in \mathbb{Z}^+ \) is fixed to be sufficiently large. Moreover, assume that the gradients and function value of \( \mathcal{F}(\Omega), V \) and \( f \) are uniformly bounded

\[
\max \left\{ \sup_{u \in \mathcal{F}(\Omega)} \|u\|_{L^\infty(\Omega)}, \sup_{u \in \mathcal{F}(\Omega)} \|\Delta u\|_{L^\infty(\Omega)}, \|u^*\|_{L^\infty(\Omega)}, \|\Delta u^*\|_{L^\infty(\Omega)}, V_{\text{max}}, \|f\|_{L^\infty(\Omega)} \right\} \leq C.
\]

For any \( \rho > 0 \), we consider a localized set \( M_\rho \) defined by:

\[
M_\rho(\Omega) := \{ u : u \in \mathcal{F}(\Omega), \|u - u^*\|_{H^2} \leq \rho \}.
\]

Then for any \( \rho \gtrsim n^{-2} \), the Rademacher complexity of a localized function space \( \mathcal{T}_\rho(\Omega) := \{ h := |\Omega| \cdot [(\Delta u - Vu + f)^2 - (\Delta u^* - Vu^* + f)^2] \} \) can be upper bounded by a sub-root function

\[
\phi(\rho) := O \left( \sqrt{\frac{S3L^3 \rho}{n \log (BWn)}} \right),
\]

i.e. we have

\[
(A.48) \quad \phi(4\rho) \leq 2\phi(\rho) \text{ and } R_n(\mathcal{T}_\rho(\Omega)) \leq \phi(\rho).
\]

holds for all \( \rho \gtrsim n^{-2} \).

**Proof.** Firstly, we will check that for any \( u \in L_\rho(\Omega) \), the corresponding function \( h \) in \( \mathcal{S}_\rho(\Omega) \) is Lipschitz with respect to \( u - u^* \) and \( \Delta u - \Delta u^* \). Note that for any \( u_1, u_2 \in L_\rho(\Omega) \) with corresponding functions \( h_1, h_2 \in \mathcal{S}_\rho(\Omega) \), applying boundedness condition 4.11 yields:

\[
|h_1(x) - h_2(x)| \leq |\Delta u_1 - \Delta u_2 - V(u_1 - u_2)||\Delta u_1 - Vu_1 + \Delta u_2 - Vu_2 + 2f|
\leq (2C^2 + 4C) (|\Delta u_1 - \Delta u_2| + C|u_1 - u_2|)
= (2C^2 + 4C) \left| (\Delta u_1(x) - \Delta u^*(x)) - (\Delta u_2(x) - \Delta u^*(x)) \right|
+ (2C^3 + 4C^2) \left| (u_1(x) - u^*(x)) - (u_2(x) - u^*(x)) \right|
\]

Let’s pick \( L = \max\{2C^2 + 4C, 2C^3 + 4C^2\} \). Applying the Talagrand Contraction Lemma A.4.
helps us upper bound the local Rademacher complexity $R_n(T_\rho(\Omega))$ by

$$R_n(T_\rho(\Omega)) = \mathbb{E}_x \mathbb{E}_{\sigma} \left[ \sup_{u \in \mathcal{M}_\rho(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i \left[ (\Delta u(x_i) - Vu(x_i))^2 - (\Delta u^*(x_i^*) - Vu^*(x_i^*))^2 \right] \right]$$

$$\leq 2L \mathbb{E}_x \mathbb{E}_{\sigma} \left[ \sup_{u \in \mathcal{M}_\rho(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma_i \left[ u(x_i) - u^*(x_i) \right] \right]$$

$$+ 2L \mathbb{E}_x \mathbb{E}_{\sigma'} \left[ \sup_{u \in \mathcal{M}_\rho(\Omega)} \frac{1}{n} \sum_{i=1}^{n} \sigma'_i \left[ \Delta u(x'_i) - \Delta u^*(x'_i) \right] \right]$$

$$\lesssim R_n \left( \left\{ u - u^* : u \in \mathcal{M}_\rho \right\} \right) + R_n \left( \left\{ \Delta u - \Delta u^* : u \in \mathcal{M}_\rho \right\} \right)$$

$$\lesssim R_n \left( \left\{ u - u^* : u \in \Phi(L, W, S, B), \|u - u^*\|_{L^2(\Omega)} \leq \sqrt{\rho} \right\} \right)$$

$$+ R_n \left( \left\{ \Delta u - \Delta u^* : u \in \Phi(L, W, S, B), \|\Delta u - \Delta u^*\|_{L^2(\Omega)} \leq \sqrt{\rho} \right\} \right)$$

$$\leq R_n \left( \left\{ u - u^* : u \in \Phi(L, W, S, B), \|u - u^*\|_{n,2} \leq 2\sqrt{\rho} \right\} \right)$$

$$+ R_n \left( \left\{ \Delta u - \Delta u^* : u \in \Phi(L, W, S, B), \|\Delta u - \Delta u^*\|_{n,2} \leq 2\sqrt{\rho} \right\} \right)$$

$$\lesssim \inf_{0 < \alpha < 2\sqrt{\rho}} \left\{ 4\alpha + \frac{12}{n} \int_{\alpha}^{2\sqrt{\rho}} \sqrt{\log N(\delta, \Phi(L, W, S, B), \|\cdot\|_n)} d\delta \right\}$$

$$+ \inf_{0 < \alpha < 2\sqrt{\rho}} \left\{ 4\alpha + \frac{12}{n} \int_{\alpha}^{2\sqrt{\rho}} \sqrt{\log N(\delta, \Delta\Phi(L, W, S, B), \|\cdot\|_{n,2})} d\delta \right\}$$

$$\lesssim \inf_{0 < \alpha < 2\sqrt{\rho}} \left\{ 4\alpha + \frac{12}{n} \int_{\alpha}^{2\sqrt{\rho}} \sqrt{\log N(\delta, \Phi(L, W, S, B), \|\cdot\|_{\infty})} d\delta \right\}$$

$$+ \inf_{0 < \alpha < 2\sqrt{\rho}} \left\{ 4\alpha + \frac{12}{n} \int_{\alpha}^{2\sqrt{\rho}} \sqrt{\log N(\delta, \Delta\Phi(L, W, S, B), \|\cdot\|_{\infty})} d\delta \right\}$$

For any $\rho \gtrsim \frac{1}{n^2}$, we pick $\alpha = \frac{1}{n} \lesssim \sqrt{\rho}$ and plug in the upper bounds proved in Theorem A.18 and Theorem A.22, which implies:

$$R_n(T_\rho(\Omega)) \lesssim \frac{1}{n} + \frac{1}{n} \int_{\frac{1}{n}}^{2\sqrt{\rho}} \sqrt{S \left[ \log(\delta^{-1}) + 3L \log(WB) \right]} d\delta + \frac{1}{n} \int_{\frac{1}{n}}^{2\sqrt{\rho}} \sqrt{S \left[ \log(\delta^{-1}) + 3L \log(WB) \right]} d\delta$$

$$\lesssim \sqrt{\frac{S^3 L\rho}{n} \log(BWn)}$$

**A.4. Proof of The Meta-Theorem for PINN.**

**Proof.** To upper bound the excess risk $\Delta \mathcal{E}^{(n)}$, following [78, 47, 14], we decompose the
We’ll focus on providing fast rate upper bounds of the generalization error for the two estimators where the expectation is on all sampled data. The inequality of the third line is because using the localization technique [3, 78]. To achieve the fast generalization bound, we focus on\[3, 78\]. According to the Brenstein inequality, we know with probability \(1 - e^{-t}\) we have

\[
\mathbb{E}_{n}(u_{F}) - \mathbb{E}_{n}(u^{*}) - \mathbb{E}(u_{F}) + \mathbb{E}(u^{*}) \leq \sqrt{\frac{t [\mathbb{E}(u_{F}) - \mathbb{E}(u^{*})]}{n}} \leq \frac{1}{2} [\mathbb{E}(u_{F}) - \mathbb{E}(u^{*})] + \frac{t}{2n}.
\]

