

# **CS107, Lecture 6**

## **More Pointers and Arrays**

Reading: K&R (5.2-5.5) or Essential C section 6

# **CS107 Topic 3:** How can we effectively manage all types of memory in our programs?

# Lecture Plan

- Pointers and Parameters
- Double Pointers
- Arrays in Memory
- Arrays of Pointers
- Pointer Arithmetic
- Other topics: **const, struct** and ternary

```
cp -r /afs/ir/class/cs107/lecture-code/lect6 .
```

# Lecture Plan

- Double Pointers
- Arrays in Memory
- Arrays of Pointers
- Pointer Arithmetic
- Other topics: **const, struct** and ternary

```
cp -r /afs/ir/class/cs107/lecture-code/lect6 .
```

# Pointers

- A *pointer* is a variable that stores a memory address.
- Because there is no pass-by-reference in C like in C++, pointers let us pass around the address of one instance of memory, instead of making many copies.
- One (8 byte) pointer can represent any size memory location!
- Pointers are also essential for allocating memory on the heap, which we will cover later.
- Pointers also let us refer to memory generically, which we will cover later.

# Memory

- Memory is a big array of bytes.
- Each byte has a unique numeric index that is commonly written in hexadecimal.
- A pointer stores one of these memory addresses.

Address	Value
...	...
0x105	'\0'
0x104	'e'
0x103	'l'
0x102	'p'
0x101	'p'
0x100	'a'
...	...

# Memory

- Memory is a big array of bytes.
- Each byte has a unique numeric index that is commonly written in hexadecimal.
- A pointer stores one of these memory addresses.

Address	Value
	...
261	'\0'
260	'e'
259	'l'
258	'p'
257	'p'
256	'a'
	...

# Pointers

```
int x = 2;
```

```
// Make a pointer that stores the address of x.  
// (& means "address of")
```

```
int *xPtr = &x;
```

```
// Dereference the pointer to go to that address.  
// (*) means "dereference")  
printf("%d", *xPtr); // prints 2
```

# Pointers

A pointer is a variable that stores a memory address.

```
void myFunc(int *intPtr) {  
    *intPtr = 3;  
}
```

```
int main(int argc, char *argv[]) {  
    int x = 2;  
    myFunc(&x);  
    printf("%d", x); // 3!  
    ...  
}
```

Address	Value
x 0x1f0	2

# Pointers

A pointer is a variable that stores a memory address.

```
void myFunc(int *intPtr) {  
    *intPtr = 3;  
}
```

```
int main(int argc, char *argv[]) {  
    int x = 2;  
    myFunc(&x);  
    printf("%d", x); // 3!  
    ...  
}
```

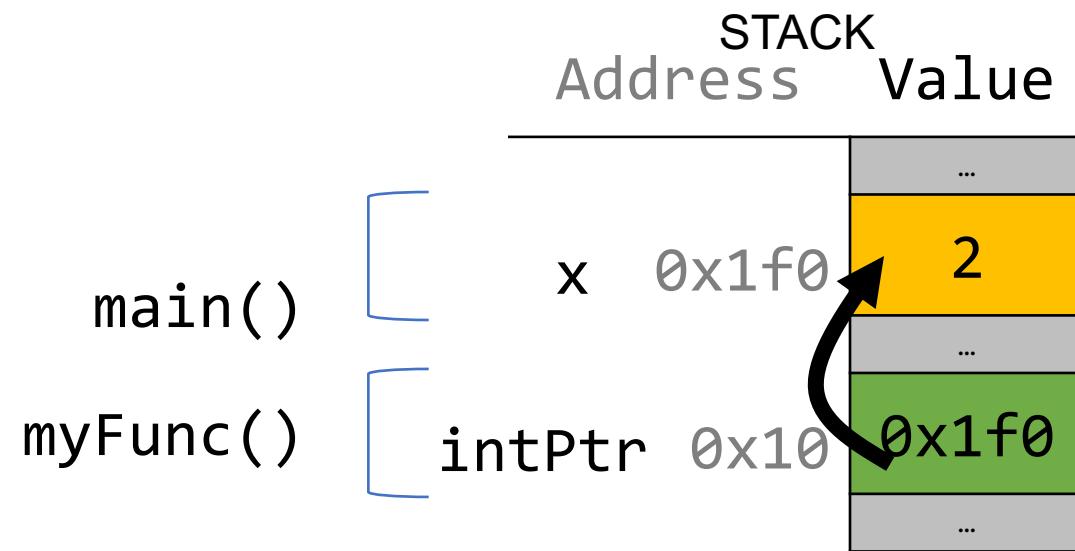

Address	Value
x 0x1f0	2

# Pointers

A pointer is a variable that stores a memory address.

```
void myFunc(int *intPtr) {  
    *intPtr = 3;  
}
```

```
int main(int argc, char *argv[]) {  
    int x = 2;  
    myFunc(&x);  
    printf("%d", x); // 3!  
    ...  
}
```

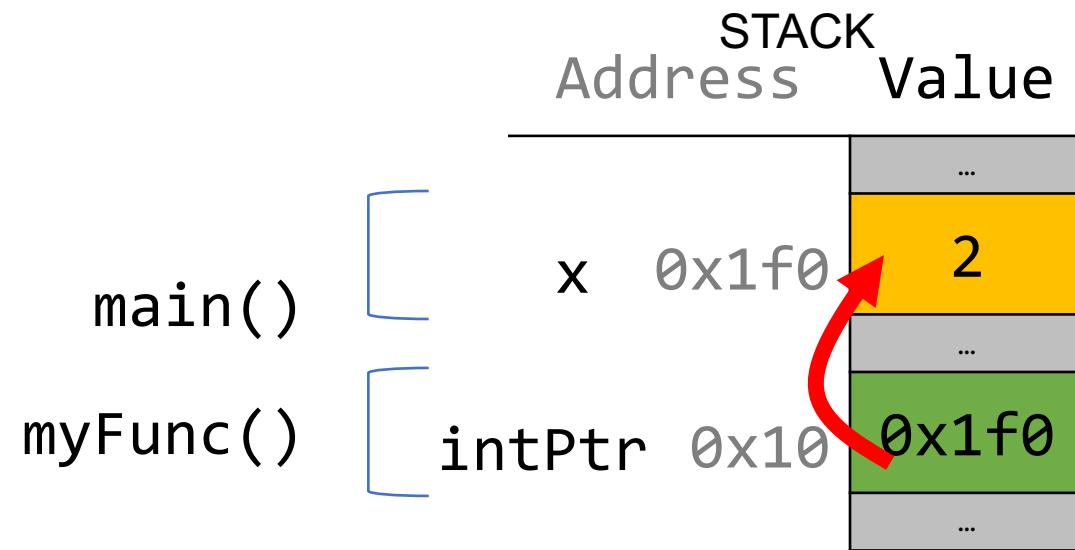

# Pointers

A pointer is a variable that stores a memory address.

```
void myFunc(int *intPtr) {  
    *intPtr = 3;  
}
```

```
int main(int argc, char *argv[]) {  
    int x = 2;  
    myFunc(&x);  
    printf("%d", x);    // 3!  
    ...  
}
```

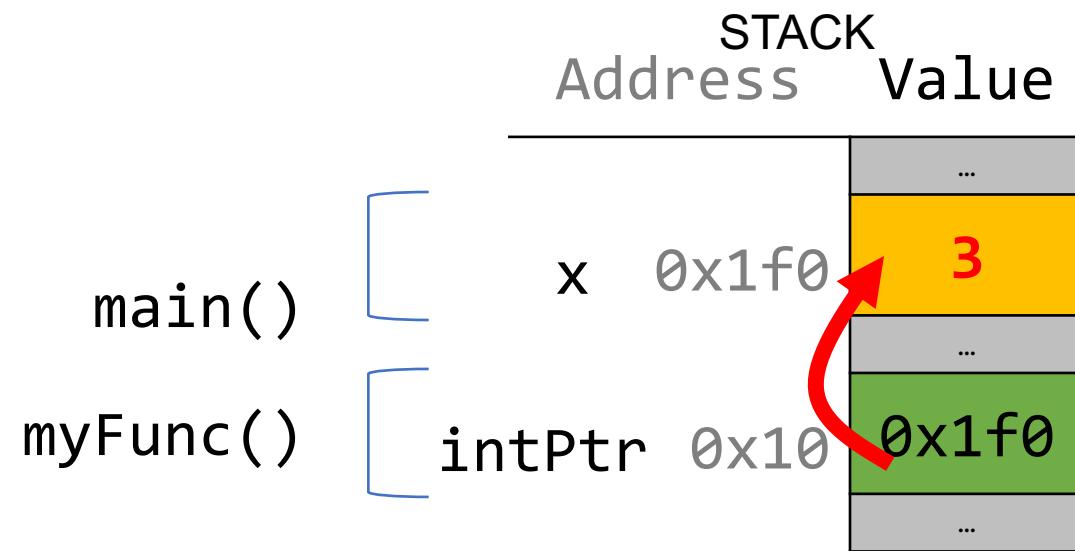

# Pointers

A pointer is a variable that stores a memory address.

```
void myFunc(int *intPtr) {  
    *intPtr = 3;  
}
```

```
int main(int argc, char *argv[]) {  
    int x = 2;  
    myFunc(&x);  
    printf("%d", x);    // 3!  
    ...  
}
```

# Pointers

A pointer is a variable that stores a memory address.

```
void myFunc(int *intPtr) {  
    *intPtr = 3;  
}
```

```
int main(int argc, char *argv[]) {  
    int x = 2;  
    myFunc(&x);  
    printf("%d", x);    // 3!  
    ...  
}
```

Address	Value
x 0x1f0	3

# Pointers

A pointer is a variable that stores a memory address.

```
void myFunc(int *intPtr) {  
    *intPtr = 3;  
}
```

```
int main(int argc, char *argv[]) {  
    int x = 2;  
    myFunc(&x);  
    printf("%d", x); // 3!  
    ...  
}
```

Address	Value
x 0x1f0	3

# C Parameters

When you pass a value as a parameter, C passes a copy of that value.

```
void myFunction(int x) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    int num = 4;  
    myFunction(num);          // passes copy of 4  
}
```

# C Parameters

When you pass a value as a parameter, C passes a copy of that value.

```
void myFunction(int *x) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    int num = 4;  
    myFunction(&num);          // passes copy of e.g. 0xffed63  
}
```

# C Parameters

When you pass a value as a parameter, C passes a copy of that value.

```
void myFunction(char ch) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = "Hello!";  
    myFunction(myStr[1]);           // passes copy of 'e'  
}
```

# C Parameters

If you are performing an operation with some input and do not care about any changes to the input, pass the data type itself.

# C Parameters

If you are performing an operation with some input and do not care about any changes to the input, pass the data type itself.

```
void myFunction(char ch) {  
    printf("%c", ch);  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = "Hello!";  
    myFunction(myStr[1]);           // prints 'e'  
}
```

# C Parameters

If you are performing an operation with some input and do not care about any changes to the input, pass the data type itself.

```
int myFunction(int num1, int num2) {  
    return x + y;  
}  
  
int main(int argc, char *argv[]) {  
    int x = 5;  
    int y = 6;  
    int sum = myFunction(x, y);      // returns 11  
}
```

# C Parameters

If you are modifying a specific instance of some value, pass the *location* of what you would like to modify.

Do I care about modifying *this* instance of my data? If so, I need to pass where that instance lives, as a parameter, so it can be modified.

# Pointers

If you are modifying a specific instance of some value, pass the *location* of what you would like to modify.

```
void capitalize(char *ch) {  
    // modifies what is at the address stored in ch  
}  
  
int main(int argc, char *argv[]) {  
    char letter = 'h';  
    /* We don't want to capitalize any instance of 'h'.  
     * We want to capitalize *this* instance of 'h'! */  
    capitalize(&letter);  
    printf("%c", letter); // want to print 'H';  
}
```

# Pointers

If you are modifying a specific instance of some value, pass the *location* of what you would like to modify.

```
void doubleNum(int *x) {  
    // modifies what is at the address stored in x  
}  
  
int main(int argc, char *argv[]) {  
    int num = 2;  
    /* We don't want to double any instance of 2.  
     * We want to double *this* instance of 2! */  
    doubleNum(&num);  
    printf("%d", num); // want to print 4;  
}
```

# Pointers

If a function takes an address (pointer) as a parameter, it can *go to* that address if it needs the actual value.

```
void capitalize(char *ch) {  
    // *ch gets the character stored at address ch.  
    char newChar = toupper(*ch);  
  
    // *ch = goes to address ch and puts newChar there.  
    *ch = newChar;  
}
```

# Pointers

If a function takes an address (pointer) as a parameter, it can *go to* that address if it needs the actual value.

```
void capitalize(char *ch) {  
    /* go to address ch and put the capitalized version  
     * of what is at address ch there. */  
    *ch = toupper(*ch);  
}
```

# Pointers

If a function takes an address (pointer) as a parameter, it can *go to* that address if it needs the actual value.

```
void capitalize(char *ch) {  
    // this capitalizes the address ch! ☹  
    char newChar = toupper(ch);  
  
    // this stores newChar in ch as an address! ☹  
    ch = newChar;  
}
```

# char \*

- A char \* is technically a pointer to a single character.
- We commonly use char \* as string by having the character it points to be followed by more characters and ultimately a null terminator.
- A char \* could also just point to a single character (not a string).

**String Behavior #7:** If we change characters in a string parameter, these changes will persist outside of the function.

# Strings as Parameters

When we pass a **char \*** string as a parameter, C makes a *copy* of the address stored in the **char \***, and passes it to the function. This means they both refer to the same memory location.

```
void myFunc(char *myStr) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    char *str = "apple";  
    myFunc(str);  
    ...  
}
```

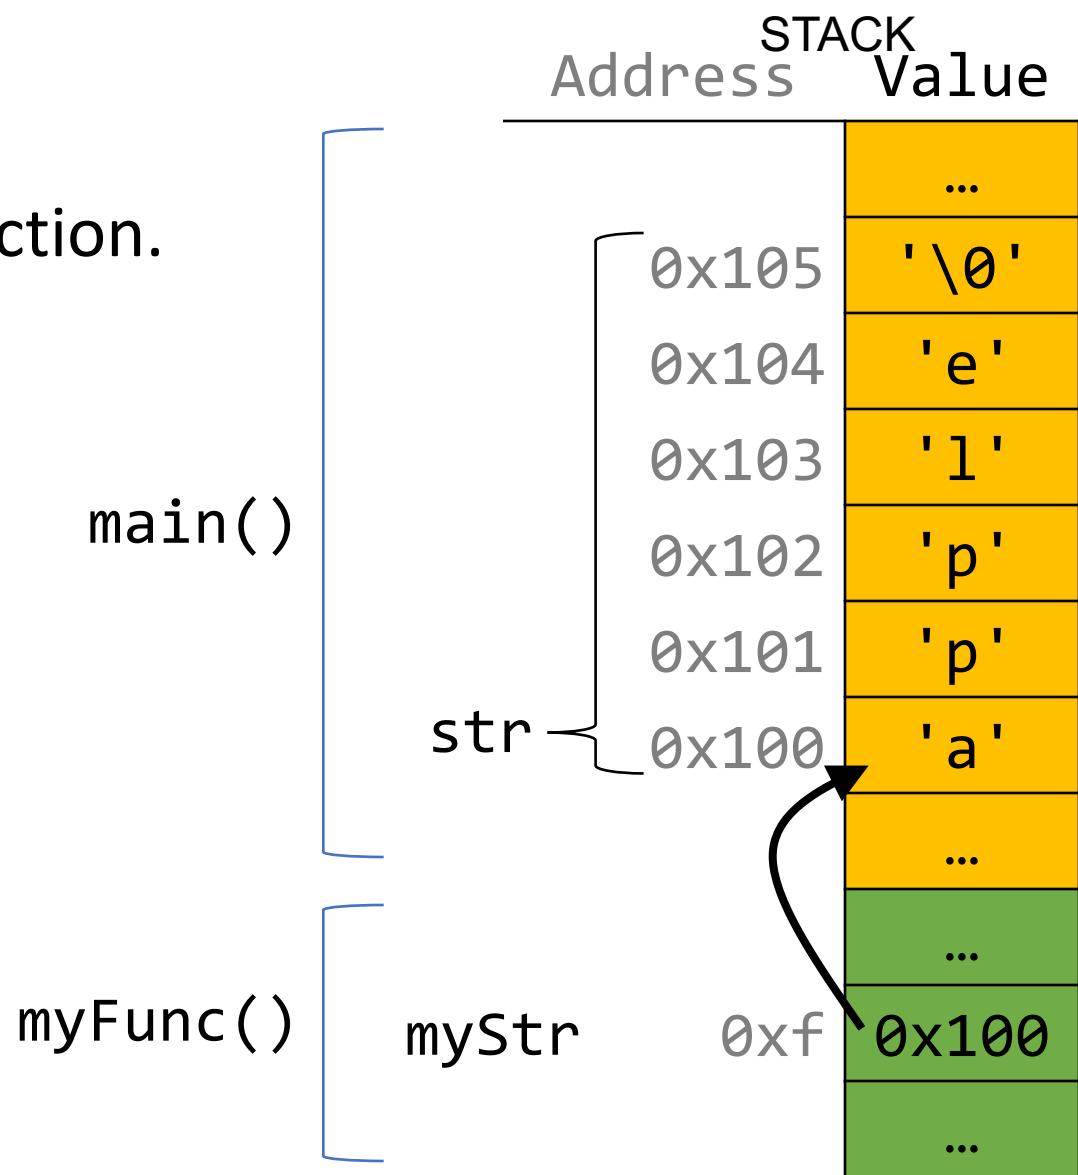

```
main()  
myFunc()
```

Address	STACK Value
str	0xffff0 ...
myStr	0xff0 ...

