Using this problem set. The goal of this problem set is to become friends with low genus curves by taking a tour though some constructions and techniques that appear frequently when studying their geometry and arithmetic. The problem set is broken into two chapters as follows:

Chapter I: Geometry. The philosophy of this chapter is that one encounters interesting low genus curves “in nature”: as covers of other curves, as divisors on surfaces, and so on. Since we care about arithmetic, in this section we do not assume that the ground field is algebraically closed, and pay careful attention to fields of definition.

Chapter II: Arithmetic. The main theme of this section is techniques for understanding the rational points on curves defined over number fields, especially étale descent. We’ve focused on descent, since it is both a powerful tool to bound the rank of a Jacobian (which is an input to classical Chabauty’s method), and can be used in combination with Chabauty arguments to find rational points. We present these ideas in some generality because of their prevalence and usefulness in other contexts.
CHAPTER 1

Geometry

For this section, \( C \) denotes a nice (smooth, projective, and geometrically integral) curve of genus \( g \) defined over a perfect field \( k \). We will write \( \overline{k} \) for an algebraic closure of \( k \). We write \( \mathcal{O}_C \) for the structure sheaf on \( C \).

- Given a coherent sheaf \( \mathcal{F} \) on \( C \), we write \( h^i(C, \mathcal{F}) \) for the dimension of the coherent cohomology group \( H^i(C, \mathcal{F}) \) as a \( k \)-vector space.
- We use \( K_C \) to denote the canonical line bundle on \( C \); by definition \( g = h^0(C, K_C) \).
- We will use divisor notation for line bundles, and write \( L_1 + L_2 \) for \( L_1 \otimes L_2 \) and \( -L \) for \( L' \).
- A curve \( C \) is called hyperelliptic if it admits a map of degree 2 to a nice curve of genus 0.
- We write \( \mathcal{O}_C \) for the structure sheaf on \( C \).
- We write \( \text{Pic}(C) \) for the group of line bundles on \( C \) over \( k \) (equivalently divisors on \( C \) over \( k \) modulo principal divisors). We write \( \text{Pic}^0(C/k) \) for the Picard scheme of \( C/k \).
- The Jacobian of \( C/k \) is the identity component \( \text{Pic}^0(C/k) \) and will be denoted \( J_C \) (or simply \( J \) when the curve \( C \) is implicit).

1. Background exercises on linear systems and Riemann–Roch

I.1.1 A subspace \( V \subseteq H^0(C, L) \) is called \( p \)-very ample if for all length \( p + 1 \) subschemes \( Z \subseteq C \), the evaluation map

\[
V \xrightarrow{\text{ev}} L|_Z
\]

is surjective. When \( p = 0 \), we call it basepoint-free and when \( p = 1 \), we call it simply very ample. When \( H^0(C, L) \) is \( p \)-very ample, we say that \( L \) itself is \( p \)-very ample.

Give a bijection between

\[
\{\text{morphisms } \varphi_V : C \to \mathbb{P}^r_k\} \quad \text{and} \quad \{(L, \sigma_0, \ldots, \sigma_r)\}/\simeq,
\]

where \( L \) is a line bundle and \( \sigma_0, \ldots, \sigma_r \in H^0(C, L) \) span a basepoint-free subspace \( V \). (When \( V = H^0(C, L) \), we will write \( \varphi_L \) for the corresponding morphism.)

Show, further, that the associated map is a closed immersion if and only if the sections \( \sigma_0, \ldots, \sigma_r \in H^0(C, L) \) span a very ample subspace.

**Hint:** The target \( \mathbb{P}^r_k \) is intrinsically \( \mathbb{P}^r \) in Grothendieck’s sense: codimension 1 subspaces in \( V \). In the second part, a map is a closed immersion if and only if it “separates points and tangent vectors”.

I.1.2 Let \( L \) be a line bundle on \( C \).

(a) If \( \deg L < 0 \), then \( h^0(C, L) = 0 \).

(b) If \( \deg L = 0 \), then \( h^0(C, L) = 1 \) if and only if \( L \cong \mathcal{O}_C \).

(c) If \( \deg L = 1 \), then \( h^0(C, L) > 1 \) if and only if \( C \cong \mathbb{P}^1_k \).
**Hint:** Use the definition of degree of a line bundle in terms of a global section.

**I.1.3** Let $L$ be a line bundle on $C$. By the Riemann–Roch theorem, we have

$$h^0(C, L) - h^1(C, L) = \deg L + 1 - g.$$ 

Furthermore, as a consequence of the Serre duality theorem, we have

$$h^i(C, L) = h^{1-i}(C, K_C - L).$$ 

(a) If $h^0(C, L) = r + 1$, give a formula for $h^1(C, L)$.
(b) Prove that $h^0(C, L) \leq \deg L + 1$.
(c) Compute the degree of $K_C$ and show that it is the only bundle of that degree with $g$ global sections.
(d) Prove that if $g > 0$, the canonical bundle $K_C$ is basepoint-free.
(e) Show that if $\deg L \geq g$, then $L$ is effective (i.e., $h^0(C, L) > 0$).
(f) Show that if $\deg L \geq 2g - 1$, then $h^1(C, L) = 0$. (Show that this is sharp: exhibit a bundle $L$ of degree $2g - 2$ for which $h^1(C, L) > 0$.)
(g) Show that if $\deg L \geq 2g$, then $L$ is basepoint-free.
(h) Show that if $\deg L \geq 2g + 1$, then $L$ is very ample.
(i) A bundle is called ample if there exists some positive integer $n > 0$ such that $nL$ is very ample. Find a necessary and sufficient criterion for a line bundle on $C$ to be ample.

**Hint:** Use Serre Duality to re-express Riemann–Roch in terms of only $h^0$'s, and when necessary, use Exercise (I.1.2) to address global sections of line bundles of low degree.

**I.1.4** The gonality – denoted $\text{gon}(C)$ – of a curve $C$ is the minimal degree of a dominant map $C \to \mathbb{P}^1_k$.

(a) Prove that if $K_C$ is $p$-very ample, then $\text{gon}(C) \geq p + 2$.
(b) Conversely, show that if $K_C$ is not $p$-very ample, then $\text{gon}(C) \leq p + 1$.
(c) * Give an example showing that when $K_C$ is not $p$-very ample, $\text{gon}(C)$ can be larger than $p + 1$.
(d) In the case $p = 1$, show the stronger statement that $K_C$ is very ample if and only if $C$ is not hyperelliptic. Therefore, if $C$ is not hyperelliptic, the morphism $\varphi_{K_C}: C \to \mathbb{P}^{g-1}_k$ is an embedding called the canonical embedding. The image is called a canonical curve of genus $g$.

**Hint:** Let $Z \subseteq C_{\mathbb{F}}$ be a hypothetical length $p+1$ subscheme. Apply the long exact sequence in cohomology to exact sequence of sheaves

$$0 \to K_C(-Z) \to K_C \to K_C|_Z \to 0,$$

and use Riemann–Roch and Serre Duality. In the last part, it might help to solve Exercise (I.3.6). This is also quite related to Exercise (I.3.9).

**I.1.5** Let $D$ be an effective divisor on a curve $C$ of degree $d$. Suppose that $h^0(C, \mathcal{O}(D)) = r + 1$. Show that under $\varphi_{K_C}$, the image of the points of $D$ span a linear space $\mathbb{P}^{d-1-r}_k$. (This statement is sometimes called geometric Riemann–Roch.)

**Hint:** Use the Riemann–Roch theorem to understand the vector space $H^0(C, K_C - D)$.

**I.1.6** Compute the following dimensions:

(a) $h^0(C, T_C)$
(b) $h^1(C, T_C)$
(c) $h^2(C, T_C)$
Comment: These dimensions all have significance in the moduli of curves. By deformation theory, the vector space $H^0(C, T_C)$ is space of infinitesimal automorphisms of a curve $C$. The vector space $H^1(C, T_C)$ is the space of first order deformations of $C$. The obstructions to lifting first order deformations to all orders live in the vector space $H^2(C, T_C)$.

I.1.7 Let $C$ be a curve and $L$ a line bundle on $C$. Let $p \in C(\overline{k})$ be a geometric point.

(a) Show that $h^0(C, L(-p)) \geq h^0(C, L) - 1$. If equality holds, what do we know about $p$?

**Hint:** Use the long exact sequence in cohomology associated to

\[ 0 \to L(-p) \to L \to L|_p \to 0. \]

(b) Show that if $h^0(C, L) > 0$ and $p$ is a general geometric point, then

\[ h^0(C, L(-p)) = h^0(C, L) - 1. \]

(c) If $L$ and $M$ are two line bundles such that $h^0(C, L) > 0$ and $h^0(C, M) > 0$, show that

\[ h^0(C, L \otimes M) \geq h^0(C, L) + h^0(C, M) - 1. \]

When does equality hold?

**Hint:** Base change to $\overline{k}$ and use part (b).

I.1.8 (Clifford’s Theorem) Let $C$ be a curve of genus $g$ and let $L$ be a line bundle of degree $d$ on the curve $C$.

(a) If $d > 2g - 2$, what is $h^0(C, L)$?

(b) If $0 \leq d \leq 2g - 2$, show that

\[ h^0(C, L) \leq 1 + \frac{d}{2}. \]

**Hint:** Use Exercise (I.1.7).

(c) * What can you say if equality holds in part (b)?

2. Genus 0 curves

In this section, $C$ is a nice curve of genus 0 defined over a field $k$.

I.2.1 The simplest example of a curve of genus 0 is $\mathbb{P}^1_k$.

(a) Show that $\text{Pic}(\mathbb{P}^1_k) \simeq \mathbb{Z}$ by the degree. Write $\mathcal{O}(d)$ for the unique (up to isomorphism) line bundle of degree $d$ on $\mathbb{P}^1_k$.

(b) In this notation, what is the canonical bundle?

(c) Determine the cohomology

\[ h^0(\mathbb{P}^1_k, \mathcal{O}(d)), \quad \text{and} \quad h^1(\mathbb{P}^1_k, \mathcal{O}(d)). \]

**Hint:** Use Riemann–Roch.

I.2.2 Choose a coordinate $x$ such that $k(\mathbb{P}^1_k) \simeq k(x)$; write $\infty$ for the point in $\mathbb{P}^1_k$ where $x$ has a pole so that $(x) = 0 - \infty$.

(a) Let $L = \mathcal{O}_{\mathbb{P}^1}(\infty)$ be the line bundle associated to the divisors $\infty$. Using the identification

\[ H^0(\mathbb{P}^1_k, L) = \{ f \in k(\mathbb{P}^1_k) \text{ s.t. } (f) + \infty \text{ is effective} \}, \]

give a basis for $H^0(\mathbb{P}^1_k, L)$.

(b) Similarly, give a basis for $H^0(\mathbb{P}^1_k, nL)$ for all $n$. Compare you answers to those for Exercise (I.2.1).

(c) What is the divisor of the meromorphic differential $dx$?
I.2.3 More generally, show that $\text{Pic}_{C/k}(k) \cong \mathbb{Z}$. Exhibit a field $k$ and a genus 0 curve $C$ defined over $k$ where $\text{deg}: \text{Pic}(C) \to \mathbb{Z}$ is not surjective. In this case, what is $\# \text{Pic}_{C/k}(k)/\text{Pic}(C)$?

**Hint:** Using Exercise (I.2.1), the existence of certain line bundles implies the existence of closed points of prescribed degree.

I.2.4 Show that every genus 0 curve admits an embedding $C \hookrightarrow \mathbb{P}^2_k$. What is the degree of the image?

**Hint:** By Exercise (I.1.1) it suffices to show that every genus 0 curve admits a line bundle with a 3-dimensional very ample subspace of sections.

I.2.5 Show that $C(k) \neq \emptyset$ if and only if $C$ has a closed point of odd degree.

I.2.6 Determine the gonality of $C$.

**Hint:** This is going to depend on $\# C(k)$.

3. Finite branched covers

**Description of the canonical bundle:** Riemann–Hurwitz.

Given a finite separable map $\pi: X \to Y$ of nice curves, the relative cotangent sheaf $\Omega^1_{X/Y}$ is defined by

$$\Omega^1_{X/Y} = K_X - \pi^* K_Y.$$ 

Write $g_X$ and $g_Y$ for the genera of $X$ and $Y$ respectively.

I.3.1 Given a closed point $P \in X$ with image $Q = \pi(P) \in Y$, let $e_P$ be such that $m_Q \cdot \mathcal{O}_{X,P} = m_P^{e_P}$.

