## getline issue

I am using the function getline from simpio library

```
string line = getline("animate, tick, quit? ");
```

When I run the code it will print the prompt but it will not stop to take an input from the console. I can't figure out why this might be, any thoughts?

hw1

### **S** the students' answer, *where students collectively construct a single answer*

I have a similar problem of the prompt printing out twice when I use both "getline()" and "cin".  
Should we stick to using only "cin" or only "getline()" throughout our code?

Updated 18 hours ago by

### **i** the instructors' answer, *where instructors collectively construct a single answer*

If you use both getline() and cin, the problem y'all have will occur. To fix this, just stick to only using the Stanford library functions for input(the ones in

~ An instructor (Marty Stepp) endorsed this answer ~

```

# getline vs >> Bug

What happens if we mix cin and getline?

```
favNum    = 1729  
fullName  = ""
```

# getline vs >> Bug

We can fix this by consuming the newline character after using cin!

```
int favNum;
cin >> favNum;

cin >> ws;    // extracts as many whitespace chars as possible
               from current position in stream

string fullName;
getline(cin, fullName); // no residual newline char in stream
```

# Useful Aside

# Structs

You can define your own mini-types that bundle multiple variables together:

```
struct point {  
    int x;  
    int y;  
};
```

Useful for Assignment 1

# Structs