Note that \[A.53\] holds for all function lies in the function space \(\mathcal{F}\). Thus, we can take \(u_{F} := \arg \min_{u_{0} \in \mathcal{F}(\Omega)} (\mathbb{E}(u_{0}) - \mathbb{E}(u^{*}))\) and finally get

\[
\Delta \mathcal{E}(n) \leq \mathbb{E}(\hat{u}_{\text{PINN}}) - \mathbb{E}(u^{*}) + \mathbb{E}(\hat{u}_{\text{PINN}}) + \frac{3}{2} \inf_{u_{F} \in \mathcal{F}(\Omega)} \mathbb{E}(u_{F}) - \mathbb{E}(u^{*}) + \frac{t}{2n}.
\]

This inequality decompose the excess risk to the generalization error \(\Delta \mathcal{E}_{\text{gen}} := \mathbb{E}(\hat{u}_{\text{PINN}}) - \mathbb{E}(u^{*}) + \mathbb{E}(\hat{u}_{\text{PINN}})\) and the approximation error \(\Delta \mathcal{E}_{\text{app}} = \inf_{u_{F} \in \mathcal{F}(\Omega)} (\mathbb{E}(u_{F}) - \mathbb{E}(u^{*}))\). We’ll focus on providing fast rate upper bounds of the generalization error for the two estimators using the localization technique[3, 78]. To achieve the fast generalization bound, we focus on the following normalized empirical process

\[
\hat{T}_{r}(\Omega) := \{ \hat{h}(x) := \frac{\mathbb{E}[h] - h(x)}{\mathbb{E}[h] + r} \mid h \in \mathcal{T}(\Omega) \} \quad (r > 0).
\]

First, we try to bound the expectation of the normalized empirical process. Applying the Symmetrization Lemma \[A.3\], we can first bound the expectation as

\[
\sup_{h \in \hat{T}_{r}(\Omega)} \mathbb{E}_{x'} \left[ \frac{1}{n} \sum_{i=1}^{n} \hat{h}(x'_{i}) \right] \leq \mathbb{E}_{x'} \left[ \sup_{h \in \mathcal{T}(\Omega)} \left| \frac{1}{n} \sum_{i=1}^{n} \frac{h(x'_{i}) - \mathbb{E}[h]}{\mathbb{E}[h] + r} \right| \right] \leq 2R_{n}(\hat{T}_{r}(\Omega)).
\]

where the function class \(\hat{S}_{r}(\Omega)\) is defined as:

\[
\hat{T}_{r}(\Omega) := \{ \hat{h}(x) := \frac{h(x)}{\mathbb{E}[h] + r} \mid h \in \mathcal{T}(\Omega) \}.
\]
where $\mathcal{T}(\Omega) = \left\{ h := |\Omega| \cdot ((\Delta_0 - Vu + f)^2 - (\Delta u^* - Vu^* + f)^2) \right\}$. Then Applying the Peeling Lemma to any function $h \in \mathcal{T}(\Omega)$ helps us upper bound the local Rademacher complexity $R_n(\tilde{T}_r(\Omega))$ with the function $\phi$ defined in equation 4.25:

$$R_n(\tilde{T}_r(\Omega)) = \mathbb{E}_x \left[ \mathbb{E}_r \left[ \sup_{h \in \mathcal{T}(\Omega)} \frac{1}{n} \sum_{i=1}^n \sigma_i h(x_i) \right] \right] \leq \frac{4\phi(r)}{r}.$$ Combining all inequalities derived above yields:

$$(A.50) \sup_{h \in \mathcal{T}_r(\Omega)} \mathbb{E}_x \left[ \frac{1}{n} \sum_{i=1}^n \tilde{h}(x_i) \right] \leq 2R_n(\tilde{T}_r(\Omega)) \leq \frac{8\phi(r)}{r} \quad (r > 0).$$ Secondly we'll apply the Talagrand concentration inequality, which requires us to verify the condition needed. We will first check that the expectation value $\mathbb{E}[h]$ is always non-negative for any $h \in \mathcal{S}(\Omega)$:

$$\mathbb{E}[h] = \frac{1}{|\Omega|} \int_{\Omega} |\Omega| \cdot \left( \frac{1}{2} |\nabla u(x)|^2 + \frac{1}{2} V(x)|u(x)|^2 - f(x)u(x) \right) dx$$

$$- \frac{1}{|\Omega|} \int_{\Omega} |\Omega| \cdot \left( \frac{1}{2} |\nabla u^*(x)|^2 + \frac{1}{2} V(x)|u^*(x)|^2 - f(x)u^*(x) \right) dx$$

$$= \mathcal{E}(u) - \mathcal{E}(u^*) \geq 0 \Rightarrow \mathbb{E}[h] \geq 0.$$ We will proceed to verify that any $\tilde{h} = \frac{\mathbb{E}[h] - h}{|\mathbb{E}[h]| + r} \in \tilde{T}_r(\Omega)$ is of bounded inf-norm. We need to prove that any $h \in \mathcal{T}(\Omega)$ is of bounded inf-norm beforehand. Using boundedness condition listed in equation 4.24 implies:

$$\|h\|_\infty = |\Omega| \cdot \|((\Delta_0 - Vu + f)^2 - (\Delta u^* - Vu^* + f)^2)\|_\infty = |\Omega| \cdot \|((\Delta_0 - Vu + f)^2\|_\infty$$

$$\leq |\Omega| \cdot (\|\Delta_0\|_\infty + V_{\text{max}}\|u\|_\infty + \|f\|_\infty)^2 \leq |\Omega|(V_{\text{max}} + 2)^2 C^2$$

By taking $M := |\Omega|(V_{\text{max}} + 2)^2 C^2$, we then have $\|h\|_\infty \leq M$ for all $h \in \mathcal{T}(\Omega)$. Note that the denominator can be lower bounded by $|\mathbb{E}[h]| + r \geq r > 0$. Combining these two inequalities help us upper bound the inf-norm $\|\tilde{h}\|_\infty = \sup_{x \in \Omega} |\tilde{h}(x)|$ as follows:

$$\|\tilde{h}\|_\infty = \frac{|\mathbb{E}[h] - h|_\infty}{|\mathbb{E}[h]| + r} \leq \frac{2|\mathbb{E}[h]|_\infty}{r} \leq \frac{2M}{r} =: \beta.$$ We will then check the normalized functions $\frac{\mathbb{E}[h] - h(x)}{|\mathbb{E}[h]| + r}$ in $\tilde{T}_r(\Omega)$ have bounded second moment, which is satisfied because of the regularity results of the PDE. We aim to show that there exist some constants $\alpha, \alpha' > 0$, such that for any $h \in \mathcal{T}(\Omega)$, the following inequality holds:

$$(A.51) \alpha \mathbb{E}[h^2] \leq \|u - u^*\|_{H^2(\Omega)}^2 \leq \alpha' \mathbb{E}[h].$$ The RHS of the inequality follows from strong convexity of the PINN objective function proved in Theorem A.2:

$$\mathbb{E}[h] = \mathcal{E}(u) - \mathcal{E}(u^*) \geq \frac{1}{\min\{1, C_{\text{min}}\}} \|u - u^*\|_{H^2(\Omega)}^2.$$
The LHS of the inequality follows from boundedness condition listed in equation 4.24 and the QM-AM inequality:

\[
E[h(t)] = \int_\Omega [(\Delta u - Vu + f)^2 - (\Delta u - Vu^*)^2] dx = \int_\Omega (\Delta u - Vu + f)^2 dx \\
\leq M^2 \int_\Omega (\Delta u - Vu - \Delta u^* + Vu^*)^2 dx \leq 2M^2 \int_\Omega [(\Delta u - \Delta u^*)^2 + V^2(u - u^*)^2] dx \\
\leq 2M^2 \max\{1, V^2_{\text{max}}\} ||u - u^*||^2_{L^2(\Omega)}
\]

By picking \(\alpha' = \frac{1}{\min\{1, C_{\text{min}}\}}\) and \(\alpha = \frac{1}{M^2 \max\{1, V_{\text{max}}\}}\), we have finished proving inequality A.51. Then we can upper bound the expectation \(E[h^2]\) as:

\[
E[h(t)] = \frac{E[(h - E[h])^2]}{E[h] + r} \leq \frac{E[h^2] - E[h|^2]}{E[h] + r} \leq \frac{E[h^2]}{E[h] + r^2}.
\]

Using the fact that \(E[h] \geq 0\) and inequality A.51, we can lower bound the denominator \(|E[h] + r|^2\) as follows:

\[
|E[h] + r|^2 \geq 2E[h]r \geq \frac{2r\alpha}{\alpha' E[h^2]}.
\]

Therefore, we can deduce that:

\[
E[h(t)] \leq \frac{E[h^2]}{|E[h] + r|^2} \leq \frac{E[h^2]}{2r\alpha E[h^2]} = \frac{\alpha'}{2r\alpha} =: \sigma^2.
\]

Hence, any function in the localized class \(\tilde{H}_{\text{r}}(\Omega)\) is of bounded second moment.

