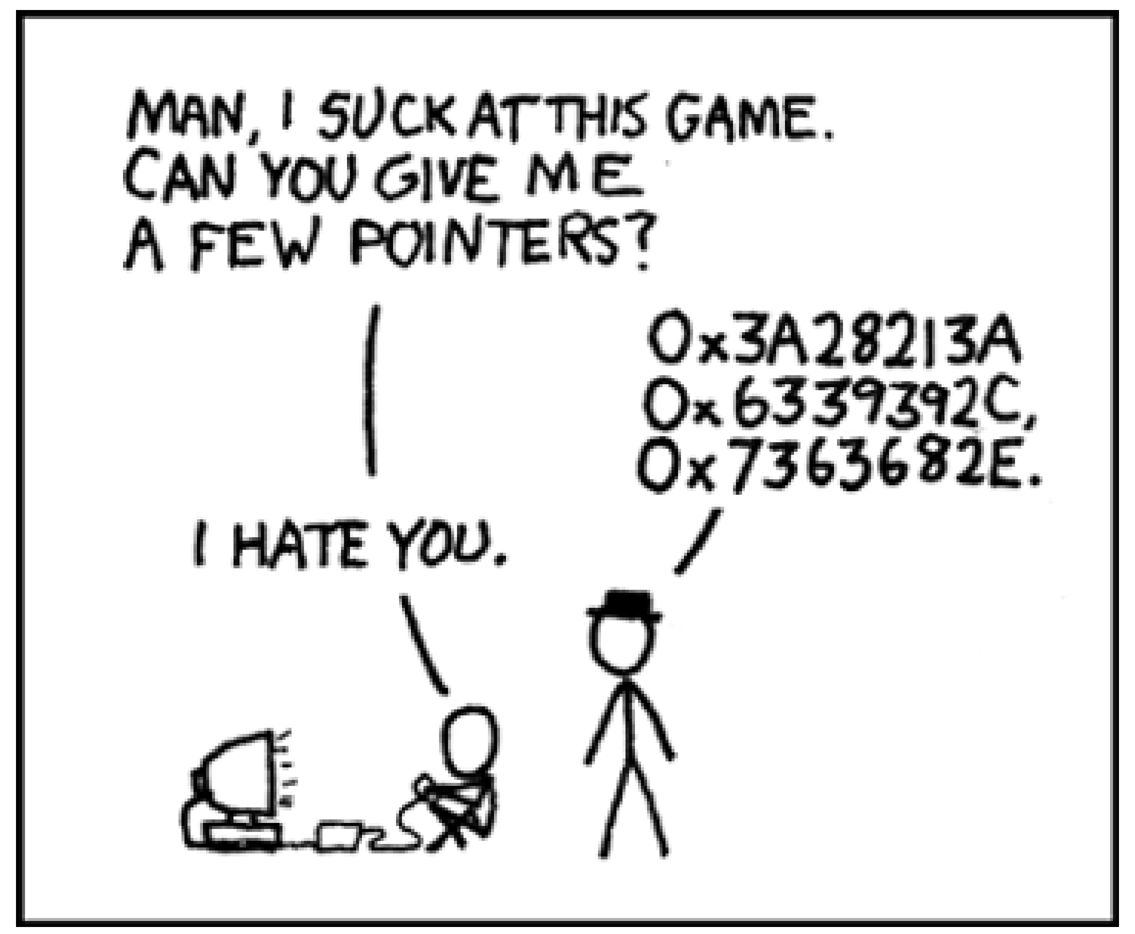
CS107 Topic 3: How can we effectively manage all types of memory in our programs?

Some Pointers



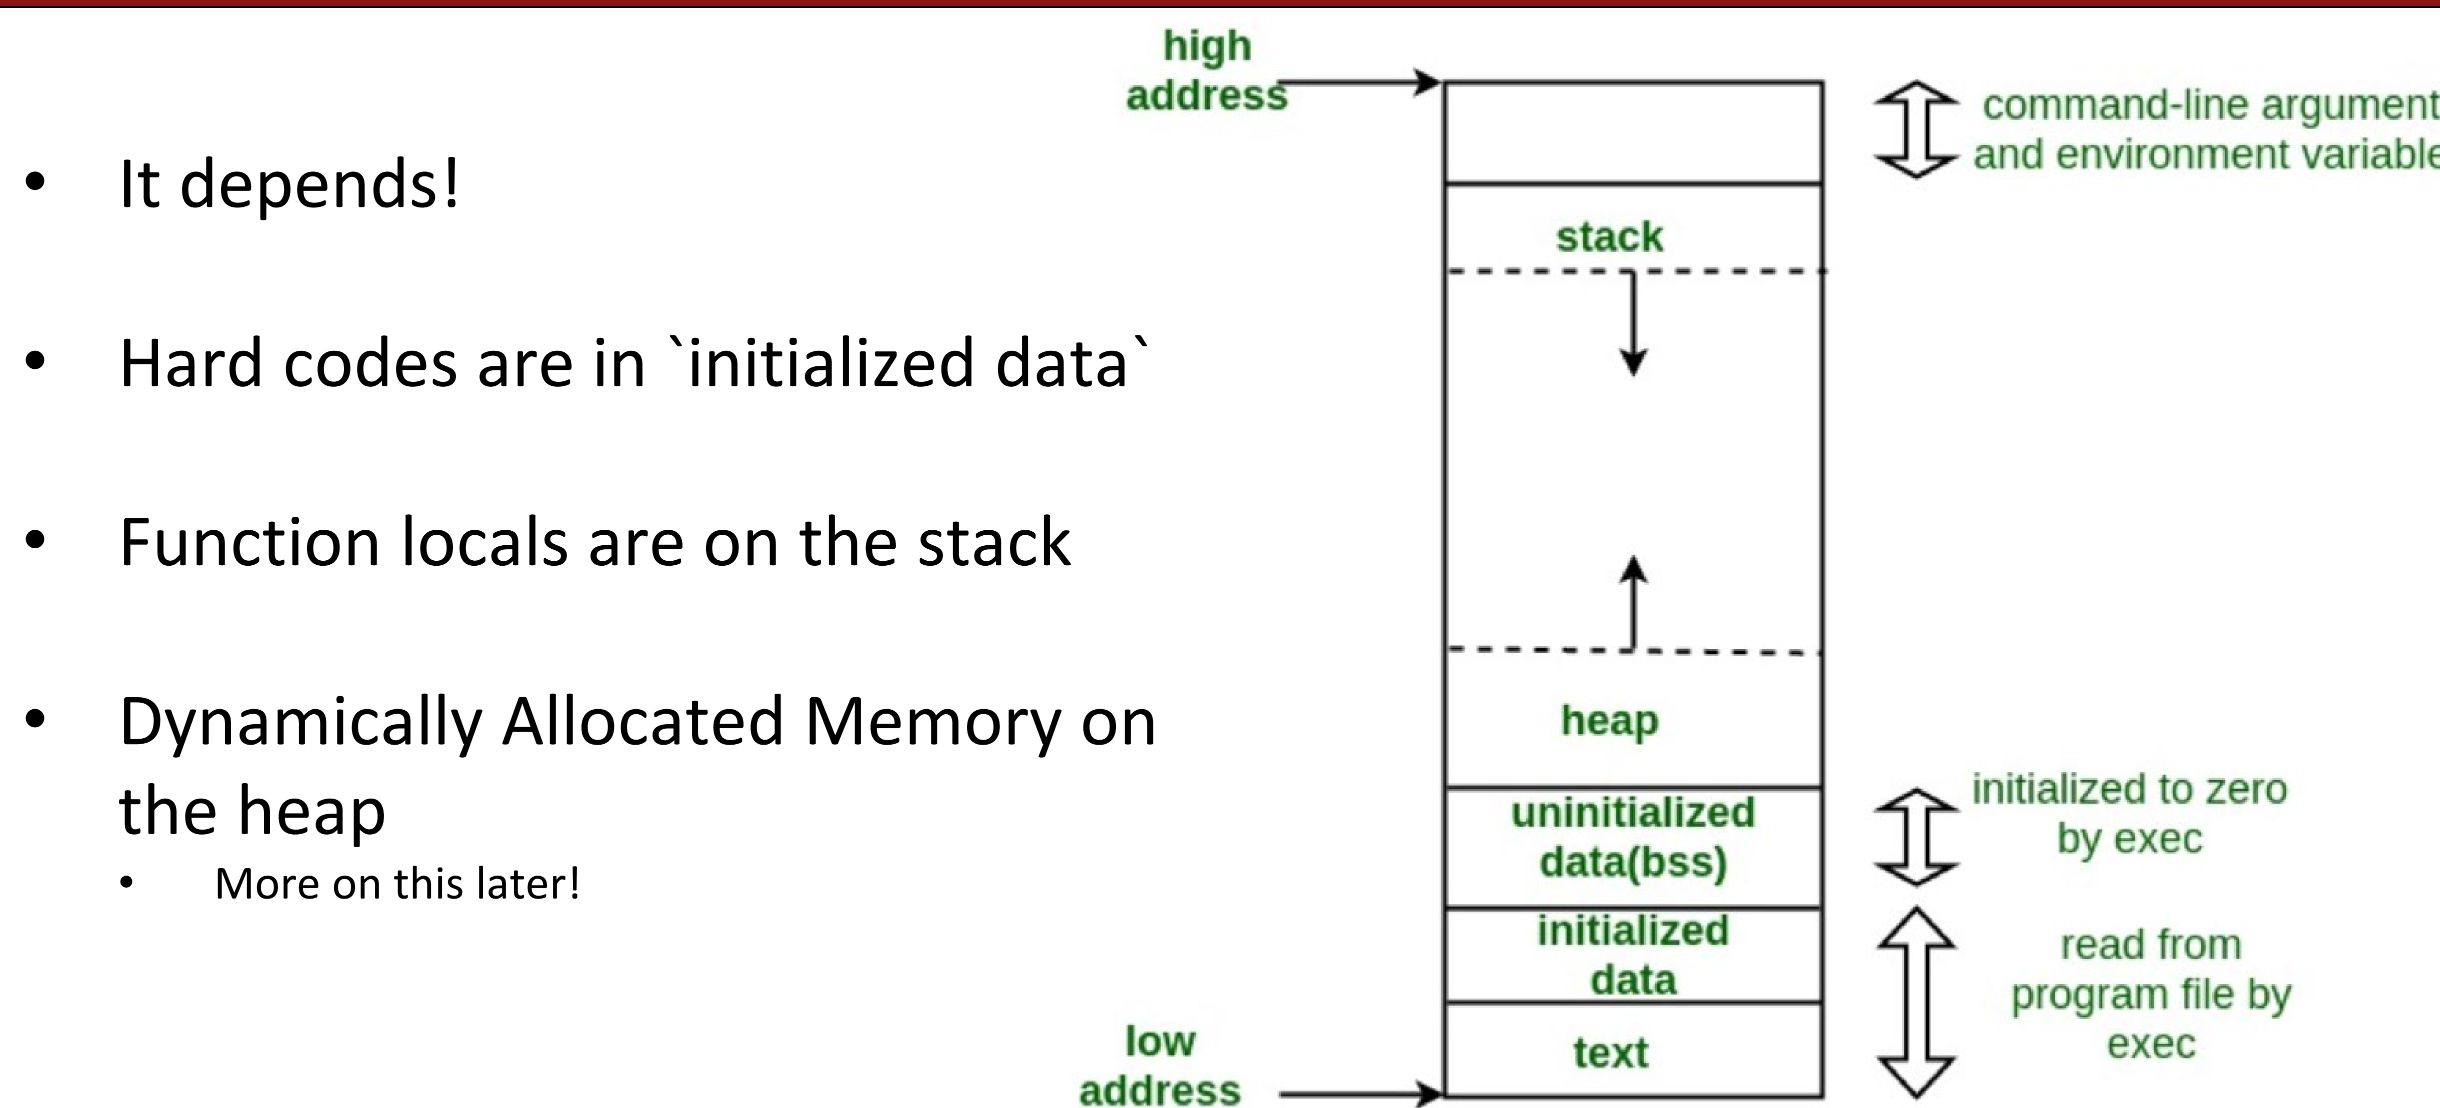
https://xkcd.com/138/

Lecture Plan

- **Pointers, Parameters, & Memory**
- Arrays in Memory
- Arrays of Pointers
- Pointer Arithmetic
- Other topics: **const**, **struct** and ternary

Where is our data?