Show that if the map $\pi$ is tamely ramified – i.e., the characteristic of $k$ does not divide $e_P$ for any closed point $P$ – then

$$\Omega^1_{X/Y} = \sum_{P \in X \text{ closed point}} (e_P - 1) P.$$ 

Deduce the Riemann–Hurwitz formula:

$$2g_X - 2 = (\text{deg} \pi)(2g_Y - 2) + \sum_{P \in X(k)} (e_P - 1).$$

Closed points $P \in X$ where $e_P > 1$ are called **ramification points** of $\pi$. Closed points $Q \in Y$ such that there exists a ramification point $P \in \pi^{-1}(Q)$ are called **branch points** of $\pi$.

**Hint:** The equation $m_Q \cdot \mathcal{O}_{X,P} = m_P^{e_P}$ tells you how to write a local equation for the cover in a neighborhood of $P$.

I.3.2 Let $G$ be a finite group. A finite branched cover $\pi: X \to Y$ is called a Galois cover with **Galois group** $G$ (or simply a $G$-Galois cover) if $k(X)/k(Y)$ is a Galois extension of function fields with Galois group $G$.

(a) Interpret $G$ as a constant finite group scheme over $k$. Show that if $\pi: X \to Y$ is a $G$-Galois cover, then $X$ admits a right $G$-action

$$X \times G \to X,$$

$$(x, g) \mapsto xg$$
that respects $\pi: X \to Y$; i.e., such that for all $g \in G$, the diagram
\[
\begin{array}{ccc}
X & \xrightarrow{g} & X \\
\downarrow{\pi} & & \downarrow{\pi} \\
Y & & 
\end{array}
\]
commutes.

(b) Given an action of a group $G$ on a scheme $X$, a scheme $Y$ is called the scheme-quotient of $X$ by $G$ if it is universal for schemes fitting into diagram (2). We write $Y = X/G$. Phrase this precisely and show that $\pi$ is a $G$-Galois cover if and only if $Y = X/G$.

(c) If $\pi: X \to Y$ is a $G$-Galois cover, what can you say about the ramification indices $e_P$ for $P \in X$?

(d) Suppose further now that $\pi: X \to Y$ is a $G$-Galois étale cover (i.e., all $e_P = 1$). Show that
\[
X \times G \to X \times_Y X, \\
(x, g) \mapsto (x, xg)
\]
is an isomorphism of $k$-varieties.

**Hint:** Remember that giving a nice curve is the same as giving it’s function field. If you need a hint on the function field side, look forward to Exercise (II.1.11).

I.3.3 If the genus $g$ of $C$ is at least 2, then the group of automorphisms $\text{Aut}(C)$ is finite. Assuming this fact, this exercise will lead you through the proof of the 84(g-1) theorem: if $g \geq 2$ and the characteristic of $k$ is 0, then $\# \text{Aut}(C) \leq 84(g - 1)$.

Let $K := k(C)^{\text{Aut}(C)}$ denote the fixed field of the $\text{Aut}(C)$-action on $k(C)$.

(a) Show that $K$ is a finitely-generated extension of $k$ of transcendence degree 1 that contains no finite extensions of $K$, and therefore the function field of a nice curve $Y$ over $k$.

(b) Give a formula for $\#G$ in terms of $g$, $g_Y$, and the ramification of $\pi: C \to Y$ over its branch points.

(c) If the genus of $Y$ is at least 1, derive an upper bound on $\# \text{Aut}(C)$.

(d) If the genus of $Y$ is 0, show that $\# \text{Aut}(C) \leq 84(g - 1)$.

(e) * Where did you use that the characteristic of the ground field was 0?

**Hint:** It might be helpful to break into cases based on the number of branch points and the ramification indices over each point.

**Comment:** This bound is sharp for infinitely many genera; for example genus 3 and 7. Curves achieving this bound are called Hurwitz curves. The proof of this theorem shows that it is sharp only if the curve can be exhibited as a certain Galois cover of $\mathbb{P}^1$; therefore finding Hurwitz curves in fact amounts to a problem in group theory.

I.3.4 Suppose that $f: X \to Y$ is a $G$-cover of curves over $k$ and assume that $\#G$ is coprime to the characteristic of $k$.

(a) Show that the subspace of differentials pulled back from $Y$ lies in $H^0(X, K_X)^G$.

(b) Conversely, show that every $G$-invariant differential on $X$ gives rise to a differential on $Y$.

**Hint:** Do this calculation in local coordinates; our assumptions imply that the map $f$ is tamely ramified, so you’ve worked out in Exercise (I.3.1) what the local equations are.

---

1Compare this to Exercise (I.1.6), which computed the infinitessimal automorphisms.
(c) Show that the genus $g_Y$ of $Y$ can be computed as

$$g_Y = \dim H^0(X, K_X)^G.$$ 

**Hyperelliptic curves.** For this section, let $Y$ be a nice curve of genus 0 and assume that $C$ admits a degree 2 map to $Y$.

**I.3.5** For what genera do there exist hyperelliptic curves?

**Hint:** Relate the genus of $C$ to the number of ramification points.

**I.3.6** For this problem, $C$ is a nice hyperelliptic curve of genus at least 2.

(a) Suppose that $L$ is a line bundle of degree 2 on $C$ with $h^0(C, L) = 2$. Determine $h^0(C, nL)$ as a function of $n$.

(b) What can you say about $(g - 1)L$? Describe $\varphi_{(g-1)L}$.

(c) If $C$ is hyperelliptic of genus at least 2, show that the hyperelliptic map $C \to Y$ is unique.

**Hint:** Use Exercise (1.1.3). It suffices to prove the final part after base-changing to the algebraic closure; use the previous part.

The next two problems do these calculations (and more) explicitly.

**I.3.7** Suppose that $C$ has gonality 2. Let $L$ be such that $\varphi_L$ is a degree 2 map onto $\mathbb{P}^1$.

(a) Let $D_x = \varphi_L^*(\infty) \in \text{Div}(C)$. Write $x \in k(C)$ for the pullback of a coordinate function such that $\{1, x\}$ form a basis for $H^0(C, D_x)$ (as in Exercise (1.2.2)). What is the relationship between $D_x$ and $L$?

(b) Give a basis for $H^0(C, nD_x)$ for $n \leq g$.

(c) What does an explicit basis for $H^0(C, (g+1)D_x)$ look like?

(d) In terms of your previous answer, give a basis for $H^0(C, nD_x)$ for $g < n \leq 2g + 1$. What happens when $n = 2g + 2$?

(e) Assume that the characteristic of the ground field is not 2. Show that every nice curve of gonality 2 is birational to a plane curve with affine equation

$$y^2 = f(x) = a_{2g+2}x^{2g+2} + a_{2g+1}x^{2g+1} + \cdots + a_0.$$  

Show that we may further assume that $f$ is monic, square-free, and of degree $2g + 2$ or $2g + 1$. What happens in arbitrary characteristic?

**Hint:** Compare this to Exercise (1.2.2).

**I.3.8** Suppose that $C_i$ is birational to the plane curve with equation

$$C_1 : y^2 = f_1(x) = x^{2g+2} + a_{2g+1}x^{2g+1} + \cdots + a_0,$$

$$C_2 : y^2 = f_2(x) = x^{2g+1} + b_2x^{2g} + \cdots + b_0$$

for $g \geq 1$, where $f_i$ is squarefree. We will refer to a curve of type $C_1$ as gonality 2 of even degree and type $C_2$ as gonality 2 of odd degree. (Or we will drop the pedantic “gonality 2” and simply refer to them as hyperelliptic of even/degree.) As in the previous problem, write $D_x := \varphi_L^*(\infty)$.

(a) Compute the ramification of the $x$-coordinate map using (1) and the equations of $C_1$ and $C_2$. Comment on the difference between these two situations. The closed points $P \in C$ for which $e_P > 1$ are called Weierstrass points of the hyperelliptic curve $C$.

(b) Compute the ramification divisor of the $x$-coordinate map using Riemann–Hurwitz by comparing the divisor of $dx$ to the pullback of the divisor of the corresponding differential on $\mathbb{P}^1$. 

(c) Show that the divisor of the differential $dx/y$ is $(g - 1)D_x$. Compare this to Exercise (D).

(d) Show that
\[
\frac{dx}{y}, \frac{xdx}{y}, \frac{x^2dx}{y}, \ldots, \frac{x^{g-1}dx}{y}
\]
form a basis for the space of regular differentials on $C_i$.

I.3.9 Assume that $g \geq 1$.

(a) Show that $C$ is hyperelliptic if and only if $\text{gon}(C_{\overline{k}}) = 2$.

(b) Show that if $g$ is even, then $\text{gon}(C) = 2$.

**Hint:** Use Exercise (I.3.6).

I.3.10 More generally, can you find (birational) equations for any hyperelliptic curve over $k$?

I.3.11 (Mumford coordinates on the Jacobian) Let $\pi: C \to \mathbb{P}^1_k$ be a gonality 2 curve of odd degree with affine equation $y^2 = f(x)$ and let $L$ be a degree 0 line bundle on $C$. Write $\infty \in C$ for the unique point of $C$ over $\infty \in \mathbb{P}^1_k$.

(a) Show that for some $d \leq g$, we have that $h^0(C, L(d\infty)) > 0$.

**Hint:** Use Riemann-Roch.

(b) Show that for the minimal such $d$, $h^0(C, L(d\infty)) = 1$. Call $D$ the unique effective divisor linearly equivalent to $L(d\infty)$. Show:
   i. $\infty \notin \text{supp}(D)$.
   ii. If $P \in \text{supp}(D)$, then $\iota(P) \notin \text{supp}(D)$ (where $\iota$ is the hyperelliptic involution).
We will refer to such an effective divisor as general relative to $\pi$.

**Hint:** What would you know about $h^0(C, D)$ if any of these conditions was violated?

(c) Let $D$ be an effective divisor of degree $d$ on $C$ that is general relative to $\pi$. Show that there exist unique polynomials $a(x), b(x) \in k[x]$ with $a$ monic of degree $d$ and $\deg(b) < d$ such that
   i. $a$ divides $f - b^2$.
   ii. For all $P = (x_0, y_0) \in \text{supp}(D)$,

\[
a(x_0) = 0, \quad b(x_0) = y_0.
\]

And the multiplicity of $P$ in $\text{supp}(D)$ is the order of vanishing of $a(x)$ at $x_0$.

The pair $(a(x), b(x))$ are called Mumford coordinates for the divisor $D$. When $d \leq g$, the pair $(a(x), b(x))$ are called the Mumford representation for the point $[\mathcal{O}(D - d\infty)] \in J(k)$.

**Hint:** This is, essentially, Lagrange interpolation to find a polynomial with certain values at certain points.

(d) Suppose that $(a, b)$ are Mumford coordinates for a divisor $D$. Describe the principal divisor $(y - b)$ on $C$.

I.3.12 (Group law on hyperelliptic Jacobians) In this problem we will explicitly see the group law on the Jacobian $J$ of an odd degree gonality 2 curve $\pi: C \to \mathbb{P}^1$ using Mumford coordinates.

(a) Let $L_1$ and $L_2$ be line bundles on $C$, and suppose that $D_1$ and $D_2$ are the unique divisors of minimal degrees $d_1, d_2 \leq g$ such that $L_i \cong \mathcal{O}(D_i - d_i\infty)$. By Exercise (I.3.11), these are general relative to $\pi$. Describe the line bundle

\[
L = L_1 + JL_2.
\]

(b) Is the divisor $D = D_1 + D_2$ general relative to $\pi$? If not, how can you make it so?
(c) Let \((a_i, b_i)\) be the Mumford coordinates of \(D_i\) (and hence the Mumford representation for \(L_i\)). Show that the following is an algorithm which terminates with the Mumford representation of \(L_1 +_\mathbb{F}_2 L_2\):

i. Let \(e = \gcd(a_1, a_2, b_1 + b_2)\). Let \(a = \frac{a_1 a_2}{e^2}\). Let \(b\) be the unique polynomial of degree less than \(\deg(a)\) such that
\[
\frac{a_i}{e} \text{ divides } b - b_i, \quad \text{and} \quad a \text{ divides } f - b^2.
\]

ii. While \(\deg(a) > g\):
   - Write \(f - b^2 = \lambda a c\) for some \(\lambda \in k^\times\) and \(c\) monic. Replace \(a\) with \(c\).
   - Replace \(b\) with \(-b \mod a\).

**Hint:** The steps of the algorithm should follow your description of the group law in parts (a) and (b). Use the Chinese remainder theorem. To complete the reduction step in part ii., think about Exercise ((d)).

