

Minimum Spanning Trees

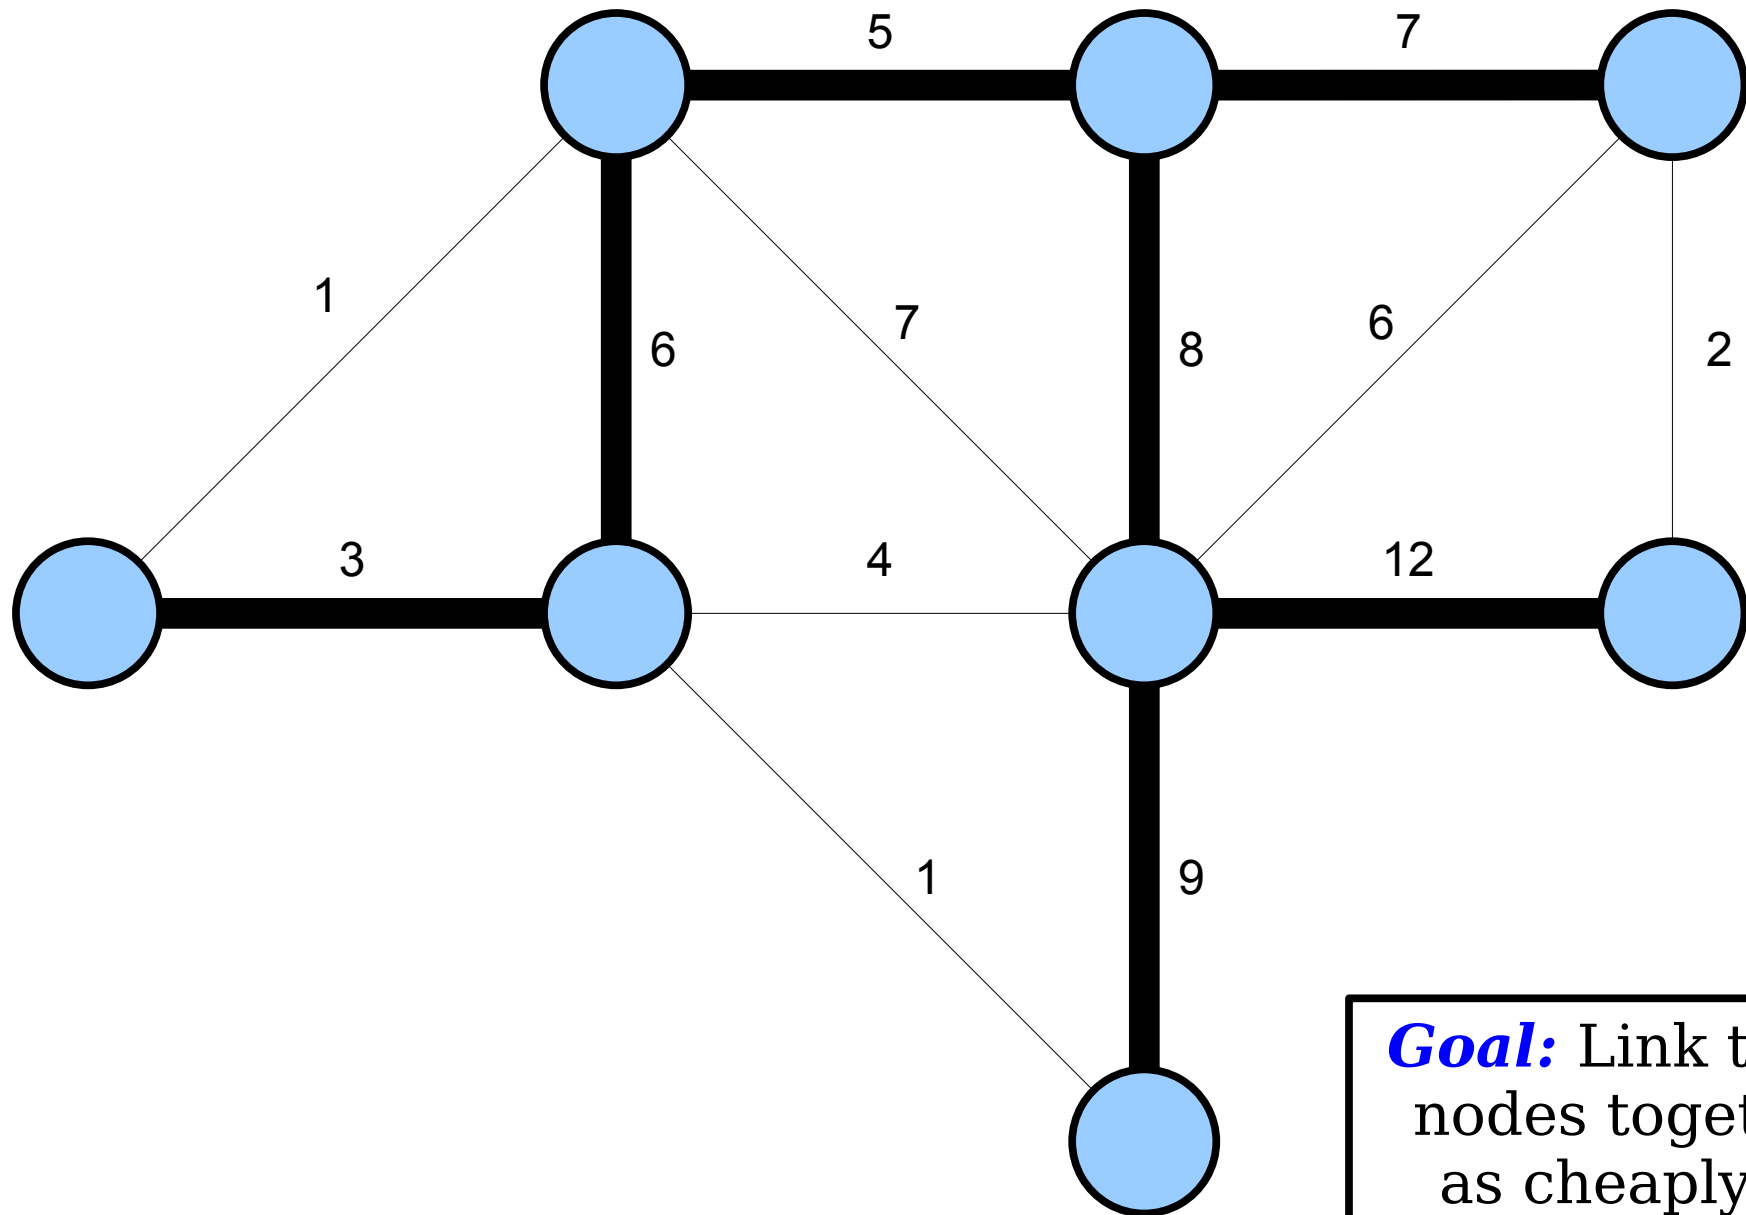

Outline for Today

- ***Minimum Spanning Trees***
 - Wiring things cheaply.
- ***Kruskal's Algorithm***
 - A beautiful and elegant algorithm.
- ***Applications of MSTs***
 - ...to lots of problems!

