CS107, Lecture 16Assembly: Arithmetic and Logic

Reading: B&O 3.5-3.6

Ed Discussion: https://edstem.org/us/courses/28214/discussion/2063817

Data Sizes

Data sizes in assembly have slightly different terminology to get used to:

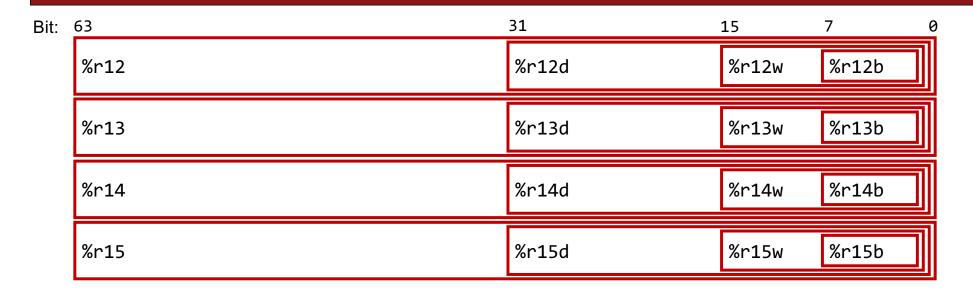

- A **byte** is 1 byte.
- A word is 2 bytes.
- A double word is 4 bytes.
- A quad word is 8 bytes.

Assembly instructions can have suffixes to refer to these sizes:

- b means byte
- w means word
- 1 means double word
- q means quad word

Bit:	63	31	15	7 0
	%rax	%eax	%ax	%al
	%rbx	%ebx	%bx	%b1
	%rcx	%ecx	%сх	%c1
	%rdx	%edx	%dx	%d1
	%rsi	%esi	%si	%sil
	%rdi	%edi	%di	%dil

Bit:	63	31	15	7 0
	%rbp	%ebp	%bp	%bpl
	%rsp	%esp	%sp	%spl
	%r8	%r8d	%r8w	%r8b
	%r9	%r9d	%r9w	%r9b
	%r10	%r10d	%r10w	%r10b
	%r11	%r11d	%r11w	%r11b

Register Responsibilities

Some registers take on special responsibilities during program execution.

- %rax stores the return value
- %rdi stores the first parameter to a function
- %rsi stores the second parameter to a function
- %rdx stores the third parameter to a function
- **%rip** stores the address of the next instruction to execute
- **%rsp** stores the address of the current top of the stack

Reference Sheet: cs107.stanford.edu/resources/x86-64-reference.pdf See more guides on Resources page of course website!

mov Variants

- **mov** can take an optional suffix (b,w,l,q) that specifies the size of data to move: movb, movw, movl, movq
- mov only updates the specific register bytes or memory locations indicated.
 - Exception: movI writing to a register will also set high order 4 bytes to 0.

Practice: mov And Data Sizes

For each of the following mov instructions, determine the appropriate suffix based on the operands (e.g. **movb**, **movw**, **movl** or **movq**).

- 1. mov___ %eax, (%rsp)
- 2. mov__ (%rax), %dx
- 3. mov__ \$0xff, %bl
- 4. mov (%rsp,%rdx,4),%dl
- 5. mov__ (%rdx), %rax
- 6. mov___ %dx, (%rax)

Practice: mov And Data Sizes

For each of the following mov instructions, determine the appropriate suffix based on the operands (e.g. **movb**, **movw**, **movl** or **movq**).

- 1. movl %eax, (%rsp)
- 2. movw (%rax), %dx
- 3. movb \$0xff, %bl
- 4. movb (%rsp,%rdx,4),%dl
- 5. movq (%rdx), %rax
- 6. movw %dx, (%rax)

mov

- The **movabsq** instruction is used to write a 64-bit immediate (constant) value.
- The regular **movq** instruction can only take 32-bit immediates.
- 64-bit immediate as source, only register as destination.

movabsq \$0x0011223344556677, %rax

movz and movs

- There are two mov instructions that can be used to copy a smaller source to a larger destination: **movz** and **movs**.
- movz fills the remaining bytes with zeros
- movs fills the remaining bytes by sign-extending the most significant bit in the source.
- The source must be from memory or a register, and the destination is a register.

movz and movs

MOVZ S,R

R ← ZeroExtend(S)

Instruction	Description
movzbw Move zero-extended byte to word	
movzbl	Move zero-extended byte to double word
movzwl	Move zero-extended word to double word
movzbq	Move zero-extended byte to quad word
movzwq	Move zero-extended word to quad word

movz and movs

MOVS S,R

R ← SignExtend(S)

Instruction	Description
movsbw	Move sign-extended byte to word
movsbl	Move sign-extended byte to double word
movswl	Move sign-extended word to double word
movsbq	Move sign-extended byte to quad word
movswq	Move sign-extended word to quad word
movslq	Move sign-extended double word to quad word
cltq	Sign-extend %eax to %rax %rax <- SignExtend(%eax)

- The operand forms with parentheses (e.g., **mov** (%rax), %rdi) require that registers in parentheses be the 64-bit registers.
- For that reason, you may see smaller registers extended with e.g., **movs** into the larger registers before these kinds of instructions.