**I.3.13** (Explicit arithmetic in a hyperelliptic Jacobian) Let \(C\) be the odd degree hyperelliptic curve of genus 2 with affine equation
\[
y^2 = x(x - 1)(x - 2)(x^2 - 3)
\]
over \(\mathbb{F}_5\).

(a) What are the Mumford coordinates of every point in \(J(\mathbb{F}_5)[2]\)?

(b) Let \(P = (3,1)\) be a point in \(J(\mathbb{F}_5)\). What are the Mumford coordinates of \(P\)? What are the Mumford coordinates of \(2P\)? What are the Mumford coordinates of \(3P\)? What is the order of \(P\) in \(J(\mathbb{F}_5)[2]\)?

**I.3.14** (Jacobian arithmetic in Magma) Given a hyperelliptic curve of odd degree, Magma represents points on the Jacobian via their Mumford coordinates \(P = (a, b, d)\), where \(a\) and \(b\) are the polynomials giving the Mumford representation of the effective divisor general with respect to the hyperelliptic map (c.f., Exercise (I.3.11)), and \(d\) records the (negative) multiple of \(\infty\) (i.e., the degree of this divisor). For example, to create the previous curve and point \(P\), one could type:

```magma
R<x> := PolynomialRing(GF(5));
C := HyperellipticCurve(x*(x-1)*(x-2)*(x^2-3));
J := Jacobian(C);
P := elt<J|x + 2, 1, 1>;
```
Using this, redo the previous problem in Magma.

**I.3.15** Let \(\pi: C \to \mathbb{P}^1\) be a gonality 2 curve.

(a) A line bundle \(L\) on a curve is called special if \(h^1(C, L) > 0\). Show that every special line bundle on \(C\) is of the form
\[
L = r \cdot \pi^* \mathcal{O}_{\mathbb{P}^1}(1) + L_0,
\]
where \(h^0(C, L_0) = 0\) and \(r + 1 = h^0(C, L)\). Conclude that if \(L\) is special, then \(\varphi_L\) is never an embedding.

(b) Show that the smallest degree of an embedding of \(C\) into \(\mathbb{P}^r\) is \(g + r\) (\(r \geq 3\) if \(g \geq 2\)).

**Hint:** Use Exercise (I.1.5).
Bielliptic curves.
A curve $C$ is called bielliptic if it admits a degree 2 map to a nice curve of genus 1.

I.3.16 Let $C$ be a nice curve. Show that $C$ is bielliptic if and only if there exists an involution $\alpha \in \text{Aut}(C)$ such that the induced action of $\alpha$ on the regular differential $H^0(C, K_C)$ has a 1-dimensional $+1$-eigenspace.

**Hint:** What do the differentials in the $+1$-eigenspace correspond to (c.f., Exercise (I.3.4))? 

I.3.17 (Bielliptic genus 2 curves – adapted from Exercise 5.8 of [Poo]) Let $C$ be a nice genus 2 curve over a field $k$ of characteristic not 2. Write $\iota \in \text{Aut}(C)$ for the hyperelliptic involution. Suppose that $C$ has another involution $\alpha \in \text{Aut}(C)$.

(a) Show that $\alpha$ and $\iota$ commute.
(b) Write $Y := C/\langle \alpha \rangle$ and $Y' := C/\langle \alpha \iota \rangle$ for the nice curves corresponding to the fixed fields of $\alpha$ and $\alpha \iota$ acting on $k(C)$ (c.f. Exercise (I.3.2)).
(c) Show that $Y$ and $Y'$ are of genus 1.
(d) Show that there is a diagram of finite covers:

\[
\begin{array}{ccc}
C & \xrightarrow{\pi} & \mathbb{P}^1 \\
\downarrow{f} & & \downarrow{\pi} \\
Y & \xrightarrow{g} & \mathbb{P}^1 \\
\downarrow{g'} & & \downarrow{f'} \\
Y' & & \mathbb{P}^1 \\
\end{array}
\]

(e) What is the ramification of the map $g' \circ f'$: $C \to \mathbb{P}^1$?

**Hint:** This is a Galois extension!

(f) Compute the ramification of $g$, $g'$ and $\alpha$. Show that there is a unique point in $\mathbb{P}^1$ that is a branch point of $g$ and $\alpha$. Show that this is a $k$-point.

**Hint:** All of the squares in the above diagram of curves are Cartesian.

(g) Prove that $Y$ has affine equation

\[ y^2 = h(x) = h_3x^3 + h_2x^2 + h_1x + h_0, \]

for some polynomial $h(x)$ of degree 3.
(h) Prove that $C$ has affine equation $y^2 = h(x^2)$.
(i) Prove that $Y'$ has affine equation

\[ y^2 = h^{\text{rev}}(x) = h_0x^3 + h_1x^2 + h_2x + h_3. \]

(j) Explicitly, what is the action of $\iota$ and $\alpha$ on the vector space $H^0(C, K_C)$? Verify the genus calculations you did.

(k) * Show that $J_C$ is isogenous to $Y \times Y'$.

4. CURVES ON SURFACES

Description of the canonical bundle: Adjunction.
The adjunction formula says that if $C \subseteq X$ is a nice curve on a nice surface, then

\[ K_C = (K_X + C)|_C. \]
Smooth plane curves. In this section, unless otherwise stated, let $C \subseteq \mathbb{P}^2_k$ be a smooth plane curve of degree

$$\deg C = \deg \mathcal{O}_{\mathbb{P}^2}(1)|_C = d.$$

I.4.1 Show that $K_{\mathbb{P}^2} = \det \Omega^1_{\mathbb{P}^2/k} = \mathcal{O}_{\mathbb{P}^2}(-3)$.

**Hint:** Explicitly write down a (meromorphic) top form and compute its divisor. Or, perhaps, construct the Euler sequence

$$0 \rightarrow \mathcal{O}_{\mathbb{P}^2} \rightarrow \mathcal{O}_{\mathbb{P}^2}(1)^{\oplus 3} \rightarrow T_{\mathbb{P}^2} \rightarrow 0,$$

and use the determinant there.

I.4.2 (a) Give a formula for the canonical bundle $K_C$ in terms of line bundles on $\mathbb{P}^2_k$.

(b) Prove the degree-genus formula

$$g = \frac{(d-1)(d-2)}{2}.$$

(c) When $d \geq 3$, prove that the canonical bundle $K_C$ is $(d-3)$-very ample.

**Hint:** Use the adjunction formula.

I.4.3 Compute the gonality of $C$.

**Hint:** This will depend on $\#C(k)$.

I.4.4 (Explicit Adjunction) Suppose that the characteristic of $k$ does not divide $d$ and that $C \subseteq \mathbb{P}^2_k$ is the vanishing of a single homogeneous equation $F(X,Y,Z)$ of degree $d$.

(a) Show that symbolically

$$\frac{X \cdot dY - Y \cdot dX}{\partial F/\partial Z} = \frac{Y \cdot dZ - Z \cdot dY}{\partial F/\partial X} = \frac{Z \cdot dX - X \cdot dZ}{\partial F/\partial Y}.$$

(b) Using this, give an explicit basis for the space of global regular differentials on $C$.

**Hint:** In the first part, use the two identities $dF = 0$ and $d \cdot F = 0$ ($d$ means two different things here!) In the second part, use the first part; why is that expression NOT a differential on the curve? How can you use it to obtain a single regular differential?

I.4.5 Show that the smooth curve $C$ in $\mathbb{P}^2_k$ with equation

$$X^4 + Y^4 = Z^4$$

is bielliptic.

**Hint:** Work this out explicitly, or use Exercise [I.3.16].

I.4.6 For what degrees $d \leq 4$ do all automorphisms of a smooth plane curve of degree $d$ come from automorphisms of $\mathbb{P}^2_k$?

**Hint:** How canonical is the map to $\mathbb{P}^2$?

I.4.7 If $C$ is a smooth plane curve, write $\mathcal{O}_C(k)$ for the restriction of $\mathcal{O}_{\mathbb{P}^2}(k)$ to $C$. Show that every section of $\mathcal{O}_C(k)$ is the restriction of a section of $\mathcal{O}_{\mathbb{P}^2}(k)$. (This means that $C$ is what is called projectively normal.)

**Hint:** What is the kernel of the surjective map of sheaves $\mathcal{O}_{\mathbb{P}^2}(k) \rightarrow \mathcal{O}_C(k)$? Use the long exact sequence in cohomology.
Curves on Hirzebruch surfaces. In this section we make a brief foray into the geometry of surfaces, for the eventual purpose of understanding the curves on these surfaces. For that reason, this section requires a bit more background in algebraic geometry.

A Hirzebruch surface over $Y$ is a surface $S$ that is isomorphic (over $k$) to the projectivization of a rank 2 vector bundle on a nice genus 0 curve $Y$. (We use the Grothendieck convention for projective space: the fiber of $\mathbb{P}(E)$ over point $y \in Y$ is $\mathbb{P}(E_y)$, the space of codimension 1 subspaces in $E_y$.)

I.4.8 Show that every Hirzebruch surface over $\mathbb{P}^1_k$ is isomorphic to $\mathbb{F}_n$, the projective bundle $\mathbb{P}(\mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(n))$ over $\mathbb{P}^1_k$.

**Hint:** Recall the Birkoff-Grothendieck Theorem on vector bundles on $\mathbb{P}^1$. Then show that $\mathbb{P}(E) \cong \mathbb{P}(E \otimes L)$ for any line bundle $L$.

I.4.9 (a) Describe all maps of a curve $C$ to the Hirzebruch surface $\mathbb{P}(E)$. (This should be, in part, reminiscent of the case of maps to projective space as in Exercise (1.1.1).)

(b) A section of a Hirzebruch surface $S$ is a map $Y \to S$, such that post-composition with the projection to $Y$ is the identity. Describe all sections.

(c) Let $\sigma(Y)$ be a the image of a section of $S \to Y$. In terms of your description above, what is the self-intersection $\sigma(Y)^2$?

(d) For $n > 0$, show that the Hirzebruch surface $\mathbb{F}_n$ over $\mathbb{P}^1_k$ has a unique section with negative self-intersection. What is the self-intersection?

I.4.10 Let $n > 0$ and let $C_n$ be the image of the unique section with negative self-intersection on $\mathbb{F}_n$. Let $F$ be a fiber of $\mathbb{F}_n \to \mathbb{P}^1$ over a $k$-point of $\mathbb{P}^1_k$.

(a) Show that the Picard group of $\mathbb{F}_n$ is a free abelian group of rank 2 with generators $C_n$ and $F$.

(b) What is the self-intersection of a curve in class $aC_n + bF$?

(c) Use adjunction on $\mathbb{F}_n$ to determine the canonical class $K_{\mathbb{F}_n}$.

I.4.11 Show that $\mathbb{F}_0 \cong \mathbb{P}^1_k \times \mathbb{P}^1_k$.

(a) Show that the Picard group of $\mathbb{F}_0$ is the free abelian group with generators $F_1$ and $F_2$, the fibers over rational points under the two natural projections. Write $\mathcal{O}(a,b)$ for the line bundle $aF_1 + bF_2$.

(b) Let $C$ be a smooth curve on $\mathbb{P}^1 \times \mathbb{P}^1$ with $\mathcal{O}(C) \cong \mathcal{O}(a,b)$. What is the genus of $C$?

(c) What is the canonical class $K_{\mathbb{F}_0}$?

(d) What is $h^0(\mathbb{P}^1 \times \mathbb{P}^1, \mathcal{O}(a,b))$?

(e) Show that the line bundle $\mathcal{O}(1,1)$ is very ample and describe the embedding into projective space this gives.

I.4.12 (a) (Castelnuovo–Severi inequality) Suppose that $C$ has two independent maps to $\mathbb{P}^1$ of degrees $d_1$ and $d_2$. Then show that the genus $g$ of $C$ satisfies

$$g \leq (d_1 - 1)(d_2 - 1).$$

(b) Use the Castelnuovo–Severi inequality to give another proof that if $g \geq 1$, the hyper-elliptic map on a curve of genus $g$ is unique (up to obvious post-compositions with automorphisms on $\mathbb{P}^1$).

I.4.13 Consider $\mathbb{F}_1$.

(a) Show that the linear system associated to $C_1 + F$ is basepoint-free and describe the associated map.

(b) Show that $\mathbb{F}_1 \cong \text{Bl}_p \mathbb{P}^2_k$ for some point $p \in \mathbb{P}^2(k)$. What is the exceptional divisor of the blowup?
I.4.14 Consider $\mathbb{F}_2$. Show that the linear system associated to $C_2 + 2F$ is basepoint-free and describe the associated map.