- It depends!
- Hard codes are in `initialized data`
- Function locals are on the stack
- Dynamically Allocated Memory on the heap
  - More on this later!



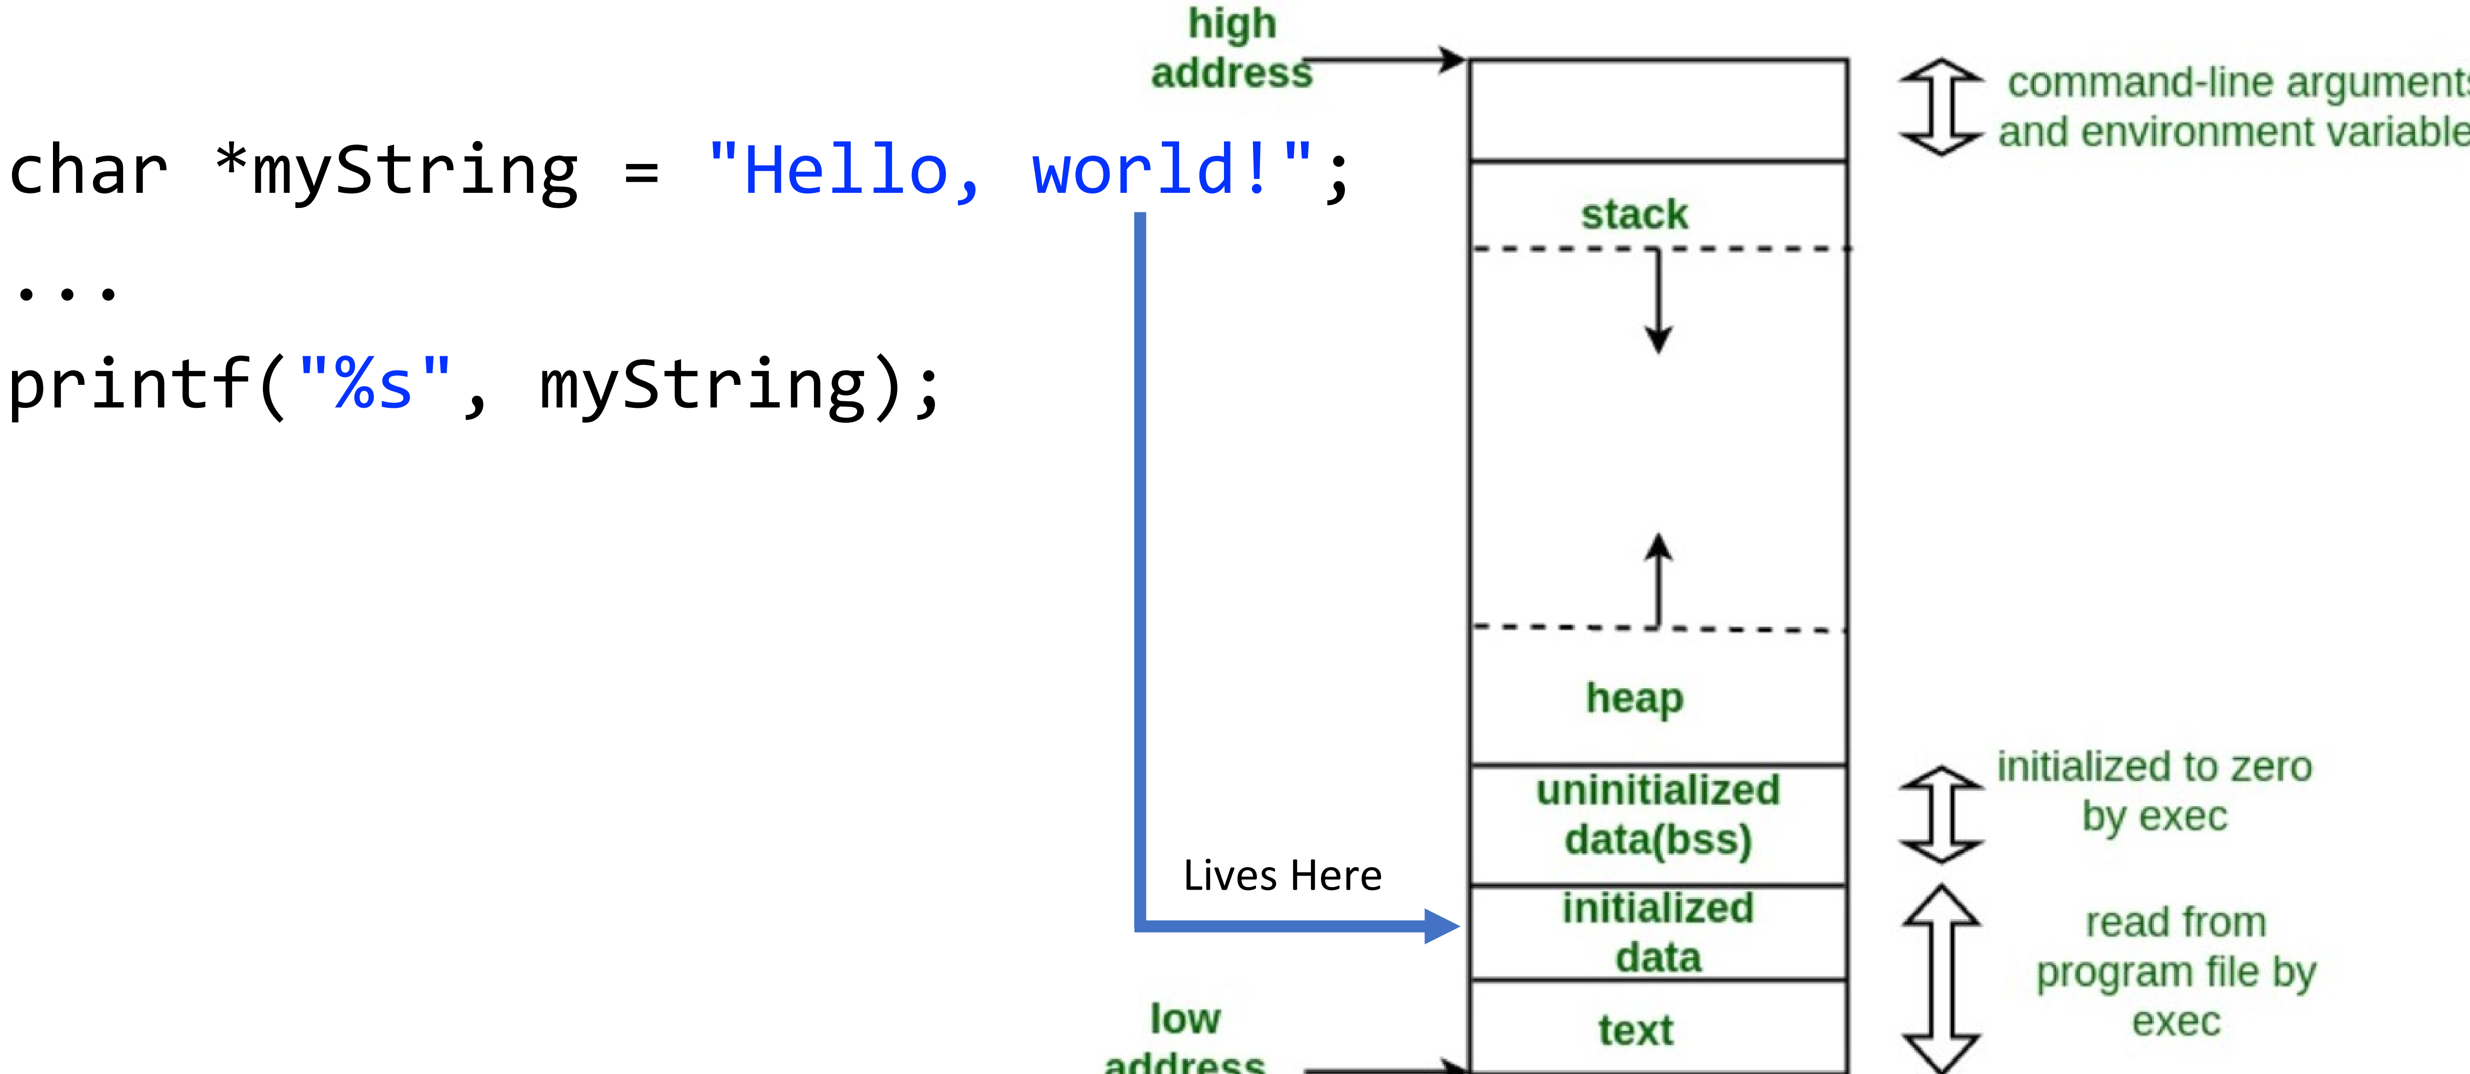
Read-only Strings

To create a string that we do **not** need to modify later.