# Strings as Parameters

When we pass a **char array** as a parameter, C makes a *copy of the address of the first array element*, and passes it (as a **char \***) to the function.

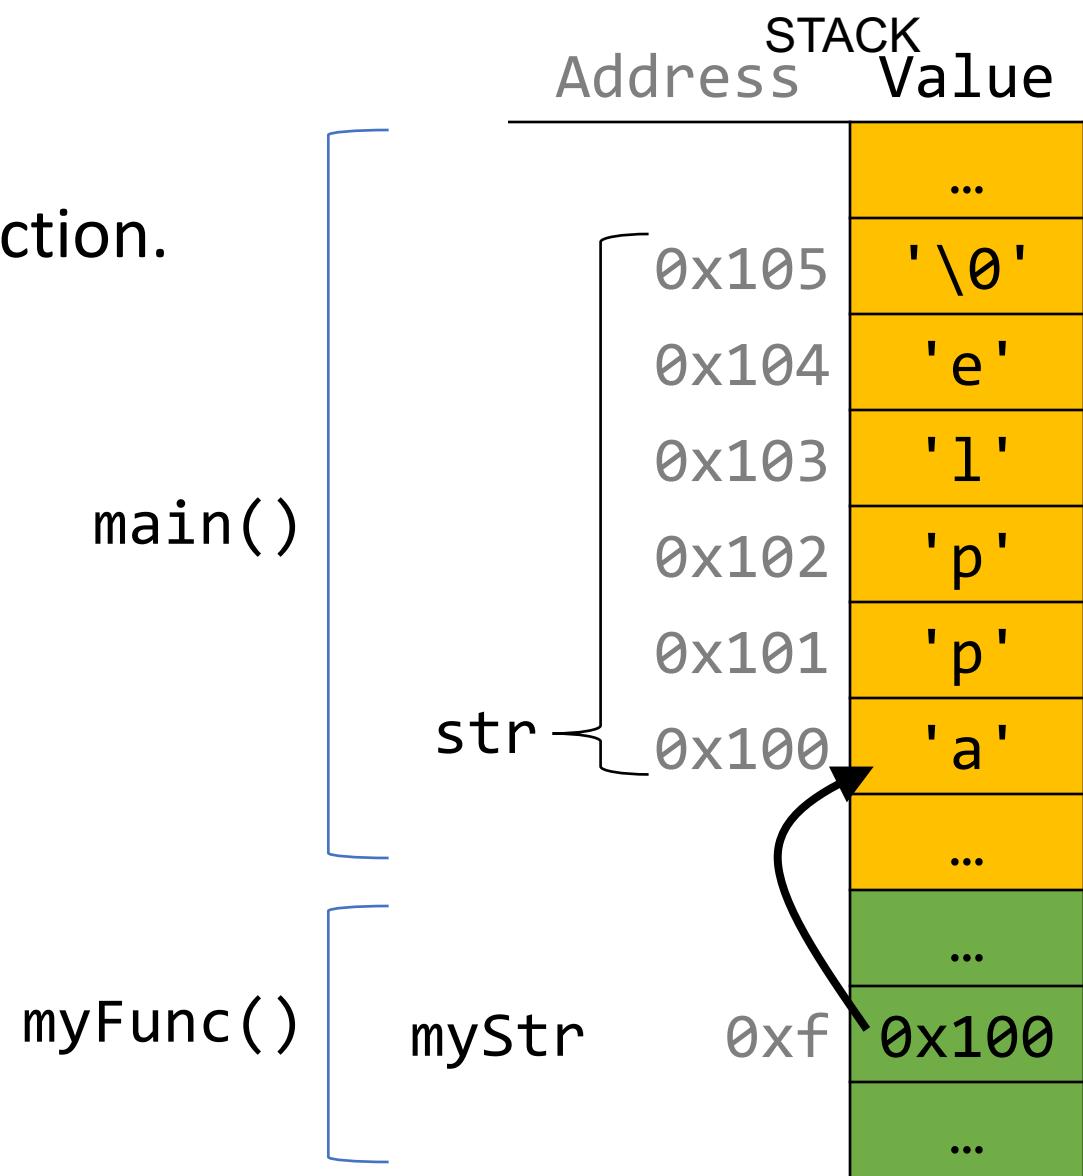

```
void myFunc(char *myStr) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    char str[6];  
    strcpy(str, "apple");  
    myFunc(str);  
    ...  
}
```

# Strings as Parameters

When we pass a **char array** as a parameter, C makes a *copy of the address of the first array element*, and passes it (as a **char \***) to the function.

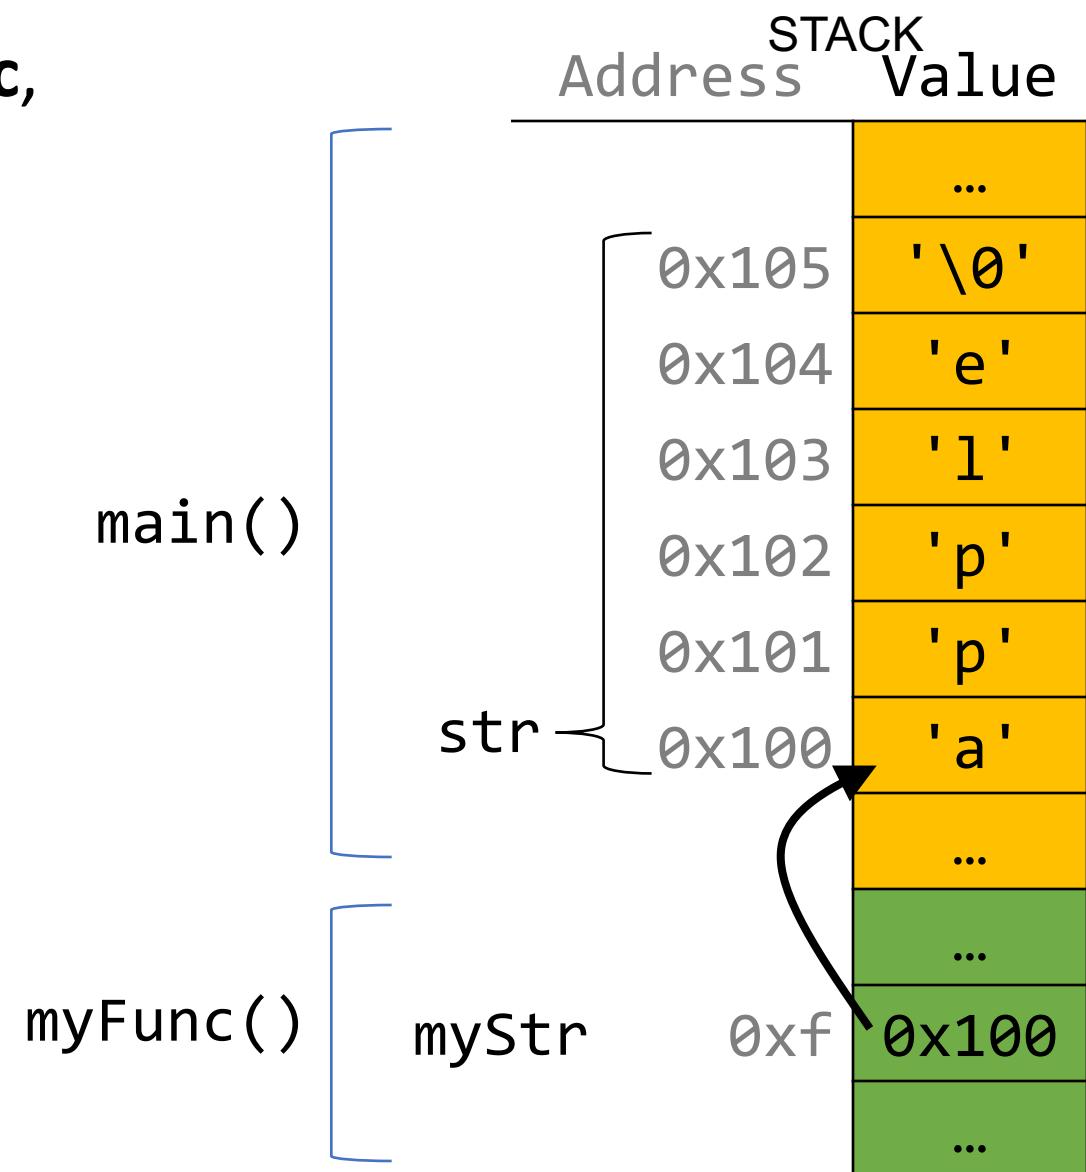

```
void myFunc(char *myStr) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    char str[6];  
    strcpy(str, "apple");  
    // equivalent  
    char *strAlt = str;  
    myFunc(strAlt);  
    ...  
}
```

# Strings as Parameters

This means if we modify characters in **myFunc**,  
the changes will persist back in **main**!

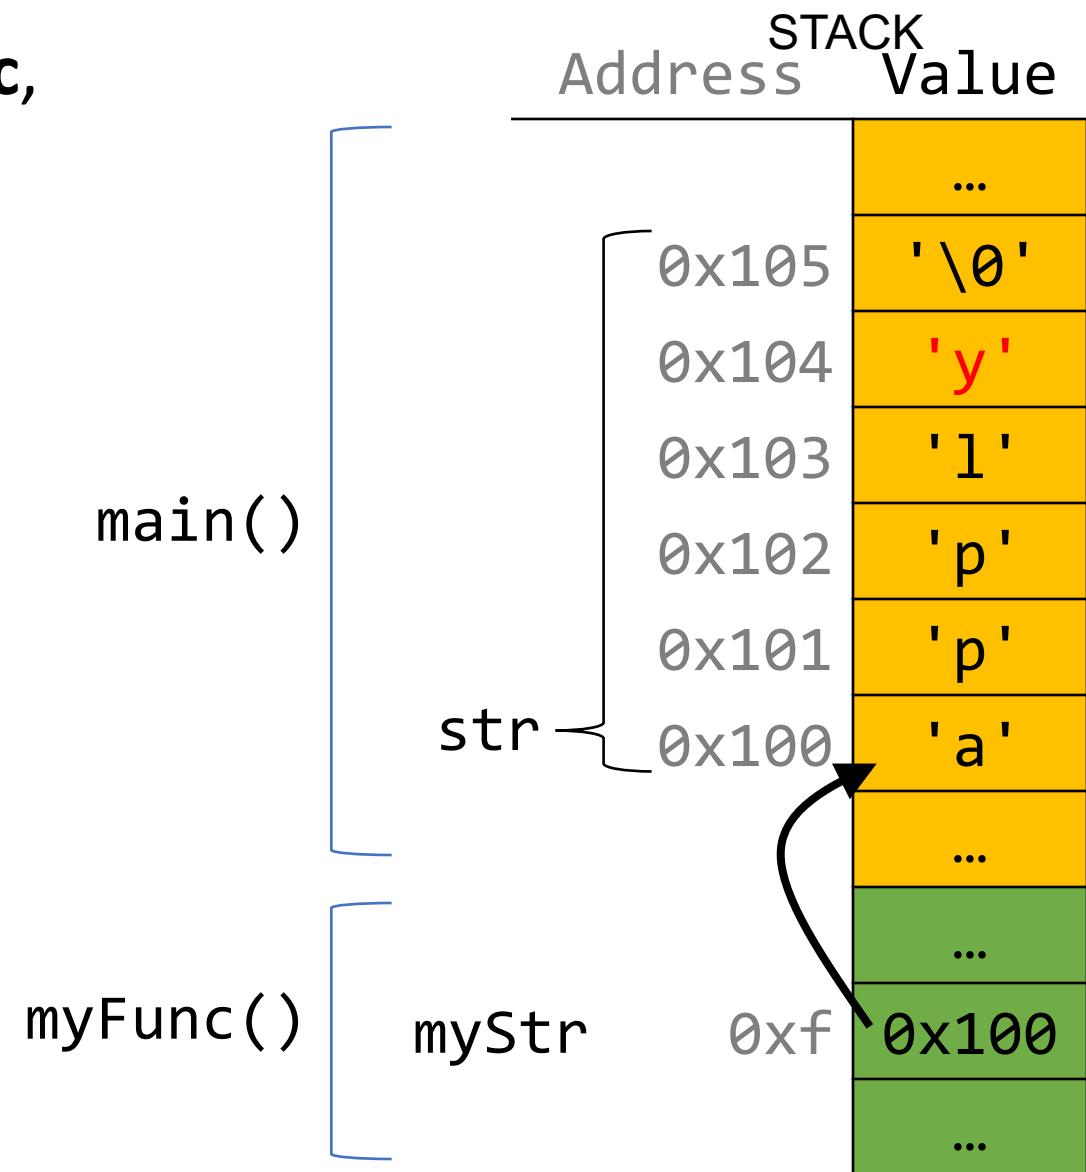

```
void myFunc(char *myStr) {  
    myStr[4] = 'y';  
}  
  
int main(int argc, char *argv[]) {  
    char str[6];  
    strcpy(str, "apple");  
    myFunc(str);  
    printf("%s", str); // apply  
    ...  
}
```

# Strings as Parameters

This means if we modify characters in **myFunc**,  
the changes will persist back in **main**!

```
void myFunc(char *myStr) {  
    myStr[4] = 'y';  
}  
  
int main(int argc, char *argv[]) {  
    char str[6];  
    strcpy(str, "apple");  
    myFunc(str);  
    printf("%s", str); // apply  
    ...  
}
```

# Exercise 1

We want to write a function that prints out the square of a number. What should go in each of the blanks?

```
void printSquare(__?__) {  
    int square = __?__ * __?__;  
    printf("%d", square);  
}  
  
int main(int argc, char *argv[]) {  
    int num = 3;  
    printSquare(__?__); // should print 9  
}
```

# Exercise 1

We want to write a function that prints out the square of a number. What should go in each of the blanks?

```
void printSquare(int x) {  
    int square = x * x;  
    printf("%d", square);  
}
```

```
int main(int argc, char *argv[]) {  
    int num = 3;  
    printSquare(num); // should print 9  
}
```

We are performing a calculation with some input and do not care about any changes to the input, so we pass the data type itself.

