

CS107, Lecture 16

Assembly: Arithmetic and Logic

Reading: B&O 3.5-3.6

Ed Discussion: <https://edstem.org/us/courses/46162/discussion/3748926>

Data Sizes

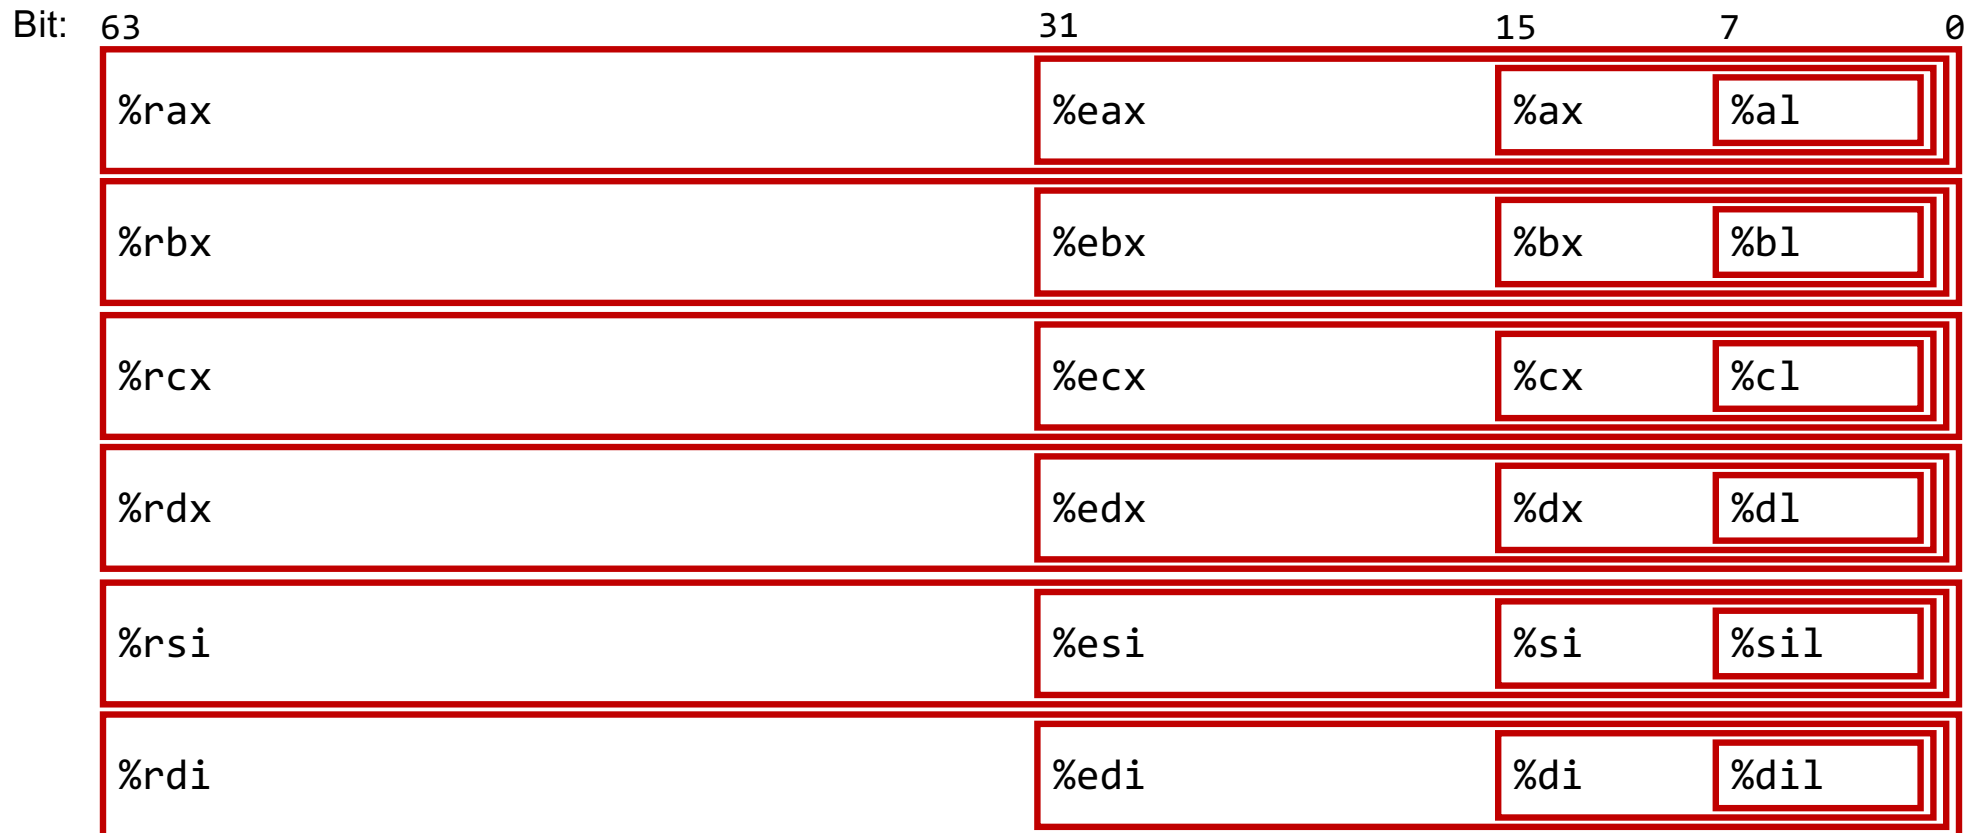

Data types in assembly are managed via a slightly different set of names:

- A **byte** is 1 byte.
- A **word** is 2 bytes.
- A **double word** is 4 bytes.
- A **quad word** is 8 bytes.

Assembly instructions can include suffixes to refer to these types:

- b means **byte**
- w means **word**
- **l** means **double word**
- q means **quad word**

Register Sizes

Register Sizes

Bit:	63	31	15	7	0
%rbp			%ebp	%bp	%bpl
%rsp			%esp	%sp	%spl
%r8			%r8d	%r8w	%r8b
%r9			%r9d	%r9w	%r9b
%r10			%r10d	%r10w	%r10b
%r11			%r11d	%r11w	%r11b

Register Sizes

Register Responsibilities

Some registers take on special responsibilities during program execution.

- **%rax** stores the return value
- **%rdi** stores the first parameter to a function
- **%rsi** stores the second parameter to a function
- **%rdx** stores the third parameter to a function
- **%rip** stores the address of the next instruction to be executed
- **%rsp** stores the address of the stack frame of the currently executing function

Reference Sheet: cs107.stanford.edu/resources/x86-64-reference.pdf
See more guides on Resources page of course website!

mov Variants

- **mov** can take an optional suffix (b/w/l/q) that specifies the size of data to move: `movb`, `movw`, `movl`, `movq`
