Programming Abstractions
Spring 2018
Stanford University
Computer Science Department

Lecturer: Chris Gregg

reading:
Programming Abstractions in C++, Chapter 3 - 4
Today's Topics

• Logistics:
  • You should find out about sections by Tuesday at 5pm.
  • Assignment 1 is due Thursday. Submit at https://cs198.stanford.edu
  • LAiR is open!
  • CS106S (CS for Social Good) still has spots! It meets 3:30-5:20 on Fridays (right after class!) in 380-380D. Email ashi.agrawal@stanford.edu for an enrollment code.

• Vector review and Big-O with Vectors
• Strings
  • C++ strings vs C strings
  • Characters
• Member Functions
• Stanford Library extensions
• Char and <cctype>
As we discussed earlier, a Vector is simply an array under the hood:

In your computer's memory, an array is just a series of contiguous locations where you can put one value after another, and the computer can access those values with random access by the index of the value:

what is the index for `ages[2]`? 2
what is the value for `ages[2]`? 15

By the way: `ages[2]` is an overloaded function, identical to `ages.get(2)`
As we discussed yesterday, a Vector is simply an array under the hood:

What is the Big O for accessing an element in a Vector? E.g., what is the Big O for the following:

ages[2]?

**Big O(1): Constant, because the computer can immediately access the value, and it doesn't matter if there are four values in the Vector, or four million.**
Let's look at the Big O for the other Vector functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Big O (worst case)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>vec.size()</code></td>
<td>O(1)</td>
</tr>
<tr>
<td>Returns the number of elements in the vector.</td>
<td></td>
</tr>
<tr>
<td><code>vec.isEmpty()</code></td>
<td>O(1)</td>
</tr>
<tr>
<td>Returns true if the vector is empty.</td>
<td></td>
</tr>
<tr>
<td><code>vec[i]</code></td>
<td>O(1)</td>
</tr>
<tr>
<td>Selects the ( i )th element of the vector.</td>
<td></td>
</tr>
<tr>
<td><code>vec.add(value)</code></td>
<td>O(1)</td>
</tr>
<tr>
<td>Adds a new element to the end of the vector.</td>
<td></td>
</tr>
<tr>
<td><code>vec.insert(index, value)</code></td>
<td>O(n)</td>
</tr>
<tr>
<td>Inserts the value before the specified index position.</td>
<td></td>
</tr>
<tr>
<td><code>vec.remove(index)</code></td>
<td>O(n)</td>
</tr>
<tr>
<td>Removes the element at the specified index.</td>
<td></td>
</tr>
<tr>
<td><code>vec.clear()</code></td>
<td>O(1)</td>
</tr>
<tr>
<td>Removes all elements from the vector.</td>
<td></td>
</tr>
</tbody>
</table>
Vectors and Big O

Can we do better than $O(n)$ (worst case) for `vec.remove(index)`?

It depends! Let's assume that the Vector is completely unordered:

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>8</td>
<td>3</td>
<td>13</td>
<td>49</td>
<td>82</td>
<td>27</td>
<td>19</td>
</tr>
</tbody>
</table>

How does `vec.remove(2)` work?
The Vector's remove(int index) function might look like this, assuming the internal array is called vec, and the number of elements in the array is called count:

```java
for (int i=index; i < count-1; i++) {
    vec[i] = vec[i+1];
}
count--;```

For `vec.remove(2)`, the loop moves 13 to index 2, then 49 to index three, etc., all the way up to the end of the array.
Vectors and Big O

The Vector's `remove(int index)` function might look like this, assuming the internal array is called `vec`, and the number of elements in the array is called `count`:

```java
for (int i=index; i < count-1; i++) {
    vec[i] = vec[i+1];
}
count--;
```

![Diagram]

For `vec.remove(2)`, the loop moves 13 to index 2, then 49 to index three, etc., all the way up to the end of the array.
The Vector's remove(int index) function might look like this, assuming the internal array is called vec, and the number of elements in the array is called count:

```java
for (int i=index; i < count-1; i++) {
    vec[i] = vec[i+1];
}
count--;
```

For `vec.remove(2)`, the loop moves 13 to index 2, then 49 to index three, etc., all the way up to the end of the array.
The Vector's remove(int index) function might look like this, assuming the internal array is called vec, and the number of elements in the array is called count:

```java
for (int i=index; i < count-1; i++) {
    vec[i] = vec[i+1];
}
count--;  // count = 8
```

For `vec.remove(2)`, the loop moves 13 to index 2, then 49 to index three, etc., all the way up to the end of the array.
The Vector's remove(int index) function might look like this, assuming the internal array is called vec, and the number of elements in the array is called count:

```java
for (int i=index; i < count-1; i++) {
    vec[i] = vec[i+1];
}
```

```java
vec[i] = vec[i+1];
```

```java
count--;
```

For `vec.remove(2)`, the loop moves 13 to index 2, then 49 to index three, etc., all the way up to the end of the array.
The Vector's remove(int index) function might look like this, assuming the internal array is called vec, and the number of elements in the array is called count:

```java
for (int i=index; i < count-1; i++) {
    vec[i] = vec[i+1];
}
count--;
```

For `vec.remove(2)`, the loop moves 13 to index 2, then 49 to index three, etc., all the way up to the end of the array.
Vectors and Big O

The Vector's remove(int index) function might look like this, assuming the internal array is called vec, and the number of elements in the array is called count:

<td>49</td>
<td>82</td>
<td>27</td>
<td>19</td>
</tr>
</tbody>
</table>
Vectors and Big O

Let's look at a program to test this!
Strings (3.1)

#include<string>
...
string s = "hello";

• A string is a sequence of characters, and can be the empty string: ""
• In C++, a string has "double quotes", not single quotes:
  "this is a string"
  'this is not a string'
• Strings are similar to Java strings, although the functions have different names and in some cases different behavior.
• The biggest difference between a Java string and a C++ string is that C++ strings are mutable (changeable).
• The second biggest difference is that in C++, we actually have two types of strings (more on that in a bit)
Strings are made up of characters of type `char`, and the characters of a string can be accessed by the index in the string:

```cpp
string s = "Fear the Tree";
```

<table>
<thead>
<tr>
<th>index</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
<th>11</th>
<th>12</th>
</tr>
</thead>
<tbody>
<tr>
<td>character</td>
<td>'F'</td>
<td>'e'</td>
<td>'a'</td>
<td>'r'</td>
<td>' '</td>
<td>'t'</td>
<td>'h'</td>
<td>'e'</td>
<td>' '</td>
<td>'T'</td>
<td>'r'</td>
<td>'e'</td>
<td>'e'</td>
</tr>
</tbody>
</table>

```cpp
char c1 = s[3]  // 'r'
char c2 = s.at(2)  // 'a'
```

Notice that `char`s have *single quotes* and are limited to one ASCII character. A space char is ' ', not '' (in fact, '' is not a valid char at all. It is hard to see on the slide, but there is an actual space character between the single quotes in a valid space `char`, and there is no space in the not-valid example)
• Characters have a numerical representation,
  `cout << (int) 'A' << endl; // 65`
• This means you can perform math on characters, but you need to be careful:

```cpp
string plainText = "ATTACK AT DAWN";
string cipherText = "";
int key = 5; // caesar shift by five