# Exercise 1

We want to write a function that prints out the square of a number. What should go in each of the blanks?

```
void printSquare(int x) {  
    x = x * x;  
    printf("%d", x);  
}
```

We are performing a calculation with some input and do not care about any changes to the input, so we pass the data type itself.

```
int main(int argc, char *argv[]) {  
    int num = 3;  
    printSquare(num); // should print 9  
}
```

# Exercise 2

We want to write a function that flips the case of a letter. What should go in each of the blanks?

```
void flipCase(__?__) {  
    if (isupper(__?__)) {  
        __?__ = __?__;  
    } else if (islower(__?__)) {  
        __?__ = __?__;  
    }  
}  
  
int main(int argc, char *argv[]) {  
    char ch = 'g';  
    flipCase(__?__);  
    printf("%c", ch);      // want this to print 'G'  
}
```

# Exercise 2

We want to write a function that flips the case of a letter. What should go in each of the blanks?

```
void flipCase(char *letter) {  
    if (isupper(*letter)) {  
        *letter = tolower(*letter);  
    } else if (islower(*letter)) {  
        *letter = toupper(*letter);  
    }  
  
int main(int argc, char *argv[]) {  
    char ch = 'g';  
    flipCase(&ch);  
    printf("%c", ch);      // want this to print 'G'  
}
```

We are modifying a specific instance of the letter, so we pass the *location* of the letter we would like to modify.

# Pointers Summary

- If you are performing an operation with some input and do not care about any changes to the input, **pass the data type itself**.
- If you are modifying a specific instance of some value, **pass the location** of what you would like to modify.
- If a function takes an address (pointer) as a parameter, it can *go to* that address if it needs the actual value.

# Pointers Summary

- **Tip:** setting a function parameter equal to a new value usually doesn't do what you want. Remember that this is setting the function's *own copy* of the parameter equal to some new value.

```
void doubleNum(int x) {  
    x = x * x;      // modifies doubleNum's own copy!  
}
```

```
void advanceStr(char *str) {  
    str += 2;        // modifies advanceStr's own copy!  
}
```

# Lecture Plan

- Pointers and Parameters
- **Double Pointers**
- Arrays in Memory
- Arrays of Pointers
- Pointer Arithmetic
- Other topics: **const, struct** and ternary

```
cp -r /afs/ir/class/cs107/lecture-code/lect6 .
```

# Exercise 3

Sometimes, we would like to modify a string's pointer itself, rather than just the characters it points to. E.g. we want to write a function **skipSpaces** that modifies a string pointer to skip past any initial spaces. What should go in each of the blanks?

```
void skipSpaces(__?__) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    char *str = "    hello";  
    skipSpaces(__?__);  
    printf("%s", str);      // should print "hello"  
}
```

# Exercise 3

Sometimes, we would like to modify a string's pointer itself, rather than just the characters it points to. E.g. we want to write a function **skipSpaces** that modifies a string pointer to skip past any initial spaces. What should go in each of the blanks?

```
void skipSpaces(char **strPtr) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    char *str = "    hello";  
    skipSpaces(&str);  
    printf("%s", str);          // should print "hello"  
}
```

We are modifying a specific instance of the string pointer, so we pass the *location* of the string pointer we would like to modify.

# Exercise 3

Sometimes, we would like to modify a string's pointer itself, rather than just the characters it points to. E.g. we want to write a function **skipSpaces** that modifies a string pointer to skip past any initial spaces. What should go in each of the blanks?

```
void skipSpaces(char *strPtr) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    char *str = "    hello";  
    skipSpaces(str);  
    printf("%s", str);        // should print "hello"  
}
```

This advances skipSpace's own copy of the string pointer, not the instance in main.

# Demo: Skip Spaces

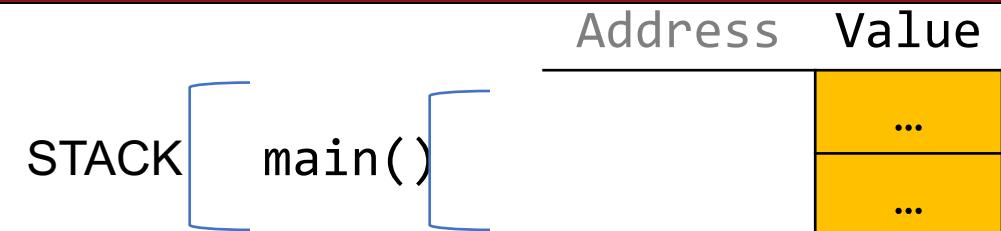

skip\_spaces.c

# Pointers to Strings

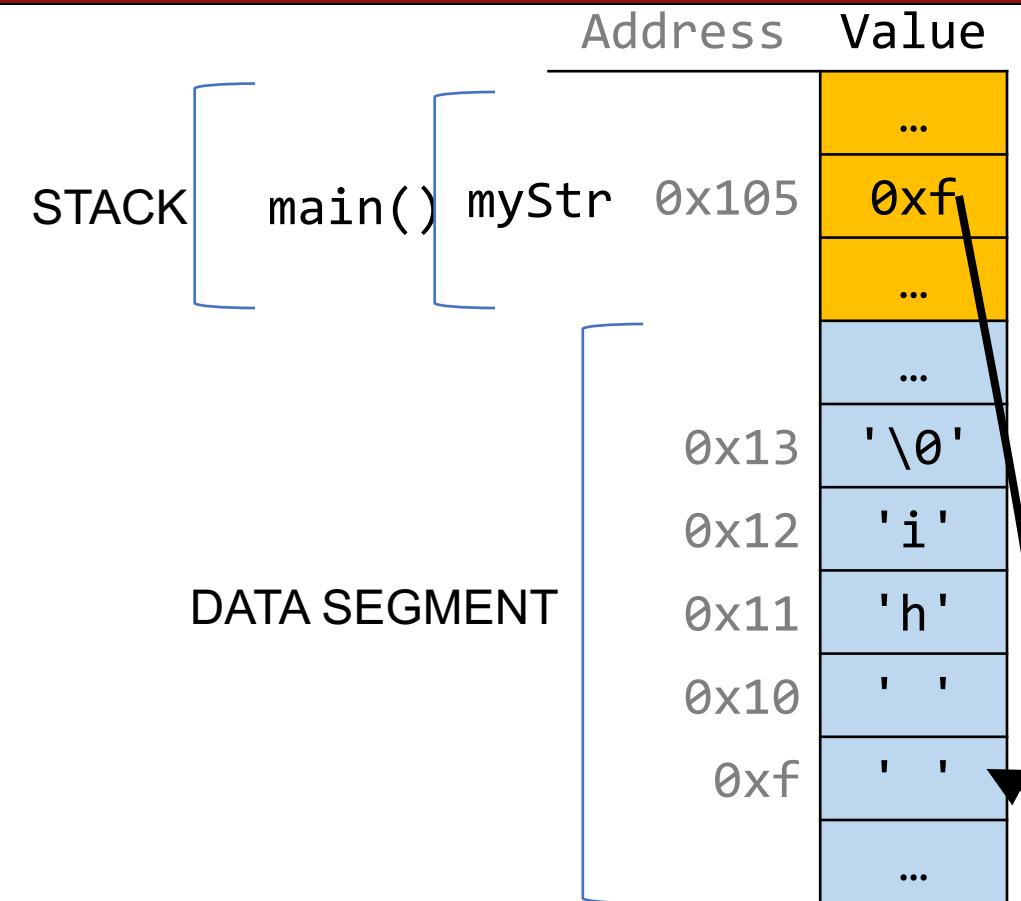

```
void skipSpaces(char **strPtr) {  
    int numSpaces = strspn(*strPtr, " ");  
    *strPtr += numSpaces;  
}
```

```
int main(int argc, char *argv[]) {  
    char *myStr = " hi";  
    skipSpaces(&myStr);  
    printf("%s\n", myStr);      // hi  
    return 0;  
}
```

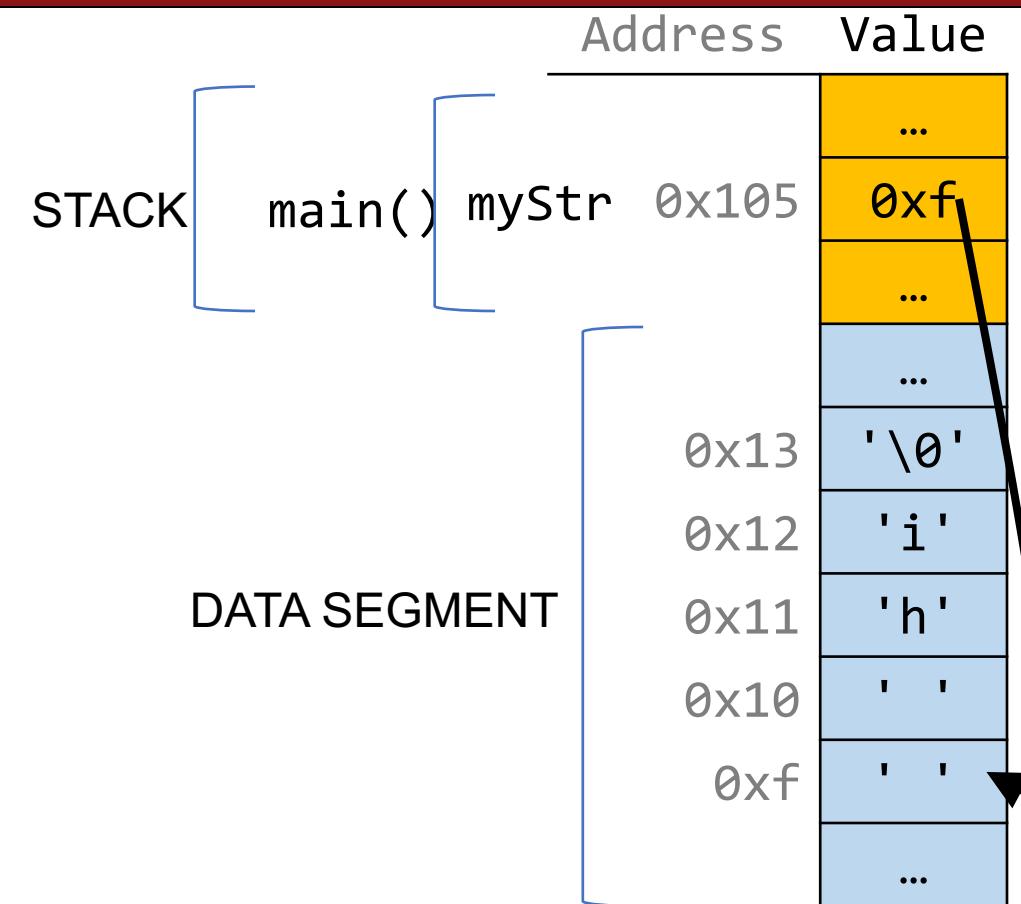

# Pointers to Strings

```
void skipSpaces(char **strPtr) {  
    int numSpaces = strspn(*strPtr, " ");  
    *strPtr += numSpaces;  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = " hi";  
    skipSpaces(&myStr);  
    printf("%s\n", myStr);      // hi  
    return 0;  
}
```

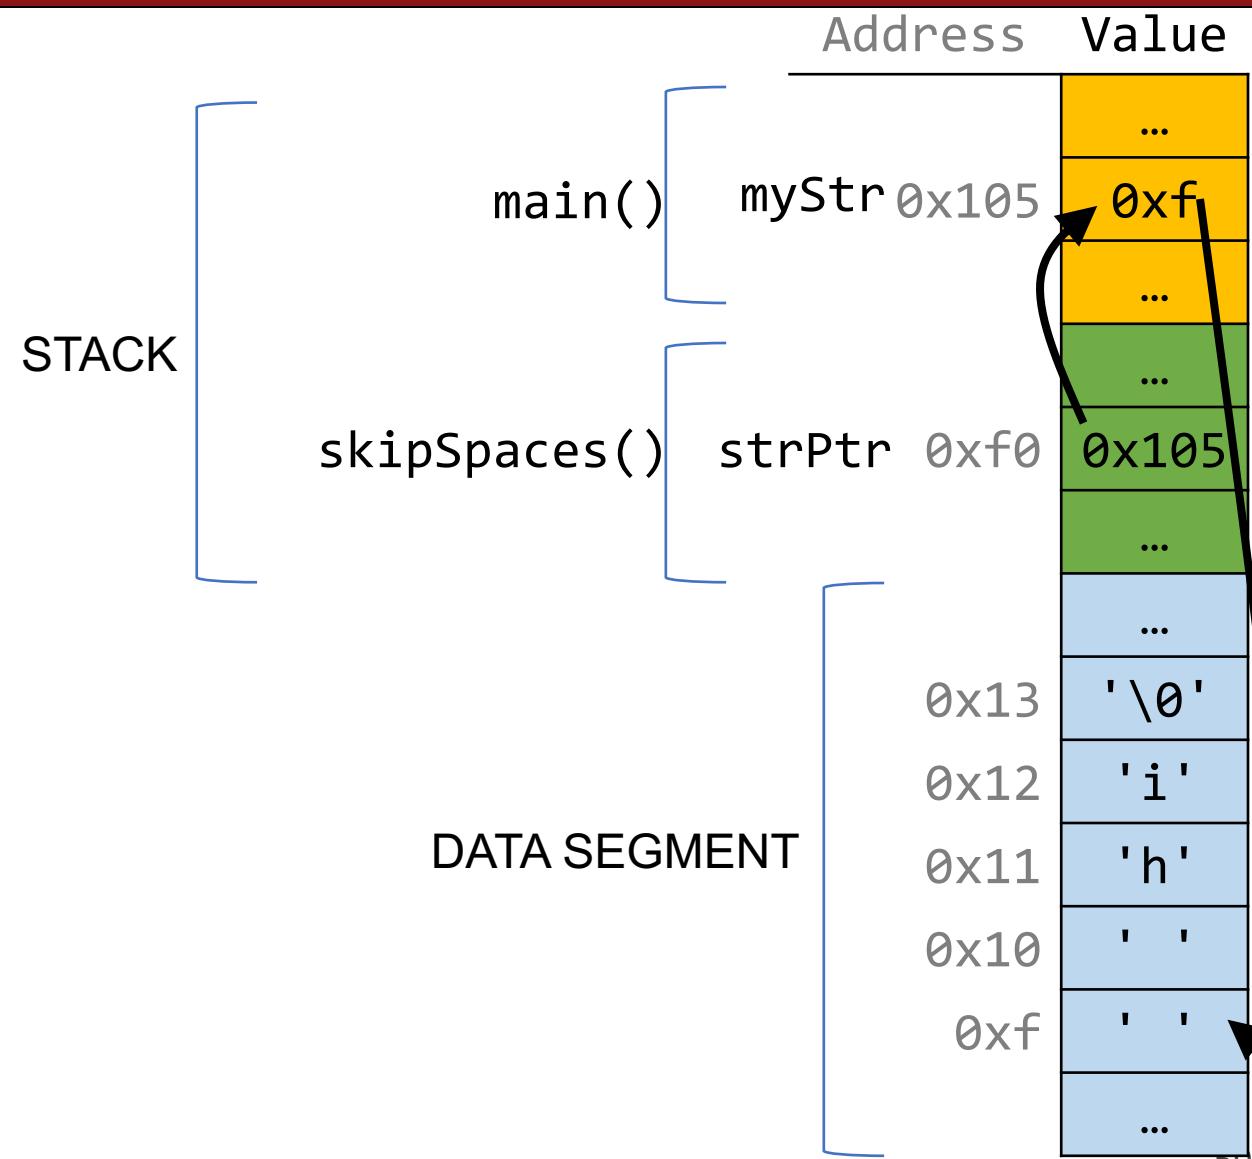

# Pointers to Strings

```
void skipSpaces(char **strPtr) {  
    int numSpaces = strspn(*strPtr, " ");  
    *strPtr += numSpaces;  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = " hi";  
    skipSpaces(&myStr);  
    printf("%s\n", myStr);      // hi  
    return 0;  
}
```