- **mov** only updates the specific register bytes or memory locations indicated.
 - **Exception: movl** writing to a register will also set high order 4 bytes to 0.

Practice: mov And Data Sizes

For each of the following **mov** instructions, determine the appropriate suffix based on the operands (e.g., **movb**, **movw**, **movl** or **movq**).

1. `mov__ %eax, (%rsp)`
2. `mov__ (%rax), %dx`
3. `mov__ $0xff, %bl`
4. `mov__ (%rsp,%rdx,4),%dl`
5. `mov__ (%rdx), %rax`
6. `mov__ %dx, (%rax)`

Practice: mov And Data Sizes

For each of the following **mov** instructions, determine the appropriate suffix based on the operands (e.g., **movb**, **movw**, **movl** or **movq**).

1. `movl %eax, (%rsp)`
2. `movw (%rax), %dx`
3. `movb $0xff, %bl`
4. `movb (%rsp,%rdx,4),%dl`
5. `movq (%rdx), %rax`
6. `movw %dx, (%rax)`

mov

- The **movabsq** instruction is used to write a 64-bit immediate (constant) value.
- The regular **movq** instruction can only take 32-bit immediates.
- 64-bit immediate as source, only register as destination.

```
movabsq $0x0011223344556677, %rax
```

movz and movs

- There are two **mov** instructions that can be used to copy a smaller source to a larger destination: **movz** and **movs**.
- **movz** fills the remaining bytes with zeros
- **movs** fills the remaining bytes by sign-extending the most significant bit of the source.
- The source must be from memory or a register, and the destination must be a register.

