

# Classes + Objects

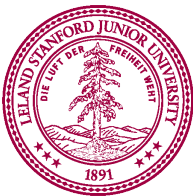

Chris Gregg

Based on Slides by Chris Piech and Mehran Sahami  
CS106A, Stanford University

# Housekeeping

- The Stanford Honor Code
  - CS106A retraction policy
  - Deadline to retract any assignments: August 10th

# Learning Goals

1. Learning about Object-Oriented Programming
2. Writing code using Classes and Objects in Python

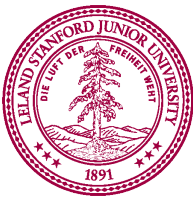

# Object-Oriented Programming (OOP)

It's not a mistake!

# Object-Oriented Programming

- There are different *paradigms* in programming
- So far, you've learned *imperative* programming
  - Provide series of direct commands for program execution
  - Commands are changing the program's *state*
- *Object-oriented* programming
  - Define *objects* that contain data and behavior (functions)
  - Program is (mostly) an interaction between objects
  - You are calling function of objects (called "methods")
- Python allows for programming in either paradigm!
  - Other programming paradigms exist, but we won't talk about those in this class

# What are Classes and Objects?

- Classes are like blueprints
  - They provide a template for a kind of object
  - They define a new **type**
  - E.g., "Human" would be a class
    - Generally, have 2 arms, have two legs, breathe air, etc.
- Objects are *instances* of Classes
  - Can have multiple objects of the same Class type
  - E.g., You would be an instance of the Human class
    - So, you have the properties of your Class (Human)
  - There are lots of other people out there too
    - You are all of type "Human"
    - You are all objects of the same Class

# Example of a Class in Python

- Let's create a Counter class
  - Can ask is for the "next" ticket number
  - Need to keep track of next ticket number
  - Class names start with Uppercase character
  - No `main()` function (Class is **not** a program)

```
class Counter:
```

```
    # Constructor
```

```
    def __init__(self):
```

```
        self.ticket_num = 0    # "instance" variable
```

```
    # Method (function) that returns next ticket value
```

```
    def next_value(self):
```

```
        self.ticket_num += 1
```

```
        return self.ticket_num
```

Let's See It In Action:  
counter.py

# Objects are Mutable

- When you pass an object as a parameter, changes to object in that function persist after function ends

```
from counter import Counter      # import the Class
```

```
def count_two_times(count):  
    for i in range(2):  
        print(count.next_value())
```

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
  
    print('Count1: ')  
    count_two_times(count1)  
  
    print('Count2: ')  
    count_two_times(count2)  
  
    print('Count1: ')  
    count_two_times(count1)
```

Output:

```
Count1:  
1  
2  
Count2:  
1  
2  
Count1:  
3  
4
```

# General Form for Writing a Class

- Filename for class is usually *classname.py*
  - Filename is usually lowercase version of class name in file

```
class Classname:  
  
    # Constructor  
    def __init__(self, additional parameters):  
        body  
        self.variable name = value    # example instance variable  
  
    # Method  
    def method name(self, additional parameters):  
        body
```

# Constructor of a Class

- Constructor

- Syntax:

- ```
def __init__(self, additional parameters):  
    body
```

- Called when a new object is being created

- Does not explicitly specify a return value

- New object is created and returned

- Can think of constructor as the "factory" that creates new objects

- Responsible for initializing object (setting initial values)

- Generally, where instance variables are created (with **self**)

- ```
self.variable name = value    # create instance variable
```

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its **own set** of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
***self.variable name = value***
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its own set of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
`self.variable name = value`
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

```
def __init__(self):  
    self.ticket_num = 0
```

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its own set of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
`self.variable name = value`
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its own set of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
`self.variable name = value`
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