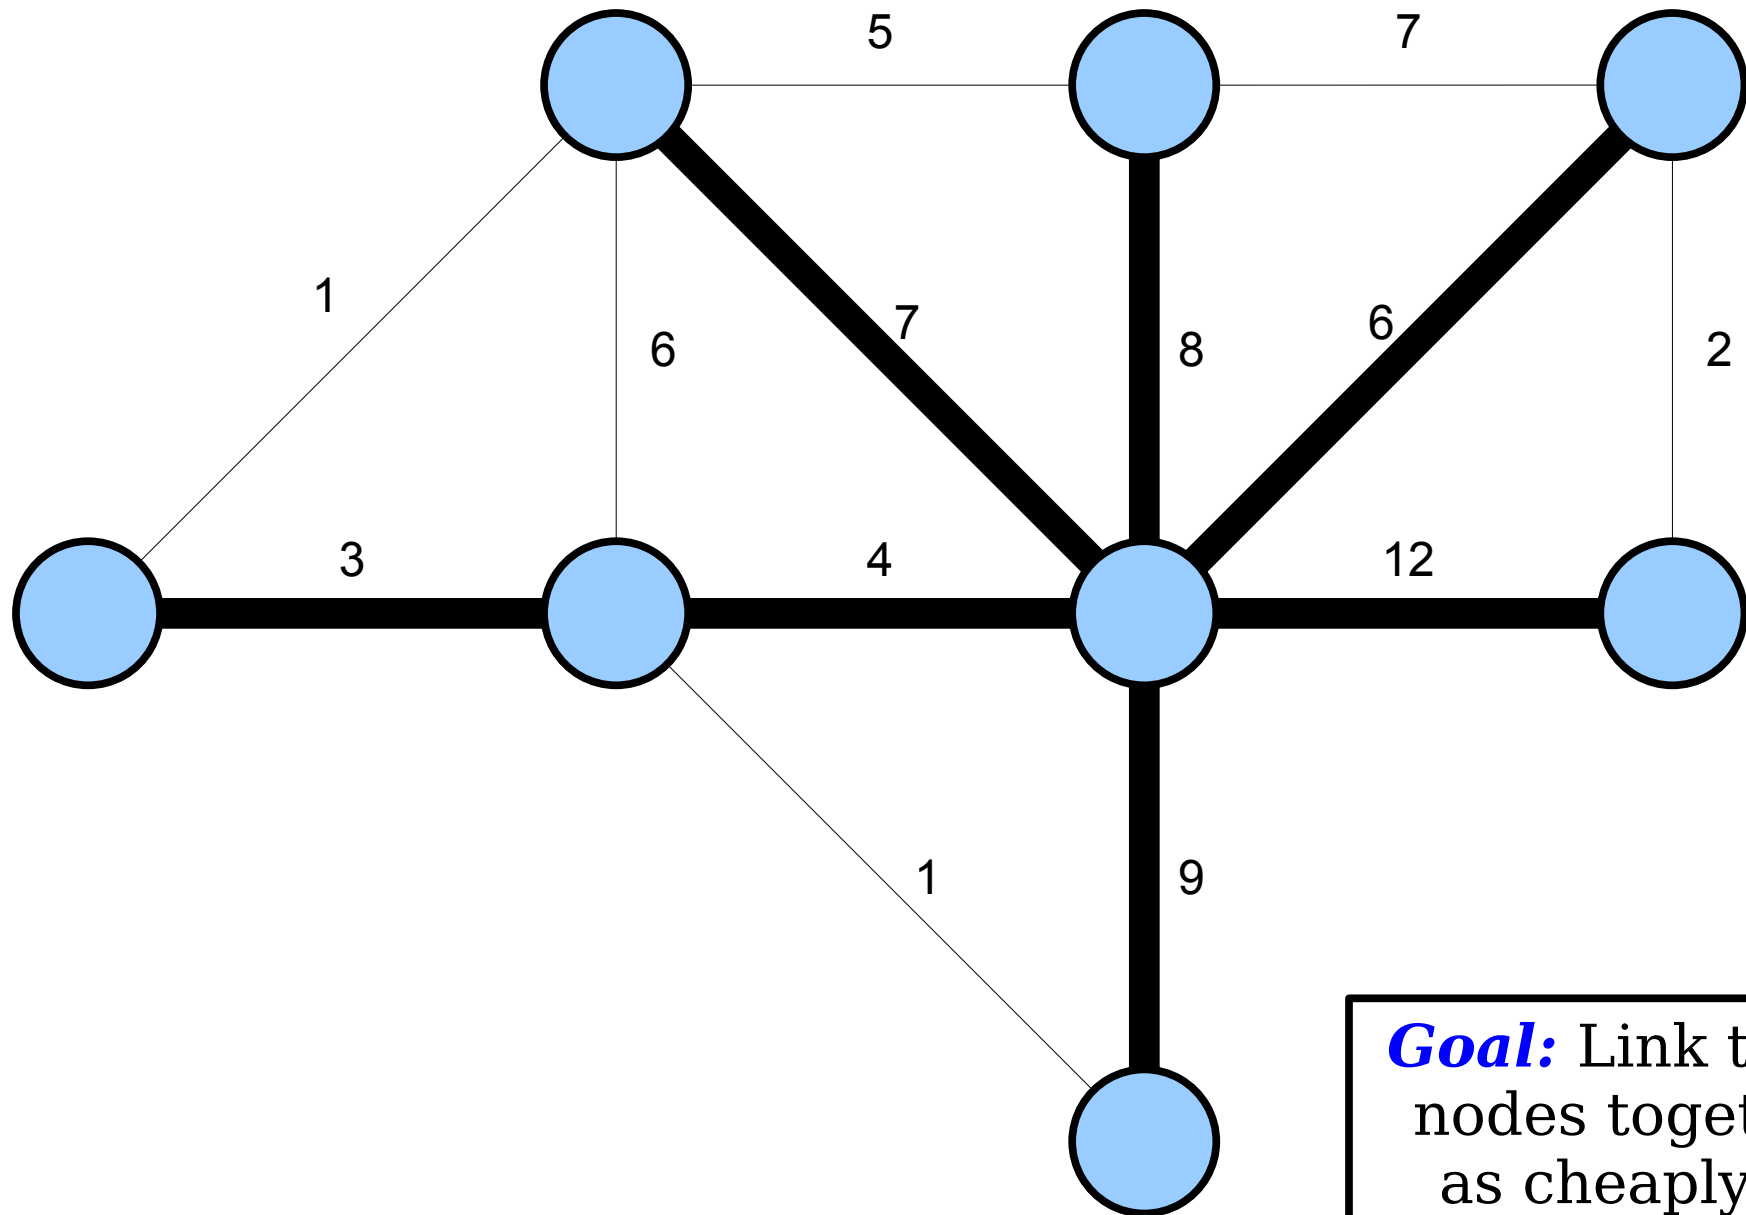

A Problem on Graphs

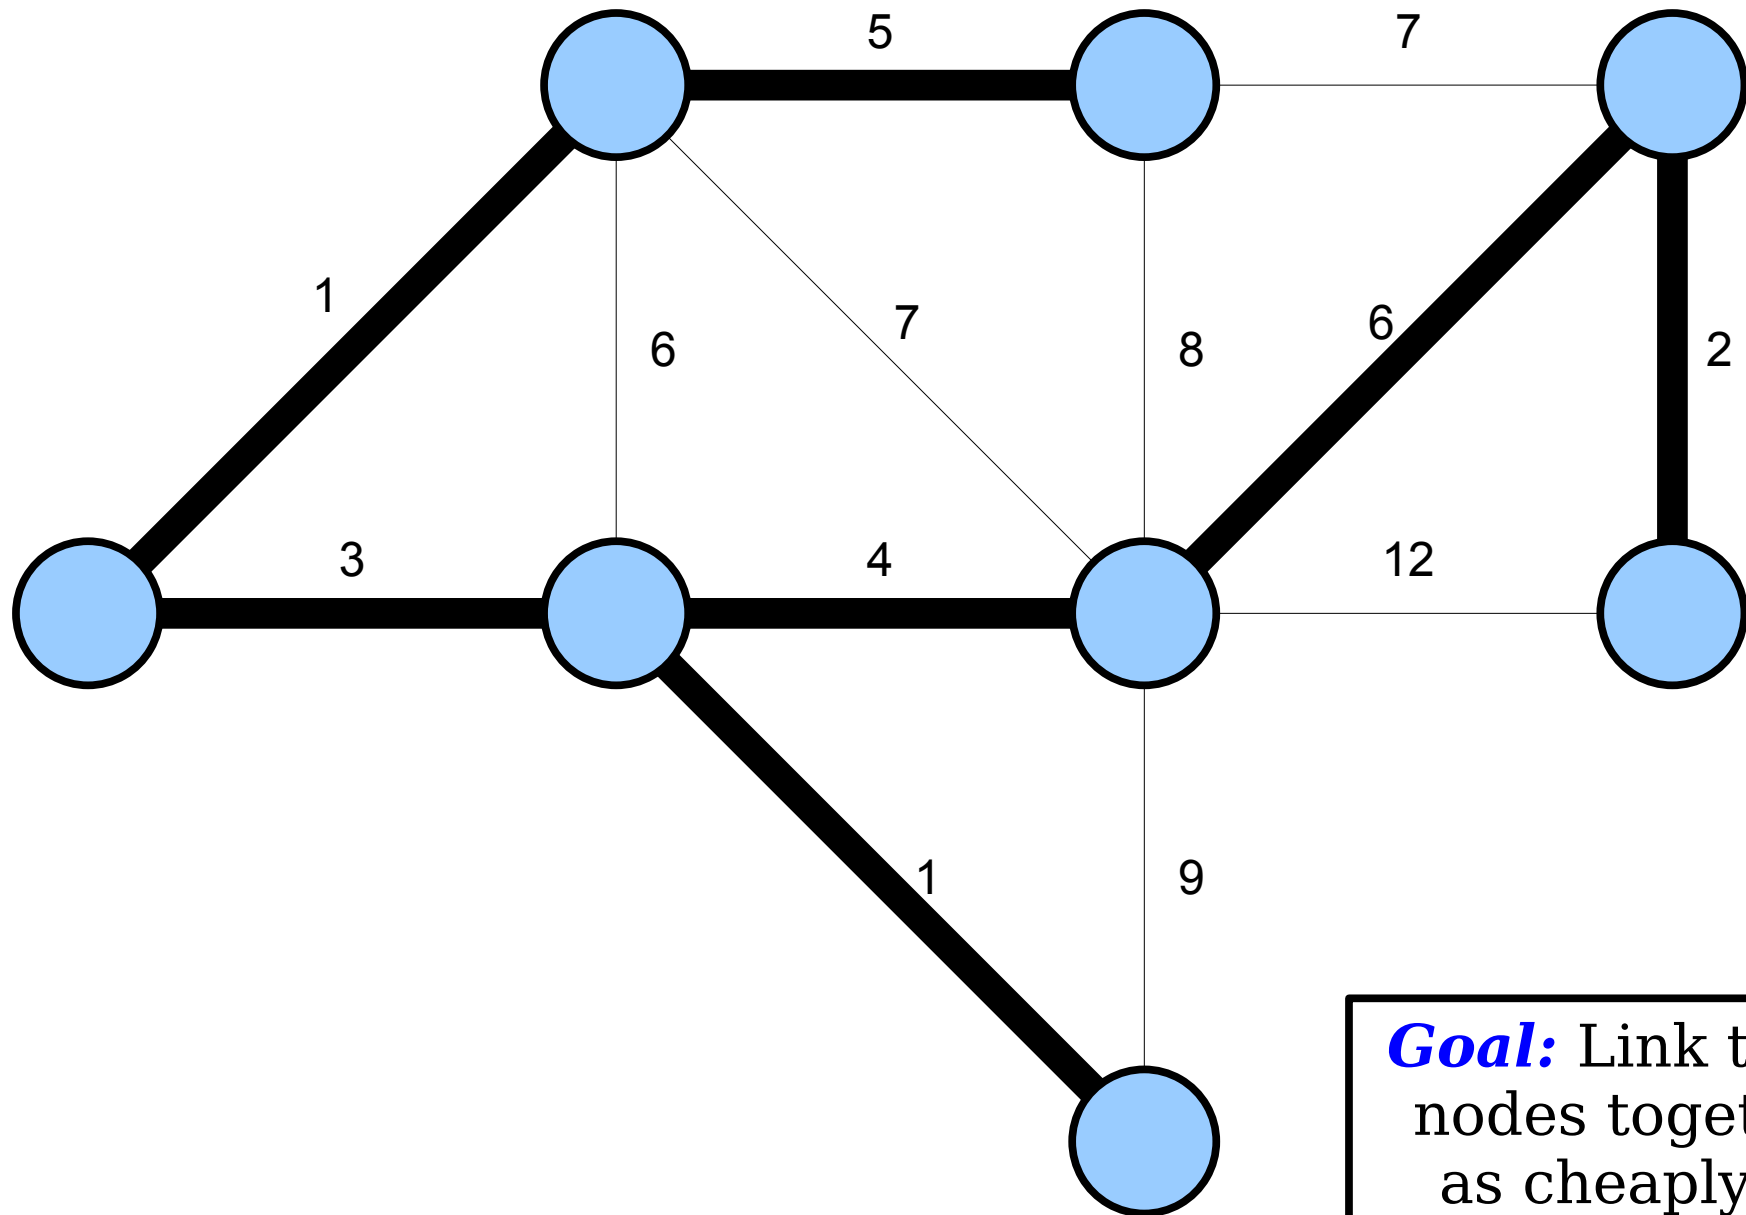

Goal: Link these nodes together as cheaply as possible.