```
struct point {  
    int x;  
    int y;  
};
```

```
point p;  
p.x = 12;  
p.y = 15;
```

# Overview of STL

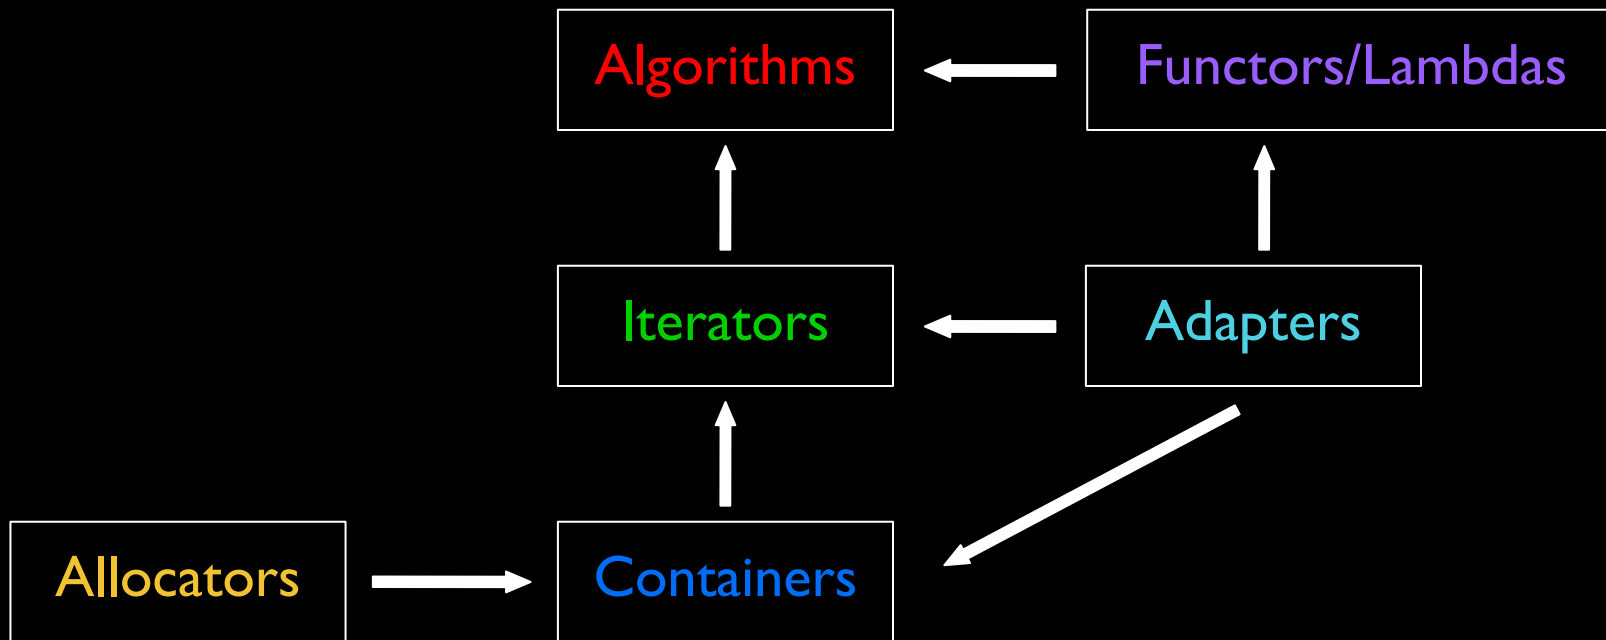

# Overview of STL

“As mathematicians learned to lift theorems into their most general setting, so I wanted to lift algorithms and data structures”

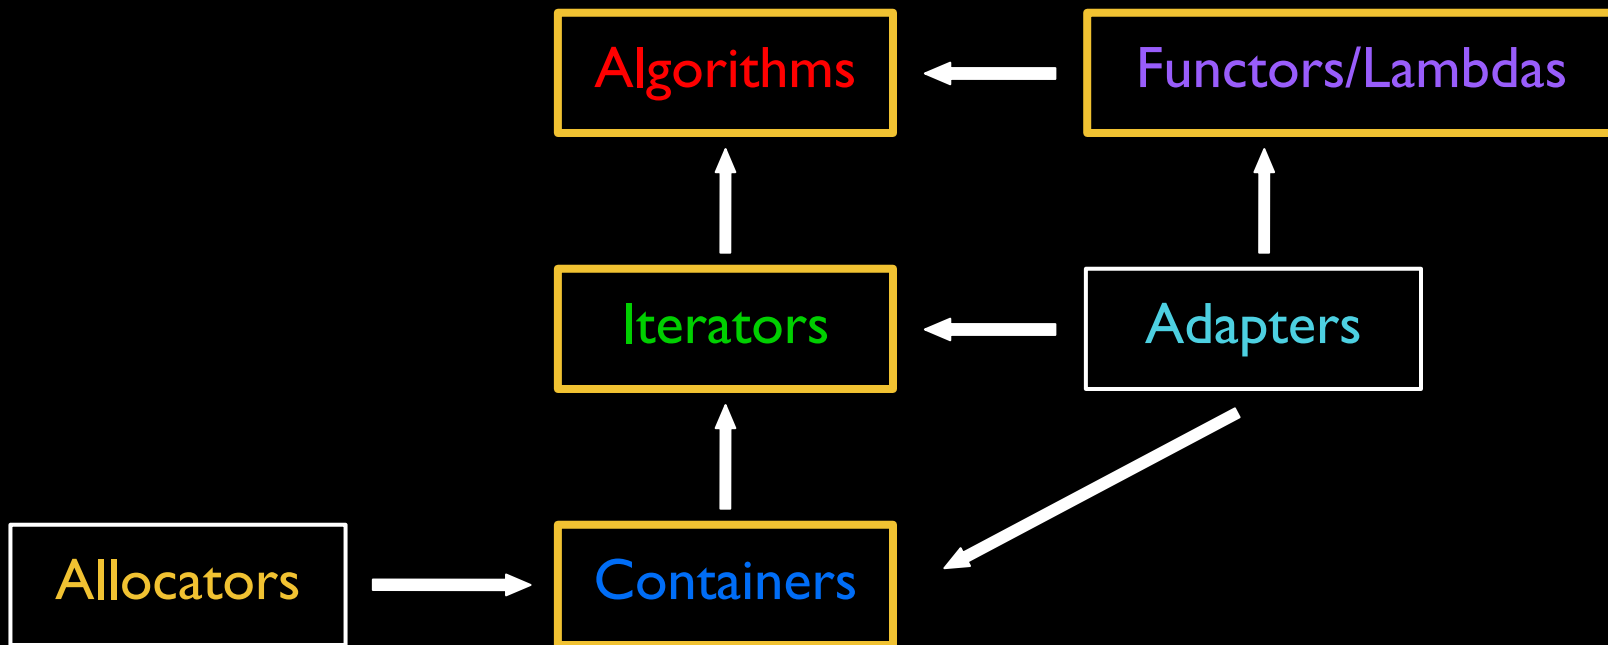

— *Alex Stepanov, inventor of the STL*

# Overview of STL

# Overview of STL

# Where we are going...

Here is a program that generates a vector with random entries, sorts it, and prints it, all in one go!