It is easy to check that for any \(h \in \tilde{H}_{\text{r}}(\Omega)\), we have

\[
E[h] = \frac{E[h] - E[h]}{E[h] + r} = 0,
\]

i.e. any function in the localized class \(\tilde{H}_{\text{r}}(\Omega)\) is of zero mean.

Now we have verified that any function \(h \in \tilde{H}_{\text{r}}(\Omega)\) satisfies all the required conditions. By taking \(\mu\) to be the uniform distribution on the domain \(\Omega\) and applying Talagrand’s Concentration Inequality given in Lemma A.6, we have:

\[
\mathbb{P}_x \left[ \sup_{\tilde{h} \in \tilde{H}_{\text{r}}(\Omega)} \frac{1}{n} \sum_{i=1}^n \tilde{h}(x_i) \geq 2 \sup_{\tilde{h} \in \tilde{H}_{\text{r}}(\Omega)} \mathbb{E}_{\tilde{h}} \left[ \frac{1}{n} \sum_{i=1}^n \tilde{h}(x_i) \right] + \sqrt{\frac{2t\sigma^2}{n} + \frac{2t\beta}{n}} \right] \leq e^{-t}.
\]

By using the upper bound deduced above and plugging in the expressions of \(\beta\) and \(\sigma\), we can rewrite Talagrand’s Concentration Inequality in the following way. With probability at least \(1 - e^{-t}\), the inequality below holds:

\[
\frac{1}{n} \sum_{i=1}^n \tilde{h}(x_i) \leq \sup_{h \in \tilde{H}_{\text{r}}(\Omega)} \frac{1}{n} \sum_{i=1}^n \tilde{h}(x_i) \leq 2 \sup_{h \in \tilde{H}_{\text{r}}(\Omega)} \mathbb{E}_{\tilde{h}} \left[ \frac{1}{n} \sum_{i=1}^n \tilde{h}(x_i) \right] + \sqrt{\frac{2t\sigma^2}{n} + \frac{2t\beta}{n}} \leq \frac{16\phi(r)}{r} + \sqrt{\frac{16\sigma^2}{n\alpha r} + \frac{4Mt}{nr}} =: \psi(r).
\]
Let’s pick the critical radius $r_0$ to be:

(A.52) \[ r_0 = \max \{ 2^{14} r^*, \frac{24Mt}{n}, \frac{36\alpha t}{\alpha n} \}. \]

Note that concavity of the function $\phi$ implies that $\phi(r) \leq r$ for any $r \geq r^*$. Combining this with the first inequality listed in 4.25 yields:

\[ \frac{16\phi(r)}{r} \leq \frac{2^{11} \phi \left( \frac{r}{2^{14} t} \right)}{2^{14} \frac{r}{t}} = \frac{1}{8} \times \phi \left( \frac{r}{2^{14} t} \right) \leq \frac{1}{8}. \]

On the other hand, applying equation A.52 yields:

\[ \sqrt{\frac{\alpha t}{n \alpha r_0}} \leq \sqrt{\frac{\alpha t}{n \alpha 36\alpha t}} = \frac{1}{6}, \]

\[ \frac{4Mt}{nr_0} \leq \frac{4Mt}{n} \times \frac{n}{24Mt} = \frac{1}{6}. \]

Summing the three inequalities above implies:

\[ \psi(r_0) = \frac{16\phi(r_0)}{r_0} + \sqrt{\frac{\alpha t}{n \alpha r_0}} + \frac{4Mt}{nr_0} \leq \frac{1}{8} + \frac{1}{6} + \frac{1}{6} < \frac{1}{2}. \]

By picking $r = r_0$, we can further deduce that for any function $u \in F(\Omega)$, the following inequality holds with probability $1 - e^{-t}$:

\[ \frac{\mathcal{E}(u) - \mathcal{E}(u^*) - \mathcal{E}_n(u) + \mathcal{E}_n(u^*)}{\mathcal{E}(u) - \mathcal{E}(u^*) + r_0} = \frac{1}{n} \sum_{i=1}^{n} \tilde{h}(x_i) \leq \psi(r_0) < \frac{1}{2}. \]

Multiplying the denominator on both sides indicates:

\[ \Delta \mathcal{E}_{\text{gen}} = \mathcal{E}(u) - \mathcal{E}(u^*) - \mathcal{E}_n(u) + \mathcal{E}_n(u^*) \leq \frac{1}{2} \left[ \mathcal{E}(u) - \mathcal{E}(u^*) \right] + \frac{1}{2} r_0 = \frac{1}{2} \Delta \mathcal{E}^{(n)} + \frac{1}{2} r_0. \]

Substituting the upper bound above into the decomposition $\Delta \mathcal{E}^{(n)} \leq \Delta \mathcal{E}_{\text{gen}} + \frac{3}{2} \Delta \mathcal{E}_{\text{app}} + \frac{t}{2n}$ yields that with probability $1 - e^{-t}$, we have:

\[ \Delta \mathcal{E}^{(n)} \leq \Delta \mathcal{E}_{\text{gen}} + \frac{3}{2} \Delta \mathcal{E}_{\text{app}} + \frac{t}{2n} \leq \frac{1}{2} \Delta \mathcal{E}^{(n)} + \frac{1}{2} r_0 + \frac{3}{2} \Delta \mathcal{E}_{\text{app}} + \frac{t}{2n}. \]

Simplifying the inequality above yields that with probability $1 - e^{-t}$, we have:

\[ \Delta \mathcal{E}^{(n)} \leq r_0 + 3\Delta \mathcal{E}_{\text{app}} + \frac{t}{n} = 3 \inf_{u, \bar{r} \in F(\Omega)} \left( \mathcal{E}(u, \bar{r}) - \mathcal{E}(u^*) \right) + \max \left\{ 2^{14} r^*, 24Mt \frac{t}{n}, \frac{36\alpha t}{\alpha n} \right\} + \frac{t}{n} \]

\[ \lesssim \inf_{u, \bar{r} \in F(\Omega)} \left( \mathcal{E}(u, \bar{r}) - \mathcal{E}(u^*) \right) + \max \left\{ r^*, \frac{t}{n} \right\}. \]

Moreover, using strong convexity of the PINN objective function proved in Theorem A.1 implies:

\[ \Delta \mathcal{E}^{(n)} = \mathcal{E}(\tilde{u}_{\text{PINN}}) - \mathcal{E}(u^*) \geq \frac{1}{\{1, C_{\min} \}} \| \tilde{u}_{\text{PINN}} - u^* \|^2_{L^1(\Omega)}. \]

Combining the two bounds above yields that with probability $1 - e^{-t}$, we have:

\[ \| \tilde{u}_{\text{PINN}} - u^* \|^2_{L^1(\Omega)} \lesssim \inf_{u, \bar{r} \in F(\Omega)} \left( \mathcal{E}(u, \bar{r}) - \mathcal{E}(u^*) \right) + \max \left\{ r^*, \frac{t}{n} \right\}. \]
A.5. Proof of The Meta-Theorem for MDRM.