// only works for uppercase!
for (int i=0;i<(int)plainText.length();i++) {
    char plainChar = plainText[i];
    char cipherChar;
    if (plainChar >= 'A' && plainChar <= 'Z') {
        cipherChar = plainText[i] + key;
        if (cipherChar > 'Z') {
            cipherChar -= 26; // wrap back around
        }
    } else {
        cipherChar = plainChar;
    }
    cipherText += cipherChar;
}

cout << "Plain text: " << plainText << endl;
cout << "Cipher text: " << cipherText << endl;
```

Output:
Plain text: ATTACK AT DAWN
Cipher text: FYYFHP FY IFBS
String Operators (3.2)

• As in Java, you can concatenate strings using + or +=
  
  string s1 = "Chris";
  string s2 = s1 + "Gregg"; // s2 == ChrisGregg

• Unlike in Java, you can compare strings using relational operators:
  
  string s3 = "Zebra";
  if ((s1 > s3) && (s3 != "Walrus")) { // false
      ...
  }

• Unlike in Java, strings are mutable and can be changed (!):
  
  • s3.append("Giraffe"); // s2 is now "ZebraGiraffe"
  • s3.erase(4,3); // s2 is now "Zebrraffe" (which would be a very cool animal)
  • s3[5] = 'i'; // s2 is now "Zebriffe"
  • s3[9] = 'e'; // BAD!!!1! PROGRAM MAY CRASH! POSSIBLE BUFFER OVERFLOW! NO NO NO!

• Unlike in Java, C++ does not bounds check for you! The compiler doesn't check for you, and Qt Creator won't warn you about this. We have entered the scary territory of "you must know what you are doing". Buffer overflows are a critical way for viruses and hackers to do their dirty work, and they can also cause hard to track down bugs.
## String Member Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>s.append(str)</code></td>
<td>add text to the end of a string</td>
</tr>
<tr>
<td><code>s.compare(str)</code></td>
<td>return -1, 0, or 1 depending on relative ordering</td>
</tr>
<tr>
<td><code>s.erase(index, length)</code></td>
<td>delete text from a string starting at given index</td>
</tr>
<tr>
<td><code>s.find(str)</code></td>
<td>first or last index where the start of <code>str</code> appears in this string (returns <code>string::npos</code> if not found)</td>
</tr>
<tr>
<td><code>s.rfind(str)</code></td>
<td>first or last index where the start of <code>str</code> appears in this string (returns <code>string::npos</code> if not found)</td>
</tr>
<tr>
<td><code>s.insert(index, str)</code></td>
<td>add text into a string at a given index</td>
</tr>
<tr>
<td><code>s.length()</code> or <code>s.size()</code></td>
<td>number of characters in this string</td>
</tr>
<tr>
<td><code>s.replace(index, len, str)</code></td>
<td>replaces <code>len</code> chars at given index with new text</td>
</tr>
<tr>
<td><code>s.substr(start, length)</code> or <code>s.substr(start)</code></td>
<td>the next <code>length</code> characters beginning at <code>start</code> (inclusive); if <code>length</code> omitted, grabs till end of string</td>
</tr>
</tbody>
</table>

```cpp
string name = "Donald Knuth";
if (name.find("Knu") != string::npos) {
    name.erase(7, 5); // "Donald"
}
```
C++ vs C strings

• C++ has (confusingly) two kinds of strings:
  • C strings (char arrays), inherited from the C language  
  • C++ strings (string objects), which is part of the standard C++ library.

• When possible, declare C++ strings for better usability (you will get plenty of C strings in CS 107!)

• Any string literal such as "hi there" is a C string.

• C strings don't have member functions, and you must manipulate them through regular functions.  
  *You also must manage the memory properly -- this is SUPER IMPORTANT and involves making sure you have allocated the correct memory -- again, this will be covered in detail in CS 107.*

• E.g., C strings do not have a .length() function (there are no member functions, as C strings are not part of a class.

• You can convert between string types:
  • string("text") converts C string into C++ string 
  • string.c_str() returns a C string out of a C++ string
C string issues

```cpp
string s1 = "hi" + "there";
• Does not compile; C strings can't be concatenated with +.

string s2 = string("hi") + "there";
string s3 = "hi"; // "hi" is auto-converted to string
s += "there";
• These all compile and work properly.

int n = (int) "42";
• Bug; sets n to the memory address of the C string "42" (ack!). Qt Creator will produce an error, too

int n = stringToInteger("42");
• Works, because of explicit conversion of "42" to a C++ string (and stringToInteger() is part of the Stanford C++ library)
```
C string issues

```cpp
string s = "hi" + '?'; // C-string + char
string s = "hi" + 41;  // C-string + int

• Both bugs. Produces garbage, not "hi?" or "hi42". (memory address stuff)

string s = string("") + "hi" + '?'
• does work because of the empty C++ string at the beginning

string s = "hi"; // char '?' is concatenated to string
s += '?'; // "hi?"
• Works, because of auto-conversion.