I.4.15 Suppose that $Y(k) = \emptyset$. (However, $Y_k \simeq \mathbb{P}_k^1$, see Exercise (I.2.6).)

(a) Show that there exists a rank 2 vector bundle $E$ on $Y$ fitting in the exact sequence

$$0 \to \mathcal{O}_Y \to E \to T_Y \to 0,$$

which is indecomposable over $k$, but for which the base change $E_{\overline{k}} \simeq \mathcal{O}_{\overline{k}}(1) \oplus \mathcal{O}_{\overline{k}}(1)$.

(b) Show that every Hirzebruch surface over $Y$ is isomorphic to $\mathbb{P}(E)$ or $\mathbb{P}(\mathcal{O}_Y \oplus (mK_Y))$.

Which $\mathbb{F}_n$ are these isomorphic to over $\overline{k}$?

(c) Give a more down-to-earth description of $\mathbb{P}(E)$.

(Fun but unnecessary exercise: can you explicitly show that we cannot construct any other indecomposable bundles other than $E$ (and its twists) as extensions of $nT_Y$ by $\mathcal{O}_Y$ by showing that the subvarieties of $\text{Ext}^1(nT_Y, \mathcal{O}_Y)$ parameterizing such a splitting types have no rational points? For example: there are no rank 2 vector bundles on $Y$ that geometrically split as $\mathcal{O}(1) \oplus \mathcal{O}(3)$ coming from $\text{Ext}^1(2T_Y, \mathcal{O}_Y)$.)

5. Canonical curves of low genus

In this section, we will assume that $C$ is a nice curve over a field $k$. Since we already know that if $C$ is hyperelliptic, the canonical map is $2 : 1$ onto a degree $g - 1$ and genus 0 curve in $\mathbb{P}^{g-1}$, we will also assume that $C$ is not hyperelliptic.

I.5.1 Show that every nice curve $C$ over a field $k$ has:

(a) A closed point of degree at most $2g - 2$ over $k$.

(b) Gonality at most $2g - 2$.

(c) Infinitely many closed points of degree at most $2g - 2$ over $k$.

Genus 3 curves.

I.5.2 Show that every non-hyperelliptic curve of genus 3 is a smooth plane quartic curve in $\mathbb{P}^2_k$ and conversely that every smooth plane quartic is a canonical curve of genus 3. What is the gonality of $C$?

Hint: Use adjunction.

I.5.3 * Can you match an “expected” dimension count for the moduli space of genus 3 curves with earlier calculations? Compare this with Exercise (I.1.6). What should be the codimension of the locus of hyperelliptic curves?

Genus 4 curves.

I.5.5 Suppose that $C$ is a nice non-hyperelliptic curve of genus 4.

(a) Show that the canonical map is an embedding

$$\varphi_K : C \hookrightarrow \mathbb{P}_k^3.$$

(b) Show that $C$ lies on a unique quadric surface $Q$. Show that this quadric has rank at least 3 (i.e., it is smooth or a quadric cone).

(c) Show that $C$ lies on a cubic surface $S$ over $k$. How unique is this surface?

(d) Show that $C$ is the complete intersection of $Q$ and $S$.

I.5.6 Show that every smooth complete intersection of a quadric surface and a cubic surface in $\mathbb{P}_k^3$ is a canonical curve of genus 4.

Hint: Use the adjunction formula to understand the canonical bundle.
I.5.7 Suppose that $C$ is a nice non-hyperelliptic curve of genus 4. If 
\[ f: C \to \mathbb{P}^1 \]
is a map of degree 3, show that the fibers of $f$ are 3 collinear points in $\mathbb{P}^3$ (i.e., in the canonical embedding). Show that the line through these points must be contained in the unique quadric containing $C$.

**Hint:** Use exercise (I.1.5).

I.5.8 Suppose that the unique quadric $Q$ containing $C$ is a quadric cone (i.e., $Q$ is the cone over a smooth plane conic $X$).

(a) Show that $C$ admits a unique map of degree 3 to a genus 0 curve (over $k$ and over $\overline{k}$). When is the gonality of $C$ equal to 3?

(b) * Show that the blow up of $Q$ at the cone point is a projective bundle over $X$. When $X$ is $\mathbb{P}^1$, do you recognize $Q$ as the image of a map from a Hirzebruch surface?

(c) * What is the class of $C$ on this Hirzebruch surface?

**Hint:** Use the previous problem; what do lines on a quadric cone look like?

I.5.9 Suppose that the unique quadric $Q$ containing $C$ is a smooth quadric.

(a) Over $\overline{k}$, $Q_{\overline{k}} \simeq \mathbb{P}^1 \times \mathbb{P}^1 = \mathbb{F}_0$. What is the class of $C_{\overline{k}}$ on this surface?

(b) Show that over $\overline{k}$, $C$ admits two maps of degree 3 to a genus 0 curve. Describe these maps geometrically.

(c) Let $L/k$ be the discriminant extension of the quadric $Q$ over $k$; i.e., if $Q$ is represented by a symmetric $4 \times 4$ matrix $A$, then
\[ L = k \left( \sqrt{\det(A)} \right). \]
Show that over $L$, $C_L$ admits two maps of degree 3 to genus 0 curves.

(d) Conversely show that if $C$ admits a degree 3 map to a genus 0 curve over $k$, then $L = k$.

**Hint:** Show that $Q_L$ is isomorphic to the product of two conics.

I.5.10 * Can you match an “expected” dimension count for the moduli space of genus 4 curves with earlier calculations? Compare this with Exercise (I.1.6). What should be the codimension of the locus of hyperelliptic curves?

Genus 5 curves.

I.5.11 Suppose that $C$ is a nice non-hyperelliptic curve of genus 5.

(a) Show that the canonical map is an embedding
\[ \varphi_K: C \hookrightarrow \mathbb{P}^4_k, \]
and exhibits $C$ as a smooth curve of degree 8 and genus 5 in $\mathbb{P}^4_k$.

(b) Show that there is a 3-dimensional vector space of quadratic polynomials on $\mathbb{P}^4_k$ that vanish along $C$. Let $Q_1$, $Q_2$ and $Q_3$ be a choice of three independent quadrics spanning this space.

(c) Show that the complete intersection of three quadrics in $\mathbb{P}^4_k$ is always a canonical curve of genus 5.

**Hint:** Use adjunction.

(d) If $C_{\overline{k}}$ admits a degree 3 map to $\mathbb{P}^1_{\overline{k}}$, show that the ideal of $C$ is not generated by $Q_1$, $Q_2$ and $Q_3$ (i.e., it is not the complete intersection).

**Hint:** Use geometric Riemann-Roch; what can you say about a quadric vanishing at three points on a line?
I.5.12 Let C be a canonical curve of genus 5. Let $Q_1$, $Q_2$ and $Q_3$ be a choice of three independent quadrics spanning the space of quadrics vanishing along $C$.

(a) If $C \subseteq V(Q_1, Q_2, Q_3)$, then show that $V(Q_1, Q_2, Q_3)$ has dimension 2.
(b) Let $S = V(Q_1, Q_2)$ be the surface cut out by the first two quadrics. If $S$ is irreducible, show that any other quadric containing $S$ must be a linear combination of $Q_1$ and $Q_2$.

**Hint:** This goes by the name of Noether’s af + by theorem.

c) Conclude that if $S$ is irreducible, $C = V(Q_1, Q_2, Q_3)$ is a complete intersection.
(d) Show that if $S$ is reducible, it must be the union of a surface of degree 3 and a surface of degree 1. Which one contains $C$?

**Hint:** Show that a surface of degree less than 3 is contained in a hyperplane.

e) A degree 3 surface is a minimal degree surface $T$ called a cubic scroll. Such a surface is the image of a map from $F_1$ or $F_3$. What is this map?

**Hint:** What is the image of the unique curve of negative self-intersection?

(f) Give an intrinsic description of $T$ in $\mathbb{P}^4$.

**Hint:** Which one contains $C$?

I.5.13 Suppose that $\text{gon}(C) = 3$.

(a) Show that $C$ lies on a cubic scroll $T$ and find its class on $T$.
(b) Show that the degree 3 map $C \rightarrow \mathbb{P}^1$ is unique.
(c) Show that $\text{gon}(C) = 3$. (This should be somewhat surprising!)

I.5.14 Now suppose that $\text{gon}(C) > 3$. Then we know that $C$ is the complete intersection of three quadrics in $\mathbb{P}^4$.

(a) Let $Q$ be a singular quadric cone containing $C$. Show that a 2-plane in $Q$ meets $C$ in 4 geometric points. Show that the divisor of these four points defines a map of degree 4 from $C$ to $\mathbb{P}^1$.
(b) Show that if the locus of singular quadrics in the projective space $\mathbb{P}^2$ of quadrics containing $C$ is smooth, then the variety parameterizing degree 4 maps from $C$ to $\mathbb{P}^1$ is a curve of genus 11.

c) **Explicitly, what is this curve?** (E.g., can you write down equations for its function field in terms of equations for $C$?)

I.5.15 **Can you match an “expected” dimension count for the moduli space of genus 5 curves with earlier calculations?** Compare this with Exercise I.1.6. What should be the codimension of the locus of hyperelliptic curves? What should be the codimension of the locus of trigonal curves?

**Genus at least 6 curves.**

I.5.16 Show that a canonical curve $C \subseteq \mathbb{P}^{g-1}$ with $g \geq 6$ is never a complete intersection.

I.5.17 **(If you know something about del Pezzo surfaces)** Descriptions of general canonical curves of genus up to 10 are known, partly worked out in a series of papers Mukai [Muk92, Muk95, Muk10].

(a) Fill in the details for the following: a general canonical curve of genus 6 is a transverse quadric section of a del Pezzo surface of degree 5 in $\mathbb{P}^5$.
(b) What does general mean in the previous sentence?
(c) Can you give a description of every canonical curve of genus 6?

I.5.18 **Try to generalize the results about geometrically trigonal curves:** is it true that if $\text{gon}(C) = 3$ and the genus of $C$ is odd and at least 5, then $\text{gon}(C) = 3$?
CHAPTER 2

Arithmetic

For this section, we focus on the technique of descent for understanding the rational points on a variety. Most of the exercises in the first part of this chapter are done in greater generality than needed in the second part, since this is a robust technique that appears in other contexts. We assume familiarity with (non-abelian) Galois cohomology, for example as in [Ser97].

As in the first chapter, $k$ will denote a perfect field, and $\bar{k}$ an algebraic closure.

1. Twists and Torsors

Twists.

- We always use the left action of $\text{Gal}(\bar{k}/k)$ on $k$, giving a right action on $\text{Spec } k$.

II.1.1 Let $X$ be a $k$-scheme and let $\sigma \in \text{Aut}(k)$, which induces a map $\text{Spec } k \xrightarrow{\sigma} \text{Spec } k$. Write $\sigma X$ for the pullback of $X$ over $\text{Spec } k$ under this map:

$$
\begin{array}{ccc}
\sigma X & \longrightarrow & X \\
\downarrow & & \downarrow \\
\text{Spec } k & \xrightarrow{\sigma} & \text{Spec } k
\end{array}
$$

(The left vertical map is not an morphism of $k$-schemes if $\sigma$ is nontrivial!)

(a) Suppose that $X$ is an affine variety cut out by equations $g_1(x_1, \ldots, x_n), \ldots, g_m(x_1, \ldots, x_m)$. Give equations for $\sigma X$.

(b) Show that $\sigma X(k)$ is in bijection with $X(k)$. (In the affine case, as above, can you make this explicit?)

(c) More generally, let $S$ be any $k$-scheme. Give a bijection

$$
X(S) \rightarrow \sigma X(S) \\
f \mapsto \sigma f
$$

(d) * While $\sigma X$ and $X$ are isomorphic as abstract schemes, give an example of $X$ and $\sigma$ for which $\sigma X$ and $X$ are not isomorphic as $k$-schemes.