Proof. To upper bound the excess risk $\Delta\mathcal{E}(N,n) := \mathcal{E}(\hat{u}_{MDRM}) - \mathcal{E}(u^*)$, following [78, 47, 14], we decompose the excess risk into approximation error and generalization error with probability $1 - e^{-t}$:

\begin{align*}
\Delta\mathcal{E}(N,n) &= [\mathcal{E}(\hat{u}_{MDRM}) - \mathcal{E}(u^*)] + [\mathcal{E}_{N,n}(\hat{u}_{MDRM}) - \mathcal{E}_{N,n}(u_F)] \\
&\leq [\mathcal{E}(\hat{u}_{MDRM}) - \mathcal{E}_{N,n}(\hat{u}_{MDRM})] + [\mathcal{E}_{N,n}(u_F) - \mathcal{E}(u_F)] + [\mathcal{E}(u_F) - \mathcal{E}(u^*)] \\
&\leq [\mathcal{E}(\hat{u}_{MDRM}) - \mathcal{E}(u^*)] + \frac{2E(u_F) - \mathcal{E}(u^*)}{\min\{N, n\}},
\end{align*}

where the expectation is on all sampled data. The inequality of the third line is because $\hat{u}_{MDRM}$ is the minimizer of the empirical loss $\mathcal{E}_n$ in the solution set $\mathcal{F}(\Omega)$, so we have $\mathcal{E}_{N,n}(\hat{u}_{MDRM}) \leq \mathcal{E}_{N,n}(u_F)$. The last inequality is based on the Bernstein inequality. For any $u_F \in \mathcal{F}(\Omega)$, we use $h_{F,1}, h_{F,2}$ to denote the following two functions:

\begin{align*}
h_{F,1} &= \frac{1}{2}\left(\|\nabla u_F\|^2 - \|\nabla u^*\|^2\right), \\
h_{F,2} &= \frac{1}{2}V(|u_F|^2 - |u^*|^2) - f(u_F - u^*).
\end{align*}

Applying Bernstein’s inequality twice to $h_{F,1}$ and $h_{F,2}$ implies that there exists some constant $C_q$, such that with probability $1 - 2e^{-C_q t}$, the following two inequalities hold simultaneously:

\begin{align*}
\mathcal{E}_N(h_{F,1}) - \mathcal{E}(h_{F,1}) &\leq \sqrt{\frac{t \alpha E[h_{F,1}^2]}{N}}, \\
\mathcal{E}_n(h_{F,2}) - \mathcal{E}(h_{F,2}) &\leq \sqrt{\frac{t \alpha E[h_{F,2}^2]}{n}}.
\end{align*}

Note that the variance sum $E[h_{F,1}^2] + E[h_{F,2}^2]$ can be upper bounded by $\frac{t \alpha}{N}[E(u_F) - \mathcal{E}(u^*)]$ due to the strong convexity of the variation objective (A.57). Adding the two inequalities above implies with probability $1 - 2e^{-C_q t}$ we have:

\begin{align*}
\mathcal{E}_{N,n}(u_F) - \mathcal{E}_{N,n}(u^*) - \mathcal{E}(u_F) + \mathcal{E}(u^*) &= \mathcal{E}_N(h_{F,1}) - \mathcal{E}(h_{F,1}) + \mathcal{E}_n(h_{F,2}) - \mathcal{E}(h_{F,2}) \\
&\leq \sqrt{\frac{t \alpha E[h_{F,1}^2]}{N}} + \sqrt{\frac{t \alpha E[h_{F,2}^2]}{n}} \\
&\leq \sqrt{\frac{2t \alpha}{N}\left(E[h_{F,1}^2] + E[h_{F,2}^2]\right)} \\
&\leq \sqrt{\frac{2t E(u_F) - \mathcal{E}(u^*)}{\min\{N, n\}}} \leq \left[\mathcal{E}(u_F) - \mathcal{E}(u^*)\right] + \frac{4t}{\min\{N, n\}}.
\end{align*}
Note that A.53 holds for all function lies in the function space $\mathcal{F}$. Thus, we can take $u_{\mathcal{F}} := \arg\min_{u_{\mathcal{F}} \in \mathcal{F}(\Omega)} \left( \mathcal{E}(u_{\mathcal{F}}) - \mathcal{E}(u^*) \right)$ and finally get:

$$
\Delta \mathcal{E}^{(N,n)} \leq \mathcal{E}(\hat{u}_{\text{MDRM}}) - \mathcal{E}(u^*) + \mathcal{E}_{N,n}(u^*) - \mathcal{E}_{N,n}(\hat{u}_{\text{MDRM}}) + 2 \inf_{u_{\mathcal{F}} \in \mathcal{F}(\Omega)} \left( \mathcal{E}(u_{\mathcal{F}}) - \mathcal{E}(u^*) \right) + \frac{4t}{n}.
$$

This inequality decomposes the excess risk to the generalization error $\Delta \mathcal{E}_{\text{gen}} := \mathcal{E}(\hat{u}_{\text{MDRM}}) - \mathcal{E}(u^*) + \mathcal{E}_{N,n}(u^*) - \mathcal{E}_{N,n}(\hat{u}_{\text{MDRM}})$ and the approximation error $\Delta \mathcal{E}_{\text{app}} = \inf_{u_{\mathcal{F}} \in \mathcal{F}(\Omega)} \left( \mathcal{E}(u_{\mathcal{F}}) - \mathcal{E}(u^*) \right)$. From the lemmata proved in Section ??, we already have an estimation of the approximation error’s convergence rate. So now we’ll focus on providing fast rate upper bounds of the generalization error for the two estimators using the localization technique[3, 78]. To achieve the fast generalization bound, we focus on the following two normalized empirical processes:

$$
\hat{\mathcal{S}}_{r,1}(\Omega) := \left\{ \hat{h}_1(x) := \frac{\mathbb{E}[h_1] - h_1(x)}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r} \mid (h_1, h_2) \in \mathcal{S}(\Omega) \right\} \quad (r > 0),
$$

$$
\hat{\mathcal{S}}_{r,2}(\Omega) := \left\{ \hat{h}_2(x) := \frac{\mathbb{E}[h_2] - h_2(x)}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r} \mid (h_1, h_2) \in \mathcal{S}(\Omega) \right\} \quad (r > 0),
$$

where the space $\mathcal{S}(\Omega)$ is defined as:

$$
\mathcal{S}(\Omega) := \left\{ (h_1, h_2) \big| h_1 := |\Omega| \cdot \left[ \frac{1}{2} \left( \| \nabla u \|^2 - \| \nabla u^* \|^2 \right) \right], 
\qquad h_2 := |\Omega| \cdot \left[ \frac{1}{2} V(\| u \|^2 - \| u^* \|^2) - f(u - u^*) \right], u \in \mathcal{F}(\Omega) \right\}.
$$

First, we try to bound the expectation of the two normalized empirical processes. Applying the Symmetrization Lemma A.3, we can first bound the two expectations as:

$$
\sup_{\hat{h}_1 \in \hat{\mathcal{S}}_{r,1}(\Omega)} \mathbb{E}_{y'} \left[ \frac{1}{N} \sum_{i=1}^{N} \hat{h}_1(y'_i) \right] \leq \mathbb{E}_{y'} \left[ \sup_{h_1 \in \mathcal{S}_1(\Omega)} \left| \frac{1}{N} \sum_{i=1}^{N} \frac{h_1(y'_i) - \mathbb{E}[h_1]}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r} \right| \right] \leq 2R_N(\hat{\mathcal{S}}_{r,1}(\Omega)),
$$

$$
\sup_{\hat{h}_2 \in \hat{\mathcal{S}}_{r,2}(\Omega)} \mathbb{E}_{y} \left[ \frac{1}{n} \sum_{j=1}^{n} \hat{h}_2(y_j) \right] \leq \mathbb{E}_{y} \left[ \sup_{h_2 \in \mathcal{S}_2(\Omega)} \left| \frac{1}{n} \sum_{j=1}^{n} \frac{h_2(y_j) - \mathbb{E}[h_2]}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r} \right| \right] \leq 2R_n(\hat{\mathcal{S}}_{r,2}(\Omega)).
$$