```
def __init__(self):  
    self.ticket_num = 0
```

count1 → 

self.ticket_num	0
-----------------	---

count2 → 

self.ticket_num	0
-----------------	---

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its own set of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
`self.variable name = value`
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

count1 → 

self.ticket_num	0
-----------------	---

count2 → 

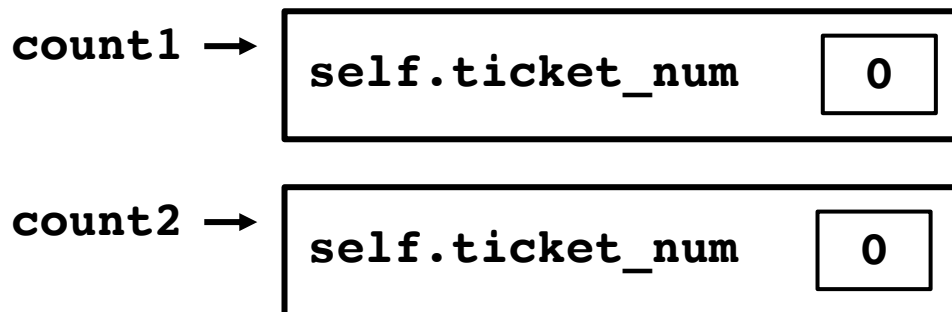

self.ticket_num	0
-----------------	---

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its own set of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
`self.variable name = value`
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

```
def next_value(self):  
    self.ticket_num += 1  
    return self.ticket_num
```

**count1**

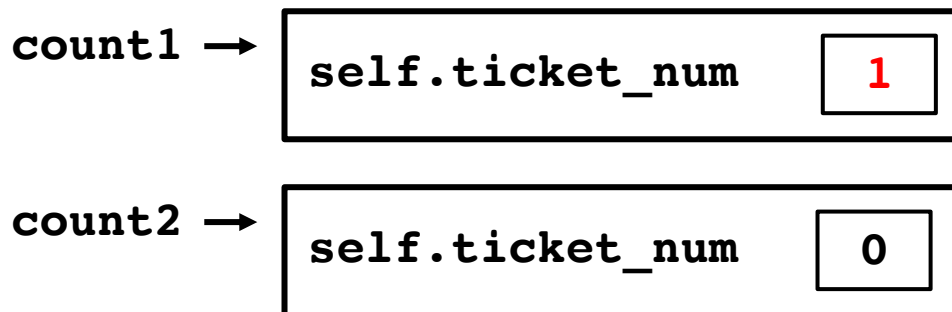

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its own set of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
`self.variable name = value`
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

```
def next_value(self):  
    self.ticket_num += 1  
    return self.ticket_num
```

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its own set of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
`self.variable name = value`
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

count1 → 

self.ticket_num	1
-----------------	---

count2 → 

self.ticket_num	0
-----------------	---

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its own set of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
`self.variable name = value`
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

**count2**

```
def next_value(self):  
    self.ticket_num += 1  
    return self.ticket_num
```

count1 →

self.ticket_num	1
-----------------	---

count2 →

self.ticket_num	0
-----------------	---

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its own set of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
`self.variable name = value`
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

**count2** ↗

```
def next_value(self):  
    self.ticket_num += 1  
    return self.ticket_num
```

count1 → 

self.ticket_num	1
-----------------	---

count2 → 

self.ticket_num	1
-----------------	---

# Instance Variables

- Instance variables are variable associated with objects
  - Each object get its own set of instance variables
  - Generally, they are initialized in constructor for class
  - Instance variables accessed using **self**:  
`self.variable name = value`
  - Self really refers to the object that a method is called on

```
def main():  
    count1 = Counter()  
    count2 = Counter()  
    x = count1.next_value()  
    y = count2.next_value()
```

count1 → 

self.ticket_num	1
-----------------	---

count2 → 

self.ticket_num	1
-----------------	---

# Methods (Functions) in Class

- Methods (name used for functions in objects)
  - Syntax:  

```
def method_name(self, additional parameters):  
    body
```
- Works like a regular function in Python
  - Can return values (like a regular function)
  - Has access to *instance* variables (through **self**):  

```
self.variable_name = value
```
  - Called using an object:  

```
object_name.method_name(additional parameters)
```
  - Recall, parameter **self** is automatically set by Python as the object that this method is being called on
    - You write: **number = count1.next\_value()**
    - Python treats it as: **number = next\_value(count1)**

# Another Example: Students

- Want a Class to keep track information for Students
  - Each student has information:
    - Name
    - ID number
    - Units completed
  - Want to specify a name and ID number when creating a student object
    - Initially, units completed set to 0
  - Student's number of units completed can be updated over time
  - Also want to be able to check if a student can graduate
    - Student needs to have at least **UNITS\_TO\_GRADUATE** units

Bring Me the Students!  
student.py

# Learning Goals

1. Learning about Object-Oriented Programming
2. Writing code using Classes and Objects in Python