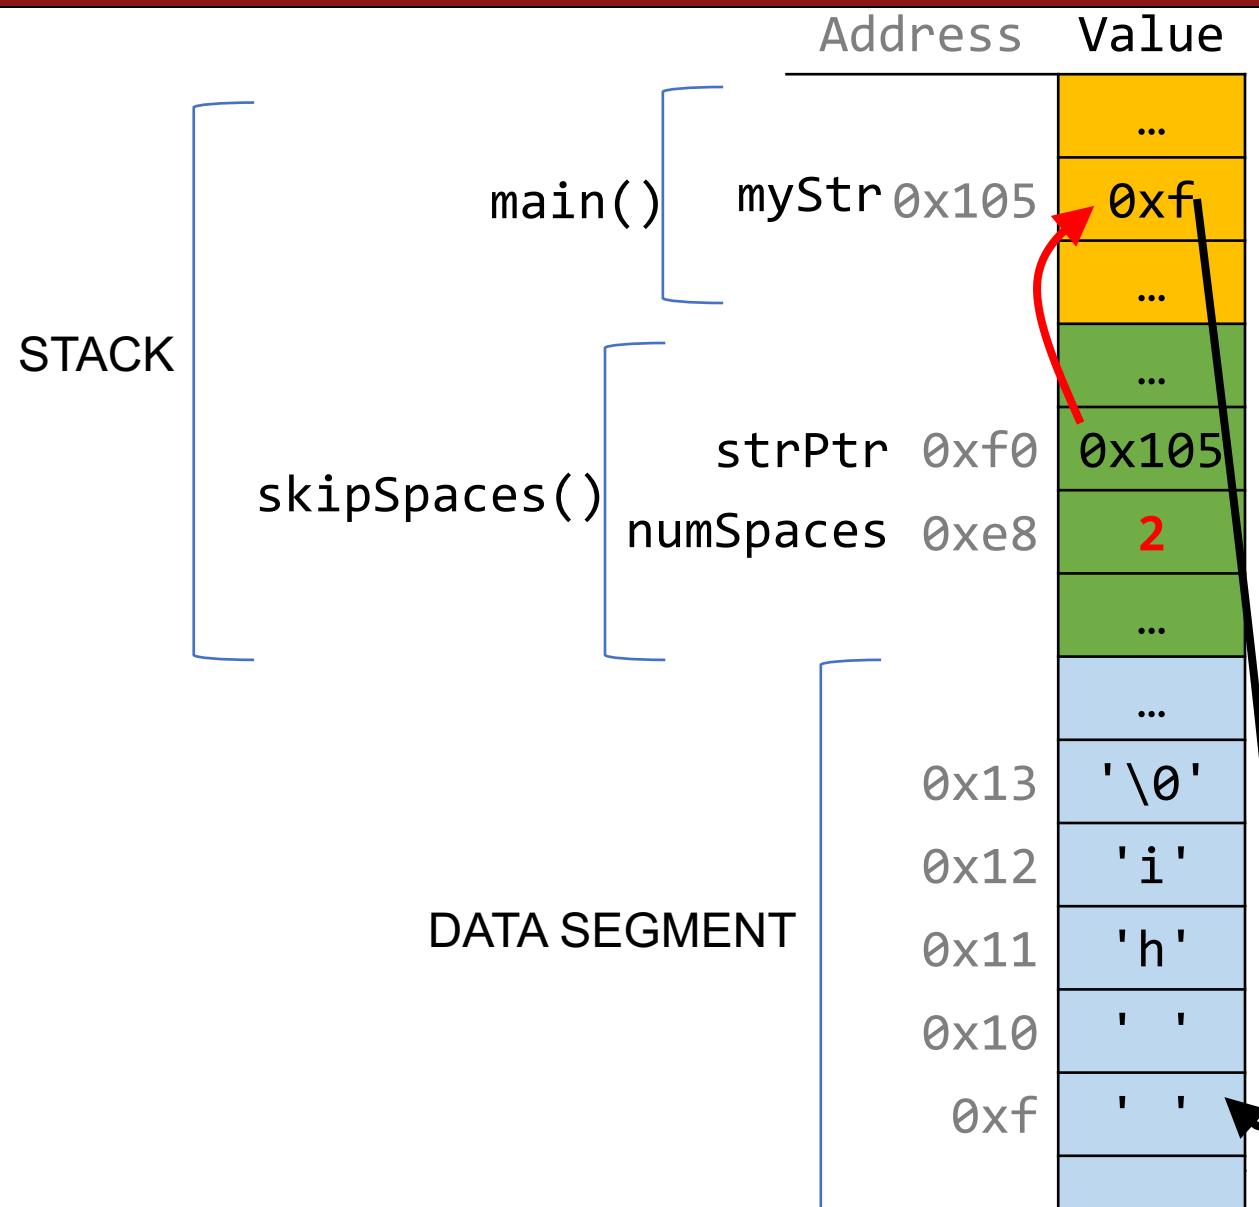

# Pointers to Strings

```
void skipSpaces(char **strPtr) {  
    int numSpaces = strspn(*strPtr, " ");  
    *strPtr += numSpaces;  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = " hi";  
    skipSpaces(&myStr);  
    printf("%s\n", myStr); // hi  
    return 0;  
}
```

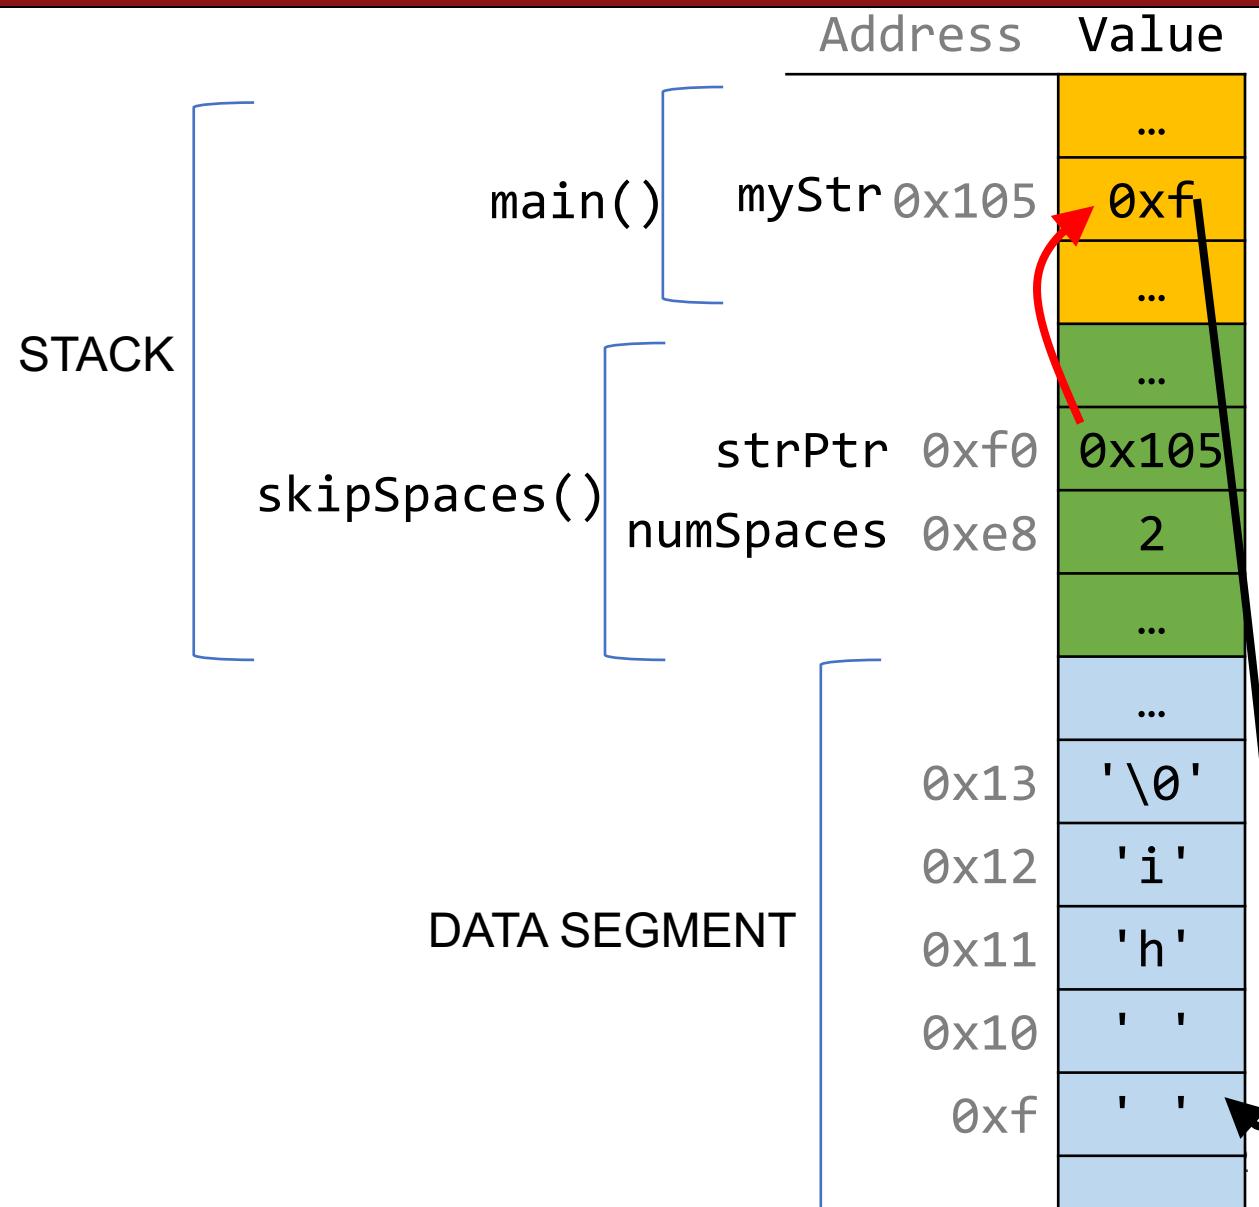

# Pointers to Strings

```
void skipSpaces(char **strPtr) {  
    int numSpaces = strspn(*strPtr, " ");  
    *strPtr += numSpaces;  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = " hi";  
    skipSpaces(&myStr);  
    printf("%s\n", myStr);      // hi  
    return 0;  
}
```

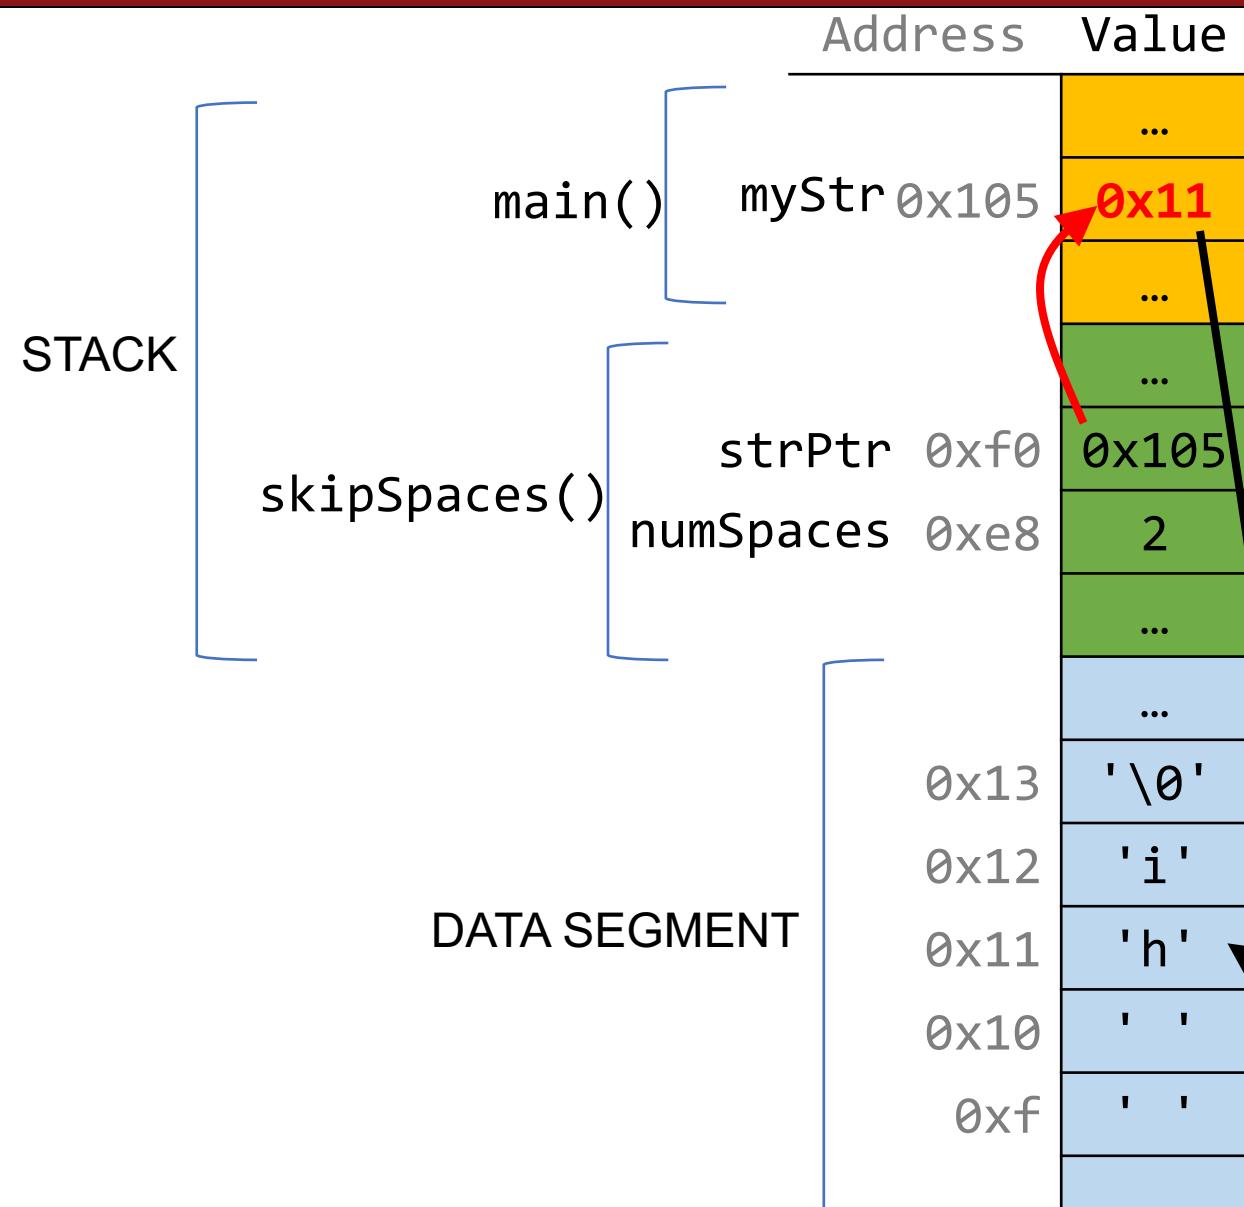

# Pointers to Strings

```
void skipSpaces(char **strPtr) {  
    int numSpaces = strspn(*strPtr, " ");  
    *strPtr += numSpaces;  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = " hi";  
    skipSpaces(&myStr);  
    printf("%s\n", myStr); // hi  
    return 0;  
}
```