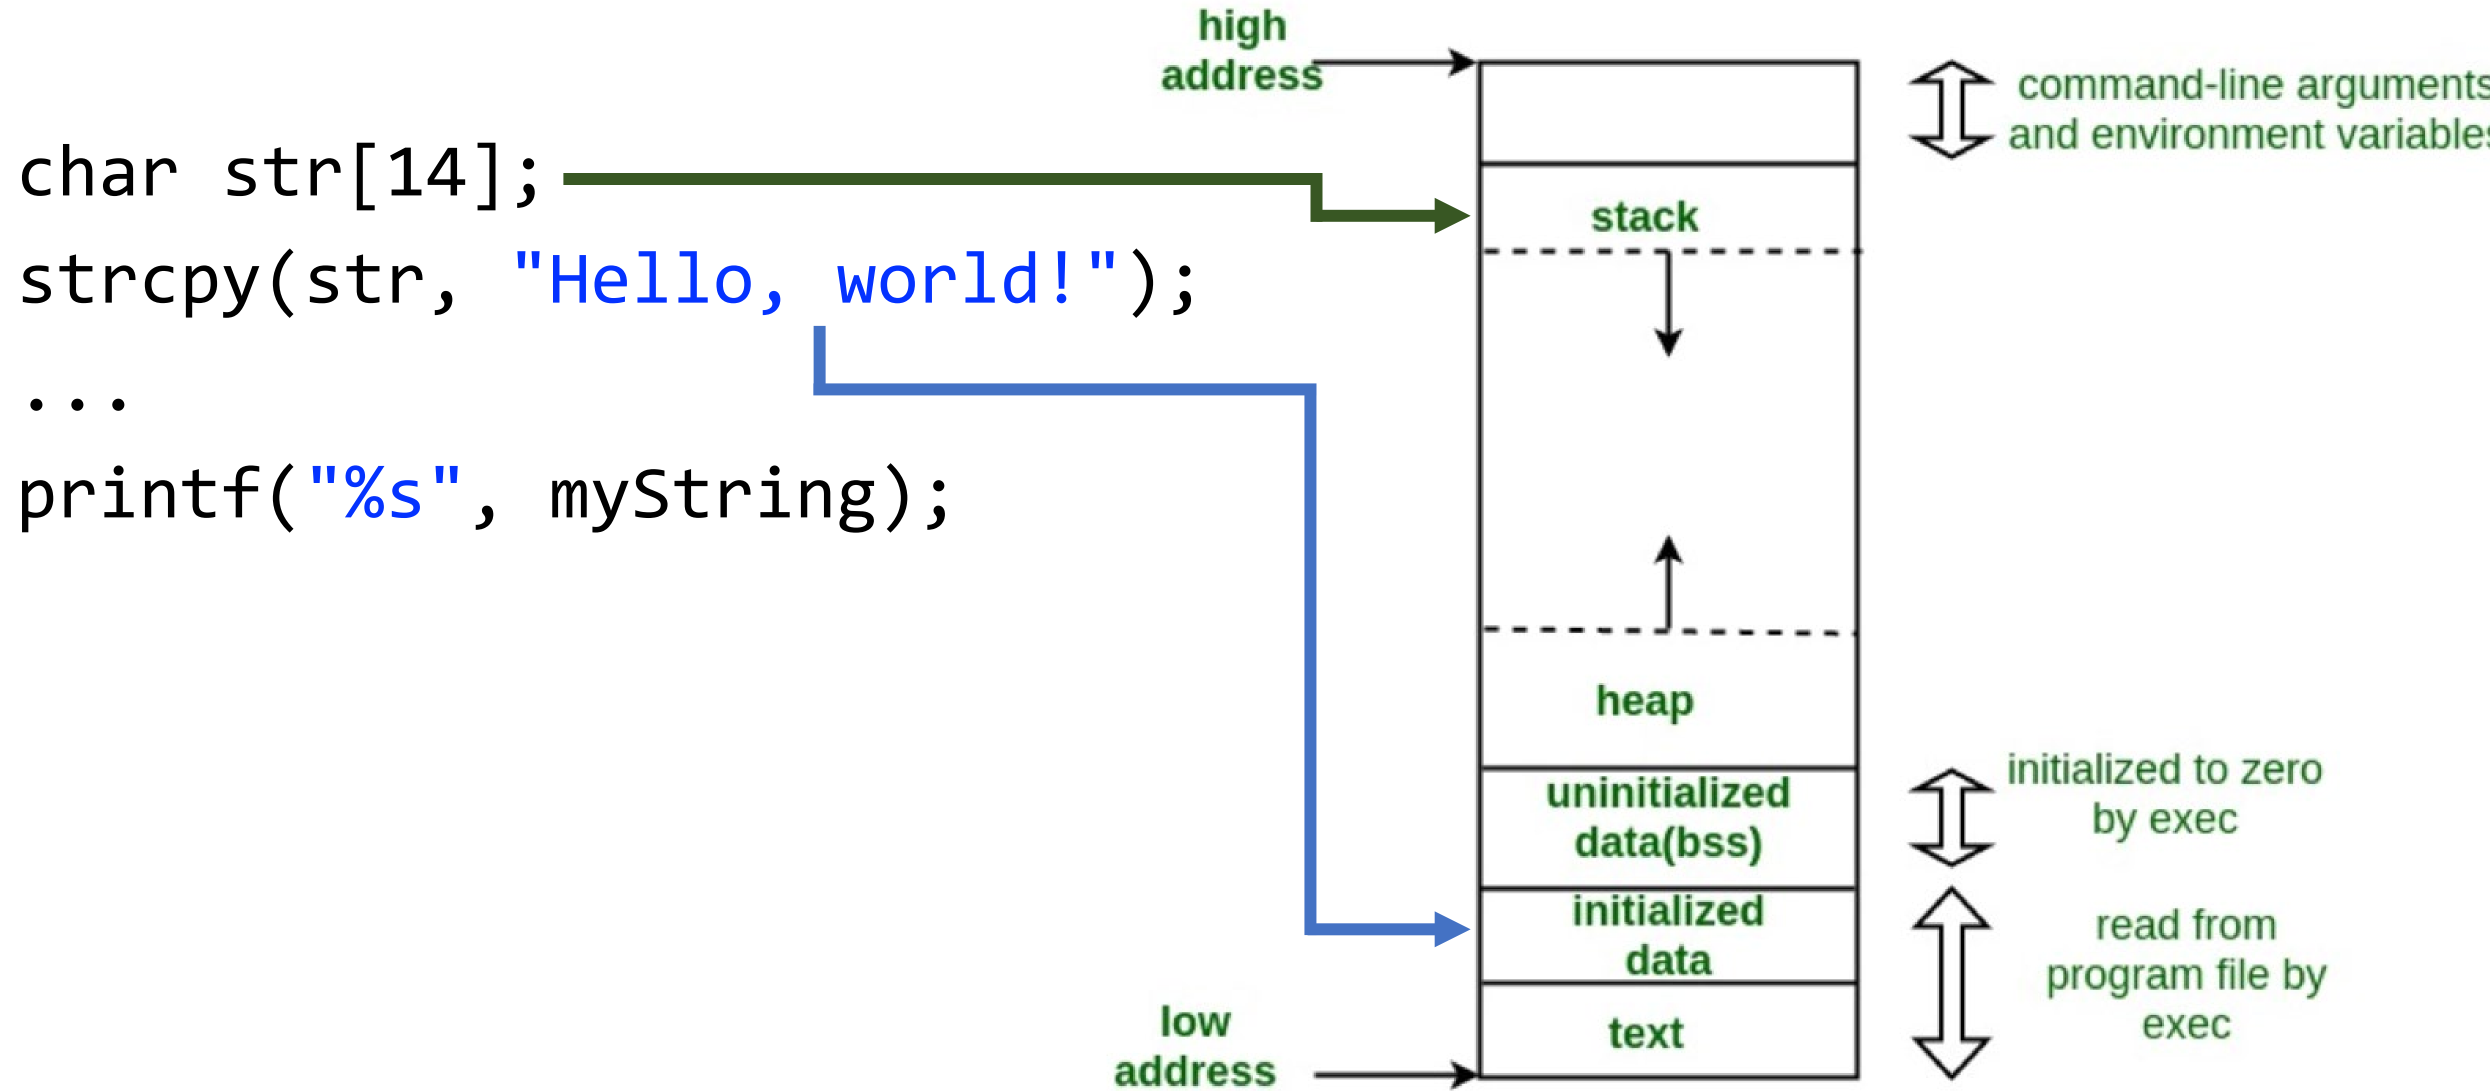
We can create a `char *` and set it directly equal to a string literal.

```
char *myString = "Hello, world!";
...
printf("%s", myString);             // Hello, world!
```