```
const int kNumInts = 200;
std::vector<int> vec(kNumInts);
std::generate(vec.begin(), vec.end(), rand);
std::sort(vec.begin(), vec.end());
std::copy(vec.begin(), vec.end(),
          std::ostream_iterator<int>(cout, "\n"));
```

# Sequence Containers

# Sequence Containers

Provides access to **sequences** of elements.

Examples:

- `std::vector<T>`
- `std::list<T>`
- `std::deque<T>`

```
std::vector<T>
```

# Summary of `std::vector<T>` vs `Stanford Vector<T>`

What you want to do	Stanford Vector<int>	<code>std::vector&lt;int&gt;</code>
Create an empty vector	<code>Vector&lt;int&gt; v;</code>	<code>vector&lt;int&gt; v;</code>
Create a vector with n copies of zero	<code>Vector&lt;int&gt; v(n);</code>	<code>vector&lt;int&gt; v(n);</code>
Create a vector with n copies of a value k	<code>Vector&lt;int&gt; v(n, k);</code>	<code>vector&lt;int&gt; v(n, k);</code>
Add k to the end of the vector	<code>v.add(k);</code>	<code>v.push_back(k);</code>
Clear vector	<code>v.clear();</code>	<code>v.clear();</code>
Get the element at index i (verify that i is in bounds)	<code>int k = v.get(i);</code> <code>int k = v[i];</code>	<code>int k = v.at(i);</code>
Check if the vector is empty	<code>if (v.isEmpty()) ...</code>	<code>if (v.empty()) ...</code>
Replace the element at index i (verify that i is in bounds)	<code>v.get(i) = k;</code> <code>v[i] = k;</code>	<code>v.at(i) = k;</code>

# Summary of `std::vector<T>` vs `Stanford Vector<T>`

## Some Differences - `std::vector<T>` vs `Stanford Vector<T>`

Get the element at index <i>i</i> without bounds checking	// Impossible!	<code>int a = x[i];</code>
Change the element at index <i>i</i> without bounds checking	// Impossible!	<code>x[i] = v;</code>
Add an element to the beginning of a vector	// Impossible! (or at least slow)	// Impossible! (or at least slow)
Apply a function to each element in <i>x</i>	<code>x.mapAll(fn)</code>	// We'll talk about this in another lecture...
Concatenate vectors <i>v1</i> and <i>v2</i>	<code>v1 += v2;</code>	// We'll talk about this in another lecture...

```
std::vector<T>
```

Problem:

Write a program that reads a list of integers and finds the median.

Vector Median

(VecMedian.pro)

```
std::vector<T>
```

Some new stuff there:

```
const int kNumInts = 5;
```

```
using vecsz_t = std::vector<int>::size_type;
```

```
std::sort(vec.begin(), vec.end());
```

# std::vector<T>

Some new stuff there:

```
const int kNumInts = 5;
```

This is a promise to the compiler that this variable won't change.