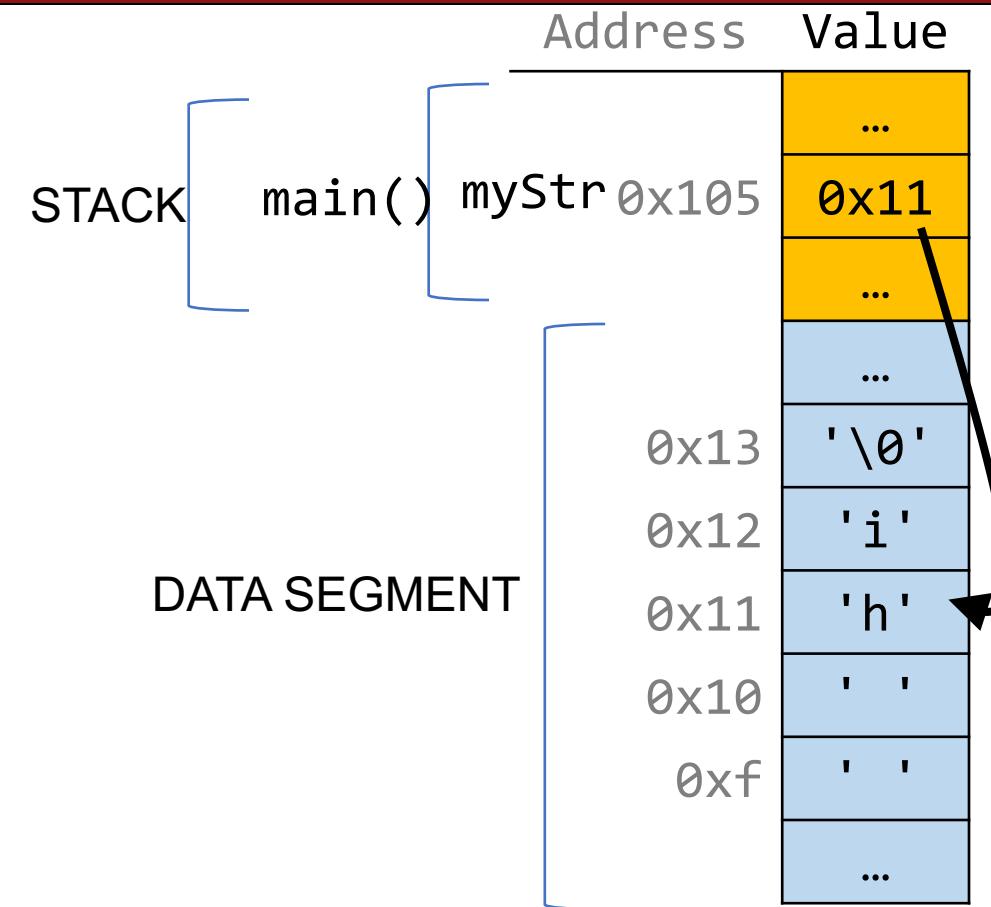

# Pointers to Strings

void skipSpaces(char **strPtr) {  
    int numSpaces = strspn(*strPtr, " ");  
    *strPtr += numSpaces;  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = " hi";  
    skipSpaces(&myStr);  
    printf("%s\n", myStr);      // hi  
    return 0;  
}
```

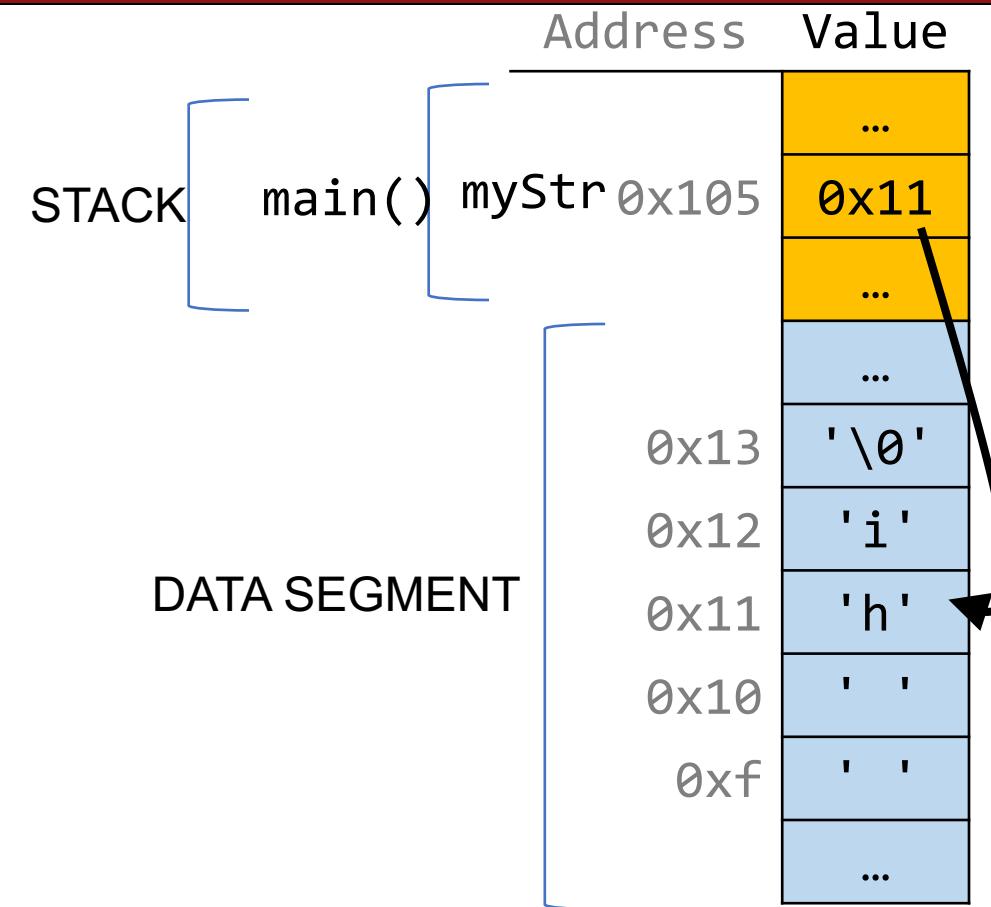

# Pointers to Strings

```
void skipSpaces(char **strPtr) {  
    int numSpaces = strspn(*strPtr, " ");  
    *strPtr += numSpaces;  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = " hi";  
    skipSpaces(&myStr);  
    printf("%s\n", myStr);      // hi  
    return 0;  
}
```

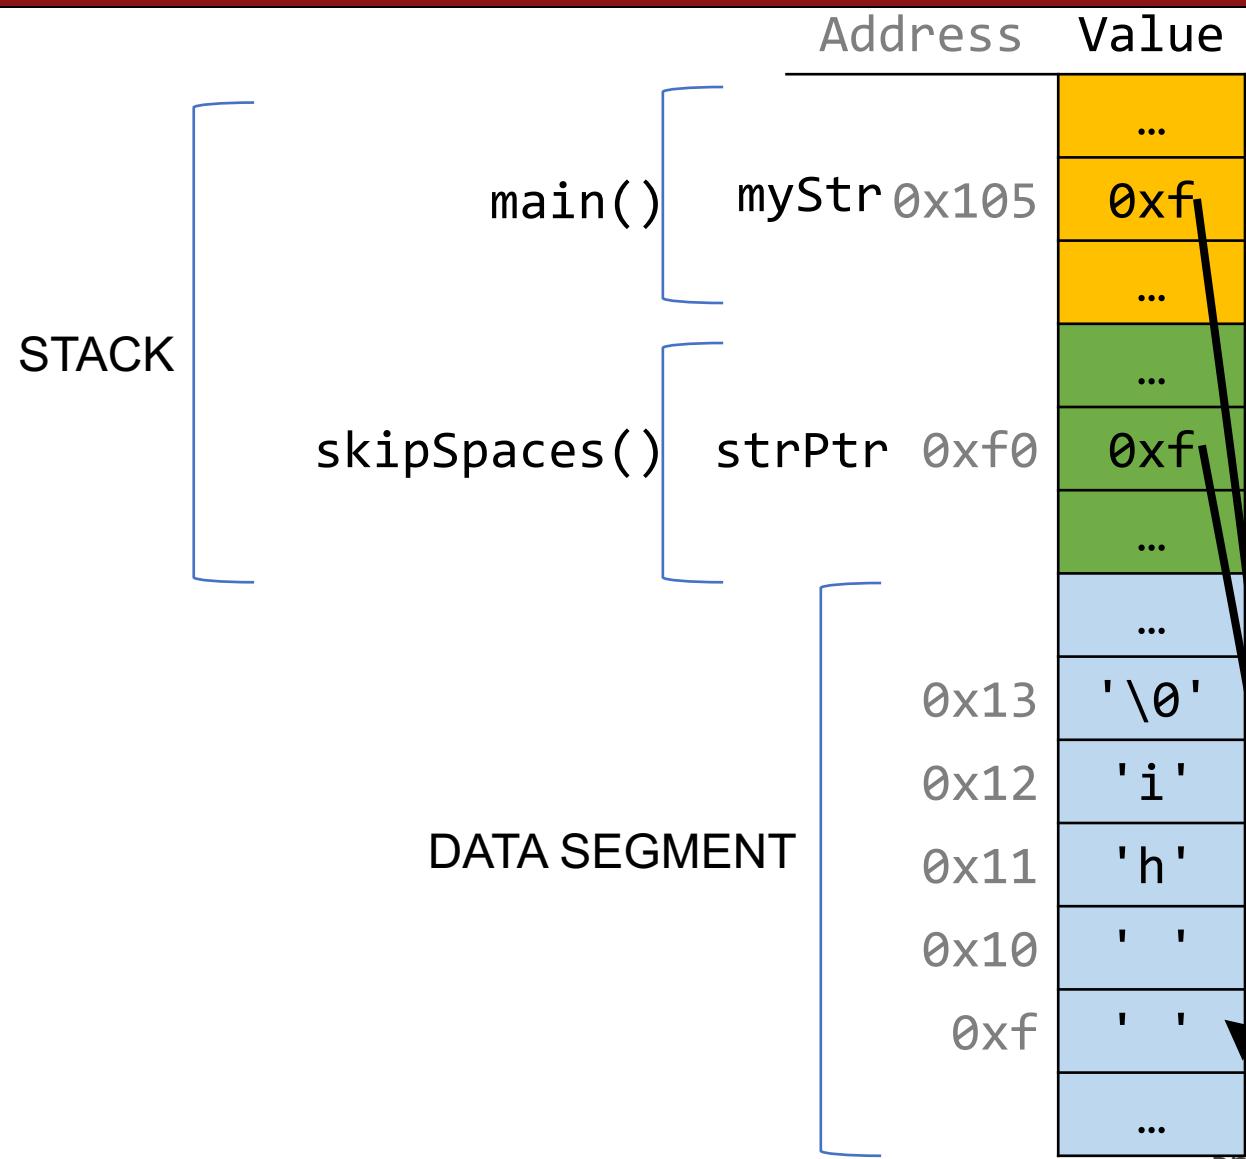

# Pointers to Strings

```
void skipSpaces(char **strPtr) {  
    int numSpaces = strspn(*strPtr, " ");  
    *strPtr += numSpaces;  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = " hi";  
    skipSpaces(&myStr);  
    printf("%s\n", myStr); // hi  
    return 0;  
}
```

# Making Copies

```
void skipSpaces(char *strPtr) {  
    int numSpaces = strspn(strPtr, " ");  
    strPtr += numSpaces;  
}  
  
int main(int argc, char *argv[]) {  
    char *myStr = " hi";  
    skipSpaces(myStr);  
    printf("%s\n", myStr); // hi  
    return 0;  
}
```

# Lecture Plan

- Pointers and Parameters
- Double Pointers
- **Arrays in Memory**
- Arrays of Pointers
- Pointer Arithmetic
- Other topics: **const, struct** and ternary

```
cp -r /afs/ir/class/cs107/lecture-code/lect6 .
```

# Arrays

When you declare an array, contiguous memory is allocated on the stack to store the contents of the entire array.

```
char str[6];  
strcpy(str, "apple");
```

The array variable (e.g. **str**) is not a pointer; it refers to the entire array contents. In fact, **sizeof** returns the size of the entire array!

```
int arrayBytes = sizeof(str); // 6
```

Address	Value
...	
0x105	'\0'
0x104	'e'
0x103	'l'
0x102	'p'
0x101	'p'
0x100	'a'
...	

str

# Arrays

An array variable refers to an entire block of memory. You cannot reassign an existing array to be equal to a new array.

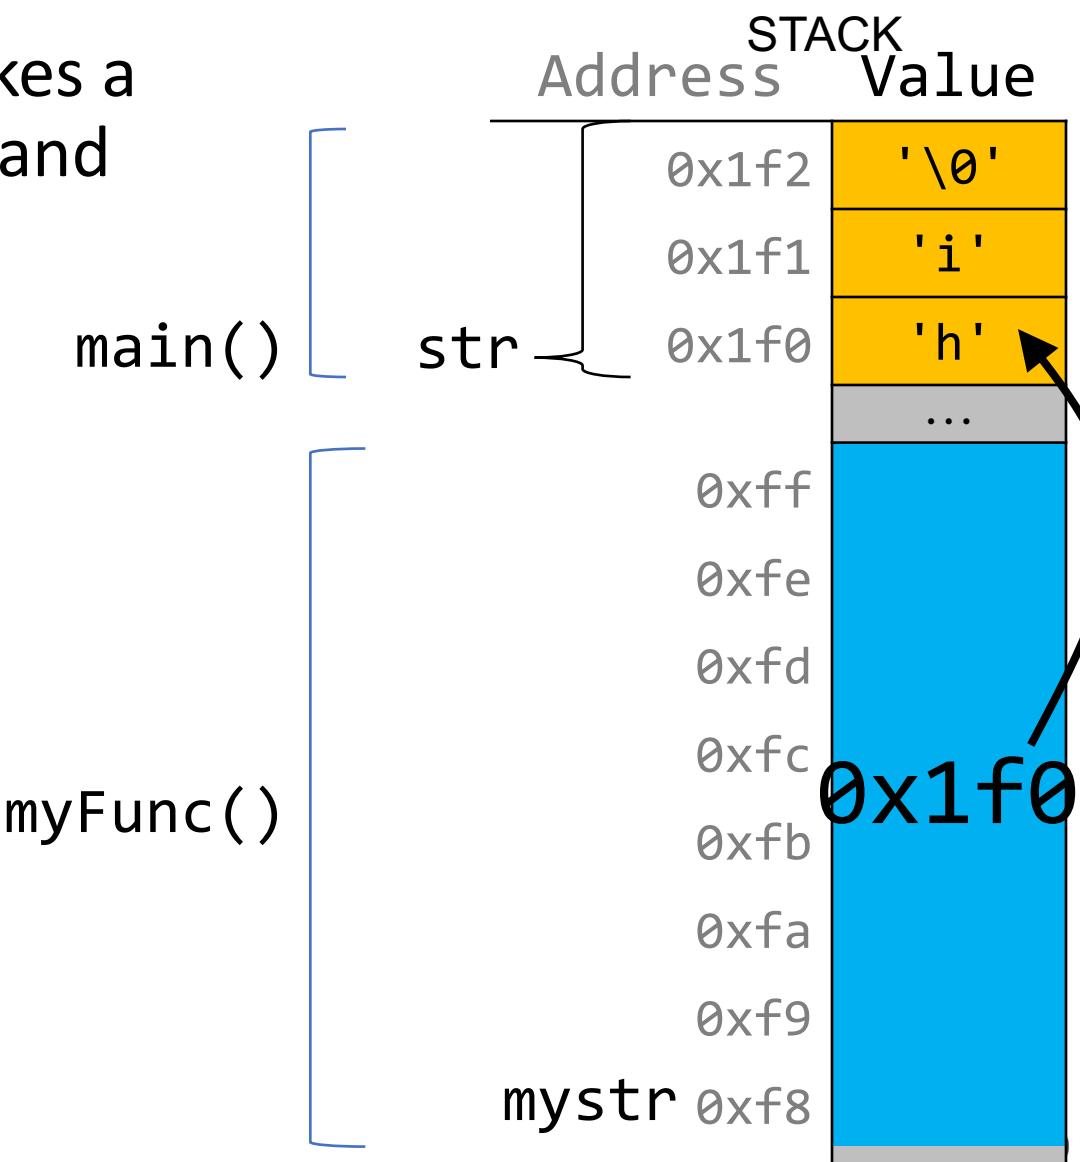