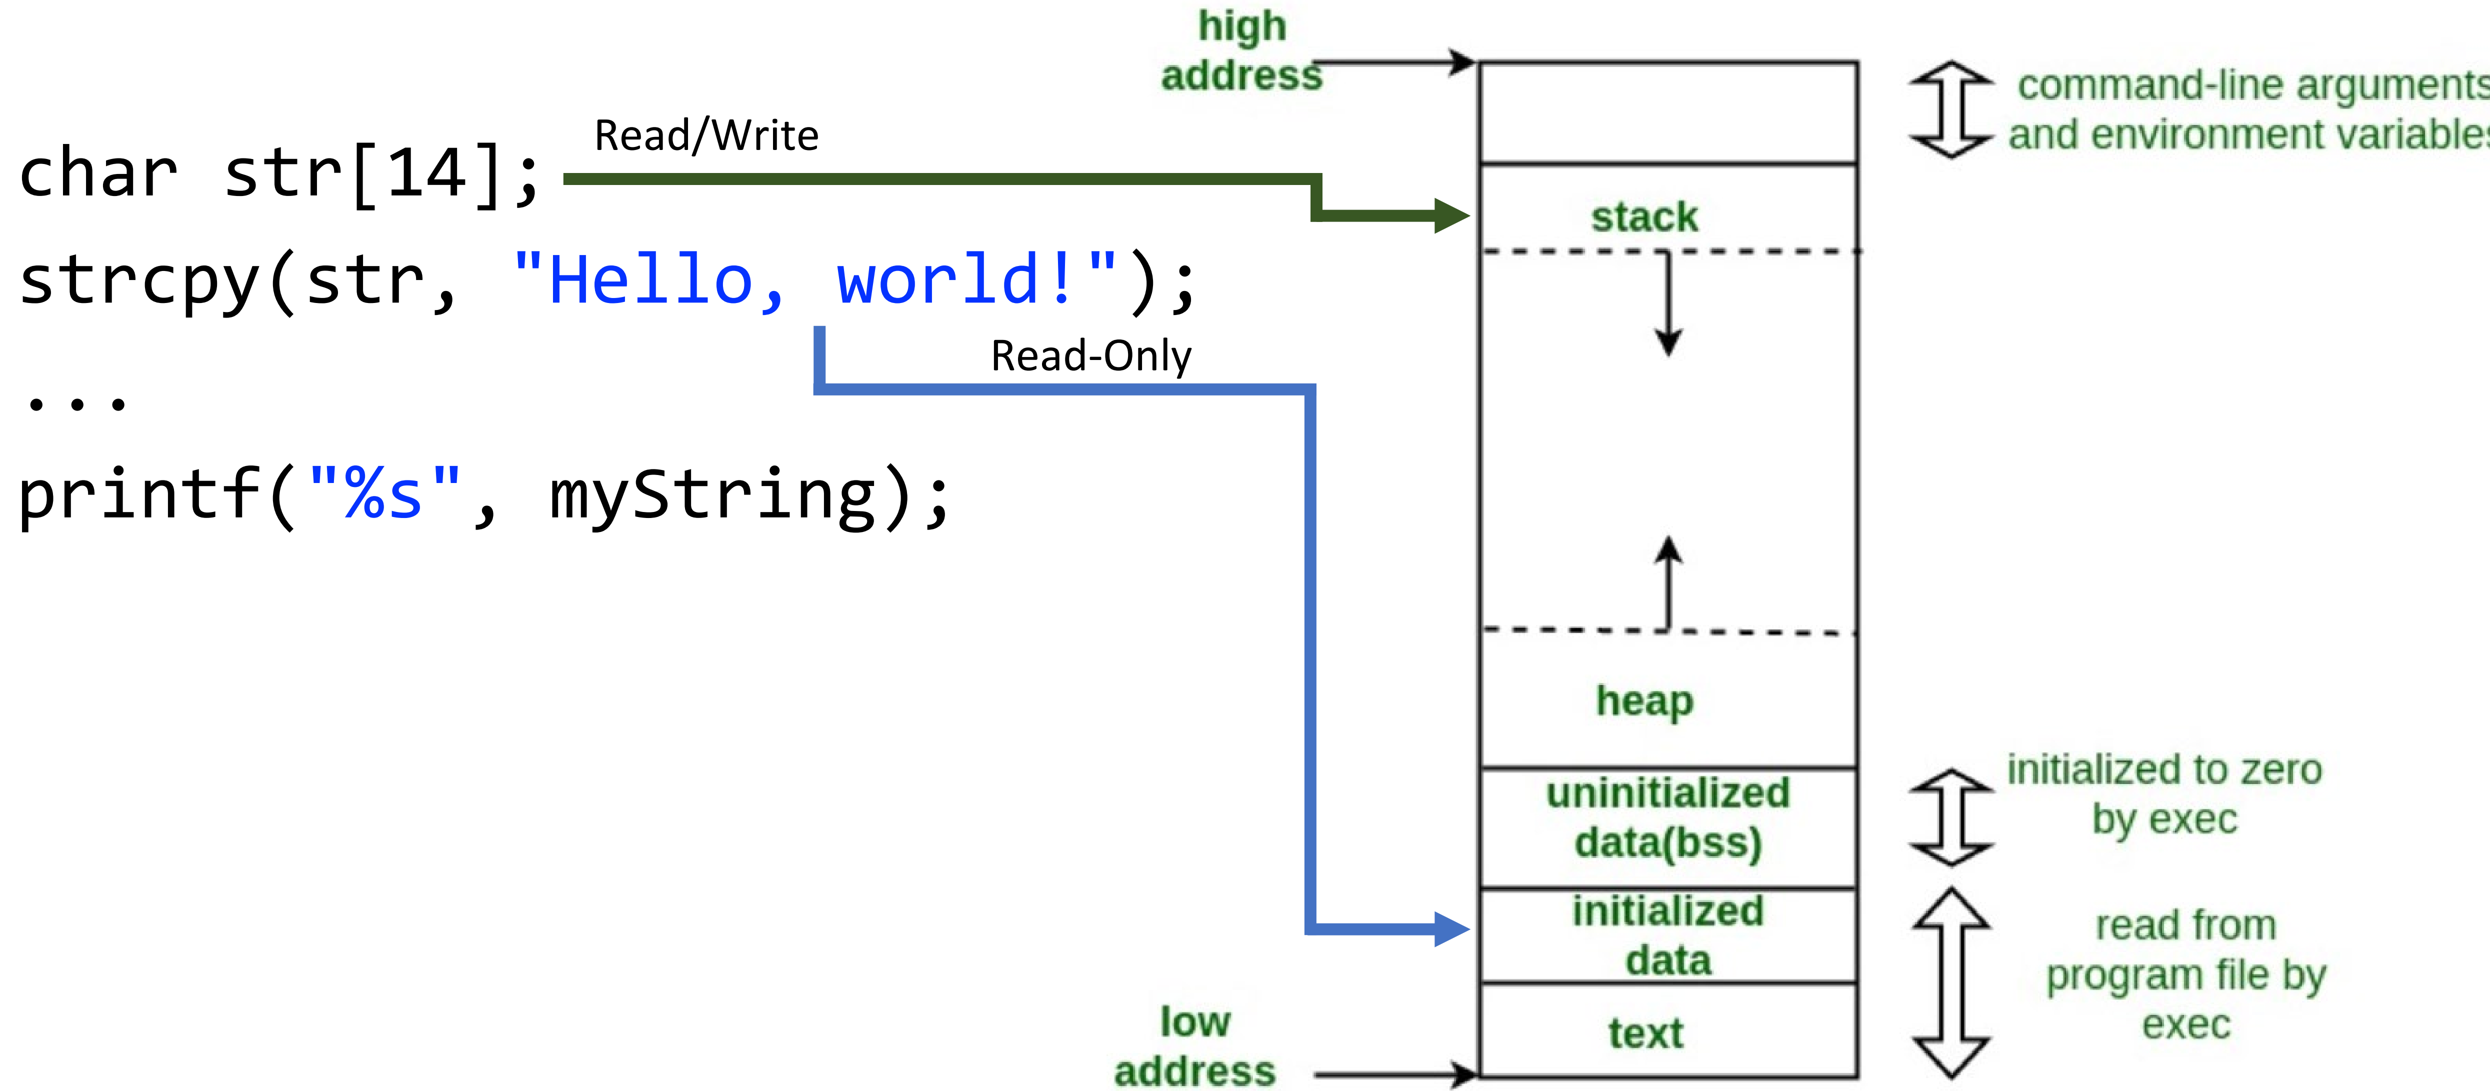
Why Read-Only?



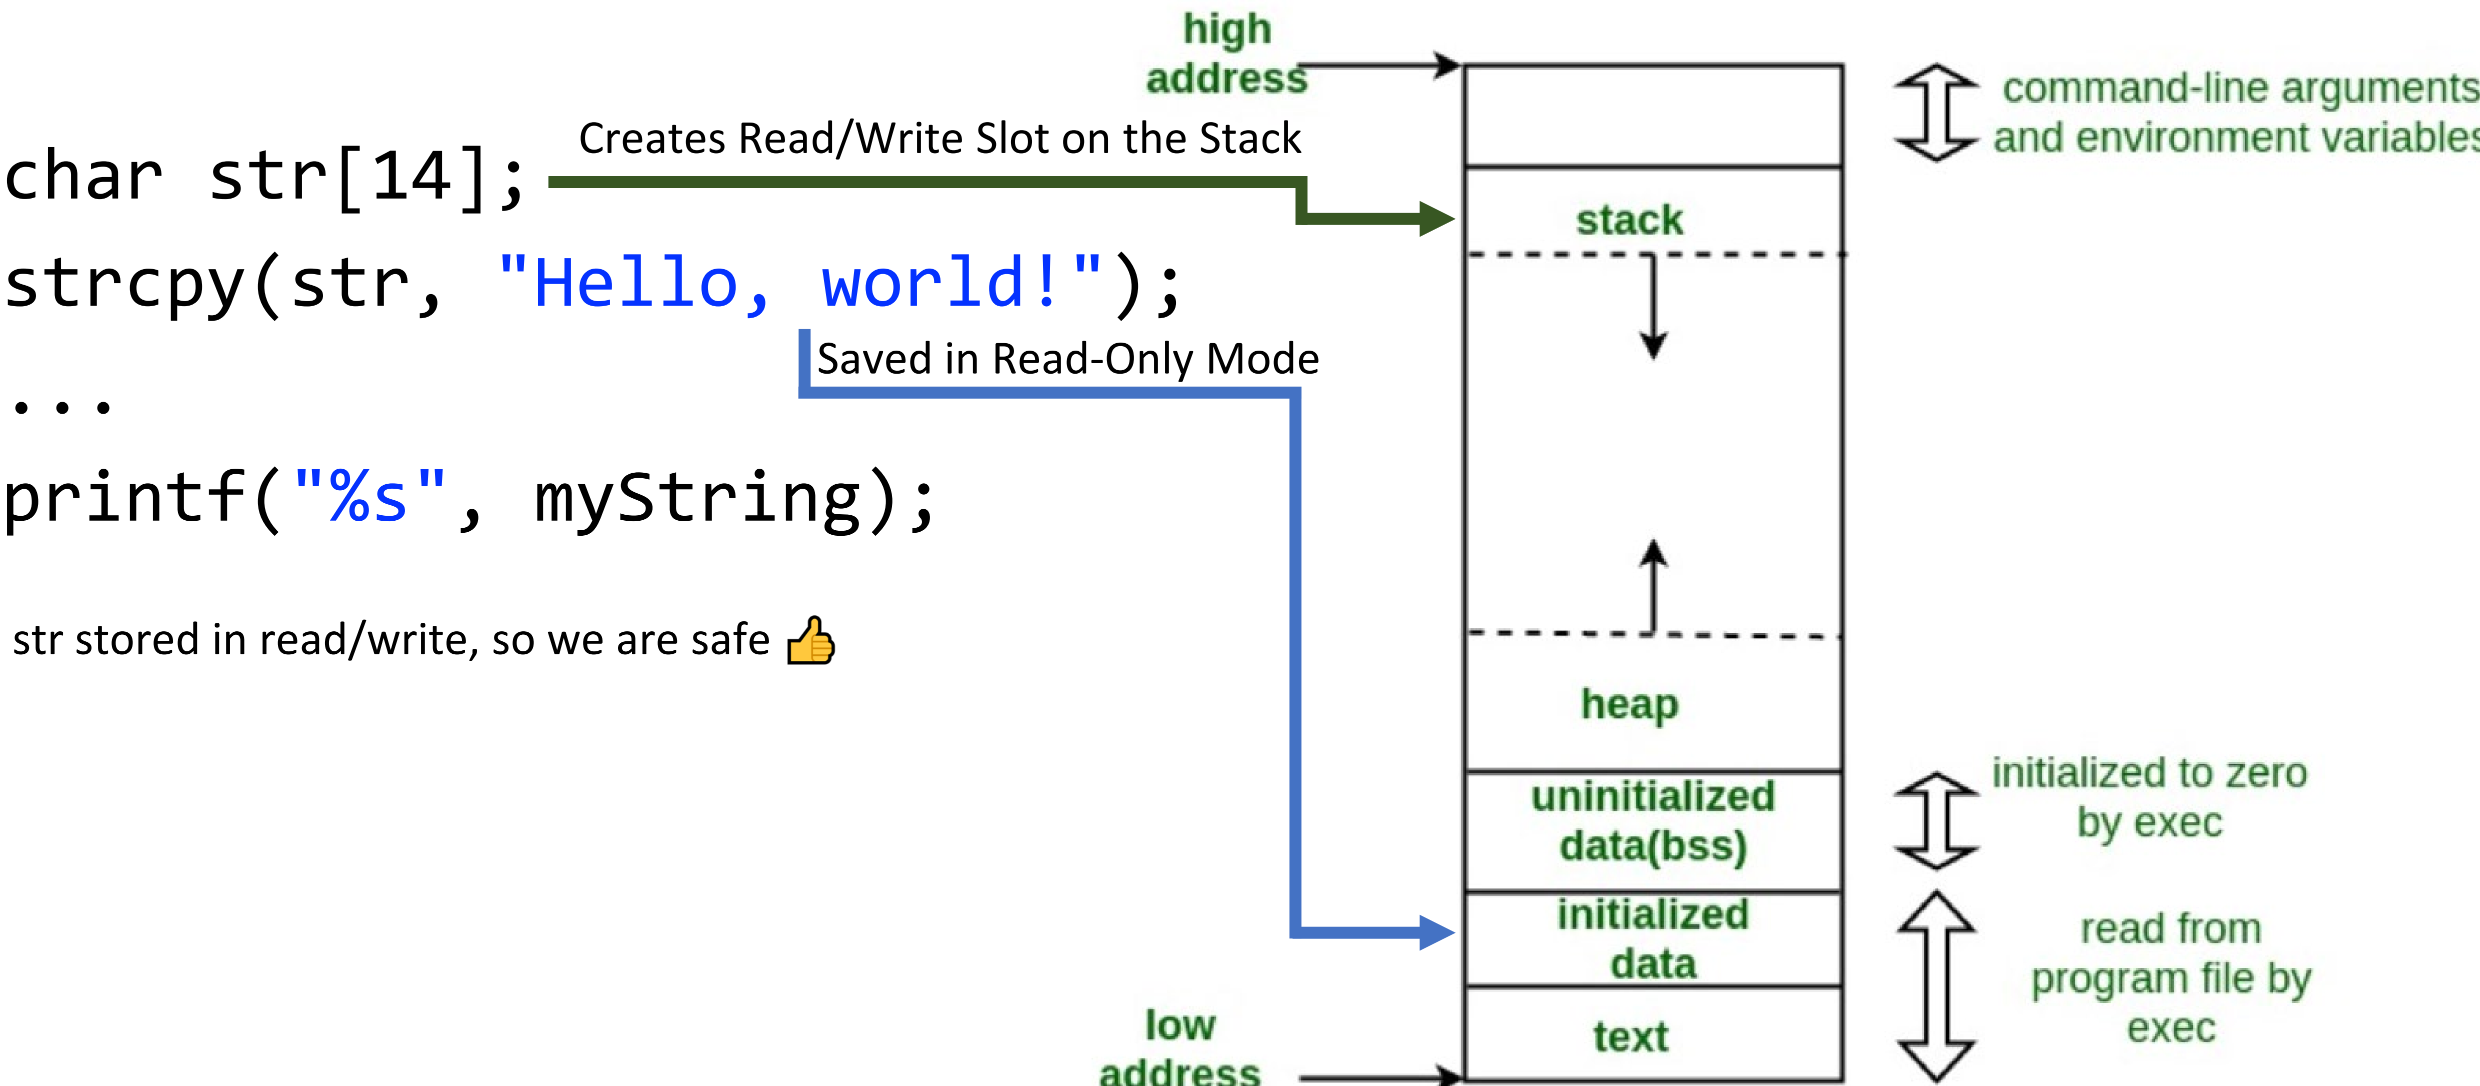
What About this?