```
using vecsz_t = std::vector<int>::size_type;
```

```
std::sort(vec.begin(), vec.end());
```

```
std::vector<T>
```

Some new stuff there:

```
const int kNumInts = 5;
```

```
using vecsz_t = std::vector<int>::size_type;
```

```
std::sort(vec.begin(), vec.end());
```

This let's us use `vecsz_t` as an alias/synonym for the type `std::vector<int>::size_type`;

```
std::vector<T>
```

Some new stuff there:

```
const int kNumInts = 5;  
  
using vecsz_t = std::vector<int>::size_type;  
  
std::sort(vec.begin(), vec.end());
```

This takes a range of the vector and sorts it

## Some Differences - `std::vector<T>` vs `Stanford Vector<T>`

Why these differences?

# Why the Differences?

Why doesn't `std::vector` bounds check by default?

**Hint:** Remember our discussion of the philosophy of C++

If you write your program **correctly**, bounds checking will just **slow** your code down.

## Some Differences - `std::vector<T>` vs `Stanford Vector<T>`

0th index

# Why is `push_front` slow?

...

↑  
0th index

# Why is `push_front` slow?

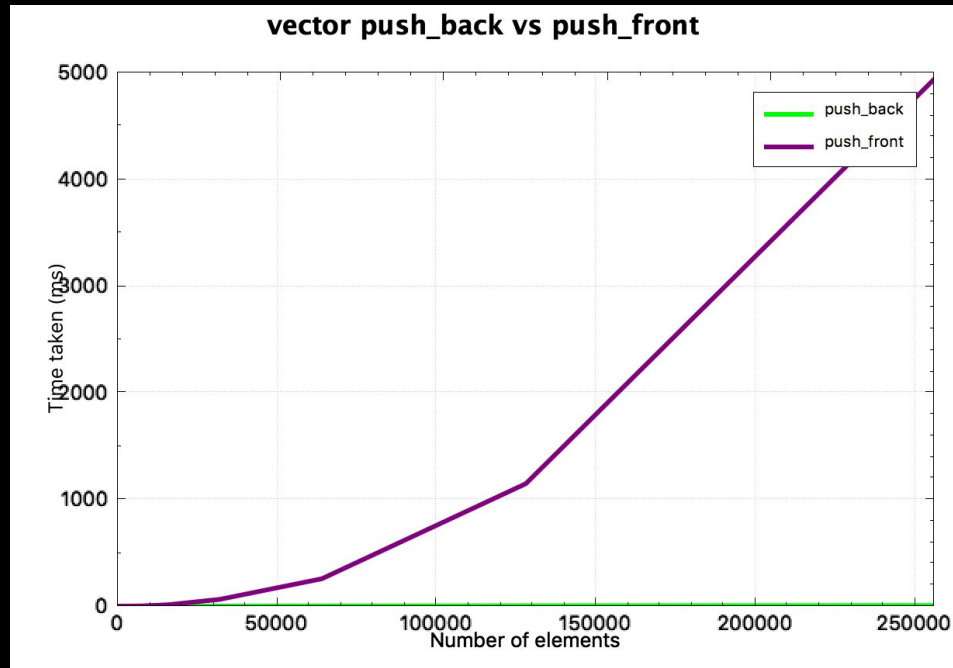

Let's get a sense of the difference:

Insertion Speed

(`InsertionSpeed.pro`)

# Why is `push_front` slow?

The results:

# Why is `push_front` slow?

A vector is the **prime** tool of choice in most applications!

- Fast
- Lightweight
- Intuitive

However, we just saw vectors only grow efficiently in **one direction**.

Sometimes it is useful to be able to `push_front` quickly!

C++ has a solution!

