

Classes + Memory

Chris Piech and Mehran Sahami
CS106A, Stanford University

Remember this?

Bouncing Balls

Housekeeping

- Hope you are all doing well

Learning Goals

1. Practice with classes
2. See how to trace memory with classes

Guiding question for today:

what does it take to go from
what you know to writing
big-scale software?

Some *large* programs are in Python

How?

Define New Variable Types

Song

Playlist

User

Song Player

Song Retriever

You Have Been *Using* Variable Types

`SimpleImage`

`Canvas`

`Karel`

`String`

`int`

What would it take to define your own?

type

Classes define new variable
types

Classes decompose your
program across files

Classes are like blueprints

class: A template for a new type of variable.

A blueprint is a helpful analogy

When defining a new variable type you make a blueprint

You must define three things

Instance Variables

1. What **sub-variables** does each instance store?

Instance Methods

2. What **methods** can you call on an instance?

Constructor

3. What happens when you make a **new** one?

*details on how to define these three things coming soon

Classes Review

dog.py

```
class Dog:
    def __init__(self):
        self.times_barked = 0

    def bark(self):
        print('woof')
        self.times_barked += 1
```

life.py

```
def main():
    simba = Dog()
    juno = Dog()

    simba.bark()
    juno.bark()
    simba.bark()

    print(simba.__dict__)
    print(juno.__dict__)
```

Classes Review

dog.py

```
class Dog:
    def __init__(self):
        self.times_barked = 0

    def bark(self):
        print('woof')
        self.times_barked += 1
```

life.py

```
def main():
    simba = Dog()
    juno = Dog()

    simba.bark()
    juno.bark()
    simba.bark()

    print(simba.__dict__)
    print(juno.__dict__)
```

1. What **variables** does each instance store?

Classes Review

dog.py

```
class Dog:
    def __init__(self):
        self.times_barked = 0

    def bark(self):
        print('woof')
        self.times_barked += 1
```

life.py

```
def main():
    simba = Dog()
    juno = Dog()

    simba.bark()
    juno.bark()
    simba.bark()

    print(simba.__dict__)
    print(juno.__dict__)
```

2. What **methods** can you call on an instance?

Classes Review

dog.py

```
class Dog:
    def __init__(self):
        self.times_barked = 0

    def bark(self):
        print('woof')
        self.times_barked += 1
```

life.py

```
def main():
    simba = Dog()
    juno = Dog()

    simba.bark()
    juno.bark()
    simba.bark()

    print(simba.__dict__)
    print(juno.__dict__)
```

3. What happens when you make a **new** one?

.__dict__

pedagogical tool

Classes Review

dog.py

```
class Dog:
    def __init__(self):
        self.times_barked = 0

    def bark(self):
        print('woof')
        self.times_barked += 1
```

life.py

```
def main():
    simba = Dog()
    juno = Dog()

    simba.bark()
    juno.bark()
    simba.bark()

    print(simba.__dict__)
    print(juno.__dict__)
```

Classes Review

dog.py

```
class Dog:
    def __init__(self):
        self.times_barked = 0

    def bark(self):
        print('woof')
        self.times_barked += 1
```

life.py

```
def main():
    simba = Dog()
    juno = Dog()

    simba.bark()
    juno.bark()
    simba.bark()

    print(simba.__dict__)
    print(juno.__dict__)
```

Did I mention that a class is like a fancy dictionary?

What is self?

dog.py

```
class Dog:
    def __init__(self):
        self.times_barked = 0

    def bark(self):
        print('woof')
        self.times_barked += 1
```

life.py

```
def main():
    simba = Dog()
    juno = Dog()

    simba.bark()
    juno.bark()
    simba.bark()

    print(simba.__dict__)
    print(juno.__dict__)
```

When authoring a class, **self** means:
"the instance (aka object) I am currently working with"

What does a `class` do?

A class defines a new variable type

How many variables for the ball?

1. oval
2. change_x
3. change_y

How many variables for 3 balls?

1: Store a list of dictionaries

2: Store a list of Balls

Recall Functions?

Coder: **Function**
Author

Writes helper functions
others can use

Coder: **Function**
Caller

Uses helper functions

Classes also split up the work!

Coder: **Class**

Author

Writes the class (often in its own file), thus defining a new variable type

Coder: **Class**

Client

Uses the new variable type to solve problems (often from main).