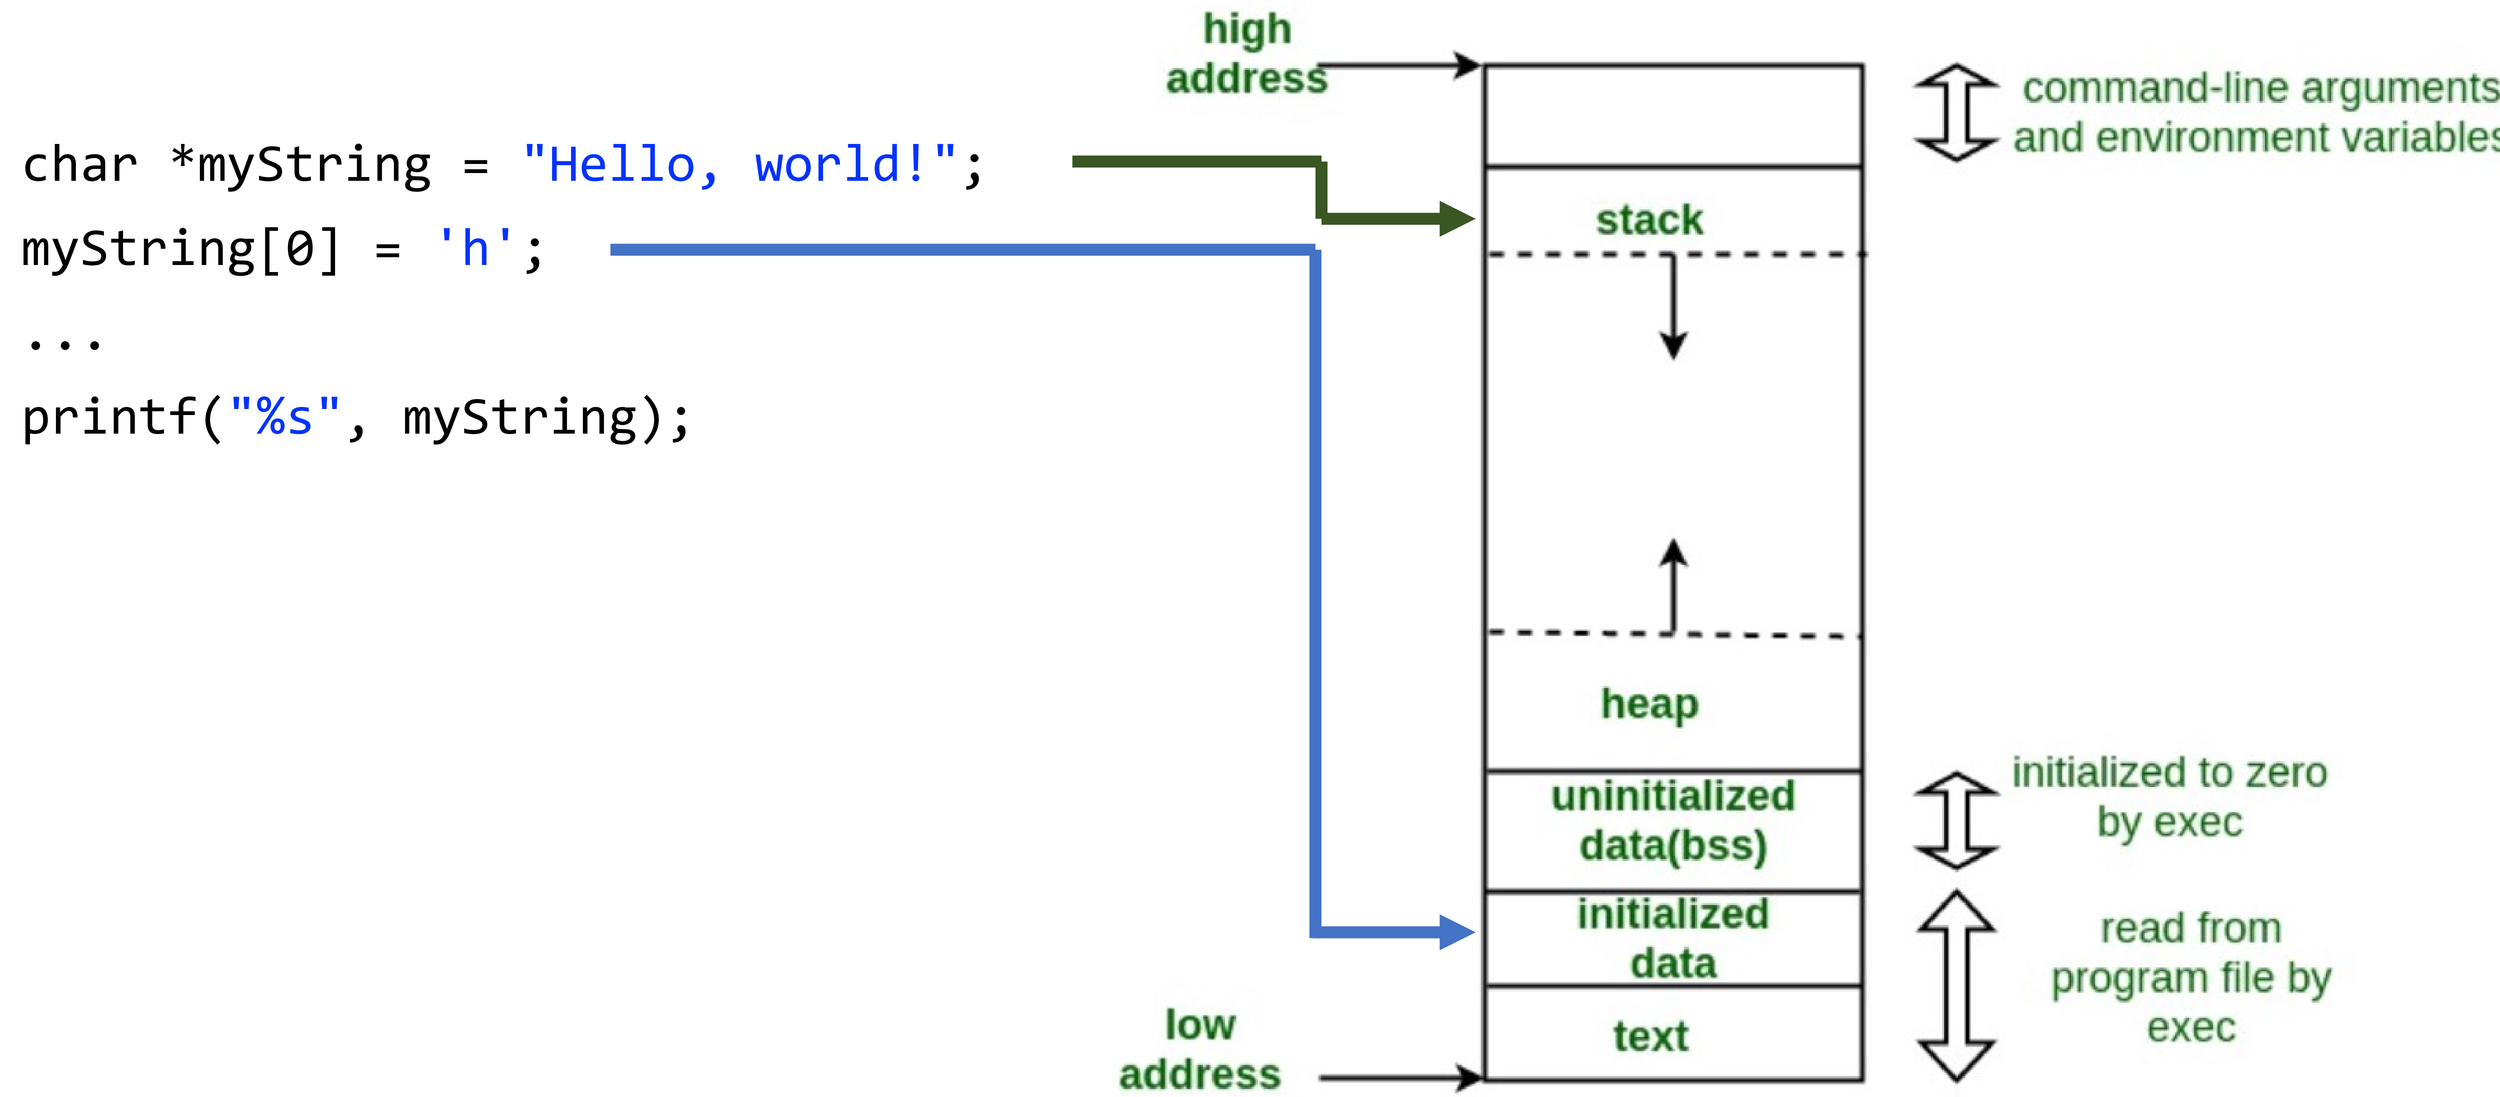
What About this?