**Hint:** It might be helpful to use the universal property of a fiber product.

II.1.2 Let $k'/k$ be a finite Galois extension. Suppose that $X$ is a $k$-scheme. Show that there exists a collection of isomorphisms $(f_\sigma)_{\sigma \in \text{Gal}(k'/k)}$ of $k'$-varieties

$$
f_\sigma : \sigma X_{k'} \rightarrow X_{k'},
$$

such that for all $\sigma, \tau \in \text{Gal}(k'/k)$

$$
(4) 
\quad f_{\sigma \tau} = f_\sigma \sigma (f_\tau).
$$

In other words, such that the following diagram commutes.

$$
\begin{array}{ccc}
\sigma X_{k'} & \xrightarrow{\sigma (f_\tau)} & \sigma X_{k'} \\
\downarrow f_{\sigma \tau} & & \downarrow f_\sigma \\
X_{k'} & \xrightarrow{f_\sigma} & X_{k'}
\end{array}
$$
II.1.3 (Necessity of Condition [4] – adapted from Exercise 4.1 of [Poo17]) Let $\sigma \in \text{Gal}(\mathbb{C}/\mathbb{R})$ be complex conjugation. Suppose that $a_0, \ldots, a_6 \in \mathbb{C}$ are such that
\[
\sigma a_{6-j} = (-1)^j+1 a_j.
\]
Let $X$ be the hyperelliptic curve with affine equation
\[
y^2 = f(x) = a_6 x^6 + a_5 x^5 + a_4 x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0,
\]
over $\mathbb{C}$. Assume that $f(x)$ is separable and $\text{Aut}(X) = \mathbb{Z}/2\mathbb{Z}$ generated by the hyperelliptic involution.

(a) What is the equation of $\sigma X$? Show that $\sigma X$ is isomorphic to $X$ as curves over $\mathbb{C}$.
(b) Show that $X$ is not the base-change of a curve from $\mathbb{R}$ to $\mathbb{C}$.
   **Hint:** In the previous part you wrote down a particular choice of $f_\sigma: \sigma X \to X$. What does any other choice of $\sigma f$ have to look like?
(c) Show that the hypotheses on $f$ and $\text{Aut}(X)$ can be satisfied for some choice of parameters $a_0, \ldots, a_6 \in \mathbb{C}$.
   **Hint:** Any automorphism of $X$ induces an automorphism of the branch points on $\mathbb{P}^1$; the only automorphism acting trivially is the hyperelliptic involution.

II.1.4 Let $k'/k$ be a finite Galois extension and let $X'$ be a quasi-projective $k'$-variety. A $k'/k$-descent datum on $X'$ is a collection of $k'$-isomorphisms $(f_\sigma)_{\sigma \in \text{Gal}(k'/k)}$ satisfying (4).

(a) Formulate what a morphism of $k'$-schemes with $k'/k$-descent data is. What is an isomorphism?
(b) By Weil’s Galois descent, there is an equivalence of categories
\[
\begin{align*}
\{ \text{quasi-projective } k\text{-varieties} \} & \leftrightarrow \{ \text{quasi-projective } k'\text{-varieties with } k'/k\text{-descent data} \}.
\end{align*}
\]
If $X$ is a $k$-variety, what should be the corresponding $k'$-variety with $k'/k$-descent data corresponding to it?
(c) Given that $k'/k$-descent data for $X'$ exists, show that the set of all $k'/k$-descent data is non-canonically isomorphic to $H^1(\text{Gal}(k'/k), \text{Aut}(X'))$.
   **Hint:** After making a choice of one descent datum, what do all other descent data looks like?

II.1.5 Varieties $X$ and $Y$ over $k$ are called twists (or forms) of each other if $X_{\overline{k}} \cong Y_{\overline{k}}$. Given an extension $k'/k$, we say that $X$ and $Y$ are $k'/k$-twists of each other if $X_{k'} \cong Y_{k'}$. A twist $Y$ of $X$ together with a choice of isomorphism $\varphi: X_{k'} \to Y_{k'}$ will be called a rigidified twist.

(a) Let $k'/k$ be a finite Galois extension. Explicitly show that the set of rigidified $k'/k$-twists of a $k$-variety $X$ are in bijection with 1-cocycles
\[
\text{Gal}(k'/k) \to \text{Aut}(X_{k'}).
\]
(b) Show that isomorphism classes of twists of $X$ are canonically isomorphic to the pointed set $H^1(k, \text{Aut}(X_{k'}))$.
   **Hint:** In the first part, verify that the following is the explicit 1-cocycle:
\[
\sigma \mapsto \varphi^{-1}(\sigma \varphi).
\]
In the second part, you may reduce to the case of $k'/k$-twists for $k'/k$ a finite Galois extension by taking appropriate inverse limits. Use your description of isomorphisms of $k'$-varieties with descent data from Exercise (II.1.4).
Classification of torsors under smooth algebraic groups over a field.

- For this section, let $G$ be a smooth algebraic group over the perfect field $k$. Every such group is quasiprojective.
- Recall that a morphism of algebraic groups is a morphism of the underlying varieties that respects the structure morphisms (multiplication, inversion, and identity).
- The trivial $G$-torsor over $k$, denoted $\underline{G}$, is the variety $G$ together with the right action of $G$ on itself by translation.
- A $G$-torsor is a twist of $\underline{G}$, i.e., a variety $X$ over $k$ with a right $G$-action such that $X_{\overline{k}}$ with the right action of $G_{\overline{k}}$ is isomorphic to $\underline{G}_{\overline{k}}$.

**II.1.6** Show that if $X$ is a $G$-torsor over $k$, then $X(\overline{k})$ is a set with a simply transitive right $G(\overline{k})$-action.

**II.1.7** Show that a $G$-torsor $X$ over $k$ is isomorphic to $\underline{G}$ if and only if $X(k) \neq \emptyset$.

**Hint:** Think about the identity section.

**II.1.8** Show that the automorphism group scheme of $\underline{G}$ over $k$ is isomorphic to $G$ acting on $\underline{G}$ by translation on the left. Conclude that $\text{Aut}(\underline{G}) \simeq G(k)$.

**Hint:** An automorphism of $\underline{G}$ is determined by where it sends the identity element.

**II.1.9** (a) Show that the set of isomorphism classes of $G$-torsors over $k$ are in bijection with the pointed set

$$H^1(k, G) := H^1(k, G(\overline{k})).$$

(In addition, can you explicitly write down a cocycle representing the cohomology class of a given torsor? Exercise [II.1.6] might be helpful.)

(b) Show that a torsor is isomorphic to $\underline{G}$ if and only if its cohomology class is the neutral element of $H^1(k, G)$.

**Hint:** For the first part, show that if $x \in X(\overline{k})$ is a geometric point, then for each $\sigma \in \text{Gal}(\overline{k}/k)$, there exists a unique $g_{\sigma} \in G(\overline{k})$ such that

$$\sigma x = x g_{\sigma}$$

and $\sigma \mapsto g_{\sigma}$ is a 1-cocycle representing this torsor.

**II.1.10** Show that every $\mathbb{G}_m$- or $\mathbb{G}_a$-torsor over $k$ is trivial.

**Hint:** Use Hilbert Theorem 90.

**II.1.11** Let $L/k$ be a finite Galois extension with Galois group $G$. Show that $\text{Spec } L$ is a $G$-torsor over $\text{Spec } k$.

**Hint:** What is $L \otimes_k L$?

**II.1.12** Let $C$ be a nice curve over $k$, and assume, to make technical issues with the Picard functor disappear, that $C(k) \neq \emptyset$. Show that the degree $e$ component $\text{Pic}^e_{C/k}$ is a $\text{Pic}^0_{C/k}$-torsor.

**II.1.13** (Twists arising from torsors) Let $G$ be an algebraic group over $k$ and let $X$ be a nice variety over $k$. Suppose that $G$ acts on $X$ on the left.

(a) First, describe “abstractly” a map $H^1(k, G) \rightarrow H^1(k, \text{Aut } X_{\overline{k}})$.

(b) Given a $G$-torsor $T$, the **contracted product** $T \times^G X$ is the quotient of $T \times_k X$ by the free $G$-action

$$(t, x) \mapsto (tg^{-1}, gx).$$

Show that $[T \times^G X]$ is the image of $[T]$ under the map you described above.

(c) $G$ acts on $\underline{G}$ on the left by Exercise [II.1.8]. Describe the map from the first part in this case.
**Hint:** For the second part, write everything out explicitly with cocycles using Exercises II.1.5 and II.1.9.

**II.1.14** (Inner twists) Let \( G \) be an algebraic group over \( k \) with the action on itself by conjugation.

(a) Using the action of inner automorphisms, describe a map of pointed sets 
\[
H^1(k, G) \to H^1(k, \text{Aut}_k G).
\]

The twist \( G^\tau \) corresponding to a class \( \tau \in H^1(k, G) \) is called an inner twist of \( G \).

(b) In terms of a cocycle in \( Z^1(k, G) \), write down a cocycle representing the corresponding inner twist of \( G \).

(c) Is \( G^\tau \) a \( G \)-torsor?

(d) What happens if \( G \) is commutative?

**II.1.15** (Left actions) If \( T \) is a (right) \( G \)-torsor with class \([T] = \tau \in H^1(k, G)\), show that \( T \) is a left \( G^\tau \)-torsor. (So it is a \( G^\tau, G \)-bitorsor.)

**Hint:** Write down everything in terms of cocycles: the trivial torsor has both a left and a right action of \( G \). How does the left action have to be twisted in order to descend to \( T \) over \( k \)?

**II.1.16** (Inverse torsors) Given a (right) \( G \)-torsor \( T \) with class \( \tau \), how can you produce a (right) \( G^\tau \)-torsor? This will be called \( T^{-1} \). (This will be a \( G, G^\tau \)-bitorsor.) What happens if \( G \) is commutative?

**Hint:** The torsor \( T \) is already a left \( G^\tau \)-torsor. Remember that to have a right action, it’s necessary that acting first by \( g \) and then by \( h \) is the same as acting at once by \( gh \). How can you arrange this?

**II.1.17** (Contraction product) As you saw in Exercise II.1.13, if \( T \) is a (right) \( G \)-torsor and \( X \) has a left-action of \( G \), we can define the contraction product \( T \times^G X \) as the quotient of \( T \times X \) by the \( G \)-action \( (t, x) \mapsto (tg^{-1}, gx) \). Similarly, if \( T \) is a left \( G \)-torsor, and \( X \) has a right action of \( G \), we define \( X \times^G T \) as the quotient by \( (x, t) \mapsto (xg, g^{-1}t) \).

Show that if \( Z \) is a right \( G \)-torsor, and \( T \) is a \( G, H \)-bitorsor, then \( Z \times^G T \) is a right \( H \)-torsor.

**II.1.18** (a) Show that \( T^{-1} \times_k^G T \) is the trivial right \( G \)-torsor. (And similarly, \( T \times_k^G T^{-1} \) is the trivial \( G^\tau \)-torsor.)

(b) Show that the contraction product map
\[
H^1(k, G) \to H^1(k, G^\tau)
\]
\[
[Z] \mapsto [Z \times_k^G T]
\]
is a bijection of pointed sets. What is the inverse?

**Torsors over more general bases.**

- More generally, we can consider families of torsors under a smooth algebraic group \( G \) over a field; i.e., a torsor over a base scheme \( S \).
- For the problems in this problem set, it will suffice to consider group schemes over \( S \) that are of the form \( G_S := G \times_k S \) for \( G \) a (smooth) algebraic group over \( k \). We will also assume that \( G \) is affine or an abelian variety (and \( S \) is sufficiently nice) to do away with technical representability problems.
• A (right) \(G\)-torsor over \(S\) (also called by some authors an \(S\)-torsor under \(G_S\)) is an \(S\)-scheme \(X\) with a right action of \(G\)

\[
X \times G \to X \\
(x, g) \mapsto xg
\]

(as \(S\)-schemes!) such that there exists an étale cover \(\{S_i\} \to S\) and an isomorphism

\[
X \times_S S_i \cong G \times_k S_i
\]

of \(S_i\)-schemes.

• Under our assumptions the first Čech étale cohomology

\[
H^1(S, G) := \check{H}^1(S, G)
\]

parameterizes \(G\)-torsor over \(S\) up to isomorphisms. (If you aren’t familiar with this, use your intuition from the case \(k\) a field and take this as a working definition of this pointed set.)

II.1.19 How does the definition of a \(G\)-torsor over \(S\) square with the definition of a torsor over a field?

II.1.20 (Étale Galois covers, compare with Exercise [II.1.11])

(a) Let \(G\) be a finite group and suppose that \(Y \to X\) is an étale \(G\)-cover of curves (c.f. Exercise [I.3.2]). Show that \(Y\) is a \(G\)-torsor over \(X\) for the constant algebraic group \(G\).

(b) * Why is the étale assumption necessary?

(c) What if \(Y \to X\) is defined over \(k\), but is only geometrically a \(G\)-cover, for some constant group \(G\)?