```
std::deque<T>
```

```
std::deque<T>
```

A deque (pronounced “deck”) is a **double ended queue**.

Can do **everything** a vector can do

and also...

Unlike a vector, it is possible (and **fast**) to `push_front` and `pop_front`.

`std::deque<T>`

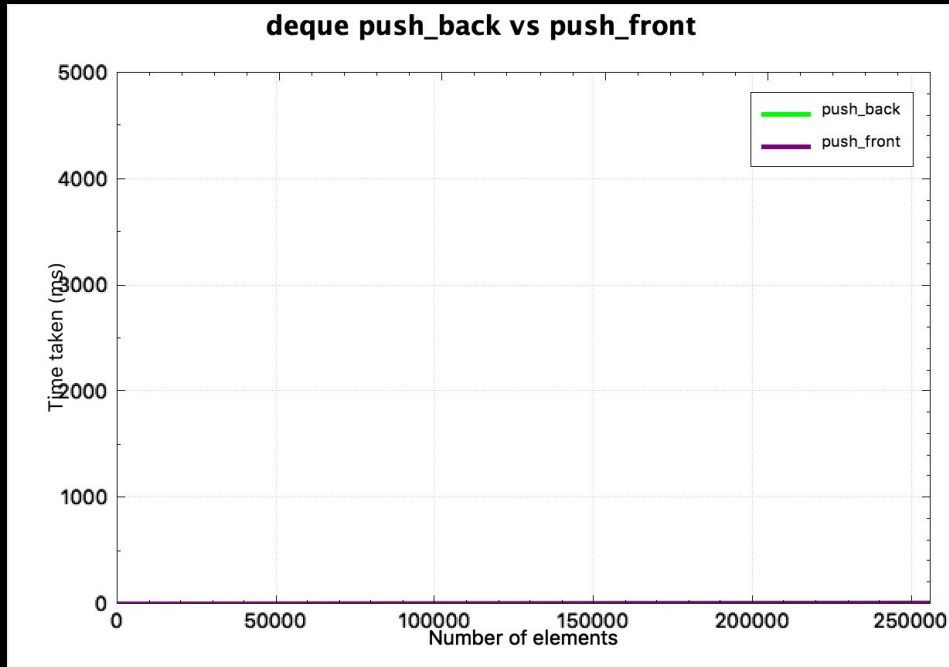

We can see the efficiency of `push_front` with a `std::deque`

Deque Speed

(DequeSpeed.pro)

`std::deque<T>`

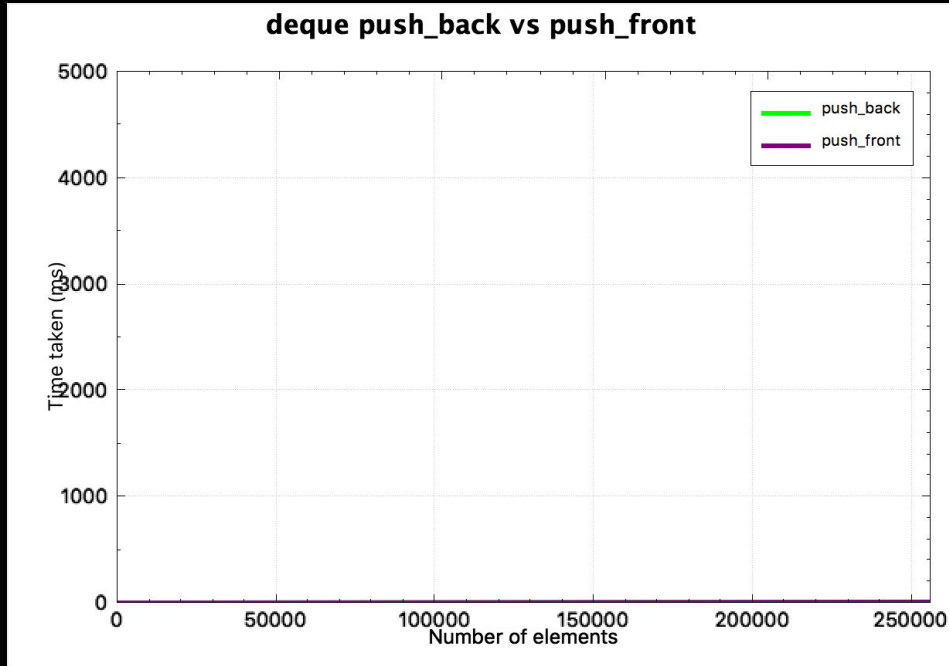

The results:

```
std::deque<T>
```

The results:

Same scale as  
previous graph

`std::deque<T>`

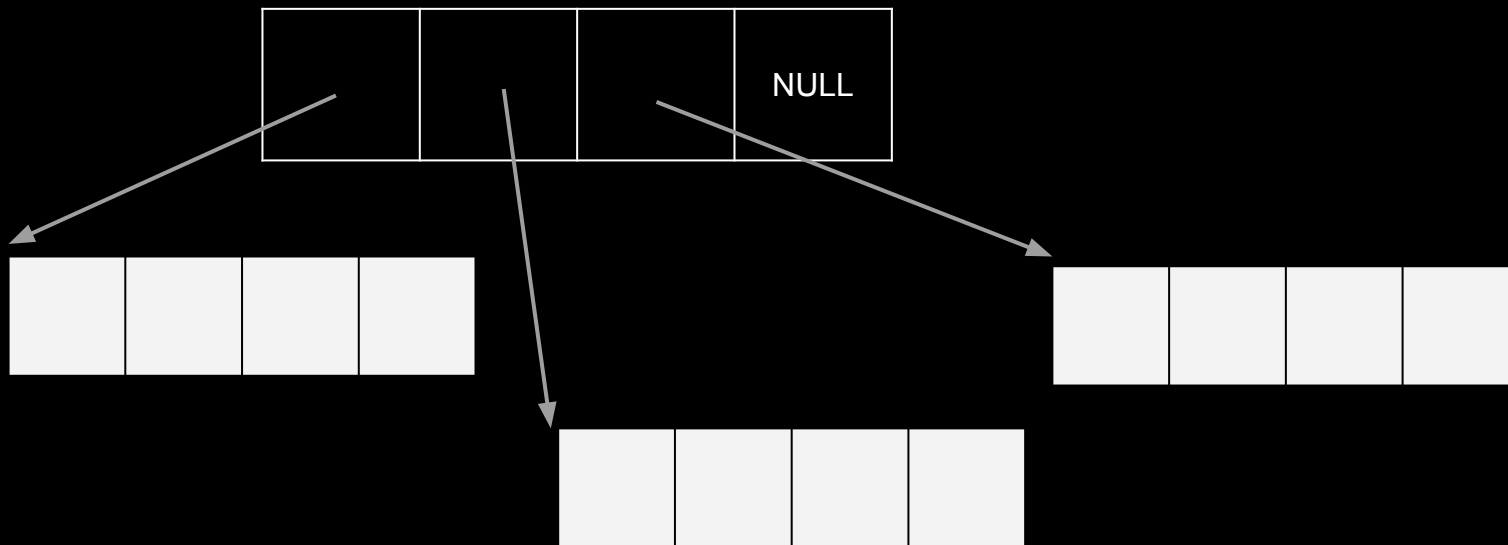

The results:

There are the lines!

# How does `std::deque<T>` work?

There is no single specific implementation of a deque, but one common one might look like this:

Wait a minute...

# Question

If deque can do **everything** a vector can do and **also** has a **fast**  
`push_front...`

Why use a vector at all?

# Downsides of `std::deque<T>`

Dequeues support **fast** `push_front` operations.

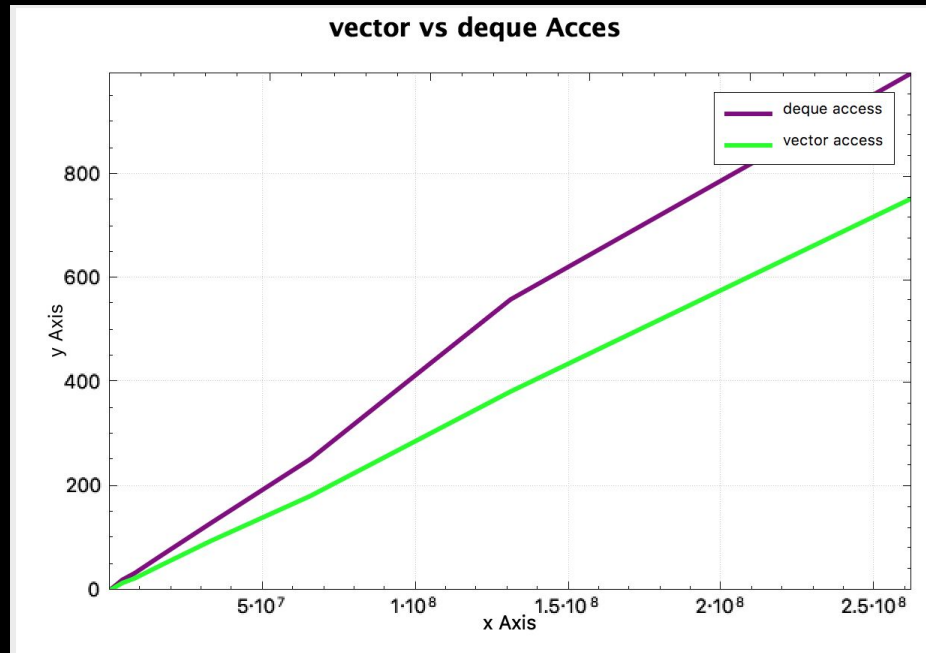

However, for other common operations like element access, vector will always outperform a deque.

Vector vs Deque

(VecDequeSpeed.pro)

# Downsides of `std::deque<T>`

The results:

# Which to Use?

*“vector is the type of sequence that should be used by **default...** deque is the data structure of choice when most insertions and deletions take place **at the beginning or at the end** of the sequence.”*

Recall stacks and queues:

# Container Adapters

Recall stacks and queues:

stack

queue

# Container Adapters

How can we implement stack and queue using the containers we have?

## Stack:

Just limit the functionality of a vector/deque to only allow `push_back` and `pop_back`.

## Queue:

Just limit the functionality of a deque to only allow `push_back` and `pop_front`.

Plus only allow access to **top** element

# Container Adapters

For this reason, stacks and queues are known as **container adapters**.

## std::stack