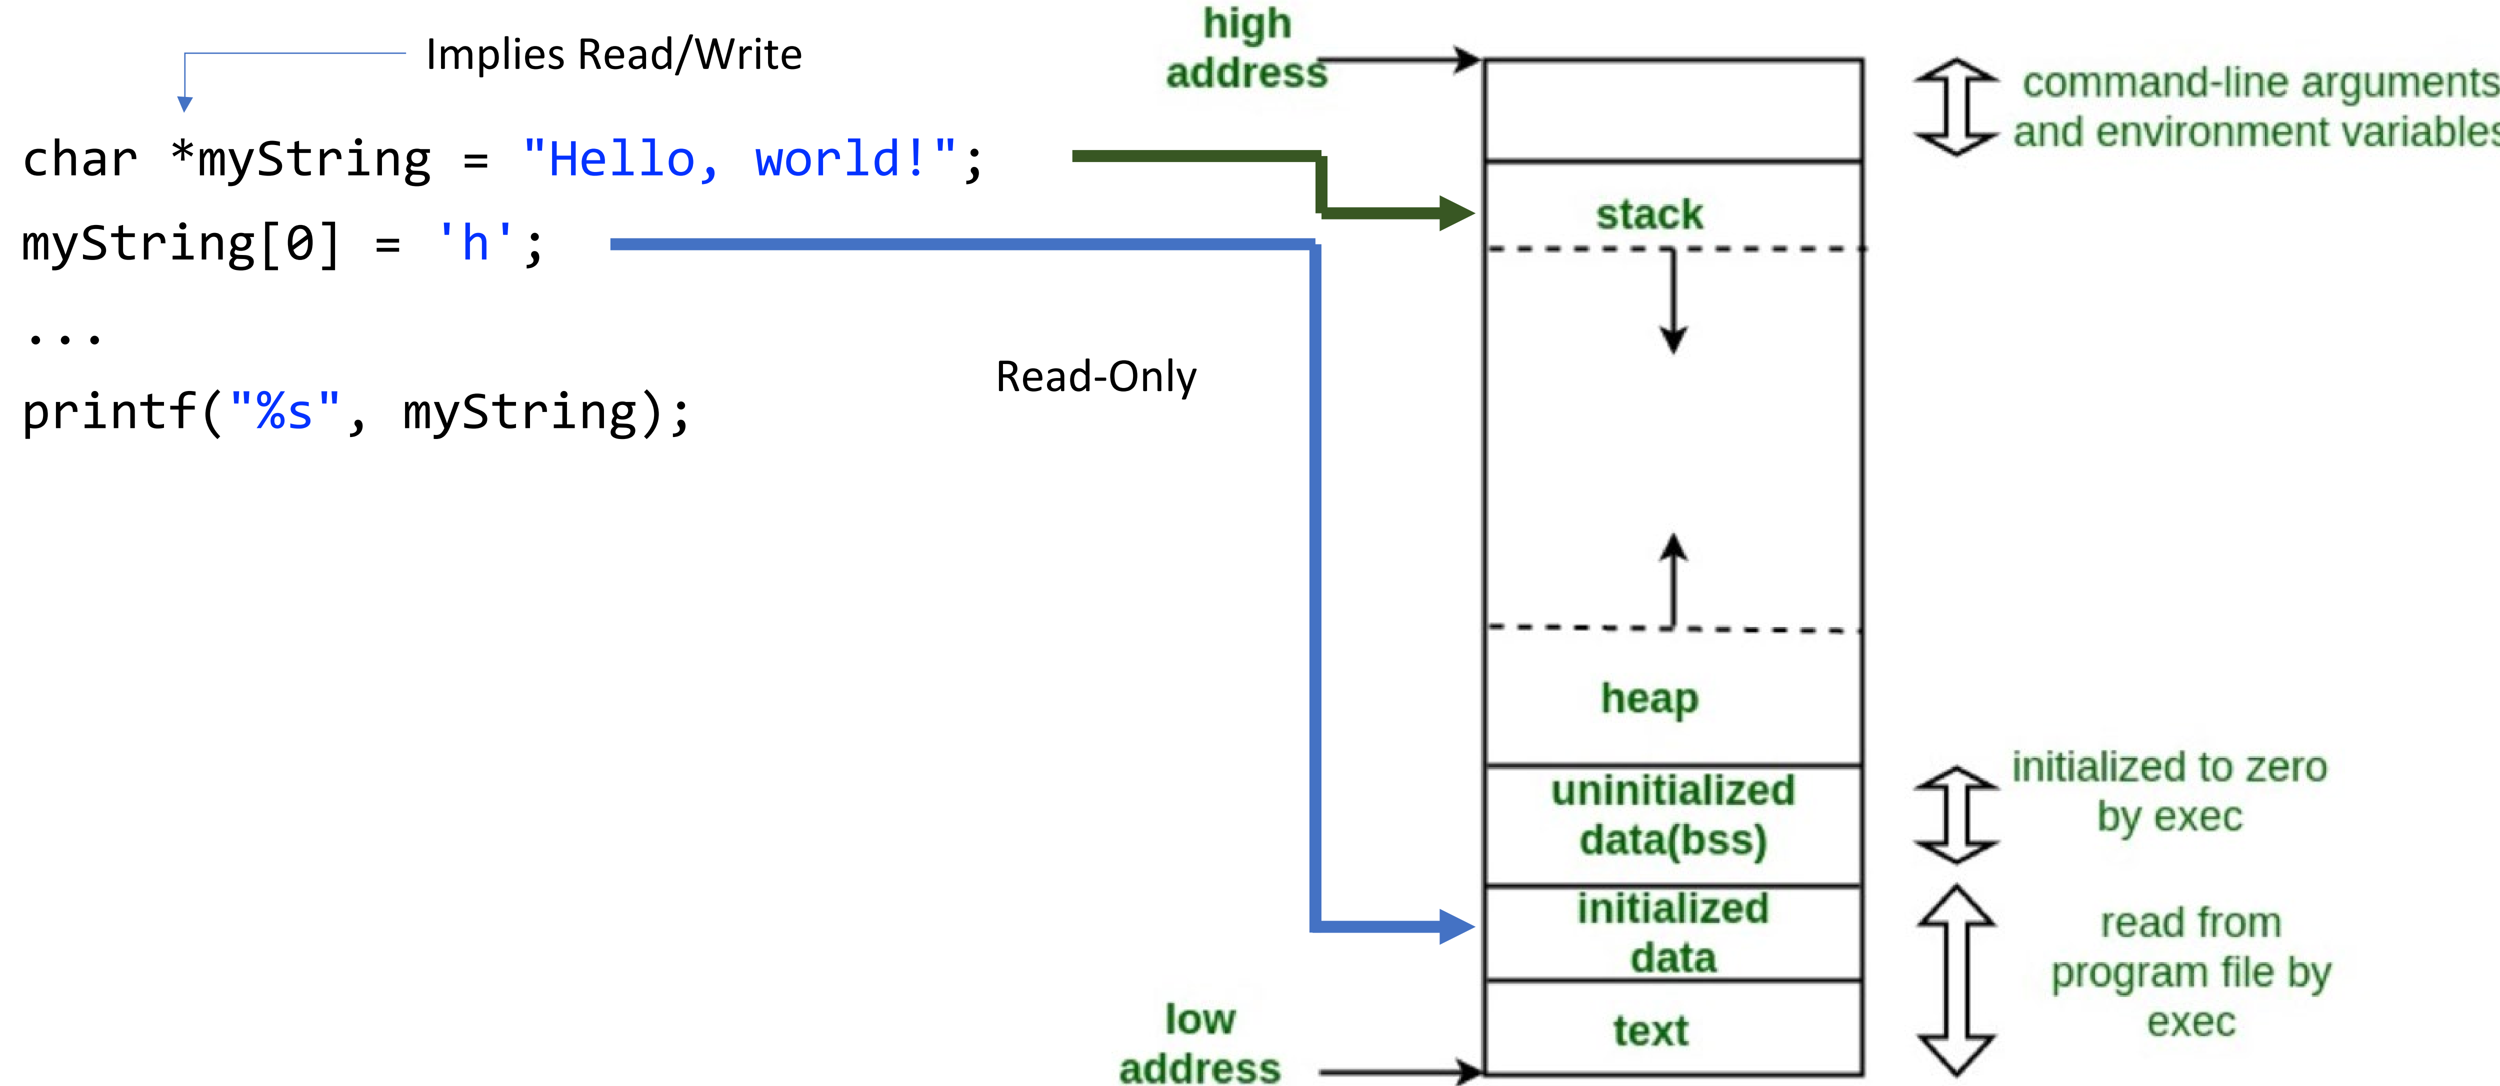
What About this?