II.1.21 (Homogeneous spaces) Let \(G\) be a (smooth) algebraic group over \(k\) and let \(H\) be a closed (smooth) algebraic subgroup. Suppose that the quotient \(X = G/H\) exists. (This is guaranteed if \(G\) is affine or \(H\) is finite.) Show that \(G\) is an \(H\)-torsor over \(X\).

Hint: Show that étale locally, the map \(G \to X\) has a section.

II.1.22 (Twisted torsor) Let \(G\) be an algebraic group over \(k\) and let \(Z \to S\) be a (right) \(G\)-torsor over \(S\). Suppose that \(T\) is a right \(G\)-torsor over \(k\) with class \(\tau\). Define

\[
Z^\tau := Z \times_k^G T^{-1},
\]

where \(Z \times_k^G T^{-1}\) is the quotient of \(Z \times_k T^{-1}\) by the free action of \(G\) acting on the right on \(Z\) by \(g\) and acting on the left on \(T^{-1}\) by \(g^{-1}\).

(a) Using the way that \(G\) acts on the left on \(T^{-1}\), show that, explicitly, \(Z^\tau\) is quotient of \(Z \times_k T\) by \((z, t) \mapsto (zg, tg)\).

(b) Show that \(Z^\tau\) is a right \(G^\tau\)-torsor over \(S\).

(c) Let \(s: \text{Spec } k \to S\) be a point. Show that the fiber \(Z^\tau_s\) is the trivial \(G^\tau\)-torsor if and only \([Z_s] = \tau \in H^1(k, G)\).

Hint: Use exercise (II.1.18).

II.1.23 (\(n\)-coverings of abelian varieties) Let \(A\) be an abelian variety, and assume that the characteristic of \(k\) is coprime to \(n\). A \(n\)-covering of \(A\) is a pair \((X, \psi)\), where \(X\) is an \(A\)-torsor over \(k\), and \(\psi: X \to A\) is a map such that \(\psi(xa) = \psi(x) + na\).

(a) Show that by the map \(\psi: X \to A\), the variety \(X\) is an \(A[n]\)-torsor over \(A\).
(b) Let τ be the class of ψ⁻¹(e) in \( H^1(k, A[n]) \), for the identity point e ∈ A. Show that the twisted torsor \( X^\tau \) is isomorphic to \( A \).

**Comment:** This shows that every \( n \)-covering \( (X, \psi) \) is a twist of the “standard” \( A[n] \)-torsor \( A \)

(c) The group \( A \) acts on itself by translations (we don’t need to be careful about left/right because it is abelian!) In this way, under the multiplication-by-\( n \) map \( A → A \), the first copy of \( A \) acts on the second copy of \( A \) (an element \( g \) acts as translation by \( ng \)). As in Exercise (II.1.17), show that the resulting contraction product \( X^\mathbb{A} k \), i.e., defined as the quotient of \( X \times_k A \) by the \( gP \mathbb{A} \) action \( p(x,a) \rightarrow \psi(p(x),a) \), is an \( A \)-torsor over \( k \). In fact, show that \( X^\mathbb{A} k \) is an isomorphism of \( A \)-torsors (and hence it is the trivial torsor). Let \( e \) be the identity element of \( A \). Show that the following is a map of \( A \)-torsors

\[
X \rightarrow X^\mathbb{A} k
\]

\[
(x,e) \rightarrow (xg^{-1}, a + ng)
\]

is an \( A \)-torsor over \( k \). In fact, show that the composition with the isomorphism \( (5) \) is the \( n \)-covering map \( \psi \).

**Comment:** This shows that \( n[X] = 0 \) in the Weil-Chatelet group \( H^1(k,A) \). This should make sense if you know the exact sequence

\[
0 \rightarrow \frac{A(k)}{nA(k)} \rightarrow H^1(k, A[n]) \rightarrow H^1(k, A[n]) \rightarrow 0.
\]

**Unramified torsors.** In this section, we make the following simplifying/necessary assumptions.

- Let \( k \) be a number field and let \( v \in \Omega_k \) be a place. Write \( \mathcal{O}_v \) for the valuation ring of \( k_v \).
- Let \( G \) be a finite étale algebraic group over \( k \). Assume that \( S \subset \Omega_k \) is a finite subset of places such that \( G \) spreads out to a finite étale group scheme \( \mathcal{G} \) over \( \mathcal{O}_{k,S} \).
- For a prime \( v \notin S \), we say that \( \tau \in H^1(k,G) \) is unramified at \( v \) if the restriction \( \text{res}_v(\tau) \) to \( k_v \) is in the image of the map

\[
H^1(\mathcal{O}_v, \mathcal{G}) \rightarrow H^1(k_v,G)
\]

restricting to the generic point.

- Using descent, one can show that if \( \tau \) is unramified at all \( v \notin S \) (i.e., unramified outside \( S \)), then \( \tau \) is in the image of

\[
H^1(\mathcal{O}_{k,S}, \mathcal{G}) \rightarrow H^1(k,G).
\]

- Write \( H^1_S(k,G) \subset H^1(k,G) \) for the set of \( \tau \) that are unramified outside \( S \).

**II.1.24** Show that if a \( \tau \in H^1(k,G) \) is unramified at \( v \), then

\[
\text{res}_v(\tau) \in \ker(\mathcal{H}^1(k_v,G) \rightarrow H^1(k_{v}^{\text{nr}},G)),
\]

where \( k_{v}^{\text{nr}} \) is the maximal unramified extension of \( k_v \).

**Hint:** A class is trivial in \( H^1(k_{v}^{\text{nr}},G) \) if and only if the corresponding torsor over \( k_v \) has a point over an unramified extension of \( k_v \).

**II.1.25** Let \( S \) be a finite subset of \( \Omega_k \). Show that \( H^1_S(k,G) \) is finite:
(a) As a $k$-scheme, what is a class $\tau \in H^1(k,G)$? (c.f. Exercise [II.1.11])

(b) For $v \notin S$, as an $O_v$-scheme what is a class in $H^1(O_v,\mathcal{G})$? What does it tell you about part (a) to know that $\text{res}_v(\tau)$ is in the image of $H^1(O_v,\mathcal{G})$?

(c) Show that the fibers of the map

$$H^1_S(k,G) \rightarrow \prod_{v \in S} H^1(k_v,G)$$

are finite.

**Hint:** Use Hermite’s Theorem: there are finitely many extensions of a number field of bounded degree and bounded discriminant.

(d) Show that $H^1(k_v, G)$ is finite.

**Hint:** Again, using Exercise [II.1.11], what do these parameterize?

**II.1.26** Let $S = \{\infty, 2, p_1, \ldots, p_n\}$ be a finite set of rational primes. Describe the set $H^1(\mathbb{Q}, \mu_2)$ and the (finite!) subset $H^1_S(\mathbb{Q}, \mu_2)$.

2. **Descent**

**Evaluation.**

Given a morphism, $\varphi : T \rightarrow S$, we have by functoriality a map

$$H^1(S, G) \xrightarrow{\varphi^*} H^1(T, G)$$

defined by sending the class $[X]$ of a $G$-torsor over $S$ to the class $[X_T]$ is called **evaluation along** $T$.

**II.2.1** (Soft question) Describe the evaluation map along rational points $s : \text{Spec } k \rightarrow S$: 

(a) First, in words, for any $G$-torsor over $S$.

(b) If $G$ is a constant finite group scheme over $S$ (c.f., Exercise [II.1.20]).

(c) When $G$ is an algebraic group, $H$ is a finite subgroup, and $X = G$, considered as an $H$-torsor over $S = G/H$. (It might also be helpful to first think through the case that $S$ is a (finite) group and $G$ is a finite subgroup.)

**II.2.2** Suppose that $H$ is a finite étale subgroup of the algebraic group $G$.

(a) Since

$$1 \rightarrow H(\overline{k}) \rightarrow G(\overline{k}) \rightarrow G/H(\overline{k}) \rightarrow 1$$

is an exact sequence of $\text{Gal}(\overline{k}/k)$-sets, show that we have an exact sequence in Galois cohomology

$$1 \rightarrow H(k) \rightarrow G(k) \rightarrow G/H(k) \xrightarrow{\delta} H^1(k, H(\overline{k})) \rightarrow H^1(k, G(\overline{k}))$$

(b) Show that the boundary map $\delta$ agrees with the evaluation map at $k$-points you described in Exercise [II.2.1].

**Hint:** In the last part, use the explicit description for the cocycle representing a torsor from Exercise [II.1.9] in combination with the explicit description of the coboundary map on Galois cohomology (see Serre Chapter I.5, in particular [Ser97, Section I, Proposition 36], for details).

**II.2.3** (Descent partition of rational points) Let $G$ be a (smooth) algebraic group over $k$ and suppose that $Z$ is a $G$-torsor over a base scheme $X$. Then evaluation gives a partition of the rational points $X(k)$: write $X^\tau(k)$ for the subset of points

$$X^\tau(k) : \{x \in X(k) : [Z_x] = \tau \in H^1(k, G)\}.$$
(a) Show that equivalently \(X^\tau(k) = f^\tau(Z^\tau(k))\), for \(f^\tau : Z^\tau \to X\) the twisted torsor \(Z \times_k^G T^{-1}\) (c.f. Exercise (II.1.22)). Therefore
\[
X(k) = \bigcup_{\tau \in H^1(k,G)} f^\tau(Z^\tau(k)).
\]
(b) Show that if \(X\) is proper over a number field \(k\), then every rational point on \(X\) is the image of a rational point on one of a finite number of twists of \(Z\).

**Hint:** For the second part, if \(Z^\tau\) has a \(k\)-point, then it must have a \(k_v\)-point for all \(v\). Spread out \(X\) and \(Z\) over \(\text{Spec} \mathcal{O}_{k,S}\) for some finite subset \(S\). How can you use the properness of \(X\) in combination with this observation about \(k_v\)-points on \(Z^\tau\)?

**II.2.4** (Chevalley-Weil Theorem) Suppose that
\[
f : Z \to X
\]
is a finite \(\acute{e}tale\) cover of proper varieties over a field \(k\). Show that there exists a finite extension \(k'/k\) such that
\[
X(k) \subseteq f(Z(k')).
\]

**Hint:** Reduce to the case of Galois covers and use Exercise (II.2.3). Or can you use the ideas of Exercise (II.2.3) to prove this directly?

**Classical descent by \(n\)-isogeny.**

Let \(A\) be an abelian variety over a number field \(k\). Write
\[
A[n] := \ker \left( A \xrightarrow{n} A \right)
\]
for the finite group scheme of \(n\)-torsion points on \(A\). We will write \(A[n](k')\) for the points of \(A[n]\) over \(k'\) (i.e., the \(n\)-torsion points defined over \(k'\)).

**II.2.6** (You may have already done this exercise in various parts in previous problems!)

(a) Show that there is an exact sequence of \(G_k\)-modules
\[
0 \to A[n](k) \to A(k) \xrightarrow{n} A(k) \xrightarrow{\delta} H^1(k, A[n](\overline{k}))
\]
(b) Show that \(A \xrightarrow{n} A\) is an \(A[n]\)-torsor over \(A\).
(c) Show that \(\delta\) is the “evaluation map” of the previous section (c.f., (II.2.2)).

**II.2.7** (The weak Mordell–Weil Theorem) Show that \(A(K) / nA(K)\) is finite for every \(n\).

**Hint:** Use the ideas in Exercise (II.2.3) (in combination with the result of (II.1.25)).

**II.2.8** (The descent lemma) Let \(\Gamma\) be a \(\mathbb{Z}\)-module and let \(V\) be a \(\mathbb{Q}\)-vector space containing \(\Gamma / \Gamma_{\text{tors}}\). Let \(x \mapsto Q(x)^2 \in \mathbb{R}\) be a positive quadratic form on \(V\). For some \(n \geq 2\), let \(\gamma_i \in \Gamma\) be representatives of \(\Gamma / n\Gamma\). Suppose that \(Q(\gamma_i)\) is at most a positive constant \(C\) for all \(i\).

(a) Given an element \(y\) and suppose that \(Q(y) \leq mC\). If we write \(y = nx + \gamma_i\), give a bound on \(Q(x)\).
(b) Show that \(\Gamma\) is generated by elements \(x\) with \(Q(x) \leq 2C\).
(c) (If you know about heights...) Let \(A\) be an abelian variety over a number field \(K\). Show that an appropriate height function on \(\Gamma = A(K)\) gives the quadratic form \(Q\). (Or assume this.) Show that \(A(K)\) is finitely generated.

**Hint:** You’ll want to use the weak Mordell-Weil theorem in the last step!
Explicit 2-descent on hyperelliptic Jacobians.