```
int nums[] = {1, 2, 3};  
int nums2[] = {4, 5, 6, 7};  
nums = nums2; // not allowed!
```

An array's size cannot be changed once you create it; you must create another new array instead.

# Arrays as Parameters

When you pass an **array** as a parameter, C makes a *copy of the address of the first array element*, and passes it (a pointer) to the function.

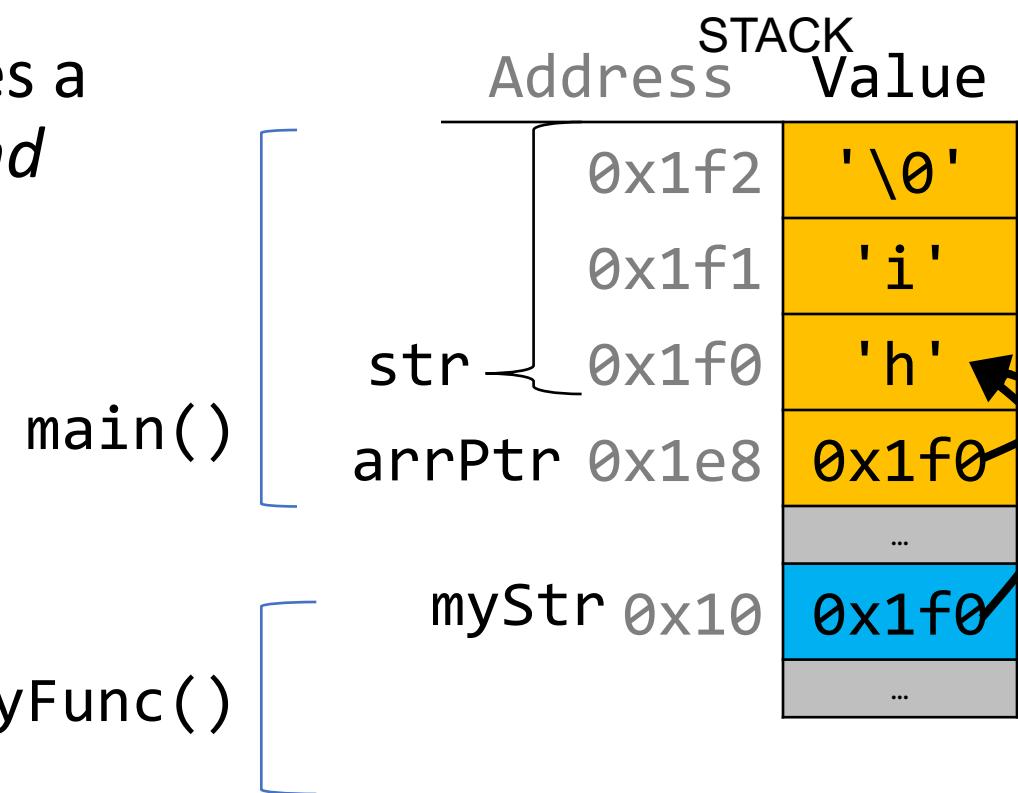

```
void myFunc(char *myStr) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    char str[3];  
    strcpy(str, "hi");  
    myFunc(str);  
    ...  
}
```

# Arrays as Parameters

When you pass an **array** as a parameter, C makes a *copy of the address of the first array element and passes it (a pointer) to the function.*

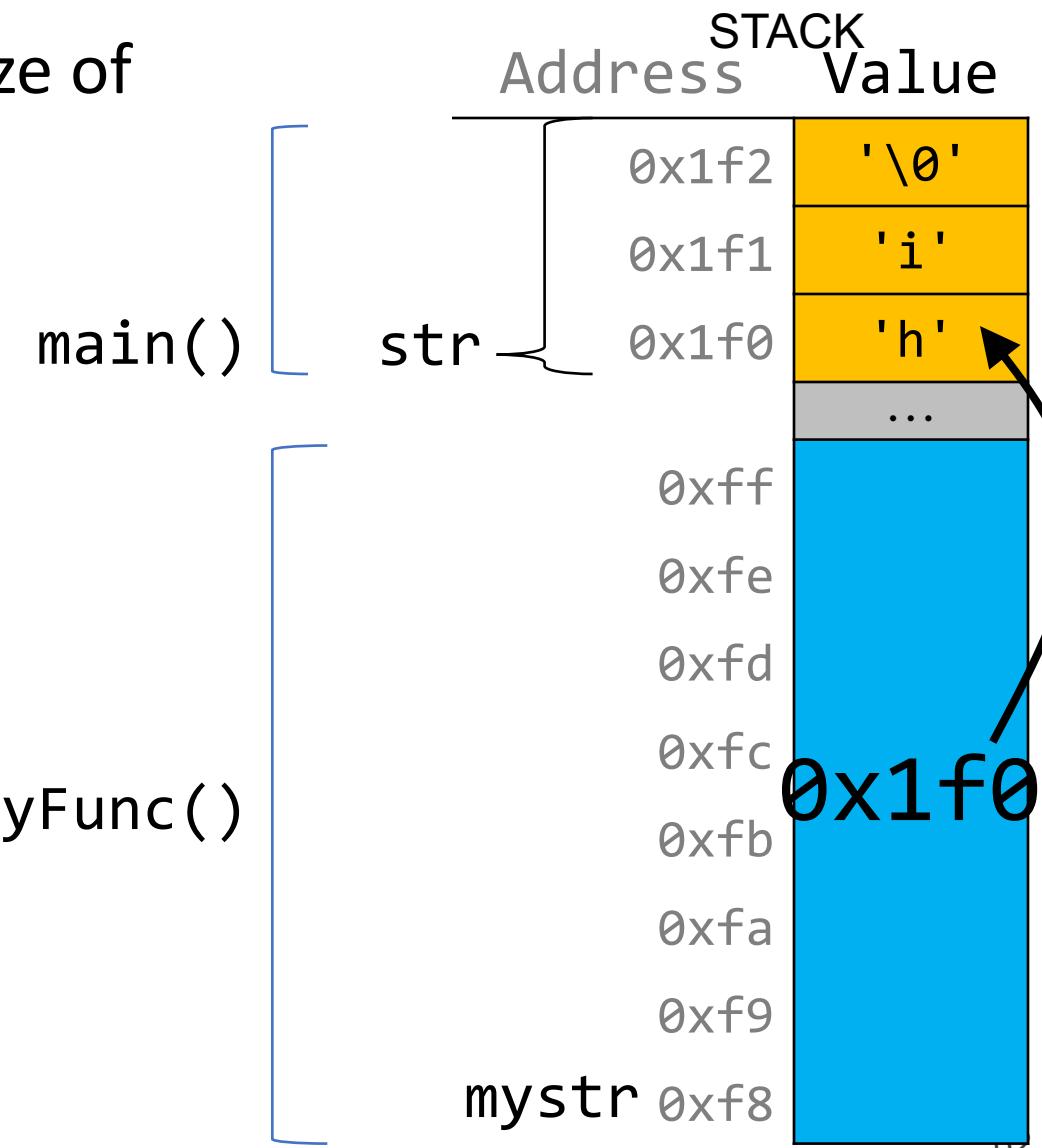

```
void myFunc(char *myStr) {  
    ...  
}  
  
int main(int argc, char *argv[]) {  
    char str[3];  
    strcpy(str, "hi");  
    // equivalent  
    char *arrPtr = str;  
    myFunc(arrPtr);  
    ...  
}
```

# Arrays as Parameters

This also means we can no longer get the full size of the array using **sizeof**, because now it is just a pointer.

```
void myFunc(char *myStr) {  
    int size = sizeof(myStr); // 8  
}  
  
int main(int argc, char *argv[]) {  
    char str[3];  
    strcpy(str, "hi");  
    int size = sizeof(str); // 3  
    myFunc(str);  
    ...  
}
```

**sizeof** returns the size of an array, or 8 for a pointer. Therefore, when we pass an array as a parameter, we can no longer use **sizeof** to get its full size.

# Arrays and Pointers

You can also make a pointer equal to an array; it will point to the first element in that array.

```
int main(int argc, char *argv[]) {  
    char str[3];  
    strcpy(str, "hi");  
    char *ptr = str;  
    ...  
}
```

Address	Value
0x1f2	'\0'
0x1f1	'i'
0x1f0	'h'
0x1ef	
0x1ee	
0x1ed	
0x1ec	
0x1eb	
0x1ea	
0x1e9	
ptr 0x1e8	0x1f0

# Arrays and Pointers

You can also make a pointer equal to an array; it will point to the first element in that array.

```
int main(int argc, char *argv[]) {  
    char str[3];  
    strcpy(str, "hi");  
    char *ptr = str;  
  
    // equivalent  
    char *ptr = &str[0];  
  
    // equivalent, but avoid  
    char *ptr = &str;  
    ...  
}
```

Address	Value
0x1f2	'\0'
0x1f1	'i'
0x1f0	'h'
0x1ef	
0x1ee	
0x1ed	
0x1ec	
0x1eb	
0x1ea	
0x1e9	
ptr 0x1e8	0x1f0

# Lecture Plan

- Pointers and Parameters
- Double Pointers
- Arrays in Memory
- **Arrays of Pointers**
- Pointer Arithmetic
- Other topics: **const, struct** and ternary

```
cp -r /afs/ir/class/cs107/lecture-code/lect6 .
```

# Arrays Of Pointers

You can make an array of pointers to e.g. group multiple strings together:

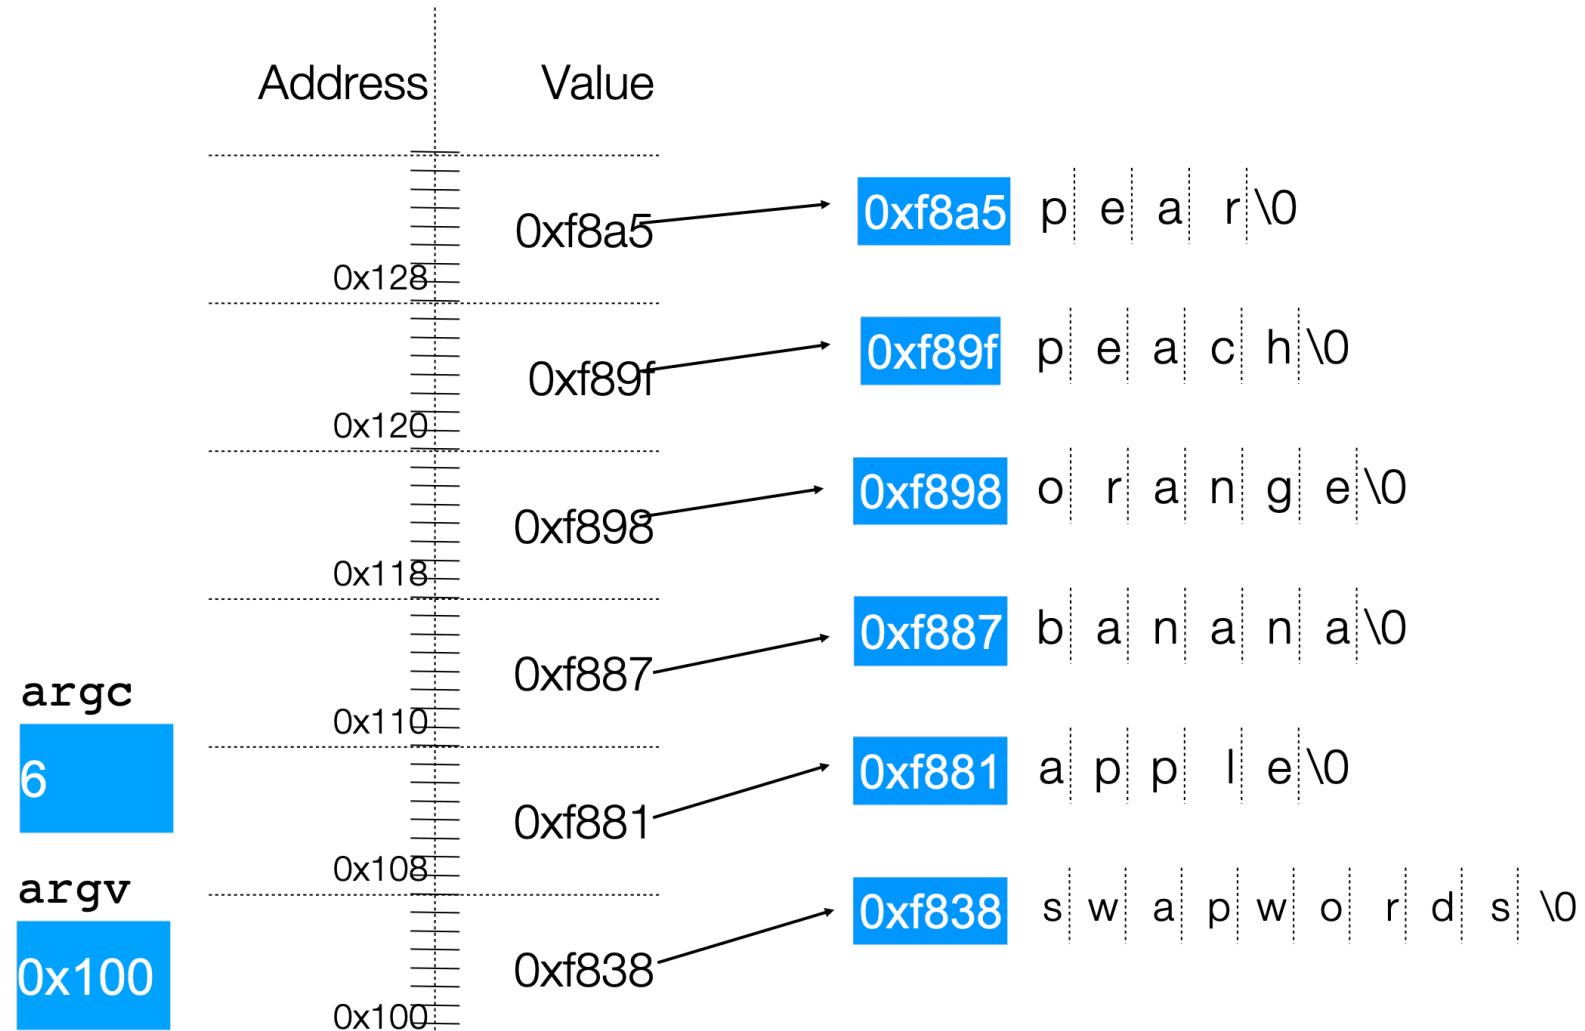

```
char *stringArray[5]; // space to store 5 char *
```

This stores 5 **char \***s, *not* all of the characters for 5 strings!