Our First Assembly

reta

```
int sum = 0;
   for (int i = 0; i < nelems; i++) {
      sum += arr[i];
   return sum;
0000000000401136 <sum array>:
 401136:
                                              $0x0,%eax
             b8 00 00 00 00
                                       mov
 40113b:
             ba 00 00 00 00
                                              $0x0,%edx
                                       mov
             39 f0
                                              %esi,%eax
 401140:
                                       cmp
                                              40114f <sum array+0x19>
 401142:
            7d 0b
                                       jge
                                       movslq %eax,%rcx
 401144: 48 63 c8
                                              (%rdi,%rcx,4),%edx
 401147:
           03 14 8f
                                       add
 40114a:
           83 c0 01
                                       add
                                              $0x1,%eax
 40114d:
           eb f1
                                       jmp
                                              401140 <sum array+0xa>
 40114f:
            89 d0
                                              %edx,%eax
                                       mov
```

int sum_array(int arr[], int nelems) {

401151:

c3

lea

The **lea** instruction <u>copies</u> an "effective address" from one place to another.

lea src,dst

Unlike **mov**, which copies data <u>at</u> the address src to the destination, **lea** copies the value of src *itself* to the destination.

The syntax for the destinations is the same as **mov**. The difference is how it handles the src.

Operands	mov Interpretation	lea Interpretation
6(%rax), %rdx	Go to the address (6 + what's in %rax), and copy data there into %rdx	Copy 6 + what's in %rax into %rdx.

Operands	mov Interpretation	lea Interpretation
6(%rax), %rdx	Go to the address (6 + what's in %rax), and copy data there into %rdx	Copy 6 + what's in %rax into %rdx.
(%rax, %rcx), %rdx	Go to the address (what's in %rax + what's in %rcx) and copy data there into %rdx	Copy (what's in %rax + what's in %rcx) into %rdx.

Operands	mov Interpretation	lea Interpretation
6(%rax), %rdx	Go to the address (6 + what's in %rax), and copy data there into %rdx	Copy 6 + what's in %rax into %rdx.
(%rax, %rcx), %rdx	Go to the address (what's in %rax + what's in %rcx) and copy data there into %rdx	Copy (what's in %rax + what's in %rcx) into %rdx.
(%rax, %rcx, 4), %rdx	Go to the address (%rax + 4 * %rcx) and copy data there into %rdx.	Copy (%rax + 4 * %rcx) into %rdx.

Operands	mov Interpretation	lea Interpretation
6(%rax), %rdx	Go to the address (6 + what's in %rax), and copy data there into %rdx	Copy 6 + what's in %rax into %rdx.
(%rax, %rcx), %rdx	Go to the address (what's in %rax + what's in %rcx) and copy data there into %rdx	Copy (what's in %rax + what's in %rcx) into %rdx.
(%rax, %rcx, 4), %rdx	Go to the address (%rax + 4 * %rcx) and copy data there into %rdx.	Copy (%rax + 4 * %rcx) into %rdx.
7(%rax, %rax, 8), %rdx	Go to the address (7 + %rax + 8 * %rax) and copy data there into %rdx.	Copy (7 + %rax + 8 * %rax) into %rdx.

Unlike **mov**, which copies data <u>at</u> the address src to the destination, **lea** copies the value of src *itself* to the destination.

Reverse Engineering Practice

```
void calculate(int x, int y, int *ptr) {
    ___?__;
}

calculate:
    leal (%rdi,%rsi,2), %eax
    movl %eax, (%rdx)
    ret
```

Note: assume x is in %rdi, y is in %rsi and ptr is in %rdx.

Reverse Engineering Practice

```
void calculate(int x, int y, int *ptr) {
    *ptr = x + 2 * y;
}

calculate:
    leal (%rdi,%rsi,2), %eax
    movl %eax, (%rdx)
    ret
```

A Note About Operand Forms

- Many instructions share the same address operand forms that mov uses.
 - e.g., 7(%rax, %rcx, 2).
- These forms work the same way for other instructions (exception, lea):
 - It interprets this form as just the calculation, not the dereferencing
 - lea 8(%rax,%rdx),%rcx -> Calculate 8 + %rax + %rdx, put it in %rcx

Unary Instructions

The following instructions operate on a single operand (register or memory):

Instruction	Effect	Description
inc D	D ← D + 1	Increment
dec D	D ← D - 1	Decrement
neg D	D ← -D	Negate
not D	D ← ~D	Complement

Examples:

incq 16(%rax)

dec %rdx

not %rcx

Binary Instructions

The following instructions operate on two operands (both can be register or memory, source can also be immediate). Both cannot be memory locations. Read it as, e.g. "Subtract S from D":

Instruction	Effect	Description
add S, D	$D \leftarrow D + S$	Add
sub S, D	D ← D - S	Subtract
imul S, D	D ← D * S	Multiply
xor S, D	D ← D ^ S	Exclusive-or
or S, D	D ← D S	Or
and S, D	D + D & S	And

Examples:

```
addq %rcx,(%rax)
xorq $16,(%rax, %rdx, 8)
subq %rdx,8(%rax)
```

Shift Instructions

The following instructions have two operands: the shift amount **k** and the destination to shift, **D**. **k** can be either an immediate value, or the byte register %**cl** (and only that register!)

Instruction	Effect	Description
sal k, D	D ← D << k	Left shift
shl k, D	D ← D << k	Left shift (same as sal)
sar k, D	D ← D >> _A k	Arithmetic right shift
shr k, D	D ← D >> _L k	Logical right shift

Examples:

```
shll $3,(%rax)
shrl %cl,(%rax,%rdx,8)
sarl $4,8(%rax)
```

Shift Amount

Instruction	Effect	Description
sal k, D	D ← D << k	Left shift
shl k, D	D + D << k	Left shift (same as sal)
sar k, D	$D \leftarrow D >>_A k$	Arithmetic right shift
shr k, D	D ← D >> _L k	Logical right shift

- When using **%cl**, the width of what you are shifting determines what portion of **%cl** is used.
- For w bits of data, it looks at the low-order log2(w) bits of %cl to know how much to shift.
 - If %cl = 0xff, then: shlb shifts by 7 because it considers only the low-order log2(8) = 3 bits, which represent 7. shlw shifts by 15 because it considers only the low-order log2(16) = 4 bits, which represent 15.