The questions in this section will lead you through a proof that a bound for the rank of the Jacobian of a hyperelliptic curve over a number field \( k \) of odd degree is computable. For this reason, the questions are intended to be done in order.

- For this section \( J \) denotes the Jacobian of an odd degree hyperelliptic curve \( C \) over \( k \) with affine equation
  \[ y^2 = f(x), \quad \text{deg}(f) = 2g + 1. \]
  Since \( C(k) \neq \emptyset \), we have that \( J(k) = \text{Pic}^0(C) \) is the set of line bundles on \( C \).

- Write \( \infty \) for the unique place of \( C \) over \( \infty \) in \( \mathbb{P}^1 \) under the hyperelliptic \( x \)-coordinate map.

- Recall that for a finite set of places \( S \subseteq \Omega_k \), the set \( H^1_S(k, J[2]) \) denotes the isomorphism classes of torsors for \( J[2] \) unramified outside \( S \).

II.2.9 (Warmup: 2-descent on an elliptic curve with rational 2-torsion) For this problem, let \( E \) be an elliptic curve over \( \mathbb{Q} \) with full rational 2-torsion, i.e., with Weierstrass equation
  \[ E : y^2 = (x - e_1)(x - e_2)(x - e_3), \quad e_1, e_2, e_3 \in \mathbb{Q}. \]

(a) Describe the group scheme \( E[2] \). Show that
  \[ H^1(\mathbb{Q}, E[2]) \simeq \mathbb{Q}^x/\mathbb{Q}^x \times \mathbb{Q}^x/\mathbb{Q}^x. \]
  For some prime \( p \), explicitly, what classes are unramified at \( p^2 \)?

(b) What is the Galois cohomology \( H^1(\mathbb{Q}_p, E[2]) \) for each prime \( p \leq \infty \)? (The prime \( \infty \) is to be interpreted as the Archimedean place, so that \( \mathbb{Q}_\infty = \mathbb{R} \).)

(c) Show that the multiplication-by-2 map \( E \xrightarrow{2} E \) corresponds to the function field extension
  \[ \mathbb{Q}(x, y, z, w)/y^2 - (x - e_1)(x - e_2)(x - e_3), z^2 - (x - e_1), w^2 - (x - e_2) \]
  \[ \downarrow \]
  \[ \mathbb{Q}(x, y)/y^2 - (x - e_1)(x - e_2)(x - e_3) \]
  (Warning: this is easier to prove over an algebraically closed field. Over \( \mathbb{Q} \), how do you know that the field extension is not \( z^2 - \lambda(x - e_1) \) for some \( \lambda \in \mathbb{Q}^x \setminus \mathbb{Q}^x \), for example?)

(d) Can you explicitly give equations for all 2-covers of \( E \)? (These correspond to classes in \( H^1(\mathbb{Q}, E[2]) \) by Exercise II.1.23, so the answer should depend on how you answered part (a).)
  **Hint:** It might be helpful to think of \( H^1(\mathbb{Q}, E[2]) \) as the elements of \( \left( \frac{\mathbb{Q}^x}{\mathbb{Q}^x} \right)^3 \) whose product is a square.

(e) Show that the descent map \( \delta \) from the previous section is explicitly given by
  \[ E(\mathbb{Q}) \to H^1(\mathbb{Q}, E(\mathbb{Q})) \simeq \mathbb{Q}^x/\mathbb{Q}^x \times \mathbb{Q}^x/\mathbb{Q}^x \]
  \[ (x_0, y_0) \mapsto (x_0 - e_1, x_0 - e_2) \]
  for all affine points with \( y_0 \neq 0 \). What happens for the remaining points on \( E \)?

(f) Describe the descent partition of rational points on \( E \).

(g) Let \( S \) be the set consisting of the infinite place \( \infty \) and all finite \( p \) which divide \( e_i - e_j \) for some \( i \neq j \in \{1, 2, 3\} \). (Since at least two \( e_i \) have the same parity, the prime 2 is always in \( S \! \)!) Show that the image of \( \delta \) lies in \( H^1_S(\mathbb{Q}, E[2]) \).

(h) Using part (e), give a bound on the rank of any elliptic curve with full 2-torsion in terms of the number of primes in \( S \).
II.2.10 (Explicit 2-descent on an elliptic curve) For this question, let $E$ be the elliptic curve with Weierstrass equation

$$E: y^2 = x(x - 1)(x + 1).$$

(This curve is one of first examples of congruent number elliptic curves. The calculation you are about to do shows that 1 is not a congruent number.)

(a) Look for some points on $E$ by testing $x$ and $y$ values in a box.
(b) Show that $S = \{\infty, 2\}$. Describe $H^1_S(\mathbb{Q}, E[2])$ as explicitly as you can.
(c) Now consider the real place. Show that $\mathbb{R}^* / \mathbb{R}^{*2} \simeq \{\pm 1\}$. Show that $E(\mathbb{R})/2E(\mathbb{R})$ has cardinality two. Identify its image under $\delta_2$:

$$E(\mathbb{R})/2E(\mathbb{R}) \xrightarrow{\delta_2} H^1(\mathbb{R}, E[2]) \simeq \{\pm 1\} \oplus \{\pm 1\}.$$  

**Hint:** How many components does $E(\mathbb{R})$ have? Show that the double of any point is in the identity component.

(d) Using the diagram,

$$E(\mathbb{Q})/2E(\mathbb{Q}) \xleftarrow{\delta} H^1_S(\mathbb{Q}, E[2]) \xrightarrow{\delta} E(\mathbb{R})/2E(\mathbb{R}) \xrightarrow{\delta_2} \{\pm 1\} \oplus \{\pm 1\}$$

what are the local conditions coming from $\infty$?

(e) Now consider the place 2. Find representatives for $\mathbb{Q}_2^* / \mathbb{Q}_2^{*2}$. $E(\mathbb{Q}_2)/2E(\mathbb{Q}_2)$ has cardinality 8. Identify its image under $\delta_2$:

$$E(\mathbb{Q}_2)/2E(\mathbb{Q}_2) \xrightarrow{\delta_2} H^1(\mathbb{Q}_2, E[2])$$

in terms of your generators. What are the analogous local conditions coming from 2?

(f) Show using your local conditions that $E$ has rank 0. (Can you compute the torsion points also to determine $E(\mathbb{Q})$?)

II.2.11 As you can see, in the previous problems two problems, it was very helpful to know the size of $E(\mathbb{Q}_p)/2E(\mathbb{Q}_p)$ to determine the image of $\delta_p$.

(a) Show that the dimension of $E(\mathbb{R})/2E(\mathbb{R})$ as an $\mathbb{F}_2$-vector space is given by $\dim_{\mathbb{F}_2} E(\mathbb{R})[2] - 1$. What happens in general for a Jacobian $J$ at a real place?

(b) If $p \neq 2$, show that the dimension of $E(\mathbb{Q}_p)/2E(\mathbb{Q}_p)$ as an $\mathbb{F}_2$-vector space is $\dim_{\mathbb{F}_2} E(\mathbb{Q}_p)[2]$. What happens in general for a Jacobian $J$ at a finite place not dividing 2?

(c) Show that the dimension of $E(\mathbb{Q}_2)/2E(\mathbb{Q}_2)$ as an $\mathbb{F}_2$-vector space is $\dim_{\mathbb{F}_2} E(\mathbb{Q}_2)[2] + 1$. What happens in general for a Jacobian $J$ at a place above 2?

**Hint:** For finite primes, $J(\mathbb{Q}_p)$ contains a finite index subgroup isomorphic to $\mathbb{Z}_p^\vee$.

II.2.12 (Another 2-descent) Let $E$ be the elliptic curve with Weierstrass equation

$$E: y^2 = x(x - 5)(x + 5).$$

($E$ is another congruent number curve.) Repeat Exercise II.2.10 with this curve. What can you say about its rank?

We’re now ready to start doing this is general, for Jacobians of odd degree hyperelliptic curves!

II.2.13 ($J[2](\bar{k})$ as a $G_k$-module) Let $w_1, \ldots, w_{2g+1}$ denote the zeros of $f(x)$ and let $W_i = (w_i, 0)$ be the corresponding Weierstrass point on $C$. Write $\mathcal{W} = \{W_1, \ldots, W_{2g+1}\}$ for the set of all such points. Let $L = k[T]/f(T)$ denote the étale algebra determined by the polynomial $f$. 

(a) Describe the étale algebra $L$. What happens if $f$ splits completely? What happens if $f$ is irreducible over $k$? Describe the norm map $N_{L/k}$. What does $L = L \otimes_k \kbar$ look like?

(b) Write $\left( \frac{\Z}{2\Z} \right)^W$ for the trivial Galois-module $\Z/2\Z$ induced from $L$ to $k$. (As an $\F_2$-vector space, what is the dimension of this module?) Show that there is a surjective map of $G_k$-modules

$$
\left( \frac{\Z}{2\Z} \right)^W \to J[2]
$$

sending $W_i$ to the line bundle $\mathcal{O}_C(W_i - \infty)$.

(c) Identify the kernel to give an exact sequence of $G_k$-modules

$$
0 \to \frac{\Z}{2\Z} \to \left( \frac{\Z}{2\Z} \right)^W \to J[2] \to 0
$$

Show that this sequence splits.

(d) Give a formula for the $\F_2$-dimension of $J(k)[2]$.

(e) Show that $H^1(k, \Z/2\Z) \cong k^x/k^{x^2}$, and $H^1 \left( k, \left( \frac{\Z}{2\Z} \right)^W \right) \cong \frac{L^x}{L^{x^2}}$.

**Hint:** Use Shapiro’s Lemma to calculate the cohomology of an induced module.

(f) Show that $H^1(k, J[2]) \cong \ker \left( \frac{L^x}{L^{x^2}} \xrightarrow{N_{L/k}} \frac{k^x}{k^{x^2}} \right)$, where $N_{L/k}$ is the norm map from $L$ to $k$.

(g) Think through how the computations in this problem specialize when $J = E$ is an elliptic curve with full 2-torsion over $\Q$.

**II.2.14** (The $x - T$ map) Write $T$ for the image of $T$ from $\kbar[T]$ in $\mathcal{L}$.

(a) Write $\text{Div}_\perp C$ for the group of divisors on $C$ whose support is disjoint from $\mathcal{W} \cup \{ \infty \}$. Show that the map

$$
\begin{align*}
C(\kbar) \setminus (\mathcal{W} \cup \{ \infty \}) & \to \mathcal{L}^x \\
P & \mapsto x(P) - T
\end{align*}
$$

(7)

gives rise to a homomorphism

$$
\text{Div}_\perp C \to L^x.
$$

We call this map the $x - T$ map (for obvious reasons!)

(b) Show that if $D \in \text{Div}_\perp C$ is principal, then $(x - T)(D) \in L^{x^2}$.

(c) Show that the $x - T$ map extends to a well-defined map on all of $\text{Pic}^0(X)$

$$
J(k) = \text{Pic}^0(X) \to \frac{L^x}{L^{x^2}}.
$$

(d) Suppose that $f$ is reducible with factors $f_1$ and $f_2$. Write $D_1 = W_1 + \cdots + W_r$ for the sum of Weierstrass points with $x$ coordinate a root of $f_1$. Can you say where the line bundle $\mathcal{O}(D_1 - r\infty)$ is sent under this map?

(e) In fact, show that the image of $x - T$ is contained in

$$
\ker \left( \frac{L^x}{L^{x^2}} \xrightarrow{N_{L/k}} \frac{k^x}{k^{x^2}} \right).
$$

**Hint:** You can check this last part after base-changing to $\kbar$. 

(f) (If you did the problem earlier about Mumford coordinates) Explicitly, what is the image of point in $J(k)$ under the $x - T$ map whose Mumford coordinates are $(a, b)$.

(g) * Show that the $x - T$ map agrees with the descent map $\delta$ (c.f. Equation [6] for elliptic curves with full 2-torsion).

II.2.15 (The 2-Selmer group) Let $\Omega_k$ denote the set of places of $k$ (including Archimedean places). By restriction to the decomposition group for a place, we have a commutative diagram

$$
\begin{array}{ccc}
0 & \xrightarrow{\delta} & H^1(k, J[2]) \\
\downarrow & & \downarrow \prod_v \text{res}_v \\
0 & \xrightarrow{\prod_v \delta_v} & \prod_v H^1(k_v, J[2])
\end{array}
$$

Define the 2-Selmer set

$$\text{Sel}_J(k, J[2]) := \{ \tau \in H^1(k, J[2]) : \text{res}_v(\tau) \in \text{im}(\delta_v : J(k_v) \to H^1(k_v, J[2])) \text{ for all } v \in \Omega_k \}$$

(a) If $v$ is a finite place of good reduction of $J$ that is not above 2, show that

$$\text{res}_v(\tau) \in \text{im}(\delta_v : J(k_v) \to H^1(k_v, J[2]))$$

if and only if $\tau$ is unramified at $v$.