movz and movs

MOVZ S, R

$R \leftarrow \text{ZeroExtend}(S)$

Instruction	Description
movzbw	Move zero-extended byte to word
movzbl	Move zero-extended byte to double word
movzwl	Move zero-extended word to double word
movzbq	Move zero-extended byte to quad word
movzwq	Move zero-extended word to quad word

movz and movs

MOVS S,R

$R \leftarrow \text{SignExtend}(S)$

Instruction	Description
movsbw	Move sign-extended byte to word
movsbl	Move sign-extended byte to double word
movswl	Move sign-extended word to double word
movsbq	Move sign-extended byte to quad word
movswq	Move sign-extended word to quad word
movslq	Move sign-extended double word to quad word
cltq	Sign-extend %eax in place to fill all of %rax $\%rax \leftarrow \text{SignExtend}(\%eax)$

Register Sizes

- The operand forms with parentheses (e.g., **mov (%rax), %rdi**) require that registers in parentheses be the 64-bit registers.
- For that reason, you may see smaller registers extended with e.g., **movs** into the larger registers before these kinds of instructions.

Our First Assembly

```
int sum_array(int arr[], int nelems) {
    int sum = 0;
    for (int i = 0; i < nelems; i++) {
        sum += arr[i];
    }
    return sum;
}
```

0000000000401136 <sum_array>:

401136:	b8 00 00 00 00	mov	\$0x0,%eax
40113b:	ba 00 00 00 00	mov	\$0x0,%edx
401140:	39 f0	cmp	%esi,%eax
401142:	7d 0b	jge	40114f <sum_array+0x19>
401144:	48 63 c8	movslq	%eax,%rcx
401147:	03 14 8f	add	(%rdi,%rcx,4),%edx
40114a:	83 c0 01	add	\$0x1,%eax
40114d:	eb f1	jmp	401140 <sum_array+0xa>
40114f:	89 d0	mov	%edx,%eax
401151:	c3	retq	

lea

The **lea** instruction copies an "effective address" from one place to another.

lea **src, dst**

Unlike **mov**, which copies data at the address **src** to the destination, **lea** copies the value of **src** *itself* to the destination.

The syntax for the destinations is the same as **mov**. The difference is how it handles the **src**.

lea vs. mov

Operands	mov Interpretation	lea Interpretation
6(%rax), %rdx	Go to the address (6 + what's in %rax), and copy data there into %rdx	Copy 6 + what's in %rax into %rdx.

lea vs. mov

Operands	mov Interpretation	lea Interpretation
6(%rax), %rdx	Go to the address (6 + what's in %rax), and copy data there into %rdx	Copy 6 + what's in %rax into %rdx.
(%rax, %rcx), %rdx	Go to the address (what's in %rax + what's in %rcx) and copy data there into %rdx	Copy (what's in %rax + what's in %rcx) into %rdx.

lea vs. mov

Operands	mov Interpretation	lea Interpretation
6(%rax), %rdx	Go to the address (6 + what's in %rax), and copy data there into %rdx	Copy 6 + what's in %rax into %rdx.
(%rax, %rcx), %rdx	Go to the address (what's in %rax + what's in %rcx) and copy data there into %rdx	Copy (what's in %rax + what's in %rcx) into %rdx.
(%rax, %rcx, 4), %rdx	Go to the address (%rax + 4 * %rcx) and copy data there into %rdx.	Copy (%rax + 4 * %rcx) into %rdx.

lea vs. mov

Operands	mov Interpretation	lea Interpretation
<code>6(%rax), %rdx</code>	Go to the address (6 + what's in %rax), and copy data there into %rdx	Copy 6 + what's in %rax into %rdx.
<code>(%rax, %rcx), %rdx</code>	Go to the address (what's in %rax + what's in %rcx) and copy data there into %rdx	Copy (what's in %rax + what's in %rcx) into %rdx.
<code>(%rax, %rcx, 4), %rdx</code>	Go to the address ($\%rax + 4 * \%rcx$) and copy data there into %rdx.	Copy ($\%rax + 4 * \%rcx$) into %rdx.
<code>7(%rax, %rax, 8), %rdx</code>	Go to the address ($7 + \%rax + 8 * \%rax$) and copy data there into %rdx.	Copy ($7 + \%rax + 8 * \%rax$) into %rdx.