Because they are classy

```
bouncing_balls.py
9 def main():
10     # gotta have a canvas!
11     canvas = Canvas(CANVAS_WIDTH, CANVAS_HEIGHT,
12                     title="Bouncing Balls")
13     balls = create_balls(canvas)
14     while True:
15         # update world
16         for ball in balls:
17             ball.update(canvas)
18         # redraw canvas
19         canvas.update()
20         time.sleep(1/50.)
21
22 def create_balls(canvas):
23     balls = []
24     for i in range(N_BALLS):
25         ball = Ball(canvas)
26         balls.append(ball)
27     return balls
28
29 if __name__ == '__main__':
30     main()
```

Class Client: Uses the new variable type to solve problems (often from main).

```
ball.py
1 import random
2 from constants import *
3
4 class Ball:
5     """
6     This is the blueprint for a new variable type.
7     Every ball has three things: an oval, a change in position, and a color.
8     Every ball supports the "update" method which updates its position and color.
9
10    When defining a new variable type you must specify:
11    (1) What happens when you create a new instance of the class.
12    (2) What sub-variables does every instance have.
13    (3) What methods (aka functions) can you call on the instance.
14
15    """
16
17    # (1) This defines the "constructor": what happens when you create a new instance of type Ball. Note the use of 'canvas' parameter.
18    def __init__(self, canvas):
19        # When making a new ball, first choose its position and color.
20        x_1 = random.randint(0, CANVAS_WIDTH - BALL_DIAMETER)
21        y_1 = random.randint(0, CANVAS_HEIGHT - BALL_DIAMETER)
22        x_2 = x_1 + BALL_DIAMETER
23        y_2 = y_1 + BALL_DIAMETER
24        color = random.choice(COLORS)
25        self.oval = canvas.create_oval(x_1, y_1, x_2, y_2, fill=color, stroke='black', strokewidth=1)
26        self.change_x = random.choice([-1, 1]) * BALL_SPEED
27        self.change_y = random.choice([-1, 1]) * BALL_SPEED
28        self.color = color
```

Class Author: Writes the class, thus defining a new variable type (often in its own file)

Next step in writing large programs:
Better understand memory

You are now ready...

What does this do?

```
def main():  
    x = 5  
    print(id(x))  
    x += 1  
    print(id(x))
```

What does this do?

```
def main():  
    x = 5  
    print(id(x))  
    x += 1  
    print(id(x))
```

What does this do?

```
def main():  
    x = 5  
    print(id(x))  
    x += 1  
    print(id(x))
```

What does this do?

```
def main():  
    x = 5  
    print(id(x))  
    x += 1  
    print(id(x))
```

What does this do?

```
def main():  
    x = 5  
    print(id(x))  
    x += 1  
    print(id(x))
```

What does this do?

```
def main():  
    x = 5  
    print(id(x))  
    x = x + 1  
    print(id(x))
```

What does this do?

```
def main():  
    x = 5  
    print(id(x))  
    x = x + 1  
    print(id(x))
```

What does this do?

```
def main():  
    x = 5  
    print(id(x))  
    x = x + 1  
    print(id(x))
```

What does this do?

```
def main():  
    x = 5  
    print(id(x))  
    x = x + 1  
    print(id(x))
```

The stack

Each time a function is called, a new frame of memory is created.

Each frame has space for all the local variables declared in the function, and parameters

Each variable has a reference which is like a URL

When a function returns, its frame is destroyed.

The heap

<u>4563589904</u>
int
0
5

type

ref count

Where values are stored

Every value has an address
(like a URL address)

Values don't go away when
functions return

Memory is recycled when its
no longer used.

<u>4563589936</u>
int
1
6

type

ref count

value

Deconstructed Samosa

```
def main():  
    x = 5  
    x = x + 1
```

What does this do?

```
def main():  
    x = 5  
    x = x + 1
```

When a variable is “assigned”
via binding you are changing its
reference

You know a variable is being
assigned to if it is on the left
hand side of an = sign

What does this do?

```
def main():  
    x = 5  
    x = x + 1
```

When a variable is “used”
you are accessing its **value**

What does this do?

```
def main():
```

```
    x = 5
```

```
    binky(9)
```

```
def binky(y):  
    pinky(y)
```

```
def pinky(z):  
    print(z)
```

What does this do?

```
def main():  
    x = 5  
    binky(9)
```

```
def binky(y):  
    pinky(y)
```

```
def pinky(z):  
    print(z)
```

What does this do?

```
def main():  
    x = 5  
    binky(9)  
  
def binky(y):  
    pinky(y)  
  
def pinky(z):  
    print(z)
```

What does this do?

```
def main():
```

```
    x = 5
```

```
    binky(9)
```

```
def binky(y):
```

```
    pinky(y)
```

```
def pinky(z):
```

```
    print(z)
```

Challenge: Trace This!

dog.py

```
class Dog:
    def __init__(self):
        self.times_barked = 0

    def bark(self):
        print('woof')
        self.times_barked += 1
```

life.py

```
def main():
    simba = Dog()
    juno = Dog()

    simba.bark()
    juno.bark()
    simba.bark()

    print(simba.__dict__)
    print(juno.__dict__)
```

Learning Goals

1. Practice with classes
2. See how to trace memory with classes

Guiding question for today:

what does it take to go from
what you know to writing
big-scale software?

Bouncing Balls

What does a `class` do?

A class defines a new variable type