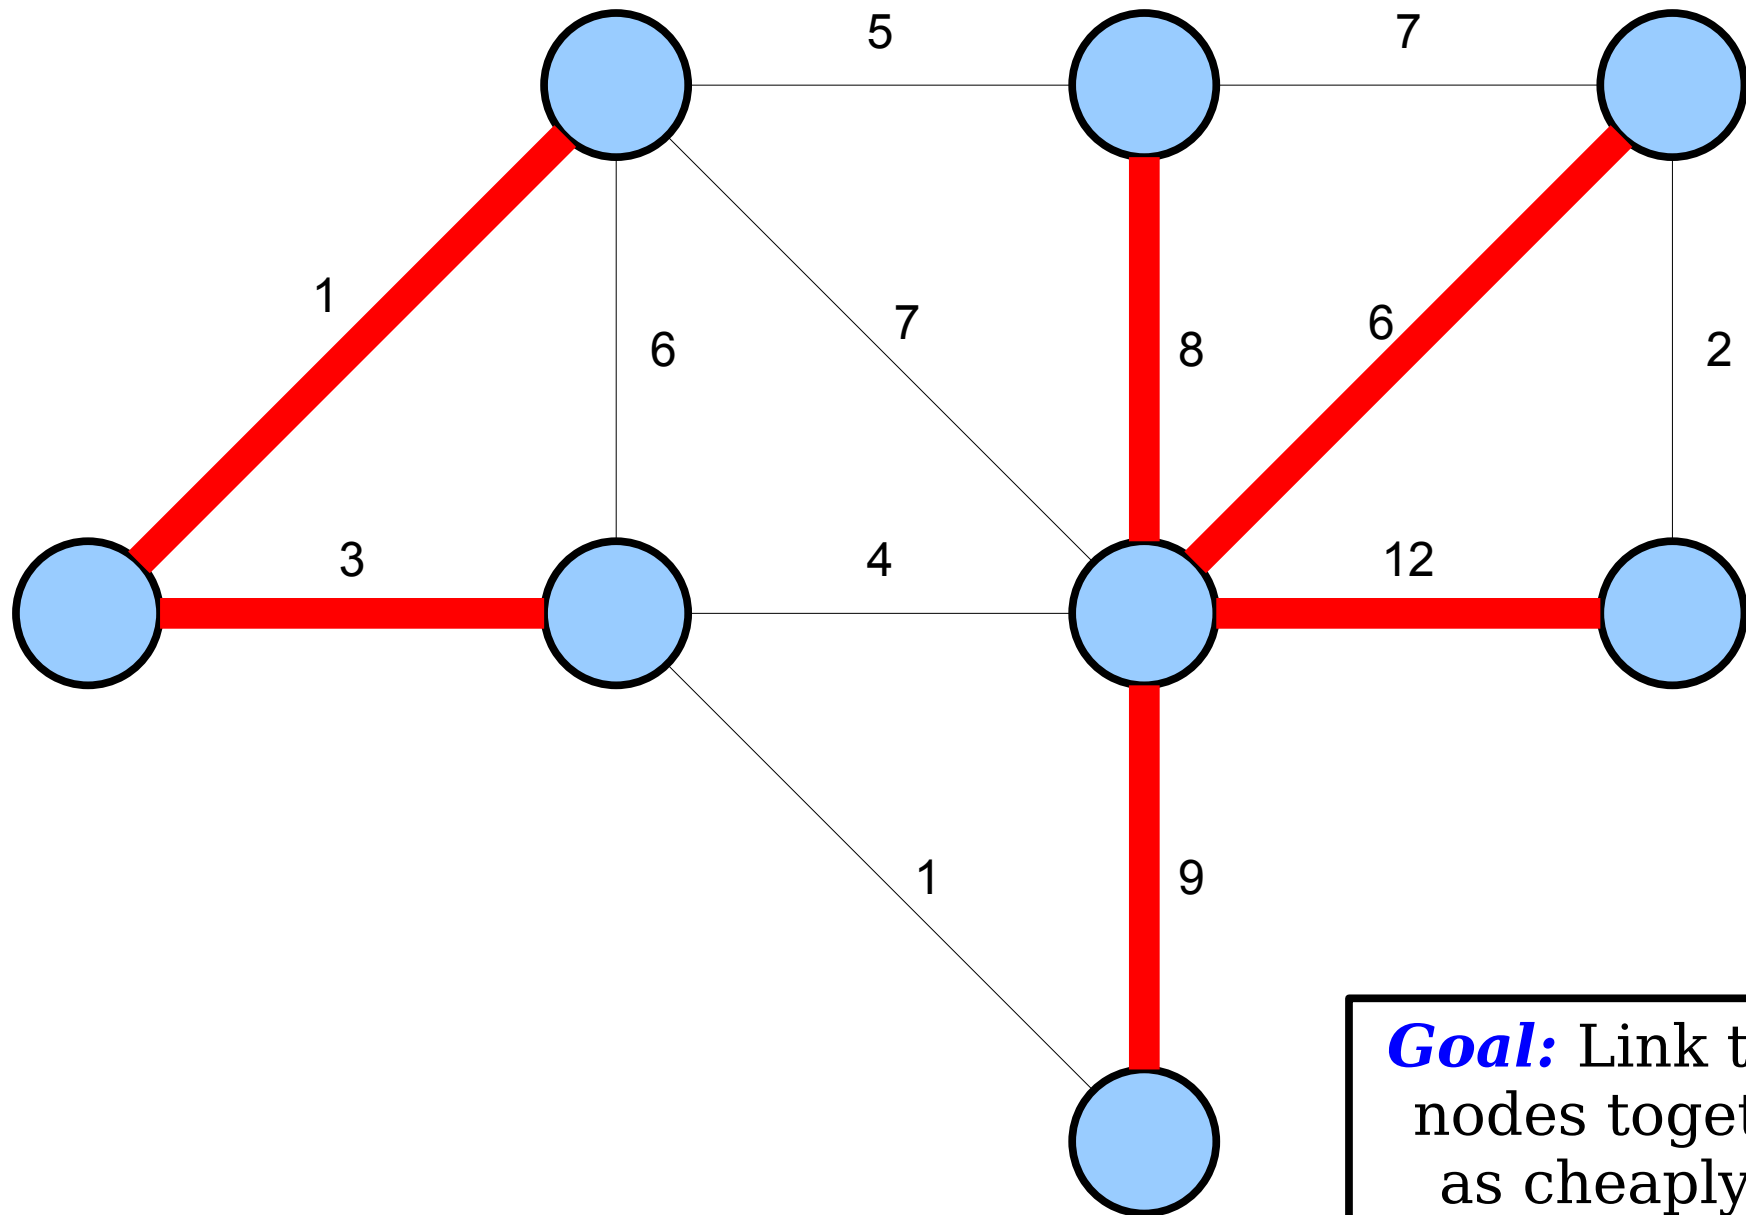

Goal: Link these nodes together as cheaply as possible.