where the function classes $\hat{\mathcal{S}}_{r,k}(\Omega) \quad (1 \leq k \leq 2)$ are defined as:

$$
\hat{\mathcal{S}}_{r,1}(\Omega) := \left\{ \hat{h}_1(x) := \frac{h_1(x)}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r} \mid (h_1, h_2) \in \mathcal{S}(\Omega) \right\},
$$

$$
\hat{\mathcal{S}}_{r,2}(\Omega) := \left\{ \hat{h}_2(x) := \frac{h_2(x)}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r} \mid (h_1, h_2) \in \mathcal{S}(\Omega) \right\}.
$$
Applying the modified Peeling Lemma A.8 to any function \( h = (h_1, h_2) \in S(\Omega) \) helps us upper bound the sum of the two local Rademacher complexities \( R_N(Sr_1(\Omega)) + R_n(Sr_2(\Omega)) \) with the function \( \phi \) defined in equation 5.5:

\[
R_N(Sr_1(\Omega)) + R_n(Sr_2(\Omega)) = \mathbb{E}_\sigma \left[ \mathbb{E}_y \left[ \sup_{h \in S(\Omega)} \frac{1}{N} \sum_{i=1}^N \sigma_i h(y_i) \right] \right] + \mathbb{E}_\tau \left[ \mathbb{E}_y \left[ \sup_{h \in S(\Omega)} \frac{1}{n} \sum_{j=1}^n \tau_j h_2(y_j) \right] \right] 
\]

\[
= E_y \left( \sup_{h_1 \in Sr_1(\Omega)} \frac{1}{N} \sum_{i=1}^N \tilde{h}_1(y_i) \right) + \sup_{h_2 \in Sr_2(\Omega)} E_{y'} \left( \frac{1}{n} \sum_{j=1}^n \tilde{h}_2(y_j) \right) 
\]

\[
\leq 2R_N(Sr_1(\Omega)) + 2R_n(Sr_2(\Omega)) = 2R_{N,n}(Sr(\Omega)) \leq \frac{8\phi(r)}{r} \quad (r > 0).
\]

Secondly, we’ll apply the Talagrand concentration inequality to the two function classes \( Sr_1(\Omega) \) and \( Sr_2(\Omega) \), which requires us to verify the conditions needed. We will first check that the expectation sum \( \mathbb{E}[h_1] + \mathbb{E}[h_2] \) is always non-negative for any \((h_1, h_2) \in S(\Omega)\):

\[
\mathbb{E}[h_1] + \mathbb{E}[h_2] = \frac{1}{|\Omega|} \int_{\Omega} |\Omega| \cdot \left( \frac{1}{2} \|
abla u(x)\|_2^2 + \frac{1}{2} V(x)|u(x)|^2 - f(x)u(x) \right) dx 
\]

\[
- \frac{1}{|\Omega|} \int_{\Omega} |\Omega| \cdot \left( \frac{1}{2} \|u^*(x)\|_2^2 + \frac{1}{2} V(x)|u^*(x)|^2 - f(x)u^*(x) \right) dx 
\]

\[
= \mathcal{E}(u) - \mathcal{E}(u^*) \geq 0 \Rightarrow \mathbb{E}[h_1] + \mathbb{E}[h_2] \geq 0.
\]

Next, we will verify that \( \tilde{S}_{\tau_1}(\Omega) \) satisfies all three requirements. At first, we will show that any \( \tilde{h}_1 = \frac{\mathbb{E}[h_1] - h_1}{\mathbb{E}[h_1] + |\mathbb{E}[h_2]|} \in \tilde{S}_{\tau_1}(\Omega) \) is of bounded inf-norm. We need to prove that any \( h_1 \in S_1(\Omega) \) is of bounded inf-norm beforehand. Using boundedness condition listed in equation 5.4 implies:

\[
\|h_1\|_\infty = \|\frac{1}{2}(\|\nabla u\|^2 - \|\nabla u^*\|^2)\|_\infty \leq \frac{1}{2}(\|\nabla u\|^2_\infty + \|\nabla u^*\|^2_\infty) \leq C^2.
\]

By taking \( M_1 := C^2 \), we then have \( \|h_1\|_\infty \leq M_1 \) for all \( h_1 \in S_1(\Omega) \). Note that the denominator of \( \tilde{h}_1 \) can be lower bounded by \( |\mathbb{E}[h_1] + |\mathbb{E}[h_2]|| \geq r > 0 \). Combining these two inequalities help us upper bound the inf-norm \( \|\tilde{h}_1\|_\infty = \sup_{x \in \Omega} |\tilde{h}_1(x)| \) as follows:

\[
\|\tilde{h}_1\|_\infty = \frac{|\mathbb{E}[h_1] - h_1|}{|\mathbb{E}[h_1] + |\mathbb{E}[h_2]| + r} \leq \frac{2\|h_1\|_\infty}{r} \leq \frac{2M_1}{r} =: \hat{\beta}_1.
\]

Also, it is easy to check that for any \( \tilde{h}_1 \in \tilde{S}_{\tau_1}(\Omega) \), we have

\[
\mathbb{E}[\tilde{h}_1] = \frac{\mathbb{E}[h_1] - \mathbb{E}[h_1]}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r} = 0,
\]

i.e. any function in the localized class $\tilde{S}_{r,1}(\Omega)$ is of zero mean.
Moreover, we take $\sigma^2 = \sup_{h_1 \in S_{r,1}(\Omega)} E[\tilde{h}_1^2]$ to be the upper bound on the second moment of functions in $\tilde{S}_{r,1}(\Omega)$. Now we have verified that any function $\tilde{h}_1 \in \tilde{S}_{r,1}(\Omega)$ satisfies all the required conditions. By taking $\mu$ to be the uniform distribution on the domain $\Omega$ and applying Talagrand’s Concentration inequality given in Lemma A.6, we have:

\[
\tag{A.55} P_x \left[ \sup_{\tilde{h}_1 \in \tilde{S}_{r,1}(\Omega)} \left( \frac{1}{N} \sum_{i=1}^{N} \tilde{h}_1(x_i) \right) \geq 2 \sup_{h_1 \in S_{r,1}(\Omega)} E_y \left[ \frac{1}{N} \sum_{i=1}^{N} \tilde{h}_1(y_i) \right] + \sqrt{\frac{2t\sigma^2}{N} + \frac{2t\beta_1}{N}} \right] \leq e^{-t}.
\]

Moreover, We will verify that $\tilde{S}_{r,2}(\Omega)$ also satisfies all three requirements. At first, we will show that any $\tilde{h}_2 = \frac{E[h_2]-h_2}{E[h_1]+E[h_2]+r} \in \tilde{S}_{r,2}(\Omega)$ is of bounded inf-norm. We need to prove that any $h_2 \in S_2(\Omega)$ is of bounded inf-norm beforehand. Using boundedness condition listed in equation 5.4 implies:

\[
\|h_2\|_{\infty} = \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*)\|_{\infty} \\
\leq \frac{1}{2} V_{\text{max}} \left( \|u\|_{\infty}^2 + \|u^*\|_{\infty}^2 \right) + \|f\|_{\infty} \left( \|u\|_{\infty} + \|u^*\|_{\infty} \right) \\
\leq \frac{1}{2} V_{\text{max}} \times 2C^2 + 2C^2 = (V_{\text{max}} + 2)C^2.
\]

By taking $M_2 := (V_{\text{max}} + 2)C^2$, we then have $\|h_2\|_{\infty} \leq M_2$ for all $h_2 \in S_2(\Omega)$. Note that the denominator of $\tilde{h}_2$ can be lower bounded by $|E[h_1] + E[h_2] + r| \geq r > 0$. Combining these two inequalities help us upper bound the inf-norm $\|\tilde{h}_2\|_{\infty} = \sup_{x \in \Omega} |\tilde{h}_2(x)|$ as follows:

\[
\|\tilde{h}_2\|_{\infty} = \frac{\|E[h_2] - h_2\|_{\infty}}{|E[h_1] + E[h_2] + r|} \leq \frac{2\|h_2\|_{\infty}}{r} \leq \frac{2M_2}{r} =: \beta_2.
\]