```
Defined in header <stack>
template<
  class T,
  class Container = std::deque<T>
> class stack;
```

The `std::stack` class is a container adapter that gives the programmer the functionality of a stack - specifically, a FILO (first-in, last-out) data structure.

The class template acts as a wrapper to the underlying container - only a specific set of functions is provided. The stack pushes and pops the element from the back of the underlying container, known as the top of the stack.

### Template parameters

**T** - The type of the stored elements. The behavior is undefined if T is not the same type as `Container::value_type`. (since C++17)

**Container** - The type of the underlying container to use to store the elements. The container must satisfy the requirements of `SequenceContainer`. Additionally, it must provide the following functions with the usual semantics:

- `back()`
- `push_back()`
- `pop_back()`

The standard containers `std::vector`, `std::deque` and `std::list` satisfy these requirements.

## std::queue

```
Defined in header <queue>
template<
  class T,
  class Container = std::deque<T>
> class queue;
```

The `std::queue` class is a container adapter that gives the programmer the functionality of a queue - specifically, a FIFO (first-in, first-out) data structure.

The class template acts as a wrapper to the underlying container - only a specific set of functions is provided. The queue pushes the elements on the back of the underlying container and pops them from the front.

### Template parameters

**T** - The type of the stored elements. The behavior is undefined if T is not the same type as `Container::value_type`. (since C++17)

**Container** - The type of the underlying container to use to store the elements. The container must satisfy the requirements of `SequenceContainer`. Additionally, it must provide the following functions with the usual semantics:

- `back()`
- `front()`
- `push_back()`
- `pop_front()`

The standard containers `std::deque` and `std::list` satisfy these requirements.

# Container Adapters