```
char *str0 = stringArray[0]; // first char *
```

# Arrays Of Pointers

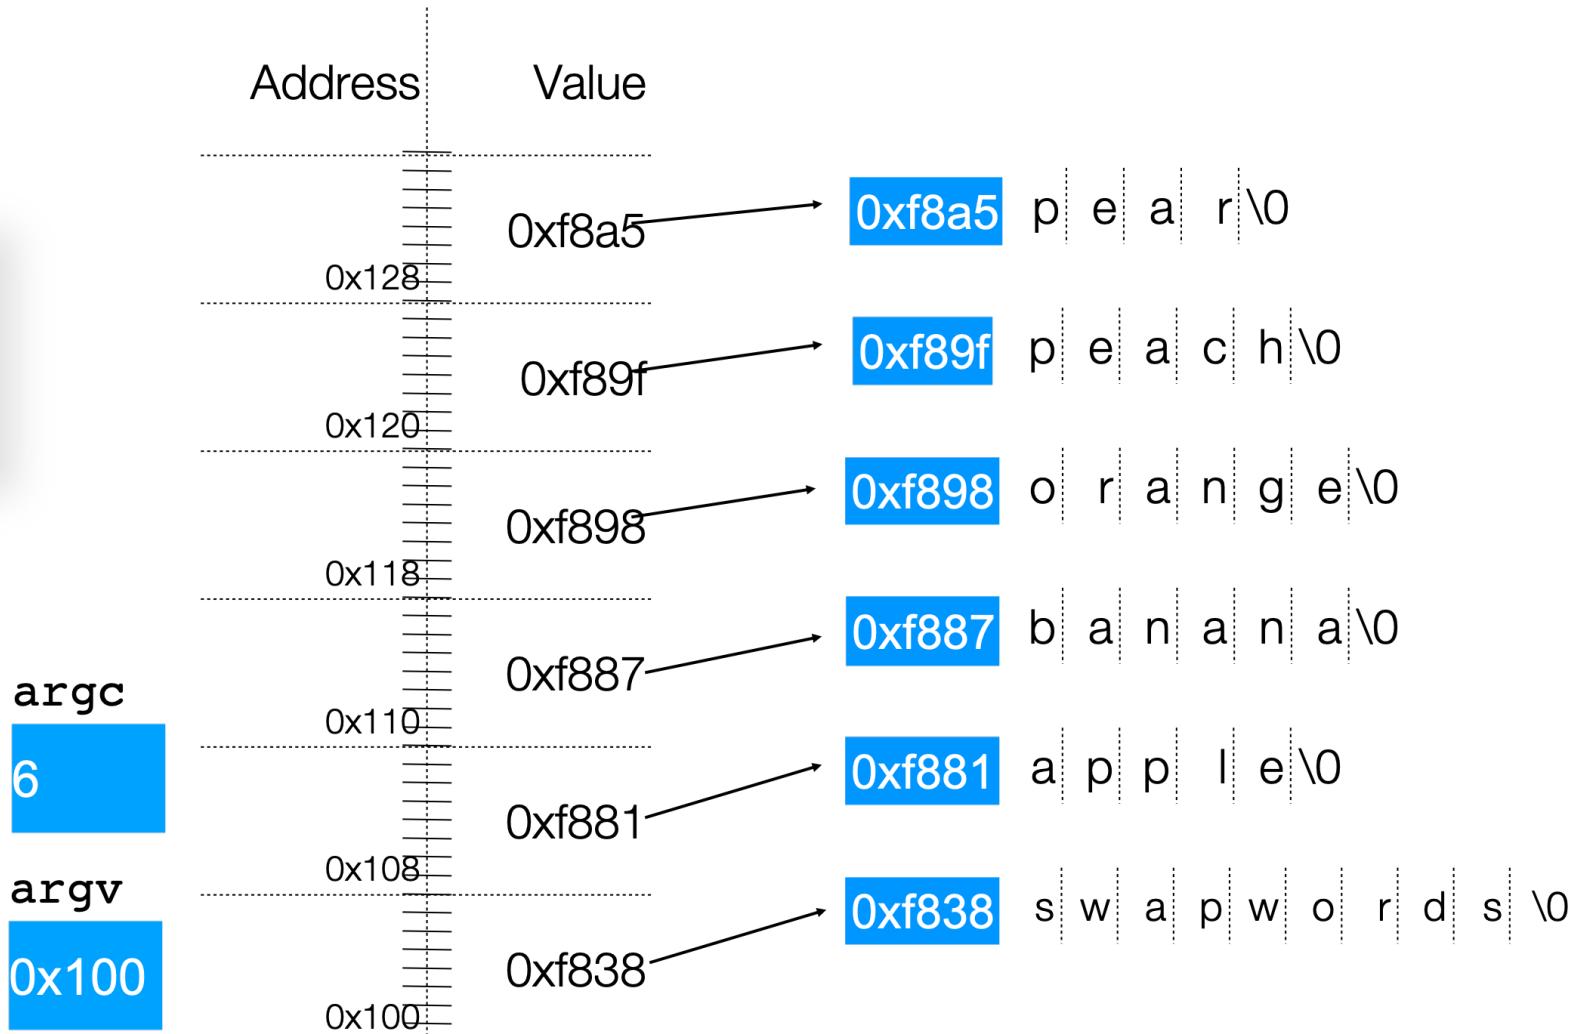

```
./swapwords apple banana orange peach pear
```

# Arrays Of Pointers

```
./swapwords apple banana orange peach pear
```

What is the value of argv[2] in this diagram?

# Lecture Plan

- Pointers and Parameters
- Double Pointers
- Arrays in Memory
- Arrays of Pointers
- **Pointer Arithmetic**
- Other topics: **const, struct** and ternary

```
cp -r /afs/ir/class/cs107/lecture-code/lect6 .
```

# Pointer Arithmetic

When you do pointer arithmetic, you are adjusting the pointer by a certain *number of places* (e.g. characters).

```
char *str = "apple"; // e.g. 0xff0
```

```
char *str1 = str + 1; // e.g. 0xff1
```

```
char *str3 = str + 3; // e.g. 0xff3
```

```
printf("%s", str); // apple
```

```
printf("%s", str1); // pple
```

```
printf("%s", str3); // le
```

DATA SEGMENT	
Address	Value
...	...
0xff5	'\0'
0xff4	'e'
0xff3	'l'
0xff2	'p'
0xff1	'p'
0xff0	'a'
...	...

# Pointer Arithmetic

Pointer arithmetic does *not* work in bytes. Instead, it works in the *size of the type it points to*.

```
// nums points to an int array
int *nums = ... // e.g. 0xff0
int *nums1 = nums + 1; // e.g. 0xff4
int *nums3 = nums + 3; // e.g. 0ffc

printf("%d", *nums); // 52
printf("%d", *nums1); // 23
printf("%d", *nums3); // 34
```

STACK	
Address	Value
...	...
0x1004	1
0x1000	16
0xfffc	34
0xff8	12
0xff4	23
0xff0	52
...	...

# Pointer Arithmetic

Pointer arithmetic does *not* work in bytes. Instead, it works in the *size of the type it points to*.

```
// nums points to an int array
int *nums = ... // e.g. 0xff0
int *nums3 = nums + 3; // e.g. 0ffc
int *nums2 = nums3 - 1; // e.g. 0ff8

printf("%d", *nums); // 52
printf("%d", *nums2); // 12
printf("%d", *nums3); // 34
```

STACK	
Address	Value
...	...
0x1004	1
0x1000	16
0ffc	34
0ff8	12
0ff4	23
0ff0	52
...	...

# Pointer Arithmetic

When you use bracket notation with a pointer, you are actually *performing pointer arithmetic and dereferencing*:

```
char *str = "apple"; // e.g. 0xff0
```

```
// both of these add two places to str,  
// and then dereference to get the char there.
```

```
// E.g. get memory at 0xff2.
```

```
char thirdLetter = str[2]; // 'p'
```

```
char thirdLetter = *(str + 2); // 'p'
```

DATA SEGMENT	
Address	Value
0xff5	...
0xff4	'\0'
0xff3	'e'
0xff2	'l'
0xff1	'p'
0xff0	'p'
	'a'
	...

# Pointer Arithmetic

Pointer arithmetic with two pointers does *not* give the byte difference. Instead, it gives the number of *places* they differ by.

```
// nums points to an int array  
int *nums = ... // e.g. 0xff0  
int *nums3 = nums + 3; // e.g. 0ffc  
int diff = nums3 - nums; // 3
```

STACK	
Address	Value
...	...
0x1004	1
0x1000	16
0xfffc	34
0xff8	12
0xff4	23
0xff0	52
...	...

**String Behavior #6:** Adding an offset to a C string gives us a substring that many places past the first character.

# Pointer Arithmetic

How does the code know how many bytes it should look at once it visits an address?

```
int x = 2;  
int *xPtr = &x;           // e.g. 0xff0  
  
// How does it know to print out just the 4 bytes at xPtr?  
printf("%d", *xPtr);    // 2
```

# Pointer Arithmetic

How does the code know how many bytes it should add when performing pointer arithmetic?

```
int nums[] = {1, 2, 3};
```

// How does it know to add 4 bytes here?

```
int *intPtr = nums + 1;
```

```
char str[6];
```

```
strcpy(str, "CS107");
```

// How does it know to add 1 byte here?

```
char *charPtr = str + 1;
```

# Pointer Arithmetic

- At compile time, C can figure out the sizes of different data types, and the sizes of what they point to.
- For this reason, when the program runs, it knows the correct number of bytes to address or add/subtract for each data type.

# Lecture Plan

- Pointers and Parameters
- Double Pointers
- Arrays in Memory
- Arrays of Pointers
- Pointer Arithmetic
- **Other topics: const, struct and ternary**

```
cp -r /afs/ir/class/cs107/lecture-code/lect6 .
```

# Const

- Use **const** to declare global constants in your program. This indicates the variable cannot change after being created.

```
const double PI = 3.1415;
const int DAYS_IN_WEEK = 7;

int main(int argc, char *argv[]) {
    ...
    if (x == DAYS_IN_WEEK) {
        ...
    }
    ...
}
```

# Const

- Use **const** with pointers to indicate that the data that is pointed to cannot change.

```
char str[6];
strcpy(str, "Hello");
const char *s = str;
```

```
// Cannot use s to change characters it points to
s[0] = 'h';
```

# Const

Sometimes we use **const** with pointer parameters to indicate that the function will not / should not change what it points to. The actual pointer can be changed, however.

```
// This function promises to not change str's characters
int countUppercase(const char *str) {
    int count = 0;
    for (int i = 0; i < strlen(str); i++) {
        if (isupper(str[i])) {
            count++;
        }
    }
    return count;
}
```

# Const

By definition, C gets upset when you set a **non-const** pointer equal to a **const** pointer. You need to be consistent with **const** to reflect what you cannot modify.

```
// This function promises to not change str's characters
int countUppercase(const char *str) {
    // compiler warning and error
    char *strToModify = str;
    strToModify[0] = ...
}
```

# Const

By definition, C gets upset when you set a **non-const** pointer equal to a **const** pointer. You need to be consistent with **const** to reflect what you cannot modify.  
**Think of const as part of the variable type.**

```
// This function promises to not change str's characters
int countUppercase(const char *str) {
    const char *strToModify = str;
    strToModify[0] = ...
}
```

# Const

`const` can be confusing to interpret in some variable types.

```
// cannot modify this char  
const char c = 'h';
```

```
// cannot modify chars pointed to by str  
const char *str = ...
```

```
// cannot modify chars pointed to by *strPtr  
const char **strPtr = ...
```

# Structs

A *struct* is a way to define a new variable type that is a group of other variables.

```
struct date {          // declaring a struct type
    int month;
    int day;           // members of each date structure
};

...
struct date today;          // construct structure instances
today.month = 1;
today.day = 28;

struct date new_years_eve = {12, 31}; // shorter initializer syntax
```

# Structs

Wrap the struct definition in a **typedef** to avoid having to include the word **struct** every time you make a new variable of that type.

```
typedef struct date {  
    int month;  
    int day;  
} date;  
  
...  
  
date today;  
today.month = 1;  
today.day = 28;  
  
date new_years_eve = {12, 31};
```

# Structs

If you pass a struct as a parameter, like for other parameters, C passes a **copy** of the entire struct.

```
void advance_day(date d) {
    d.day++;
}

int main(int argc, char *argv[]) {
    date my_date = {1, 28};
    advance_day(my_date);
    printf("%d", my_date.day); // 28
    return 0;
}
```

# Structs

If you pass a struct as a parameter, like for other parameters, C passes a **copy** of the entire struct. **Use a pointer to modify a specific instance.**

```
void advance_day(date *d) {  
    (*d).day++;  
}  
  
int main(int argc, char *argv[]) {  
    date my_date = {1, 28};  
    advance_day(&my_date);  
    printf("%d", my_date.day); // 29  
    return 0;  
}
```

# Structs

The **arrow** operator lets you access the field of a struct pointed to by a pointer.

```
void advance_day(date *d) {  
    d->day++; // equivalent to (*d).day++;  
}  
  
int main(int argc, char *argv[]) {  
    date my_date = {1, 28};  
    advance_day(&my_date);  
    printf("%d", my_date.day); // 29  
    return 0;  
}
```

# Structs

C allows you to return structs from functions as well. It returns whatever is contained within the struct.

```
date create_new_years_date() {
    date d = {1, 1};
    return d;          // or return (date){1, 1};
}

int main(int argc, char *argv[]) {
    date my_date = create_new_years_date();
    printf("%d", my_date.day); // 1
    return 0;
}
```

# Structs

`sizeof` gives you the entire size of a struct, which is the sum of the sizes of all its contents.

```
typedef struct date {  
    int month;  
    int day;  
} date;  
  
int main(int argc, char *argv[]) {  
    int size = sizeof(date);    // 8  
    return 0;  
}
```

# Arrays of Structs

You can create arrays of structs just like any other variable type.

```
typedef struct my_struct {  
    int x;  
    char c;  
} my_struct;  
  
...  
  
my_struct array_of_structs[5];
```

# Arrays of Structs

To initialize an entry of the array, you must use this special syntax to confirm the type to C.

```
typedef struct my_struct {  
    int x;  
    char c;  
} my_struct;
```

...

```
my_struct array_of_structs[5];  
array_of_structs[0] = (my_struct){0, 'A'};
```

# Arrays of Structs

You can also set each field individually.

```
typedef struct my_struct {  
    int x;  
    char c;  
} my_struct;  
  
...  
my_struct array_of_structs[5];  
array_of_structs[0].x = 2;  
array_of_structs[0].c = 'A';
```

# Ternary Operator

The ternary operator is a shorthand for using if/else to evaluate to a value.