Also, it is easy to check that for any $\tilde{h}_2 \in \tilde{S}_{r,2}(\Omega)$, we have

\[
E[\tilde{h}_2] = \frac{E[h_2] - E[h_2]}{E[h_1] + E[h_2] + r} = 0,
\]

i.e. any function in the localized class $\tilde{S}_{r,2}(\Omega)$ is of zero mean.
Moreover, we take $\sigma^2 = \sup_{h_2 \in S_{r,2}(\Omega)} E[\tilde{h}_2^2]$ to be the upper bound on the second moment of functions in $\tilde{S}_{r,2}(\Omega)$. Now we have verified that any function $\tilde{h}_2 \in \tilde{S}_{r,2}(\Omega)$ satisfies all the required conditions. By taking $\mu$ to be the uniform distribution on the domain $\Omega$ and applying Talagrand’s Concentration inequality given in Lemma A.6, we have:

\[
\tag{A.56} P_y \left[ \sup_{\tilde{h}_2 \in \tilde{S}_{r,2}(\Omega)} \frac{1}{n} \sum_{j=1}^{n} \tilde{h}_2(x'_j) \geq 2 \sup_{h_2 \in S_{r,2}(\Omega)} E_y \left[ \frac{1}{n} \sum_{j=1}^{n} \tilde{h}_2(y'_j) \right] + \sqrt{\frac{2t\sigma^2}{n} + \frac{2t\beta_2}{n}} \right] \leq e^{-t}.
\]

By applying a union bound to the two inequalities derived in A.55 and A.56, we can derive
that with probability at least $1 - 2e^{-t}$, the inequality below holds:

$$\frac{1}{N} \sum_{i=1}^{N} \tilde{h}_1(x'_i) + \frac{1}{n} \sum_{j=1}^{n} \tilde{h}(x_j) \leq \sup_{\tilde{h}_1 \in S_{r,1}(\Omega)} \frac{1}{N} \sum_{i=1}^{N} \tilde{h}_1(x_i) + \sup_{\tilde{h}_2 \in S_{r,2}(\Omega)} \frac{1}{n} \sum_{j=1}^{n} \tilde{h}_2(x'_j)$$

$$\leq 2 \sup_{\tilde{h}_1 \in S_{r,1}(\Omega)} \mathbb{E}_{y} \left[ \frac{1}{N} \sum_{i=1}^{N} \tilde{h}_1(y_i) \right] + \sqrt{\frac{2t\sigma_1^2}{N}} + \frac{2t\beta_1}{n}$$

$$+ 2 \sup_{\tilde{h}_2 \in S_{r,2}(\Omega)} \mathbb{E}_{y'} \left[ \frac{1}{n} \sum_{j=1}^{n} \tilde{h}_2(y'_j) \right] + \sqrt{\frac{2t\sigma_2^2}{n}} + \frac{2t\beta_2}{n}$$

$$\leq \frac{16\phi(r)}{r} + \sqrt{\frac{2t}{n}(\sigma_1 + \sigma_2) + \frac{2t(\beta_1 + \beta_2)}{n}}.$$  

By the definition of $\beta_1$ and $\beta_2$, we have that the term $\frac{2t(\beta_1 + \beta_2)}{n}$ can be upper bounded by:

$$\frac{2t(\beta_1 + \beta_2)}{n} = \frac{4t(M_1 + M_2)}{nr} \leq \frac{4(V_{\max} + 3)C^2t}{nr}.$$  

Now we will derive some upper bound on the sum $\sigma_1 + \sigma_2$. By definition we have that:

$$(\sigma_1 + \sigma_2)^2 \leq 2(\sigma_1^2 + \sigma_2^2) = 2 \left[ \sup_{h_1 \in S_{r,1}(\Omega)} \mathbb{E}[\tilde{h}_1^2] + \sup_{h_2 \in S_{r,2}(\Omega)} \mathbb{E}[\tilde{h}_2^2] \right]$$

$$= 2 \left[ \sup_{h \in S(\Omega)} \frac{\mathbb{E}[h_1^2] - \mathbb{E}[h_1]^2}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r^2} + \sup_{h \in S(\Omega)} \frac{\mathbb{E}[h_2^2] - \mathbb{E}[h_2]^2}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r^2} \right]$$

$$\leq 4 \sup_{h \in S(\Omega)} \frac{\mathbb{E}[h_1^2] + \mathbb{E}[h_2^2]}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r^2}.$$  

Now it suffices to derive an upper bound of $\frac{\mathbb{E}[h_1^2] + \mathbb{E}[h_2^2]}{\mathbb{E}[h_1] + \mathbb{E}[h_2] + r^2}$ for any $h \in S(\Omega)$. The existence of such an upper bound is guaranteed because of the regularity results of the PDE. We aim to show that there exist some constants $\alpha, \alpha' > 0$, such that for any $h \in S(\Omega)$, the following inequality holds:

(A.57) $\alpha(\mathbb{E}[h_1^2] + \mathbb{E}[h_2^2]) \leq \|u - u^*\|_{H_1(\Omega)}^2 \leq \alpha'(\mathbb{E}[h_1] + \mathbb{E}[h_2]).$

The RHS of the inequality follows from strong convexity of the DRM objective function proved in Theorem A.1:

$$\mathbb{E}[h_1] + \mathbb{E}[h_2] = \mathcal{E}(u) - \mathcal{E}(u^*) \geq \min \left\{ 1, \frac{1}{V_{\min}} \right\} \|u - u^*\|_{H_1(\Omega)}^2.$$  

The LHS of the inequality follows from boundedness condition listed in equation 5.4 and the
QM-AM inequality:

\[
E[h_1^2] + E[h_2^2] = \int_\Omega \frac{1}{4} \left( \|\nabla u\|^2 - \|\nabla u^*\|^2 \right)^2 dx + \int_\Omega \left[ \frac{1}{2} V(|u|^2 - |u^*|^2) - f(u - u^*) \right]^2 dx \\
\leq \frac{1}{4} \int_\Omega \left( \|\nabla u\|^2 - \|\nabla u^*\|^2 \right)^2 dx + \frac{1}{2} \int_\Omega V^2(|u|^2 - |u^*|^2)^2 dx + 2 \int_\Omega f^2(u - u^*)^2 dx \\
\leq \frac{1}{4} \int_\Omega \left\|\nabla u - \|\nabla u^*\| \right\|^2 dx + \frac{1}{2} V_{\text{max}}^2 \int_\Omega \|u - |u^*| \|^2 dx + 2C^2 \int_\Omega (u - u^*)^2 dx \\
\leq 2C^2 \int_\Omega \|u - \nabla u^*\|^2 dx + 2C^2(1 + V_{\text{max}}^2) \int_\Omega \|u - u^*\|^2 dx
\]

By picking \(\alpha' = \frac{4}{\min(1, V_{\text{max}}^2)}\) and \(\alpha = \frac{1}{2C^2(1 + V_{\text{max}}^2)}\), we have finished proving inequality A.57.

Then we can can upper bound the term \(\frac{E[h_1^2]}{|E[h_1] + E[h_2]|^2} + \frac{E[h_2^2]}{|E[h_1] + E[h_2]|^2} = \frac{\alpha'}{2r} \frac{(E[h_1] + E[h_2])}{2|E[h_1] + E[h_2]|^2} \leq \frac{\alpha'}{2\alpha r} \).