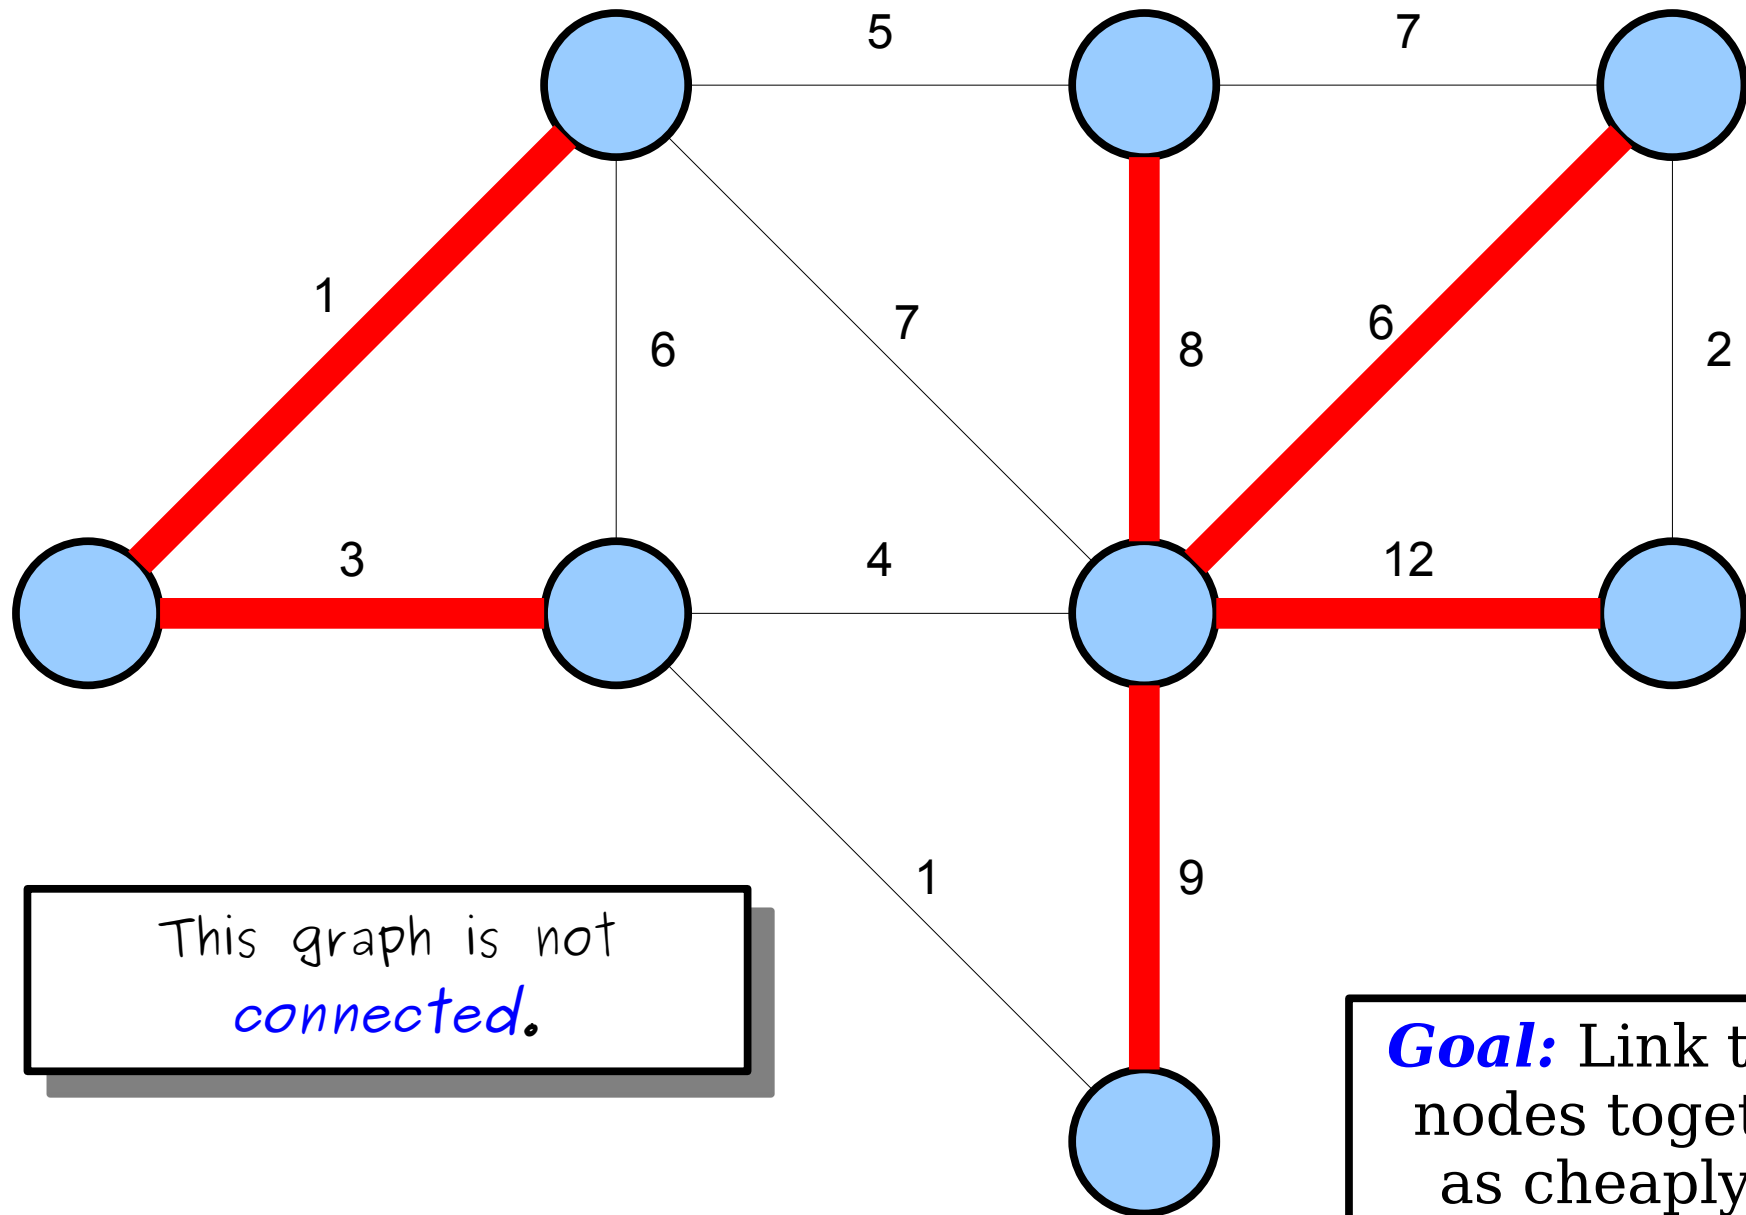

Goal: Link these nodes together as cheaply as possible.

Goal: Link these nodes together as cheaply as possible.

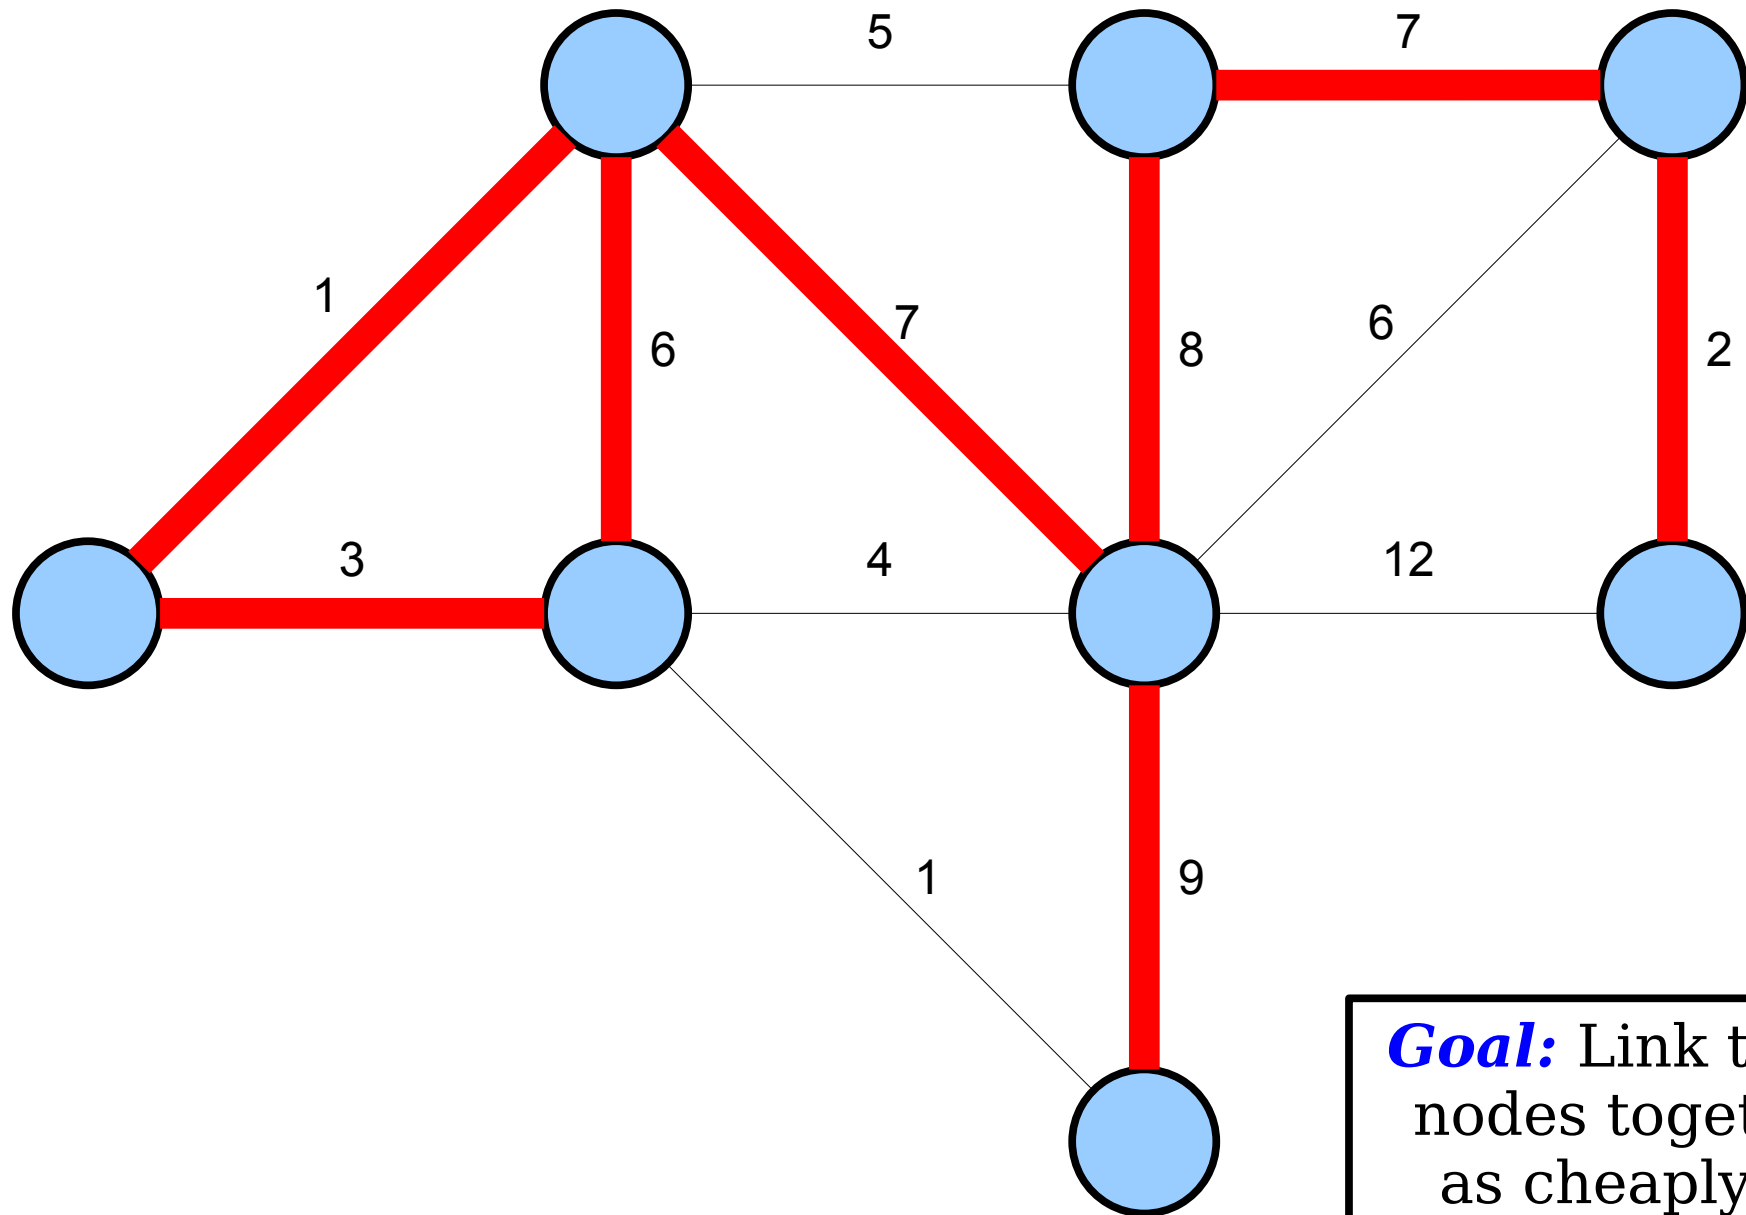

Goal: Link these nodes together as cheaply as possible.