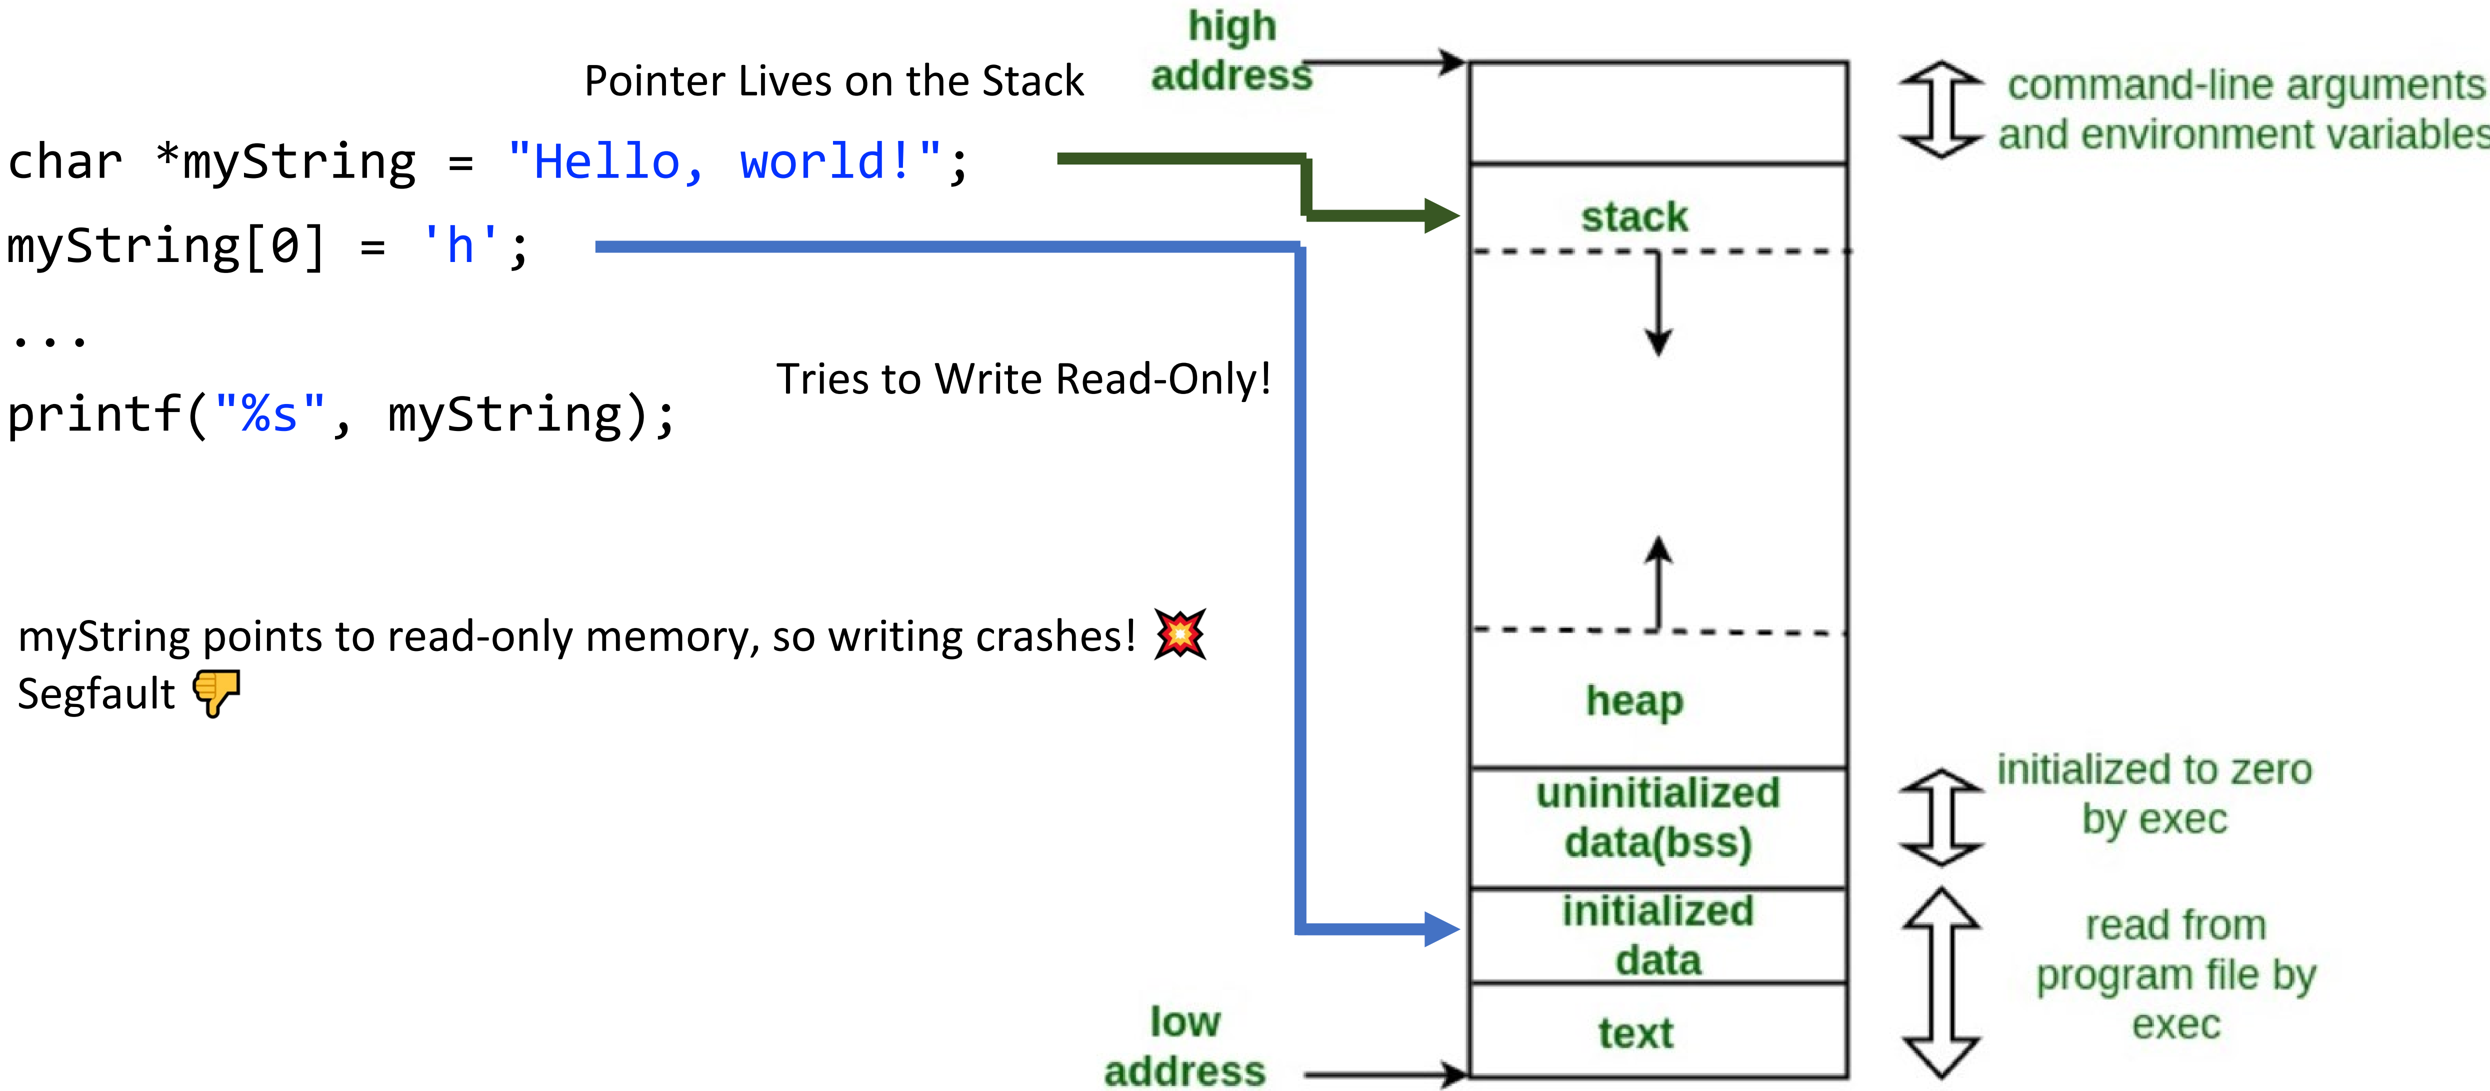
What About this?



What About this?



What About this?



Takeaway: Don't Write to String Literals

A `char *` set to a string literal points into **read-only** memory. Writing through it crashes!

```
char *myString = "Hello, world!";
myString[0] = 'h';            // 💥 crash! read-only
```

Exercise 1

We want to write a function that prints out the square of a number. What should go in each of the blanks?

```
void printSquare(__?__) {
    int square = __?__ * __?__;
    printf("%d", square);
}

int main(int argc, char *argv[]) {
    int num = 3;
    printSquare(__?__);     // should print 9
}
```

Exercise 1

We want to write a function that prints out the square of a number. What should go in each of the blanks?

```
void printSquare(int x) {
    x = x * x;
    printf("%d", x);
}

int main(int argc, char *argv[]) {
    int num = 3;
    printSquare(num);  // should print 9
}
```

We are performing a calculation with some input and do not care about any changes to the input, so we pass the data type itself.

Exercise 2

We want to write a function that flips the case of a letter. What should go in each of the blanks?

```
void flipCase(__?__) {
      if (isupper(__?__)) {
            __?__ = __?__;
      } else if (islower(__?__)) {
            __?__ = __?__;
      }
}

int main(int argc, char *argv[]) {
      char ch = 'g';
      flipCase(__?__);
      printf("%c", ch);     // We want this to print 'G'
}
```

Exercise 2

We want to write a function that flips the case of a letter. What should go in each of the blanks?

```
void flipCase(__?__) {
	if (isupper(__?__)) {
		__?__ = __?__;
	} else if (islower(__?__)) {
		__?__ = __?__;
	}
}

int main(int argc, char *argv[]) {
	char ch = 'g';
	flipCase(__?__);
	printf("%c", ch);     // should print ‘G’
}
```

ctype.h Cheat Sheet

```
#include <ctype.h>
```

Checks

```
int isupper(int c);
int islower(int c);
int isalpha(int c);
int isdigit(int c);
int isspace(int c);
```

Convert

```
int toupper(int c);
int tolower(int c);
```

Exercise 2

We want to write a function that flips the case of a letter. What should go in each of the blanks?

```
void flipCase(char *letter) {
      if (isupper(*letter)) {
            *letter = tolower(*letter);
      } else if (islower(*letter)) {
            *letter = toupper(*letter);
      }
}

int main(int argc, char *argv[]) {
      char ch = 'g';
      flipCase(&ch);
      printf("%c", ch);     // want this to print 'G'
```

We are modifying a specific instance of the letter, so we pass the *location* of the letter we would like to modify.

Exercise 3

Sometimes, we would like to modify a string's pointer itself, rather than just the characters it points to. E.g. we want to write a function **skipSpaces** that modifies a string pointer to skip past any initial spaces. What should go in each of the blanks?

```
void skipSpaces(__1__) {
     ...
}

int main(int argc, char *argv[]) {
     char *str = "    hello";
     skipSpaces(__2__);
     printf("%s", str);      // should print "hello"
}
```

Exercise 3

Sometimes, we would like to modify a string's pointer itself, rather than just the characters it points to. E.g. we want to write a function **skipSpaces** that modifies a string pointer to skip past any initial spaces. What should go in each of the blanks?

```
void skipSpaces(char **strPtr) {
    ...
}

int main(int argc, char *argv[]) {
    char *str = "    hi";
    skipSpaces(&str);
    printf("%s", str);      // should print "hi"
}
```

We are modifying a specific instance of the string pointer, so we pass the *location* of the string pointer we would like to modify.