**Hint:** Use the ideas in Exercise [II.2.3].

(b) Let $S \subset \Omega_k$ denote the set of all Archimedean places, all places above 2, and all places of bad reduction for $J$. Show that we have the following containments

$$\text{im}\left( \frac{J(k)}{2J(k)} \xrightarrow{\delta} H^1(k, J[2]) \right) \subseteq \text{Sel}_J(k, J[2]) \subseteq H^1_S(k, J[2]),$$

and the simpler definition

$$\text{Sel}_J(k, J[2]) = \{ \tau \in H^1_S(k, J[2]) : \text{res}_v(\tau) \in \text{im}(\delta_v) \text{ for all } v \in S \}.$$  

(c) Rephrase the definition of the 2-Selmer group using the concrete explicit descriptions of $H^1(k, J[2])$ and the descent maps $\delta$ and $\delta_v$. (Along the way, explicitly describe in words the set $H^1_S(k, J[2])$ and why it is finite in terms of $L$ above.)

(d) * Give an algorithm to compute the $\mathbb{F}_2$-dimension of $\text{Sel}_J(k, J[2])$.

II.2.16 (Rank calculation for the Jacobian of a genus 3 hyperelliptic curve) This problem leads you through the computation in [Sch95] of the rank of the Jacobian of a genus 3 curve over $\mathbb{Q}$. Let $C$ be the odd degree hyperelliptic curve with affine equation

$$y^2 = x(x - 2)(x - 3)(x - 4)(x - 5)(x - 7)(x - 10).$$

(a) Verify that $(1, \pm 36)$ and $(6, \pm 24)$ are rational points on $C$. We will verify that these two points together with the 8 rational 2-torsion points generate the 2-Selmer group $\text{Sel}_J(\mathbb{Q}, J[2])$.

(b) Show that the set $S$ from the previous problem is $\{ \infty, 2, 3, 5, 7 \}$. Describe $H^1_S(\mathbb{Q}, J[2])$ explicitly.

(c) Show/recall that the descent map is explicitly

$$\frac{J(\mathbb{Q})}{2J(\mathbb{Q})} \xrightarrow{(x-0,x-2,x-3,x-4,x-5,x-7,x-10)} \ker\left( \frac{\mathbb{Q}^\times}{\mathbb{Q}^\times 2} \xrightarrow{N} \mathbb{Q}^\times \right).$$

Recall how to evaluate on a Weierstrass point.
II.2.17 (Rank calculation for the Jacobian of a genus 2 curve without full 2-torsion) Let $C$ be the odd degree hyperelliptic curve over $\mathbb{Q}$ with affine equation
$$y^2 = x^5 + 1$$

(a) Compute $J[2](\mathbb{Q})$.
(b) Show that the set $S$ can be taken to be $S = \{\infty, 2, 5\}$.
(c) Let $\zeta$ be a primitive 5th root of unity. Show that
$$H^1(\mathbb{Q}, J[2]) \cong \frac{\mathbb{Q}(\zeta)^\times}{\mathbb{Q}(\zeta)^{\times 2}}.$$  
Show that in terms of this $\delta$ is the map of $x + \zeta$.
(d) Show that $\{-1, 1 + \zeta, 2, 1 - \zeta\}$ are representatives for the elements of $\frac{\mathbb{Q}(\zeta)^\times}{\mathbb{Q}(\zeta)^{\times 2}}$ that give rise to extensions unramified away from $S$.
**Hint:** The ring of integers of $\mathbb{Q}(\zeta)$ is the PID $\mathbb{Z}[\zeta]$. What is the unit group? How do the primes 2 and 5 factor in $\mathbb{Q}(\zeta)$?
(e) Does $\delta_{\infty}$ give any information?
(f) (Local information at 2)
   (a) What is dim$_{\mathbb{F}_2} J(\mathbb{Q}_5)[2]$?
   (b) Find representatives for $\frac{\mathbb{Q}_5(\zeta)^\times}{\mathbb{Q}_5(\zeta)^{\times 2}}$.
   (c) In terms of your representatives, what is the map from $H^1_{\mathbb{Q}_5}(\mathbb{Q}, J[2])$ to $H^1(\mathbb{Q}_5, J[2])$?
   (d) Can you determine the image of $\delta_5$?
   (e) What does this tell you about $\text{Sel}_J(\mathbb{Q}, J[2]) \subset H^1_{\mathbb{Q}_5}(\mathbb{Q}, J[2])$?
(g) (Local information at 2)
   (a) What is dim$_{\mathbb{F}_2} J(\mathbb{Q}_2)[2]$? What is dim$_{\mathbb{F}_2} J(\mathbb{Q}_2)/2J(\mathbb{Q}_2)$?
   (b) Find representatives for $\frac{\mathbb{Q}_2(\zeta)^\times}{\mathbb{Q}_2(\zeta)^{\times 2}}$.
   **Hint:** Show that you have a decomposition $\mathbb{Q}_2(\zeta)^\times \cong \mathbb{Z} \times \mu_{15} \times (1 + (2))^m$. Every square in $(1 + (2))$ is in $(1 + (2)^2)$. Conversely, Hensel’s Lemma tells you that every element of $(1 + (2)^m)$ for $m$ sufficiently large is a square. Can you make this precise and extract representatives from this?
(c) In terms of your representatives, what is the map from $H^1_S(\mathbb{Q}, J[2])$ to $H^1(\mathbb{Q}_2, J[2])$?

(d) By generating 2-adic points on $J$, can you determine the image of $\delta_2$?

(e) What does this tell you about $\text{Sel}_1(\mathbb{Q}, J[2]) \subset H^1_S(\mathbb{Q}, J[2])$?

(h) Show that $\text{Sel}_1(\mathbb{Q}, J[2])$ is spanned by the image of the 2-torsion point $(-1, 0)$ under $\sigma$. Conclude that $J$ has rank 0.

II.2.18 * Repeat your calculation of the previous example with the curve

$$y^2 = x^5 - 1.$$ 

What happens in this case?

II.2.19 (Genus 1 curves and pencils of quadrics) In this problem, we’ll combine some of the arithmetic and geometric theory to “see” the 2-covers of an elliptic curve $E$ as genus 1, degree 4 space curves. Assume for simplicity that $E$ has full 2-torsion over $\mathbb{Q}$, and hence has Weierstrass equation

$$y^2 = (x - e_1)(x - e_2)(x - e_3).$$

(a) If $C$ is a 2-cover of $E$ (c.f. Exercise (II.1.23)), show that there exists a line bundle $L \in \text{Pic}^4(C)$ giving $\varphi_L : C \hookrightarrow \mathbb{P}^3$. Show that under this embedding $C$ is the base locus of a pencil of quadric hypersurfaces.

(b) On the other hand, 2-covers of $E$ correspond to twists of $E \to E$ by classes in $H^1(\mathbb{Q}, E[2])$. Using your understanding of this group, give another proof that $C$ is an intersection of two quadrics in $\mathbb{P}^3$ by writing down two quadrics generating the pencil.

Hint: You wrote down equations already in Exercise (II.2.9) when $E$ has full 2-torsion.

(c) Show with your explicit equations that $E$ is also the discriminant curve of your pencil of quadrics. Namely, if quadrics $Q_1$ and $Q_2$ generate your pencil, and $A_1$ and $A_2$ are symmetric $3 \times 3$ matrices representing $Q_1$ and $Q_2$, show that the curve with equation

$$y^2 = \det(xA_1 - A_2)$$

is isomorphic to $E$ over $\mathbb{Q}$.

(d) More geometrically, the discriminant curve parameterizes the rulings on the pencil of quadrics. (Make this precise). Assume that $Q_1$ and $Q_2$ generate a pencil of quadrics over $k$ whose discriminant scheme (vanishing of $\det(xA_1 - A_2)$ in $\mathbb{P}^1_k$) is smooth, and write $X$ for the discriminant curve (which may not be an elliptic curve!) Write $B = V(Q_1, Q_2)$ for the base locus curve. Show that $X$ is canonically isomorphic to $\text{Pic}^2_{B/k}$ and that if $X$ has a $k$-point, then the map $B \to X$ is a 2-covering.

Descent with étale Galois covers.

In this section, we work directly with étale $G$-covers of curves and the descent partition of rational points, c.f., Exercise (II.2.3). This can be a powerful technique, since the twists $Z^\tau$ may map to lower-genus curves whose rational points are easier to understand.

II.2.20 (Translating previous exercises into this setup) Suppose that $f : Y \to X$ is a $G$-Galois cover of nice curves over $k$ (c.f. Exercise (I.3.2)).

(a) Explain why it suffices to find the rational points on finitely many curves $Y^\tau$ corresponding to twists $f^\tau : Y^\tau \to X$ in order to determine $X(k)$.

(b) What do these finite set of twists correspond to?

Hint: It suffices for the cover $f : Y \to X$ to spread out to $\mathcal{O}_{k,S}$ and $G$ to spread out to a finite étale group scheme over $\mathcal{O}_{k,S}$. 
II.2.21 (Example with $G = \mathbb{Z}/2\mathbb{Z}$) Suppose that $C$ is a hyperelliptic curve of genus at least 2 over $\mathbb{Q}$ with affine equation

$$y^2 = f_1(x)f_2(x),$$

with $\deg f_1 \geq \deg f_2$, and $f_1$ and $f_2$ square-free with no common factors over $\mathbb{Q}$.

(a) Show that the curve $D$ with (affine) equations

$$y^2 = f_1(x)f_2(x)$$

$$w^2 = f_1(x)$$

is an étale $\mathbb{Z}/2\mathbb{Z}$-cover of $C$. Compute the genus of $D$.

Comment: This is a specific case of Abhyankar’s Lemma.

(b) Show that $D$ maps to the curve $X$ with affine equation

$$w^2 = f_1(x).$$

Compute the genus of $X$.

(c) Describe a finite set $S$ such that the images of the rational points on twists $D^\tau$ corresponding to elements $\tau \in H^1_{f}(\mathbb{Q}, \mathbb{Z}/2\mathbb{Z})$ cover the rational points on $C$. Describe the equations for the covers $f^\tau: D^\tau \to C$.

(d) Show that $D^\tau$ covers an analogous twisted curve $X^\tau$ as in part (b). If $X^\tau(\mathbb{Q})$ is finite for every $\tau \in H^1_{f}(\mathbb{Q}, \mathbb{Z}/2\mathbb{Z})$, how can you compute $C(\mathbb{Q})$?

(e) Carry out this strategy when, as in [RZB15], one wants to find the rational points on the hyperelliptic curve

$$y^2 = x^6 - 5x^4 - 5x^2 + 1,$$

whose Jacobian has rank 2 (and therefore classical Chabauty does not suffice.)

(f) Show that every hyperelliptic curve whose Jacobian has a nontrivial rational 2-torsion point is of this form.

II.2.22 (Chabauty in Magma) Chabauty’s method (combined with a Mordell-Weil sieve to combine information at different primes) is implemented in Magma; you can read about it here: [https://magma.maths.usyd.edu.au/magma/handbook/text/1534](https://magma.maths.usyd.edu.au/magma/handbook/text/1534)

(a) Let $C$ be the hyperelliptic curve with affine model

$$y^2 = x^5 + 1$$

that we encountered in Exercise [II.2.17]. In that exercise, you showed explicitly by hand that the Jacobian has rank 0. Find all of the rational points on $C$ using the magma function Chabauty0.

(b) Let $C$ be the hyperelliptic curve with affine model

$$y^2 = x^5 - 1$$

that we encountered in Exercise [II.2.18]. In that exercise, you showed explicitly by hand that the Jacobian has rank 1. Find all of the rational points on $C$ using the magma function Chabauty.

(c) Here is a list of all genus 2 curves over $\mathbb{Q}$ in the LMFBD that have good reduction away from 2: [https://www.lmfdb.org/Genus2Curve/Q/?hst=List&bad_quantifier=exactly&bad_primes=2&search_type=List](https://www.lmfdb.org/Genus2Curve/Q/?hst=List&bad_quantifier=exactly&bad_primes=2&search_type=List)

You can download this list in a format readable by magma with a link at the bottom of the page. For which of these curves can you use magma’s built in Chabauty methods to compute the rational points?