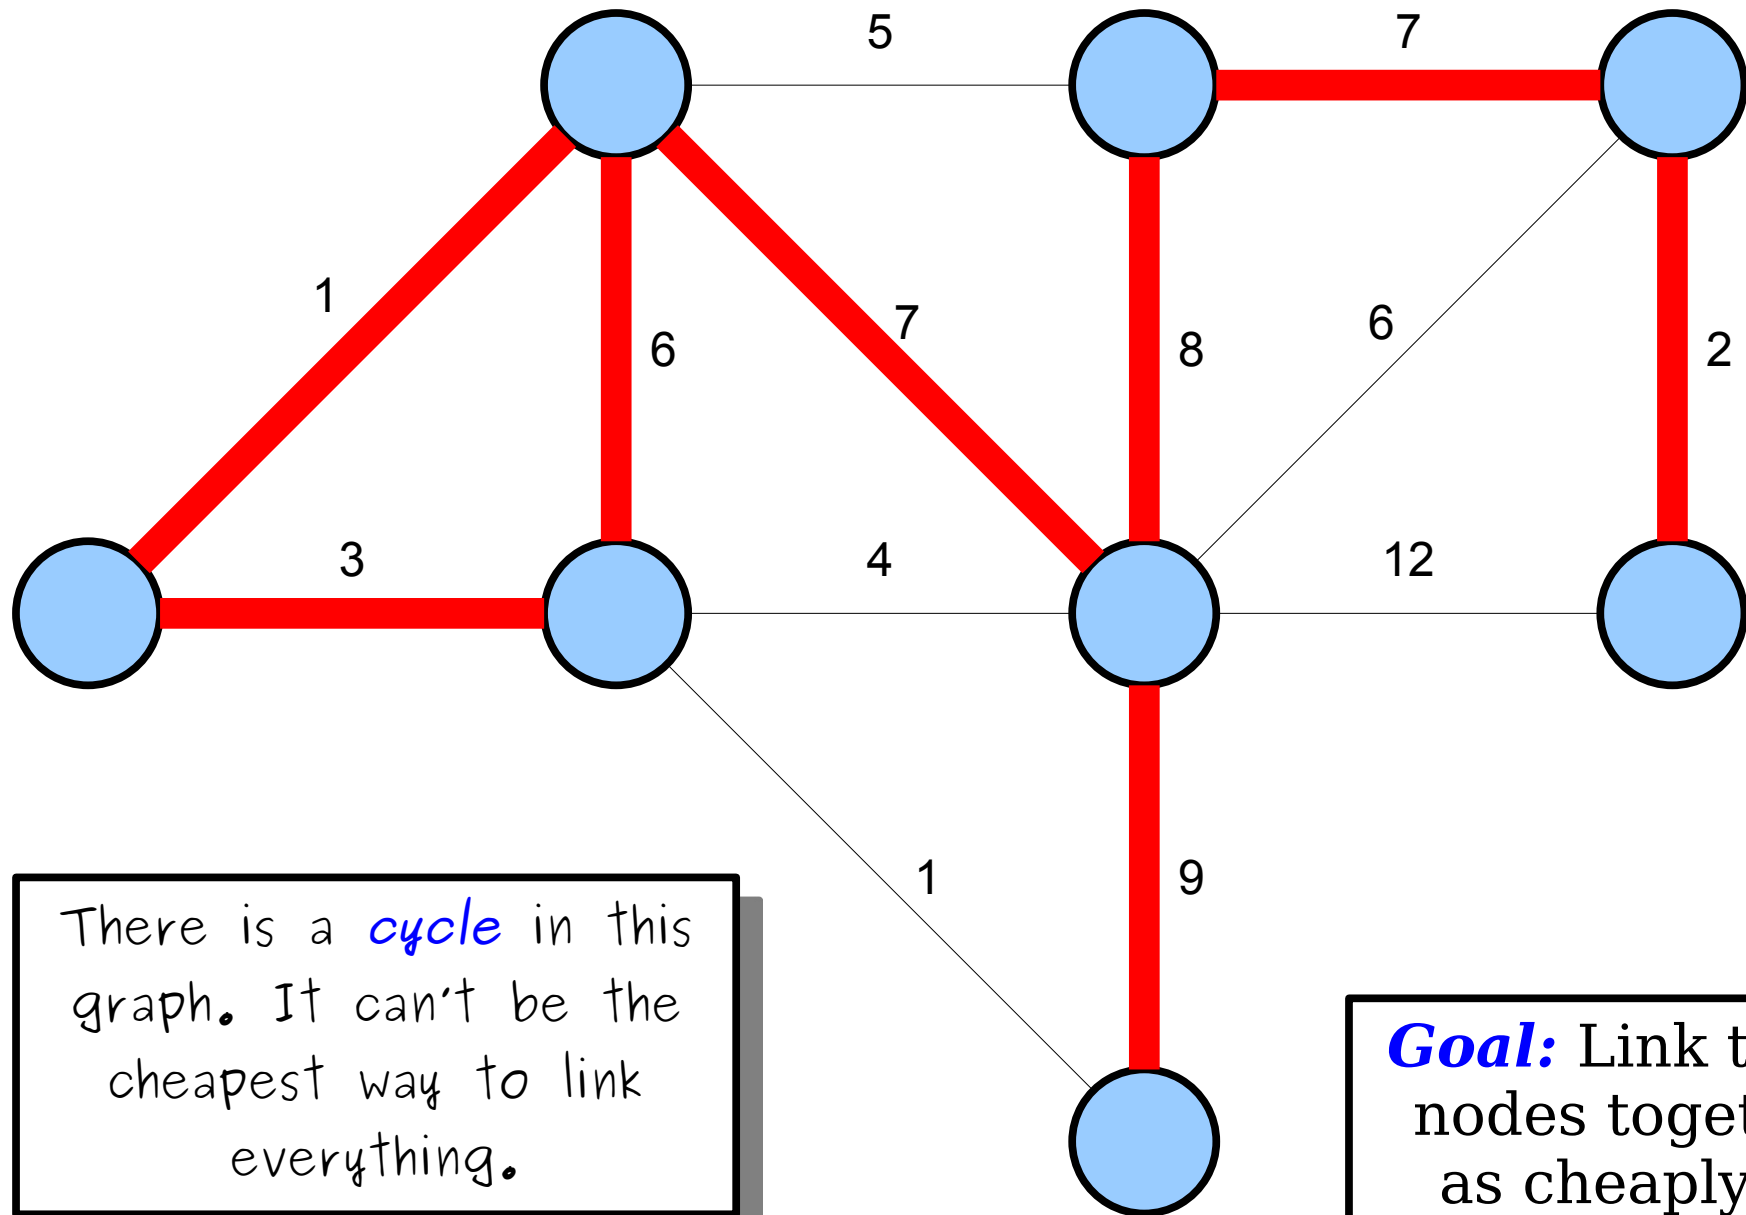

This graph is not
connected.

Goal: Link these
nodes together
as cheaply as
possible.

Goal: Link these nodes together as cheaply as possible.