Combining the bounds derived above helps us upper bound the term \(\sqrt{\frac{2t}{n}}(\sigma_1 + \sigma_2)\) as below:

\[
\sqrt{\frac{2t}{n}}(\sigma_1 + \sigma_2) \leq \sqrt{\frac{8t}{n}} \sqrt{\sup_{h \in S(\Omega)} \frac{E[h_1^2] + E[h_2^2]}{|E[h_1] + E[h_2]|^2}} \leq \sqrt{\frac{4\alpha' t}{n\alpha r}}
\]

Thus, using the two upper bounds on \(\sqrt{\frac{2t}{n}}(\sigma_1 + \sigma_2)\) and \(\frac{2t(\beta_1 + \beta_2)}{n}\), we have

\[
\frac{1}{N} \sum_{i=1}^{N} \hat{h}_1(x_i') + \frac{1}{n} \sum_{j=1}^{n} \hat{h}(x_j) \leq \frac{16\phi(r)}{r} + \sqrt{\frac{2t}{n}(\sigma_1 + \sigma_2) + \frac{2t(\beta_1 + \beta_2)}{n}} \\
\leq \frac{16\phi(r)}{r} + \sqrt{\frac{4\alpha' t}{n\alpha r} + \frac{4(V_{\text{max}} + 3)C^2t}{nr}} = \psi(r)
\]

Let’s pick the critical radius \(r_0\) to be:

(A.58) \(r_0 = \max\{2^{14}r^*, \frac{24Mt}{\alpha n}, \frac{144\alpha't}{\alpha n}\}\).

Note that concavity of the function \(\phi\) implies that \(\phi(r) \leq r\) for any \(r \geq r^*\). Combining this with the first inequality listed in 5.5 yields:

\[
\frac{16\phi(r_0)}{r_0} \leq \frac{2^{11}\phi\left(\frac{r_0}{2^{11}}\right)}{2^{14}r^*} = \frac{1}{8} \times \phi\left(\frac{r_0}{2^{11}}\right) \leq \frac{1}{8}.
\]
On the other hand, applying equation A.58 yields:

$$\sqrt{\frac{4\alpha t}{n\alpha r_0}} \leq \sqrt{\frac{4\alpha t}{n\alpha} \frac{\alpha n}{144\alpha t}} = \frac{1}{6},$$

$$\frac{4(V_{\text{max}} + 3)C^2 t}{nr_0} \leq \frac{4(V_{\text{max}} + 3)C^2 t}{n} \times \frac{n}{24(V_{\text{max}} + 3)C^2 t} = \frac{1}{6}.$$ 

Summing the three inequalities above implies:

$$\psi(r_0) = \frac{16\phi(r_0)}{r_0} + \sqrt{\frac{4\alpha t}{n\alpha r_0}} + \frac{4(V_{\text{max}} + 3)C^2 t}{nr_0} \leq \frac{1}{8} + \frac{1}{6} < \frac{1}{2}.$$ 

By picking $$r = r_0$$, we can further deduce that for any function $$u \in \mathcal{F}(\Omega)$$, the following inequality holds with probability $$1 - e^{-t}$$:

$$\frac{\mathcal{E}(u) - \mathcal{E}(u^*) - \mathcal{E}_n(u) + \mathcal{E}_n(u^*)}{\mathcal{E}(u) - \mathcal{E}(u^*) + r_0} = \frac{1}{n} \sum_{i=1}^{n} h(x_i) \leq \psi(r_0) < \frac{1}{2}.$$ 

Multiplying the denominator on both sides indicates:

$$\Delta \mathcal{E}_n = \mathcal{E}(u) - \mathcal{E}(u^*) - \mathcal{E}_n(u) + \mathcal{E}_n(u^*) \leq \frac{1}{2} \left[ \mathcal{E}(u) - \mathcal{E}(u^*) \right] + \frac{1}{2} r_0 = \frac{1}{2} \Delta \mathcal{E}(n) + \frac{1}{2} r_0.$$ 

Substituting the upper bound above into the decomposition $$\Delta \mathcal{E}(n) \leq \Delta \mathcal{E}_n + 2\Delta \mathcal{E}_{\text{app}} + \frac{4t}{n}$$ yields that with probability $$1 - 3e^{-\min(1,C_t)t}$$, we have:

$$\Delta \mathcal{E}(n) \leq \Delta \mathcal{E}_n + \frac{3}{2} \Delta \mathcal{E}_{\text{app}} + \frac{t}{2n} \leq \frac{1}{2} \Delta \mathcal{E}(n) + \frac{1}{2} r_0 + \frac{3}{2} \Delta \mathcal{E}_{\text{app}} + \frac{t}{2n}.$$ 

Simplifying the inequality above yields that with probability $$1 - 3e^{-\min(1,C_t)t}$$, we have:

$$\Delta \mathcal{E}(n) \leq r_0 + 3\Delta \mathcal{E}_{\text{app}} + \frac{t}{n} = 3 \inf_{u,F \in \mathcal{F}(\Omega)} \left( \mathcal{E}(u,F) - \mathcal{E}(u^*) \right) + \max \left\{ 2^{14}r^*, 24M \frac{36\alpha t}{n}, \frac{36\alpha t}{n} \right\} + \frac{t}{n} \leq \inf_{u,F \in \mathcal{F}(\Omega)} \left( \mathcal{E}(u,F) - \mathcal{E}(u^*) \right) + \max \left\{ r^*, \frac{t}{n} \right\}.$$ 

Moreover, using strong convexity of the DRM objective function proved in Theorem A.1 implies:

$$\Delta \mathcal{E}(n) = \mathcal{E}(\hat{u}_{\text{MDRM}}) - \mathcal{E}(u^*) \geq \|\hat{u}_{\text{MDRM}} - u^*\|^2_{H^1(\Omega)}.$$ 

Combining the two bounds above yields that with probability $$1 - 3e^{-\min(1,C_t)t}$$, we have:

$$\|\hat{u}_{\text{MDRM}} - u^*\|^2_{H^1(\Omega)} \leq \inf_{u,F \in \mathcal{F}(\Omega)} \left( \mathcal{E}(u,F) - \mathcal{E}(u^*) \right) + \max \left\{ r^*, \frac{t}{n} \right\}.$$ 

**Appendix B. Intuition Behind the Sub-optimality of the Unmodified Deep Ritz Methods.**

In this section, we aim to discuss the intuition behind the sub-optimality of the unmodified DRM via using the truncation Fourier basis. To simplify the notation, in this section we consider the following simplest Poisson equation $$\Delta u = f$$ on the hypercube with zero Dirichlet boundary condition. To illustrate the necessity of the modification we made, we consider the difference between the following two estimators.
• **Estimator 1.** We use the truncated Fourier basis estimator to learn the right hand side function $f$ and then we invert the PDE exactly to get the estimated $u$.

• **Estimator 2.** We plug in a parametrization of the truncated fourier basis into the empirical DRM objective.

We would like to point out that *estimator 1 isn’t build for computational consideration.* Instead, we use it to consider the statistical limit of our sampled data. We first show that the estimator 1 can achieve the minimax optimal estimation error.

**Error Of Estimator 1.** Firstly, we show that if one wants to learn the function $u$ in $H^1_0$, one need to learn the right hand side function $f$ in $H^{-1}_0$ norm. The $H^{-1}_0$ norm is defined as the dual norm of the $H^1$ norm, i.e. $\|u\|_{H^{-1}_0} = \max_{\|v\|_{H^1_0} \leq 1} \langle u, v \rangle$. Once we assume we have an estimate $\hat{f}$ of $f$ in $H^{-1}_0$, we can have an estimate of $u$ via $\hat{u} := (\Delta)^{-1} \hat{f}$, whose distance to $u$ in the $H^1$ norm satisfies:

$$\|\nabla u - \nabla \hat{u}\|_{H^1_0} = \max_{\|v\|_{H^1_0} \leq 1} \langle \nabla u - \nabla \hat{u}, \nabla v \rangle = \max_{\|v\|_{H^1_0} \leq 1} \langle (\Delta u - \Delta \hat{u}) - v \rangle = \max_{\|v\|_{H^1_0} \leq 1} \langle \hat{f} - \hat{f}, v \rangle = \|\hat{f} - \hat{f}\|_{H^{-1}_0}.$$  