```
condition ? expressionIfTrue : expressionIfFalse
```

```
int x;  
if (argc > 1) {  
    x = 50;  
} else {  
    x = 0;  
}
```

```
// equivalent to  
int x = argc > 1 ? 50 : 0;
```

# Recap

- Pointers and Parameters
- Double Pointers
- Arrays in Memory
- Arrays of Pointers
- Pointer Arithmetic
- Other topics: **const**, **struct** and ternary

**Next Time:** dynamically allocated memory

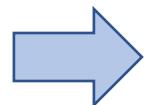

# **Extra Practice**

# const

```
1  char buf[6];
2  strcpy(buf, "Hello");
3  const char *str = buf;
4  str[0] = 'M';
5  str = "Mello";
6  buf[0] = 'M';
```

Which lines (if any) above will cause an error due to violating const? Remember that `const char *` means that the characters at the location it stores cannot be changed.

# const

```
1  char buf[6];
2  strcpy(buf, "Hello");
3  const char *str = buf;
4  str[0] = 'M';
5  str = "Mello";
6  buf[0] = 'M';
```

**Line 1** makes a typical modifiable character array of 6 characters.

Which lines (if any) above will cause an error due to violating `const`? Remember that `const char *` means that the characters at the location it stores cannot be changed.

# const

```
1  char buf[6];
2  strcpy(buf, "Hello");
3  const char *str = buf;
4  str[0] = 'M';
5  str = "Mello";
6  buf[0] = 'M';
```

**Line 2** copies characters  
into this modifiable  
character array.

Which lines (if any) above will cause an error due to violating const? Remember that `const char *` means that the characters at the location it stores cannot be changed.

# const

```
1   char buf[6];
2   strcpy(buf, "Hello");
3   const char *str = buf;
4   str[0] = 'M';
5   str = "Mello";
6   buf[0] = 'M';
```

**Line 3** makes a `const` pointer that points to the first element of `buf`. We cannot use `str` to change the characters it points to because it is `const`.

Which lines (if any) above will cause an error due to violating `const`? Remember that `const char *` means that the characters at the location it stores cannot be changed.

# const

```
1   char buf[6];
2   strcpy(buf, "Hello");
3   const char *str = buf;
4   str[0] = 'M';
5   str = "Mello";
6   buf[0] = 'M';
```

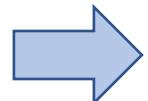

**Line 4** is not allowed – it attempts to use a const pointer to characters to modify those characters.

Which lines (if any) above will cause an error due to violating const? Remember that const char \* means that the characters at the location it stores cannot be changed.

# const

```
1   char buf[6];
2   strcpy(buf, "Hello");
3   const char *str = buf;
4   str[0] = 'M';
5   str = "Mello";
6   buf[0] = 'M';
```

Line 5 is ok – str's type means that while you cannot change the characters at which it points, you can change str itself to point somewhere else. str is not const – its characters are.

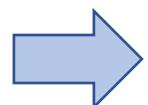

Which lines (if any) above will cause an error due to violating const? Remember that const char \* means that the characters at the location it stores cannot be changed.

# const

```
1   char buf[6];
2   strcpy(buf, "Hello");
3   const char *str = buf;
4   str[0] = 'M';
5   str = "Mello";
6   buf[0] = 'M';
```

Line 6 is ok – **buf** is a modifiable char array, and we can use it to change its characters. Declaring str as const doesn't mean that place in memory is not modifiable at all – it just means that you cannot modify it using **str**.

Which lines (if any) above will cause an error due to violating const? Remember that const char \* means that the characters at the location it stores cannot be changed.

# Pointer arithmetic

Array indexing is “syntactic sugar” for pointer arithmetic:

$$\begin{array}{ccc} \text{ptr} + i & \Leftrightarrow & \&\text{ptr}[i] \\ *(\text{ptr} + i) & \Leftrightarrow & \text{ptr}[i] \end{array}$$

⚠ Pointer arithmetic **does not work in bytes**; it works on the type it points to.  
On `int*` addresses scale by `sizeof(int)`, on `char*` scale by `sizeof(char)` .

- This means too-large/negative subscripts will compile ☺

`arr[99]`                          `arr[-1]`

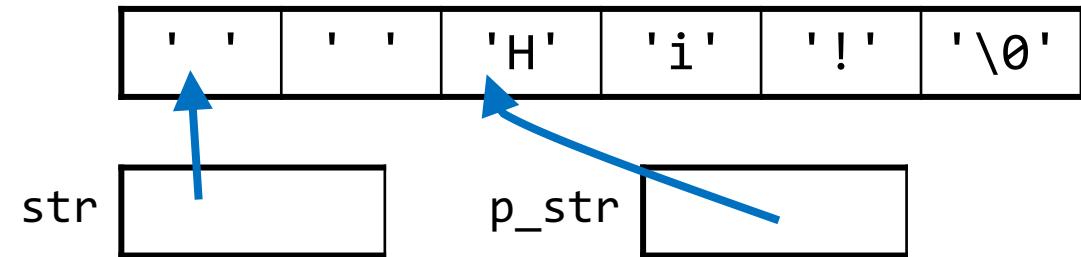

- You can use either syntax on either pointer or array.

# Skip spaces

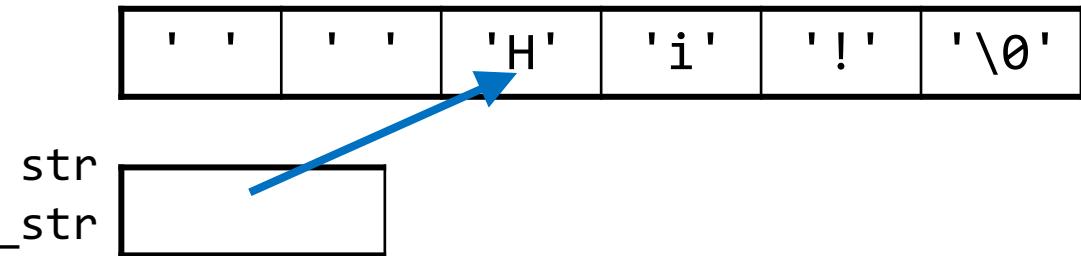

```
1 void skip_spaces(char **p_str) {  
2     int num = strspn(*p_str, " ");  
3     *p_str = *p_str + num;  
4 }  
5 int main(int argc, char *argv[]){  
6     char *str = " Hi!";  
7     skip_spaces(&str);  
8     printf("%s", str); // "Hi!"  
9     return 0;  
10 }
```

What diagram most accurately depicts program state at Line 4 (before `skip_spaces` returns to `main`)?

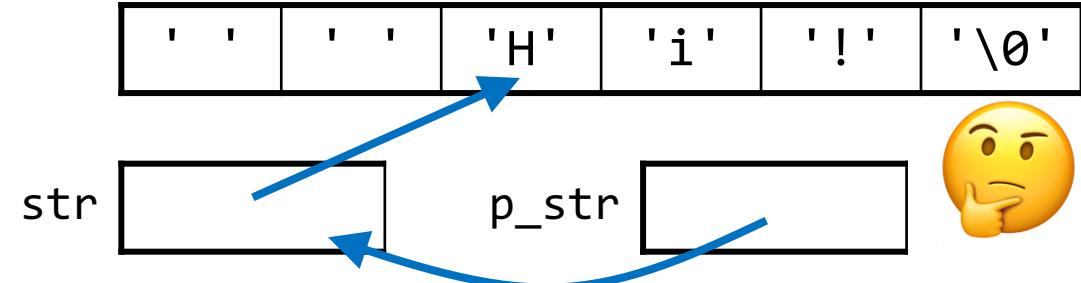

A.

B.

C.

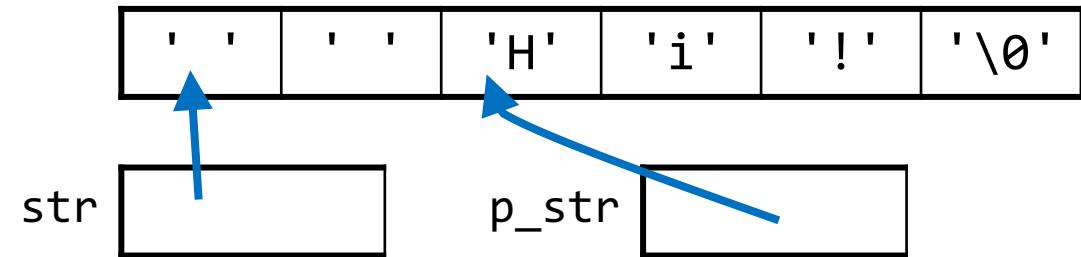

# Skip spaces

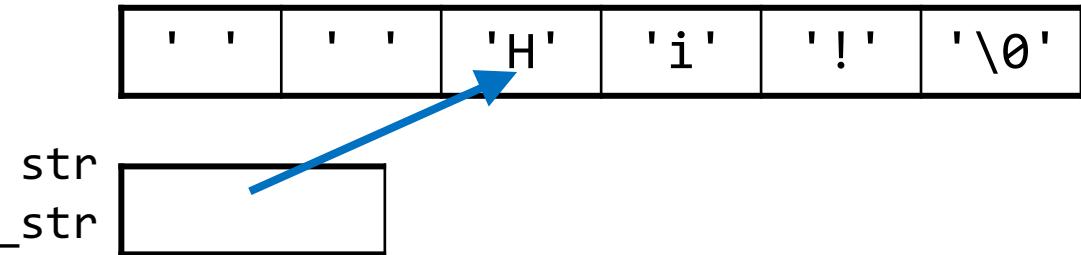

```
1 void skip_spaces(char **p_str) {  
2     int num = strspn(*p_str, " ");  
3     *p_str = *p_str + num;  
4 }  
5 int main(int argc, char *argv[]){  
6     char *str = " Hi!";  
7     skip_spaces(&str);  
8     printf("%s", str); // "Hi!"  
9     return 0;  
10 }
```

What diagram most accurately depicts program state at Line 4 (before `skip_spaces` returns to `main`)?

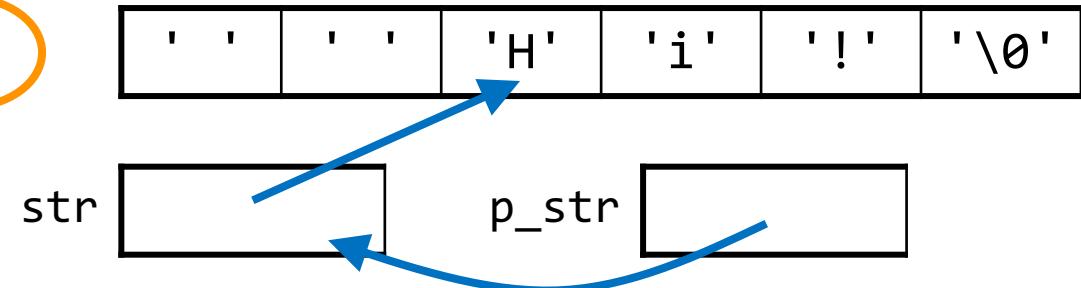

A.

B.

C.

# \* Wars: Episode I (of 2)

Review

In variable declaration, \* creates a **pointer**.

char ch = 'r';

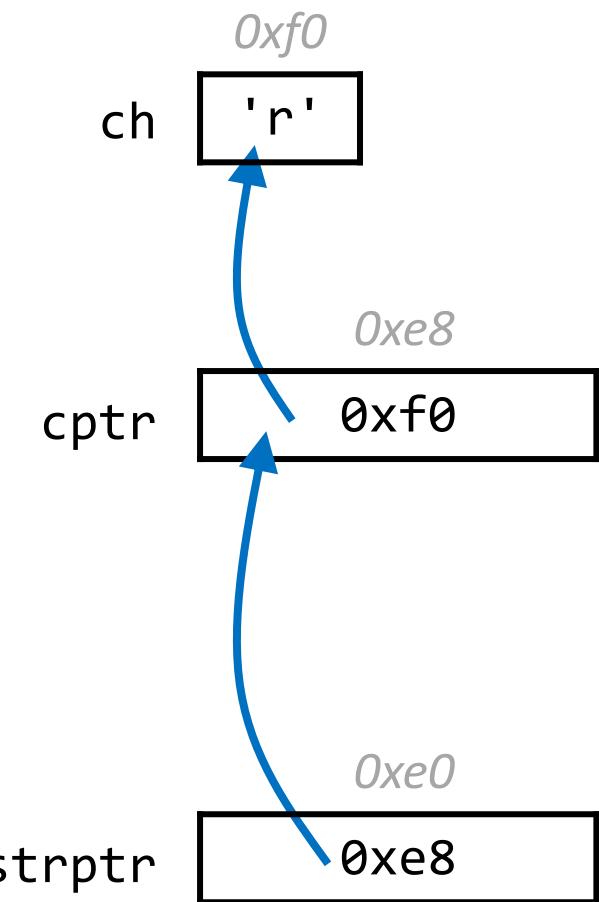

ch stores a char

char \*cptr = &ch;

cptr stores an address of  
a char  
**(points to a char)**

char \*\*strptr = &cptr;

strptr stores an address of  
a char \*  
**(points to a char \*)**

# \* Wars: Episode II (of 2)

Review

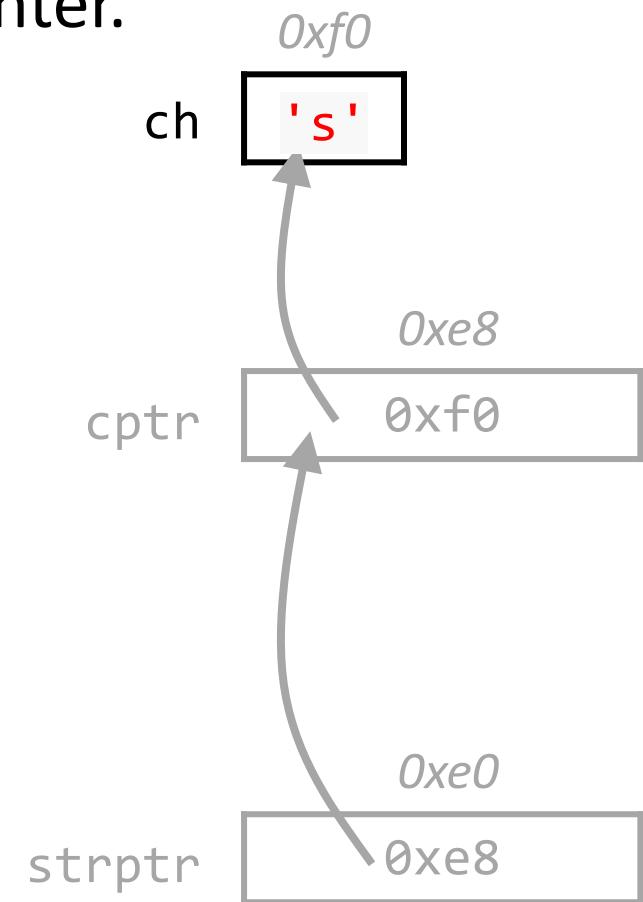

In reading values from/storing values, **\*** dereferences a pointer.

```
char ch = 'r';  
ch = ch + 1;
```

Increment value stored in ch

```
char *cptr = &ch;
```

```
char **strptr = &cptr;
```

# \* Wars: Episode II (of 2)

Review

In reading values from/storing values, `*` dereferences a pointer.

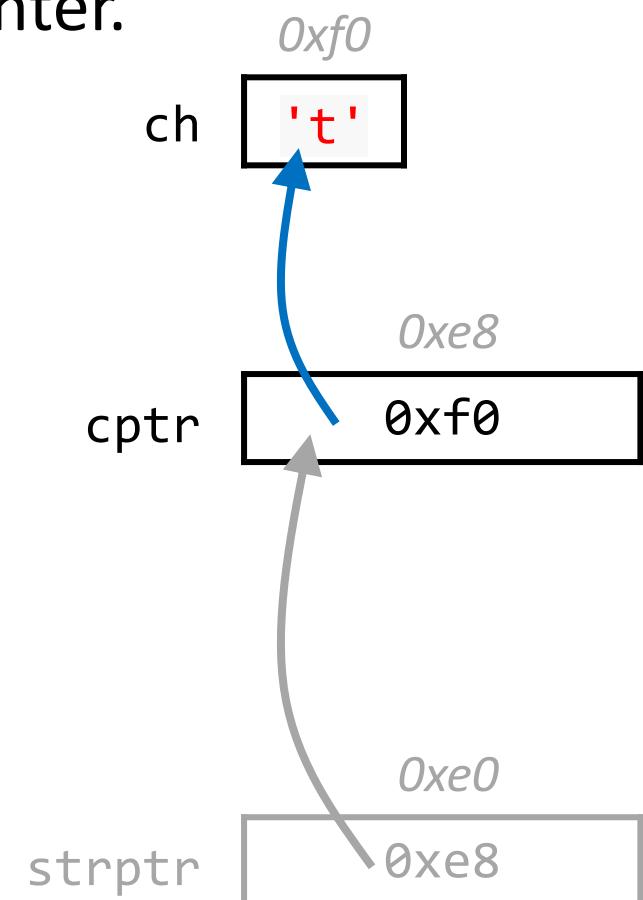

```
char ch = 'r';
ch = ch + 1;
```

Increment value stored in ch

```
char *cptr = &ch;
*cptr = *cptr + 1;
```

Increment value stored at  
memory address in cptr  
(increment char **pointed to**)

```
char **strptr = &cptr;
```