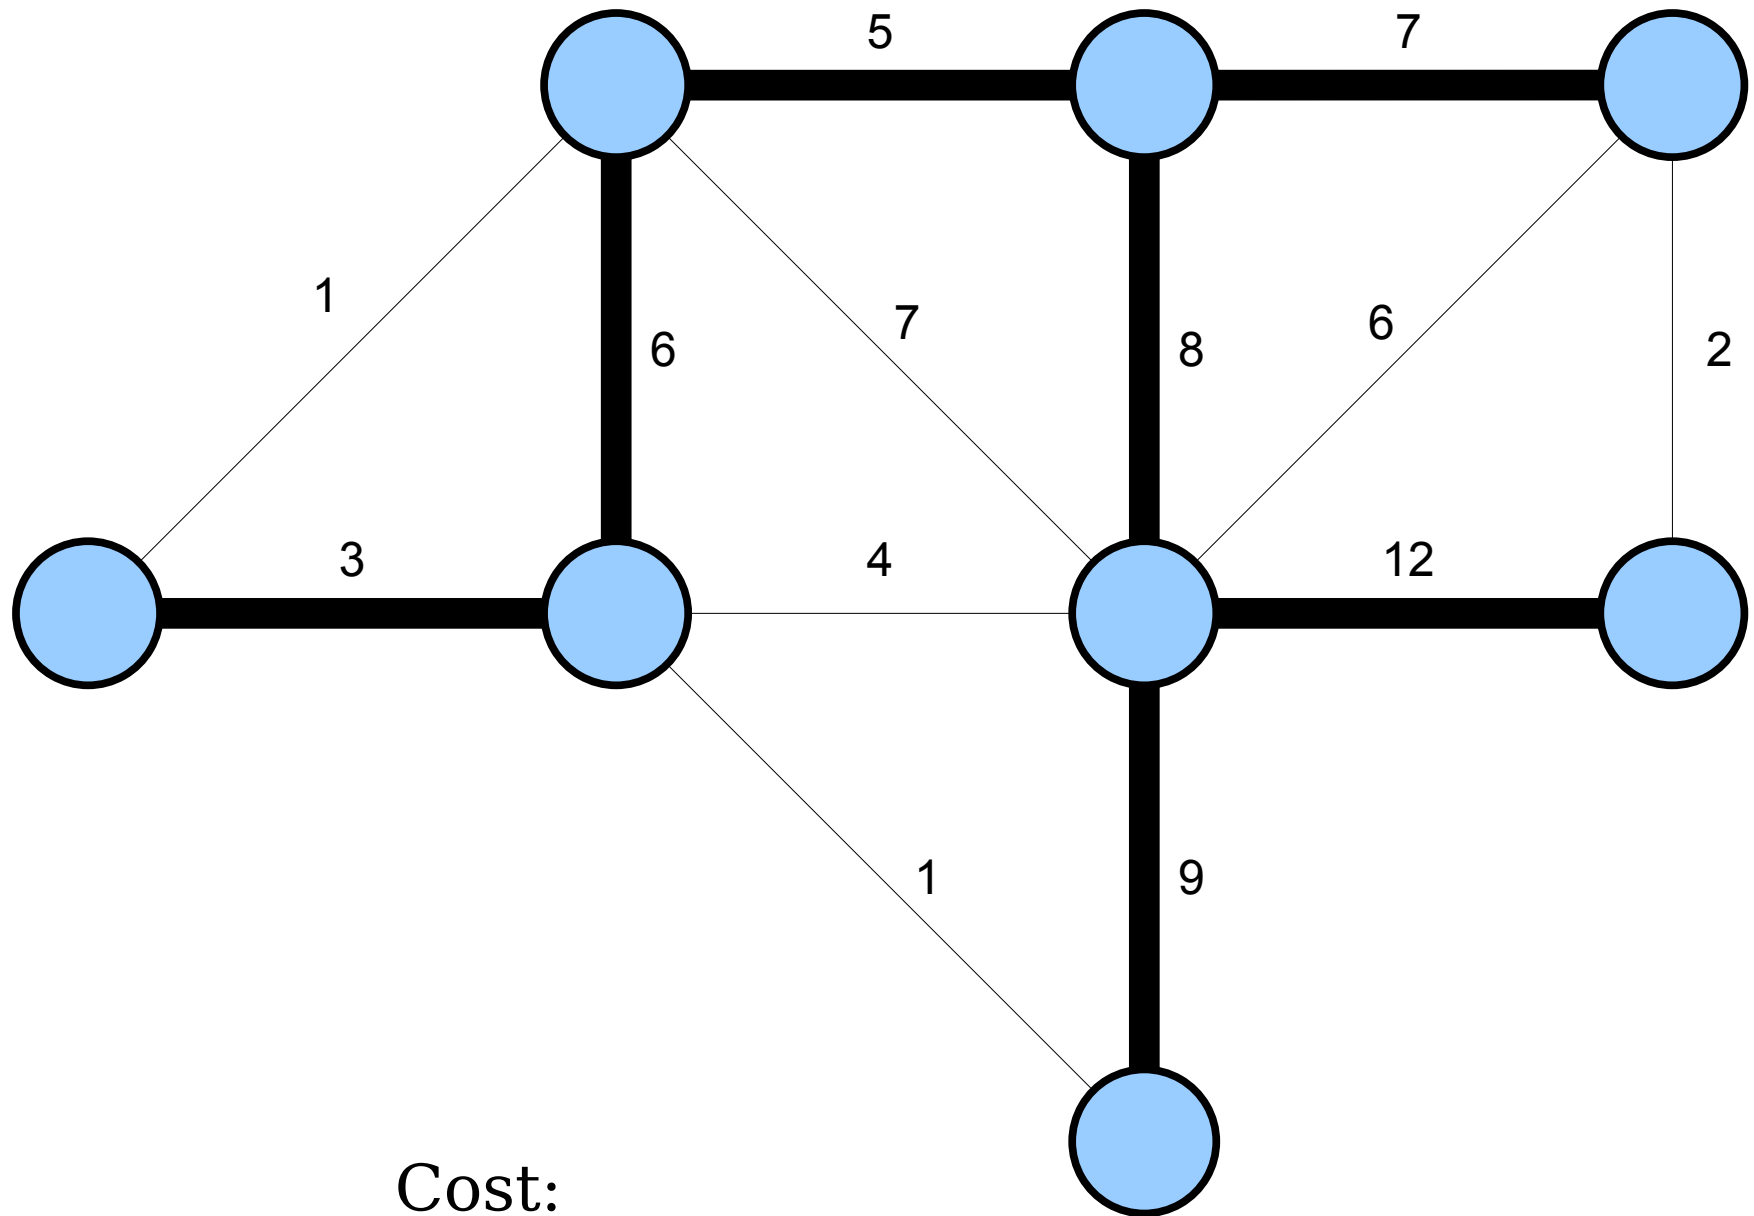

There is a *cycle* in this graph. It can't be the cheapest way to link everything.

Goal: Link these nodes together as cheaply as possible.

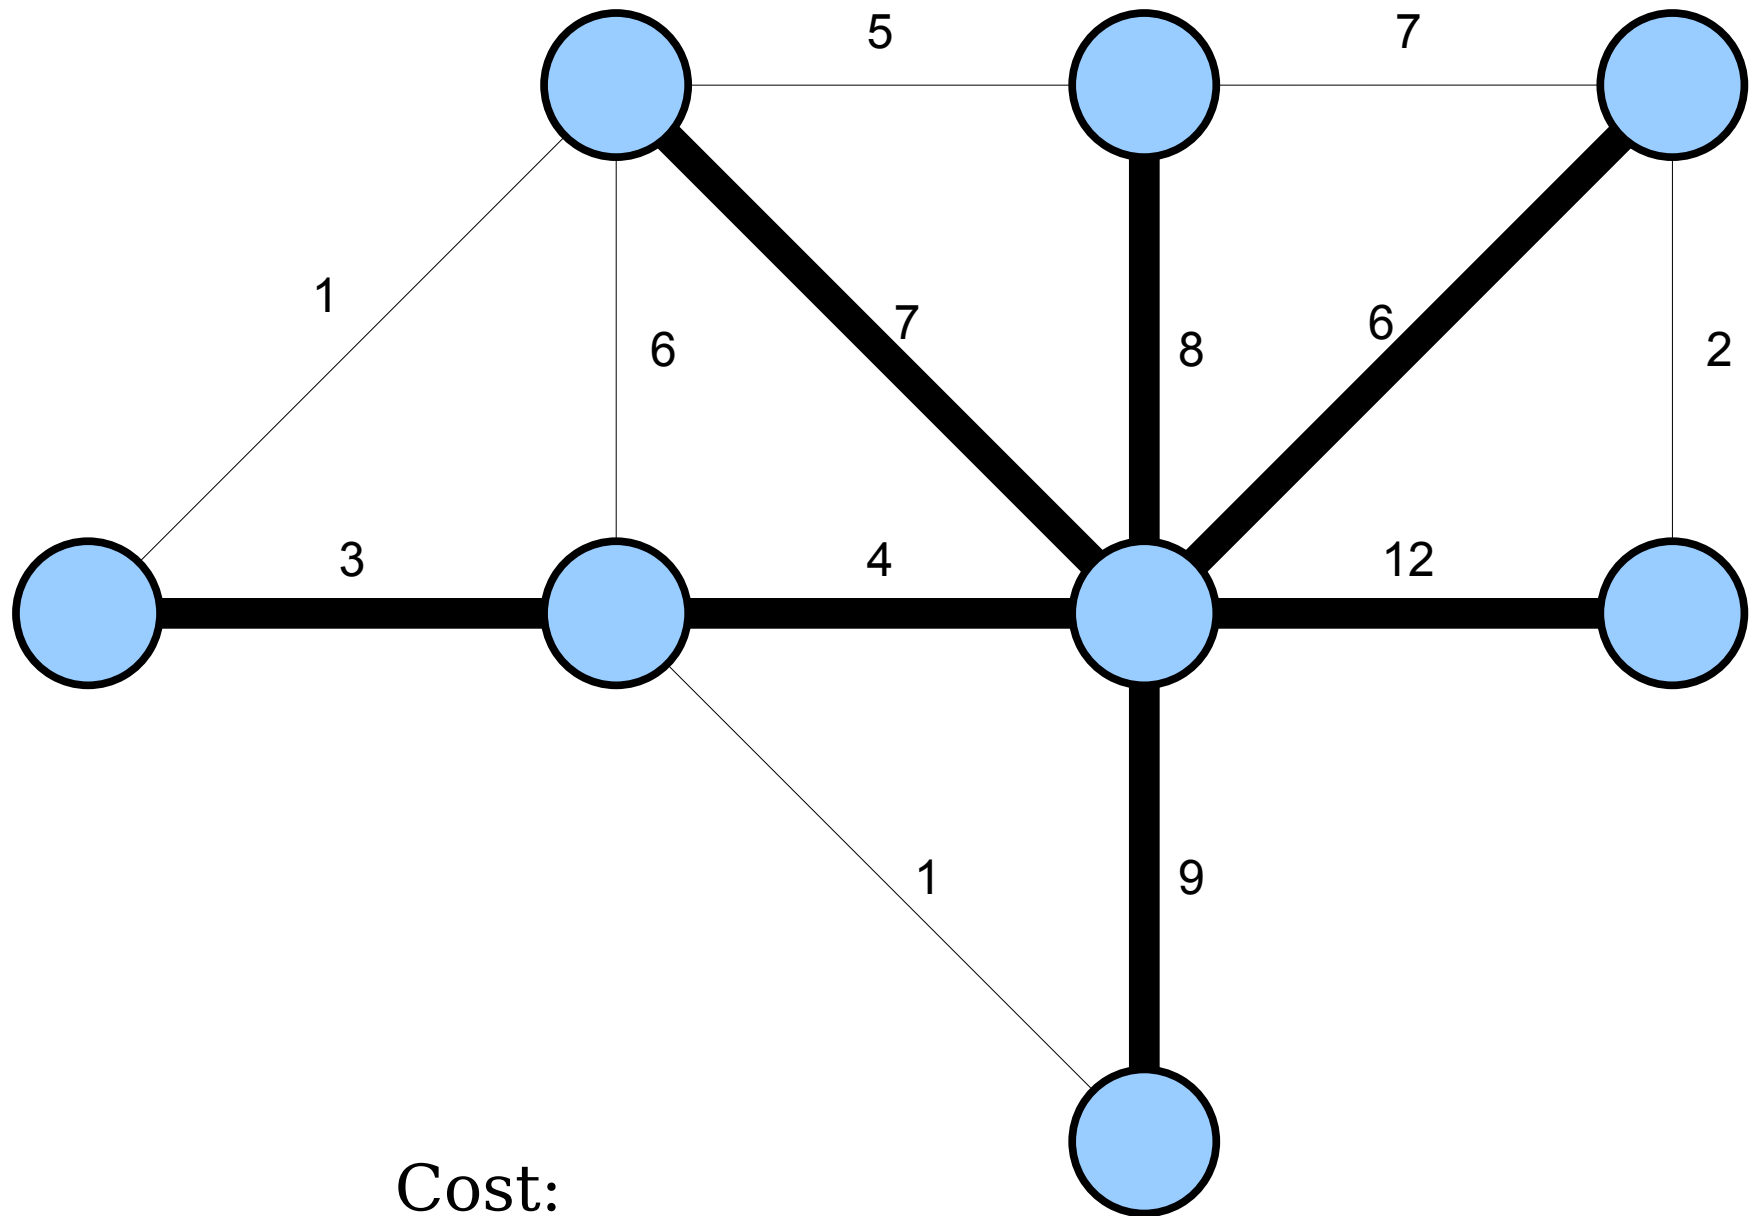

A ***spanning tree*** in an undirected graph is a set of edges with no cycles that connects all nodes.

Cost:

$$3 + 6 + 5 + 7 + 8 + 12 + 9 = \mathbf{50}$$

Cost:

$$3 + 4 + 7 + 8 + 6 + 12 + 9 = \mathbf{49}$$

Cost:

$$1 + 3 + 5 + 4 + 1 + 6 + 2 = \mathbf{22}$$

A ***minimum spanning tree*** (or ***MST***) is a spanning tree with the least total cost.

Applications

- ***Electric Grids***
 - Given a collection of houses, where do you lay wires to connect all houses with the least total cost?
 - This was the initial motivation for studying minimum spanning trees in the early 1920's. (work done by Czech mathematician ***Otakar Borůvka***)
- ***Data Clustering***
 - More on that later...
- ***Maze Generation***
 - More on that later...
- ***Computational Biology***
 - More on that later...

Finding an MST

MST Algorithms

- The original MST algorithm (1926) that Borůvka proposed is now called ***Borůvka's algorithm***.
- Later, the Czech mathematician Vojtěch Jarník (1930) invented an algorithm now called ***Prim's algorithm***.
- After that, American mathematician Joseph Kruskal (1956) developed what's now called ***Kruskal's algorithm***, which is what we'll present today.
- There's been a ton of work since then – come talk to me after class for details!

Kruskal's Algorithm:

Remove all edges from the graph.