Estimator 1 using the truncated fourier estimator to estimate the right hand side function $f$. Suppose we can access a random sample of observed data as $\{x_i, f(x_i)\}_{i=1}^n$, then the Fourier coefficient $f_z := \langle u, \phi_z \rangle$ can be estimated as $\hat{f}_z := \frac{1}{n} \sum_{i=1}^n f(x_i) \phi_z(x_i)$. To bound the estimation error of $\hat{f} := \sum_{\|z\|_{\infty} \leq Z} \hat{f}_z \phi_z$ in $H^{-1}_0$, we first apply the bias-variance decomposition:

$$\mathbb{E} \|\hat{f} - f\|^2_{H^{-1}_0} \leq \|\mathbb{E} \hat{f} - f\|^2_{H^{-1}_0} + \mathbb{E} \|f - \mathbb{E} \hat{f}\|^2_{H^{-1}_0} + \mathbb{E} \|f - \hat{f}\|^2_{H^{-1}_0}$$

We first bound the bias term $\|\mathbb{E} \hat{f} - f\|^2_{H^{-1}_0}$. Given $\mathbb{E} \hat{f} = \sum_{\|z\|_{\infty} \leq Z} f_z \phi_z$, we have that for a truncation set $Z$ of the from $Z := \{z \in \mathbb{N}^d | \|z\|_{\infty} \leq Z\}$, the bias term can be controlled by:

$$\|\sum_{\|z\|_{\infty} > Z} f_z \phi_z\|^2_{H^{-1}_0} \leq C \sum_{\|z\|_{\infty} > Z} f_z^2 z^{-2} \leq \|z\|_{\infty}^{-2(s-1)} \|f\|^2_{H^{s-2}}$$

Next we estimate the variance of the estimator by decomposing the variance into the following sum:

$$\mathbb{E} \|f - \hat{f}\|^2_{H^{-1}_0} \leq \mathbb{E} \sum_{\|z\|_{\infty} \leq Z} (\hat{f}_z - f_z)^2 \|\phi_z\|^2_{H^{-1}_0} \leq \sum_{\|z\|_{\infty} \leq Z} |z|^{-1} \text{Var}(\hat{f}_z).$$

Finally we achieve a $Z^{-2(s-1)} + \frac{Z^{d-2}}{n}$ upper bound for estimator 1. With optimal selection of $Z$, we can achieve the min-max optimal convergence rate $n^{-\frac{2s}{d+2s-4}}$. 
**Difference Between Estimator 1 and Estimator 2.** Next we aim to understand the Deep Ritz Method objective function via plugging in a truncated Fourier series estimator. We consider an estimator of the form \( u = \sum \hat{u}_z \phi_z(x) \), which lies in the space of truncated fourier series. Then the empirical DRM objective function can be expressed as

\[
(B.1) \quad \frac{1}{2n} \sum_{i=1}^{n} \left( \sum_{z} \hat{u}_z \nabla \phi_z(x_i) \right)^2 + \sum_{z} \hat{u}_z \phi_z(x_i) f(x_i).
\]

We observe that \((B.1)\) is a quadratic formula with respect to the Fourier coefficients \( u := (u_z)_{\|z\|_\infty \leq Z} \). Thus, we can rewrite it as the following matrix form

\[
(B.2) \quad \min \frac{1}{2} u^\top \hat{A} u + u^\top \hat{f}, \quad \text{where } \hat{A} = \left( \frac{1}{n} \sum_{i=1}^{n} \nabla \phi_i(x_i) \nabla \phi_j(x_i) \right)_{\|i\|_\infty \leq Z,\|j\|_\infty \leq Z}.
\]

Based on the matrix formulation \((B.2)\), we can compare the solution given by the two estimators

- **Estimator 1:** The Fourier coefficients of the solution of Estimator 1 are
  \[
  (B.3) \quad \hat{u}_1 = \text{diag} \left( \|z\|^2 \right)^{-1} \|z\|_\infty \leq Z \hat{f}.
  \]

- **Estimator 2:** The Fourier coefficients of the solution of Estimator 2 are
  \[
  (B.4) \quad \hat{u}_2 = \hat{A}^{-1} \hat{f}.
  \]

Note that \( \mathbb{E} \hat{A} = \left( \|z\|^2 \right)_{\|z\|_\infty \leq Z} \). Thus, we can further introduce another variance from the sampling of \( A \). By directly estimating \( \hat{u}_1 - \hat{u}_2 \), we will show that this term will be larger than the final convergence rate. Notice that

\[
(B.5) \quad \| \hat{u}_1 - \hat{u}_2 \|_{\mathcal{H}^1} = f^\top \left( \mathbb{E} \hat{A}^{-1} - \hat{A}^{-1} \right)^\top \text{diag} \left( \|z\|^2 \right)_{\|z\|_\infty \leq Z} \left( \mathbb{E} \hat{A}^{-1} - \hat{A}^{-1} \right) f
\]

Next we aim to bound \( \left( \mathbb{E} \hat{A}^{-1} - \hat{A}^{-1} \right) \). We first use the Matrix Bernstein Inequality\(^{73}\) to bound the \( \mathcal{H}^1 \) distance between \( \hat{u}_1 \) and \( \hat{u}_2 \). According to the Matrix Bernstein Inequality, we have that with probability \( 1 - e^{-t} \), the following inequality holds

\[
(B.6) \quad \left\| \left( \mathbb{E} \hat{A} - \hat{A} \right) \right\|_H \leq \sqrt{\frac{Z^d}{n}} + \frac{t}{n},
\]

where \( \| \cdot \|_H \) is the matrix operator norm respect to the vector \( \| \cdot \|_H \) defined as \( \|z\|_{H}^2 = z^\top \text{diag} \left( \|z\|^2 \right)_{\|z\|_\infty \leq Z} z \). Note that

\[
(B.7) \quad \left( I + \mathbb{E} \hat{A}^{-1} \left( \hat{A} - (\mathbb{E} \hat{A}) \right) \right) \left( \mathbb{E} \hat{A}^{-1} - \hat{A}^{-1} \right) = (\mathbb{E} \hat{A})^{-1} \left( \hat{A} - (\mathbb{E} \hat{A}) \right) (\mathbb{E} \hat{A})^{-1}
\]

When \( n \) is large enough, we know that \( \frac{1}{2} I \leq I + (\mathbb{E} \hat{A}^{-1} \left( \hat{A} - (\mathbb{E} \hat{A}) \right) \leq I \) with high probability. Thus the term \( \| \hat{u}_1 - \hat{u}_2 \|_{\mathcal{H}^1}^2 \) is at the scale of \( \left\| \left( \mathbb{E} \hat{A} - \hat{A} \right) \right\|_H^2 \approx \frac{Z^d}{n} \), which is of
the same magnitude as what we get from the empirical process approach in our main proof. It is also larger than \( \frac{Z_{c-2}}{m} \), which is the magnitude of the variance term for \( \hat{u}_1 \). Therefore, here we conjecture that our bound for DRM itself is tight and leads to the sub-optimal convergence rate.

Appendix C. Preliminaries on Tools for Lower Bounds. In this section, we repeat the standard tools we use to establish the lower bound. The main tool we use is the Fano’s inequality and the Varshamov-Gilber Lemma.

Lemma C.1 (Fano’s methods). Assume that \( V \) is a uniform random variable over set \( V \), then for any markov chain \( V \rightarrow X \rightarrow \hat{V} \), we always have

\[
P(\hat{V} \neq V) \geq 1 - \frac{I(V; X) + \log 2}{\log(|V|)}
\]

Lemma C.2 (Varshamov-Gilbert Lemma, [74] Theorem 2.9). Let \( D \geq 8 \). There exists a subset \( V = \{\tau^{(0)}, \ldots, \tau^{(2^D/8)}\} \) of \( D \)-dimensional hypercube \( H^D = \{0,1\}^D \) such that \( \tau^{(0)} = (0,0,\ldots,0) \) and the \( \ell_1 \) distance between every two elements is larger than \( \frac{D}{8} \)

\[
\sum_{l=1}^{D} \|\tau^{(j)} - \tau^{(k)}\|_{\ell_1} \geq \frac{D}{8}, \text{ for all } 0 \leq j, k \leq 2^D/8
\]