• s += 41; // "hi?)"
• Adds character with ASCII value 41, ') ', doesn't produce "hi?41".

s += integerToString(41); // "hi?41"
• Works, because of conversion from int to string.
```
```c++
void mystery(string a, string &b) {
    a.erase(0,1);
    b += a[0];
    b.insert(3, "FOO");
}

int main() {
    string a = "Stanford";
    string b = "Tree";
    mystery(a,b);
    cout << a << " " << b << endl;
    return 0;
}
```

Answer: Stanford TreeFOOet
#include "strlib.h"
These are not string class functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>endsWith(str, suffix)</code></td>
<td>returns <strong>true</strong> if the given string begins or ends with the given prefix/suffix text</td>
</tr>
<tr>
<td><code>startsWith(str, prefix)</code></td>
<td>return a conversion between numbers and strings</td>
</tr>
<tr>
<td><code>integerToString(int)</code></td>
<td></td>
</tr>
<tr>

<td><strong>true</strong> if s1 and s2 have same chars, ignoring casing</td>
</tr>
<tr>
<td><code>toLowerCase(str)</code></td>
<td>returns an upper/lowercase version of a string</td>
</tr>
<tr>
<td><code>toUppercae(str)</code></td>
<td>returns string with surrounding whitespace removed</td>
</tr>
</tbody>
</table>

```java
if (startsWith(nextString, "Age: ")) {
    name += integerToString(age) + " years old";
}
```
Recap

• **Strings**
  • C++ has both C strings and C++ strings. Both are, under the hood, simply arrays of characters. C++ strings handle details for you automatically, C-strings do not.
  • C++ strings are much more functional and easier to use
  • Many times (but not always), C-strings auto-convert to C++ strings when necessary
  • Characters are single-quoted, single-character ASCII numerical values (be careful when applying arithmetic to them)
  • C++ strings have many functions you can use, e.g., `s.length()` and `s.compare()`
  • The Stanford library also has some extra string functions, which are not part of the string class, but are helpful
References and Advanced Reading

References (in general, not the C++ references!):
• Textbook Chapter 3
• `<cctype>` functions: http://en.cppreference.com/w/cpp/header/cctype
• Code from class: see class website (https://cs106b.stanford.edu)
• Caesar Cipher: https://en.wikipedia.org/wiki/Caesar_cipher

Advanced Reading:
• C++ strings vs C strings: http://cs.stmarys.ca/~porter/csc/ref/c_cpp_strings.html
• String handling in C++: https://en.wikipedia.org/wiki/C%2B%2B_string_handling
• Stackoverflow: Difference between string and char[] types in C++: http://stackoverflow.com/questions/1287306/difference-between-string-and-char-types-in-c
Write a function called `nameDiamond` that accepts a string as a parameter and prints it in a "diamond" format as shown below.

- For example, `nameDiamond("CHRIS")` should print:

```plaintext
C
CH
CHR
CHRI
CHRIS
HRIS
RIS
IS
S
```
String Exercise Possible Solution

One possible solution (break into two parts!)

```cpp
void nameDiamond(string s) {
    int len = (int)s.length(); // cast length to int to avoid warning
    // print top half of diamond
    for (int i = 1; i <= len; i++) {
        cout << s.substr(0, i) << endl;
    }
    // print bottom half of diamond
    for (int i = 1; i < len; i++) {
        for (int j = 0; j < i; j++) {
            // indent
            cout << " ";
        }
        cout << s.substr(i, len - i) << endl;
    }
}
```