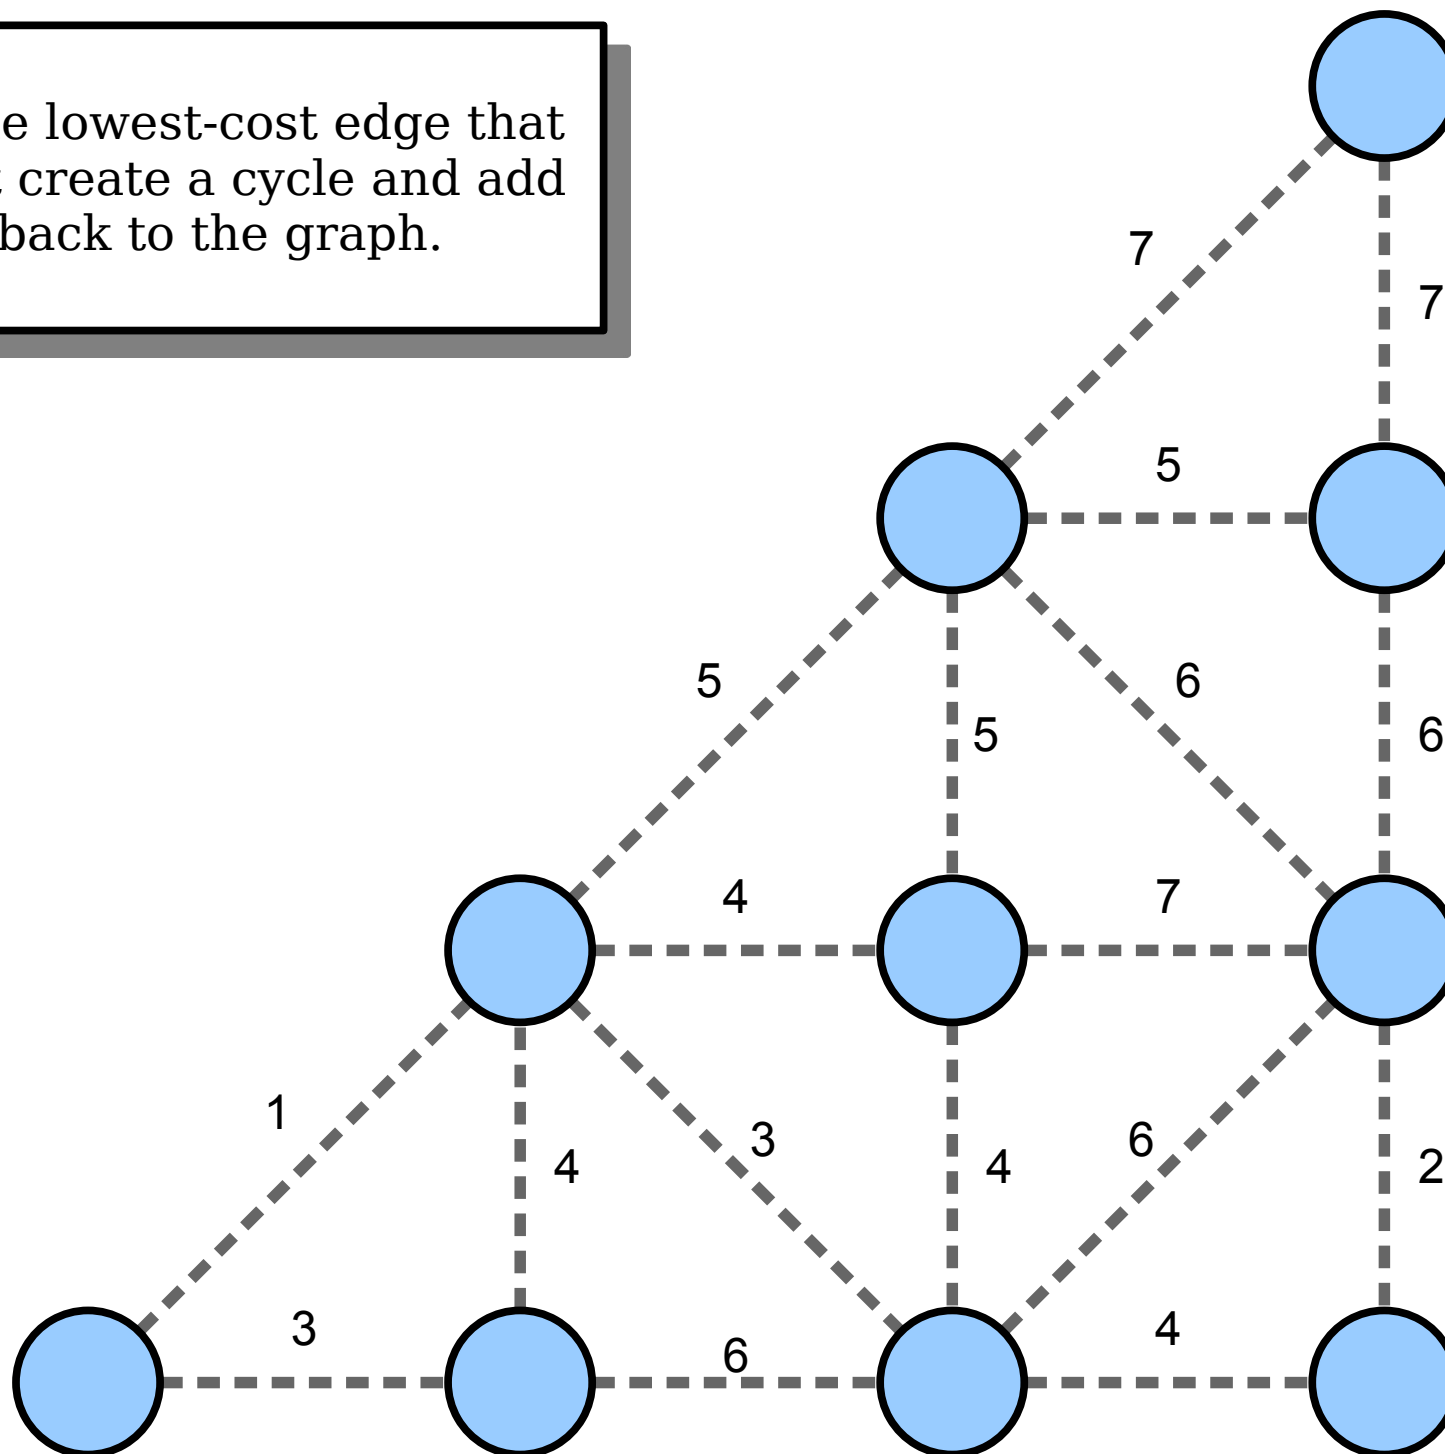

Repeatedly find the cheapest edge that doesn't create a cycle and add it back.

The result is an MST of the overall graph.

Find the lowest-cost edge that
doesn't create a cycle and add
it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that
doesn't create a cycle and add

A graph can have many
minimum spanning trees.
Here, the choice of
which length-4 edge we
visit first leads to
different results.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Find the lowest-cost edge that
doesn't create a cycle and add
it back to the graph.

Find the lowest-cost edge that doesn't create a cycle and add it back to the graph.

Here's our MST!

Try It Yourself!

Find a minimum spanning tree for the graph shown below. Then tell us the total cost of that MST.

$$3 + 4 + 1 + 5 + 2 + 9 + 4 + 8 = \mathbf{36}$$

Maintaining Connectivity

- The key step in Kruskal's algorithm is determining whether the two endpoints of an edge are already connected to one another.
- Typical approach: break the nodes apart into *clusters*.
 - Initially, each node is in its own cluster.
 - Whenever an edge is added, the clusters for the endpoints are merged together into a new cluster.