Unlike **mov**, which copies data at the address `src` to the destination, **lea** copies the value of `src` *itself* to the destination.

Reverse Engineering Practice

```
void calculate(int x, int y, int *ptr) {  
    ____?____;  
}
```

```
calculate:  
    leal (%rdi,%rsi,2), %eax  
    movl %eax, (%rdx)  
    ret
```

Note: assume x is in %rdi, y is in %rsi and ptr is in %rdx.

Reverse Engineering Practice

```
void calculate(int x, int y, int *ptr) {  
    *ptr = x + 2 * y;  
}
```

```
calculate:  
    leal (%rdi,%rsi,2), %eax  
    movl %eax, (%rdx)  
    ret
```

A Note About Operand Forms

- Many instructions share the same address operand forms that **mov** uses.
 - e.g., `7(%rax, %rcx, 2)`.
- These forms work the same way for other instructions (exception, **lea**):
 - It interprets this form as just the calculation, *not the dereferencing*
 - `lea 8(%rax,%rdx),%rcx` -> Calculate $8 + \%rax + \%rdx$, put it in `%rcx`

Unary Instructions

The following instructions operate on a single operand (register or memory):

Instruction	Effect	Description
<code>inc D</code>	$D \leftarrow D + 1$	Increment
<code>dec D</code>	$D \leftarrow D - 1$	Decrement
<code>neg D</code>	$D \leftarrow -D$	Negate
<code>not D</code>	$D \leftarrow \sim D$	Complement

Examples:

```
incq 16(%rax)
```

```
dec %rdx
```

```
not %rcx
```

Binary Instructions

The following instructions operate on two operands (both can be register or memory, source can also be immediate). Both cannot be memory locations. Read it as, e.g., 'subtract S from D':

Instruction	Effect	Description
add S, D	$D \leftarrow D + S$	Add
sub S, D	$D \leftarrow D - S$	Subtract
imul S, D	$D \leftarrow D * S$	Multiply
xor S, D	$D \leftarrow D \wedge S$	Exclusive-or
or S, D	$D \leftarrow D \mid S$	Or
and S, D	$D \leftarrow D \& S$	And

Examples:

```
addq %rcx, (%rax)
```

```
xorq $16, (%rax, %rdx, 8)
```

```
subq %rdx, 8(%rax)
```

Shift Instructions

The following instructions have two operands: the shift amount **k** and the destination to shift, **D**. **k** can be either an immediate value, or the byte register **%cl** (and only that register!)

Instruction	Effect	Description
<code>sal k, D</code>	$D \leftarrow D \ll k$	Left shift
<code>shl k, D</code>	$D \leftarrow D \ll k$	Left shift (same as <code>sal</code>)
<code>sar k, D</code>	$D \leftarrow D \gg_A k$	Arithmetic right shift
<code>shr k, D</code>	$D \leftarrow D \gg_L k$	Logical right shift

Examples:

```
shll $3, (%rax)
```

```
shr1 %cl, (%rax, %rdx, 8)
```

```
sar1 $4, 8(%rax)
```

Shift Amount

Instruction	Effect	Description
<code>sal k, D</code>	$D \leftarrow D \ll k$	Left shift
<code>shl k, D</code>	$D \leftarrow D \ll k$	Left shift (same as <code>sal</code>)
<code>sar k, D</code>	$D \leftarrow D \gg_A k$	Arithmetic right shift
<code>shr k, D</code>	$D \leftarrow D \gg_L k$	Logical right shift

- When using **%cl**, the width of what you are shifting determines what portion of **%cl** is used.
- For **w** bits of data, it looks at the low-order **log₂(w)** bits of **%cl** to know how much to shift.
 - If **%cl** = 0xff, then: **shlb** shifts by 7 because it considers only the low-order $\log_2(8) = 3$ bits, which represent 7. **shlw** shifts by 15 because it considers only the low-order $\log_2(16) = 4$ bits, which represent 15.