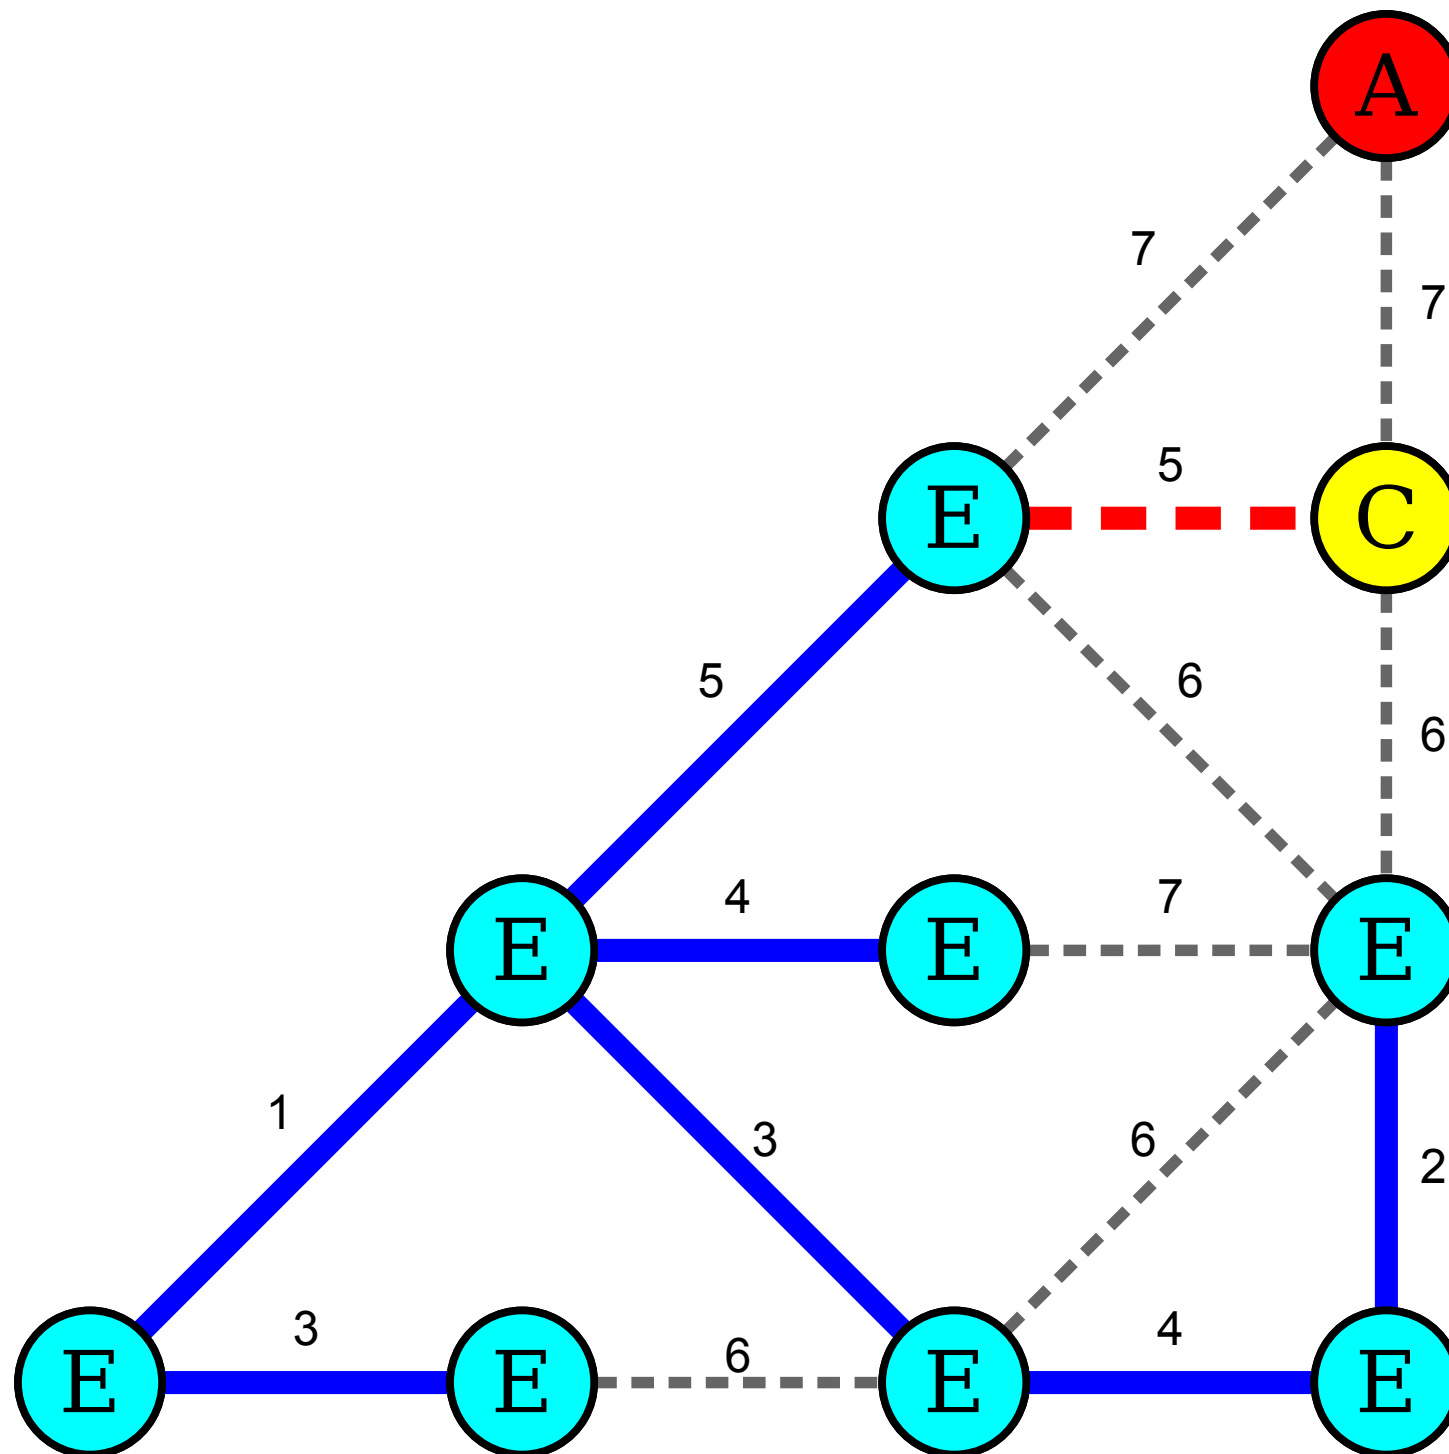

Implementing Kruskal's Algorithm

- Place every node into its own cluster.
- Place all edges into a priority queue.
- While there are two or more clusters remaining:
 - Dequeue an edge from the priority queue.
 - If its endpoints are not in the same cluster:
 - Merge the clusters containing the endpoints.
 - Add the edge to the resulting spanning tree.
- Return the resulting spanning tree.

Applications of Kruskal's Algorithm

Data Clustering

Data Clustering

Data Clustering

- Given a set of points, break those points apart into clusters.
- Immensely useful across all disciplines:
 - Cluster individuals by phenotype to try to determine what genes influence which traits.
 - Cluster images by pixel color to identify objects in pictures.
 - Cluster essays by various features to see how students learn to write.

Data Clustering

Data Clustering

Data Clustering

What makes a clustering “good?”

Maximum-Separation Clustering

- A ***maximum-separation clustering*** is one where the distance between the resulting clusters is as large as possible.
- Specifically, it maximizes the minimum distance between any two points of different clusters.
- Very good on many data sets, though not always ideal.

Maximum-Separation Clustering

Maximum-Separation Clustering

Maximum-Separation Clustering

- It is extremely easy to adopt Kruskal's algorithm to produce a maximum-separation set of clusters.
 - Suppose you want k clusters.
 - Given the data set, add an edge from each node to each other node whose length depends on their similarity.
 - Run Kruskal's algorithm until only k clusters remain.
 - The pieces of the graph that have been linked together are k maximally-separated clusters.

Maximum-Separation Clustering

This is how the
maze generator
in Assignment
7 works!

Mazes with Kruskal's Algorithm

- The algorithm:
 - Create a grid graph.
 - Give each edge a random weight.
 - Compute an MST of that graph.
- This tends to produce mazes with lots short twisty branches. It's also really easy to code up.

A square maze with a complex, non-symmetrical path. It features many dead ends and a single continuous path from the entrance to the exit.

A

A square maze with a symmetrical, cross-like pattern. It has a central square area with paths radiating outwards, and a single continuous path from the entrance to the exit.

B

Which mazes
were made with
depth-first
search?

Which were
made with
Kruskal's
algorithm?

Answer on
PollEV!

A square maze with a symmetrical, cross-like pattern. It has a central square area with paths radiating outwards, and a single continuous path from the entrance to the exit.

C

A square maze with a complex, non-symmetrical path. It features many dead ends and a single continuous path from the entrance to the exit.

Application: Stem Cells!

Question: How do you determine the patterns by which stem cells differentiate into specialized cells?

Step One: Grab a random collection of cells you know contains a bunch of stem cells.

Step Two: Measure a bunch of different features from each cell and plot those features on a coordinate axis.

Step Two: Measure a bunch of different features from each cell and plot those features on a coordinate axis.

Step Three: Cluster those nodes into smaller groups, which likely represent cells of the same type.

Step Three: Cluster those nodes into smaller groups, which likely represent cells of the same type.

Step Four: Find an MST. Nodes are clusters and edges are distances. This is the cheapest tree connecting the clusters.

Step Four: Find an MST. Nodes are clusters and edges are distances. This is the cheapest tree connecting the clusters.

Step Five: Figure out which cluster represents the original stem cells. You now have the likely differentiation pattern!

Step Five: Figure out which cluster represents the original stem cells. You now have the likely differentiation pattern!

The dynamics and regulators of cell fate decisions are revealed by pseudotemporal ordering of single cells

Cole Trapnell^{1,2,6}, Davide Cacchiarelli^{1-3,6}, Jonna Grimsby², Prapti Pokharel², Shuqiang Li⁴, Michael Morse^{1,2}, Niall J Lennon², Kenneth J Livak⁴, Tarjei S Mikkelsen¹⁻³ & John L Rinn^{1,2,5}

Defining the transcriptional dynamics of a temporal process such as cell differentiation is challenging owing to the high variability in gene expression between individual cells. Time-series gene expression analyses of bulk cells have difficulty distinguishing early and late phases of a transcriptional cascade or identifying rare subpopulations of cells, and single-cell proteomic methods rely on a priori knowledge of key distinguishing markers¹. Here we describe Monocle, an unsupervised algorithm that increases the temporal resolution of transcriptome dynamics using single-cell RNA-Seq data collected at multiple time points. Applied to the differentiation of primary human myoblasts, Monocle revealed switch-like changes in expression of key regulatory factors, sequential waves of gene regulation, and expression of regulators that were not known to act in differentiation. We validated some of these predicted regulators in a loss-of function screen. Monocle can in principle be used to recover single-cell gene expression kinetics from a wide array of cellular processes, including differentiation, proliferation and oncogenic transformation.

Such averaging artifacts can make factors that are correlated appear to be uncorrelated or even make positively correlated factors appear negatively correlated. As a population of cells captured at the same time may include many distinct intermediate differentiation states, considering only its average properties would mask trends occurring across individual cells. Solving this problem by experimental synchronization of cells or by stringent isolation of precursors at distinct stages is challenging and can sharply alter differentiation kinetics.

Computational analysis of gene expression data could help define biological progression between cellular states and reveal regulatory modules of genes that co-vary in expression across individual cells⁹. Previous analyses have used approaches from computational geometry^{10,11} to order bulk cell populations from time-series microarray experiments by progress through a biological process independently of when the samples were collected. The recently developed SPD algorithm can resolve progression along multiple lineages arising from a progenitor cell type using supervised machine learning¹². However, because these algorithms operate on bulk expression measurements, they are sensitive to mixture effects arising from Simpson's paradox and other averaging artifacts. Single-cell assays such as flow or

First the algorithm represents the expression profile of each cell as a point in a high-dimensional Euclidean space, with one dimension for each gene. Second, it reduces the dimensionality of this space using independent component analysis¹⁷. Dimensionality reduction transforms the cell data from a high-dimensional space into a low-dimensional one that preserves essential relationships between cell populations but is much easier to visualize and interpret¹⁸. Third, Monocle constructs a minimum spanning tree (MST) on the cells, a previously developed approach now commonly used in other single-cell settings, such as flow or mass cytometry^{1,13}. Fourth, the algorithm finds the longest path through the MST, corresponding to the longest sequence of transcriptionally similar cells. Finally, Monocle uses this sequence to produce a ‘trajectory’ of an individual cell’s progress through differentiation.

Building a repertoire of abstractions and algorithms helps you model and solve larger and larger classes of problems.

Your Action Items

- ***Work on Assignment 8.***
 - Home stretch! It's due this Friday. Remember that late days can't be used here.
 - Come talk to us if you have questions! That's what we're here for.
- ***(Optionally) Attend Review Sessions***
 - We have two review sessions in Hewlett 200. Tonight (7:30PM – 9:30PM) is on classes, linked structures, and the like. Tomorrow (7:30PM – 9:30PM) is on containers, recursion, and big-O notation.

Next Time

- ***Course Recap***
 - Wow, we covered a lot! What did we do this quarter, and why does it matter?
- ***Where to Go from Here***
 - What comes next in computer science?
- ***Concluding Thoughts***
 - Ending on a high note.