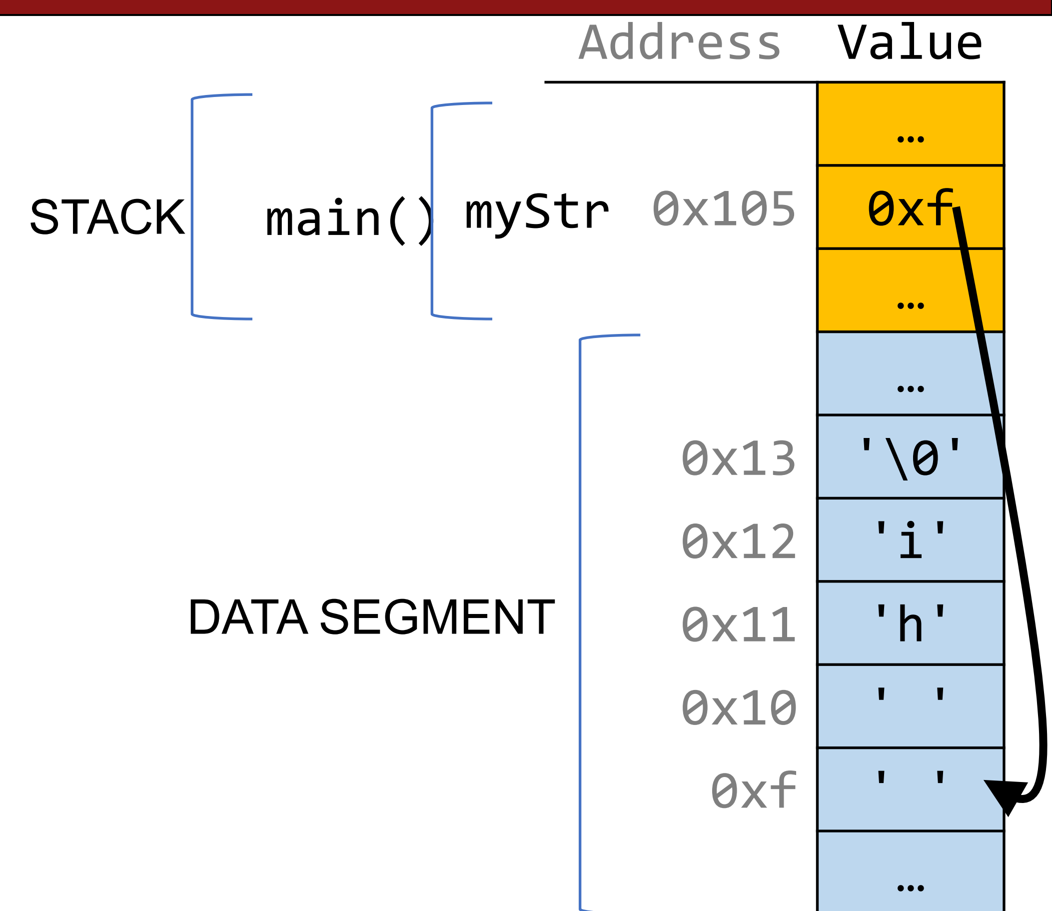
Common `string.h` Functions

Function	Description
`strlen(`***`str`***`)`	returns the # of chars in a C string (before null-terminating character).
`strcmp(`***`str1, str2`***`)`, `strncmp(`***`str1, str2, n`***`)`	compares two strings; returns 0 if identical, <0 if ***`str1`*** comes before ***`str2`*** in alphabet, >0 if ***`str1`*** comes after ***`str2`*** in alphabet. ***`strncmp`*** stops comparing after at most ***`n`*** characters.
`strchr(`***`str, ch`***`)` `strrchr(`***`str, ch`***`)`	character search: returns a pointer to the first occurrence of ***`ch`*** in ***`str`***, or ***`NULL`*** if ***`ch`*** was not found in ***`str`***. `strrchr` find the last occurrence.
`strstr(`***`haystack, needle`***`)`	string search: returns a pointer to the start of the first occurrence of ***`needle`*** in ***`haystack`***, or ***`NULL`*** if ***`needle`*** was not found in ***`haystack`***.
`strcpy(`***`dst, src`***`)`, `strncpy(`***`dst, src, n`***`)`	copies characters in ***`src`*** to ***`dst`***, including null-terminating character. Assumes enough space in ***`dst`***. Strings must not overlap. **`strncpy`** stops after at most ***`n`*** chars, and <u>does not</u> add null-terminating char.
`strcat(`***`dst, src`***`)`, `strncat(`***`dst, src, n`***`)`	concatenate ***`src`*** onto the end of ***`dst`***. **`strncat`** stops concatenating after at most ***`n`*** characters. <u>Always</u> adds a null-terminating character.
`strspn(`***`str, accept`***`)`, `strcspn(`***`str, reject`***`)`	**`strspn`** returns the length of the initial part of ***`str`*** which contains <u>only</u> characters in ***`accept`***. **`strcspn`** returns the length of the initial part of ***`str`*** which does <u>not</u> contain any characters in ***`reject`***.

Pointers to Strings

```c
void skipSpaces(char **strPtr) {
    int numSpaces = strspn(*strPtr, " ");
    *strPtr += numSpaces;
}

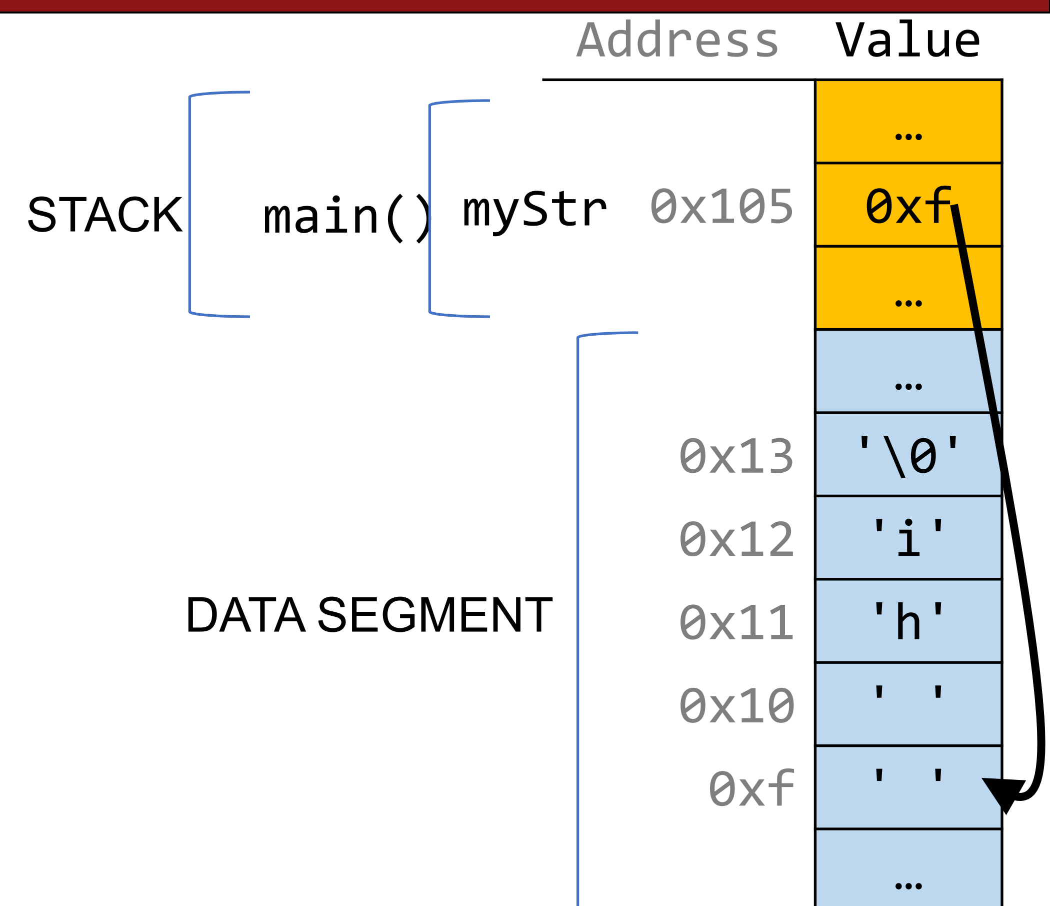
int main(int argc, char *argv[]) {
    char *myStr = "  hi";
    skipSpaces(&myStr);
    printf("%s\n", myStr);       // hi
    return 0;
}
```



Pointers to Strings

```
void skipSpaces(char **strPtr) {
    int numSpaces = strspn(*strPtr, " ");
    *strPtr += numSpaces;
}

int main(int argc, char *argv[]) {
    char *myStr = "  hi";
    skipSpaces(&myStr);
    printf("%s\n", myStr);       // hi
    return 0;
}
```



Pointers to Strings

```
void skipSpaces(char **strPtr) {
    int numSpaces = strspn(*strPtr, " ");
    *strPtr += numSpaces;
}

int main(int argc, char *argv[]) {
    char *myStr = "  hi";
    skipSpaces(&myStr);
    printf("%s\n", myStr);      // hi
    return 0;
}
```

			Address	Value
STACK	main()			…
		myStr	0x105	0xf
				…
	skipSpaces()			…
		strPtr	0xf0	0x105
				…
DATA SEGMENT				…
			0x13	'\0'
			0x12	'i'
			0x11	'h'
			0x10	' '
			0xf	' '
				…

Pointers to Strings

```
void skipSpaces(char **strPtr) {
    int numSpaces = strspn(*strPtr, " ");
    *strPtr += numSpaces;
}

int main(int argc, char *argv[]) {
    char *myStr = "  hi";
    skipSpaces(&myStr);
    printf("%s\n", myStr);      // hi
    return 0;
}
```

		Address	Value
STACK	main()		…
		myStr 0x105	0xf
			…
	skipSpaces()		…
		strPtr 0xf0	0x105
		numSpaces 0xe8	2
			…
DATA SEGMENT			…
		0x13	'\0'
		0x12	'i'
		0x11	'h'
		0x10	' '
		0xf	' '
			…

Pointers to Strings

```
void skipSpaces(char **strPtr) {
    int numSpaces = strspn(*strPtr, " ");
    *strPtr += numSpaces;
}

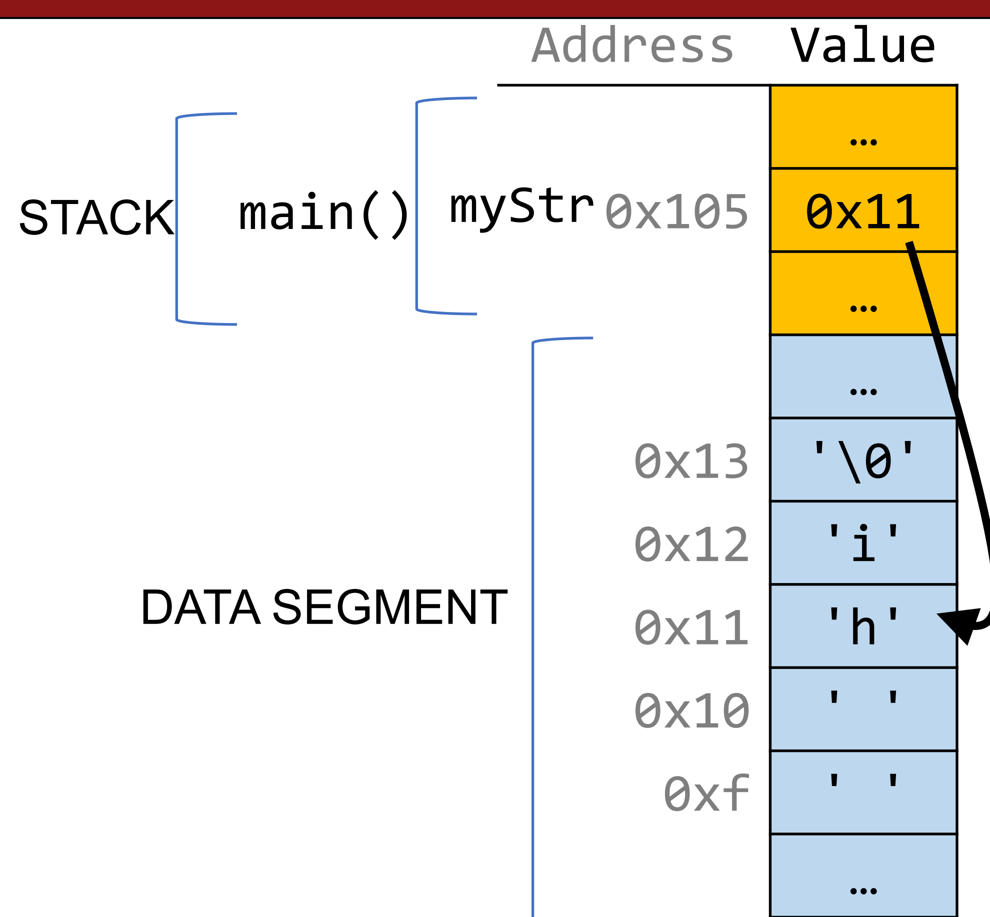
int main(int argc, char *argv[]) {
    char *myStr = "  hi";
    skipSpaces(&myStr);
    printf("%s\n", myStr);        // hi
    return 0;
}
```

		Address	Value
STACK	main()		…
		myStr 0x105	0x11
			…
	skipSpaces()		…
		strPtr 0xf0	0x105
		numSpaces 0xe8	2
			…
DATA SEGMENT			…
		0x13	'\0'
		0x12	'i'
		0x11	'h'
		0x10	' '
		0xf	' '
			…

Pointers to Strings

```
void skipSpaces(char **strPtr) {
    int numSpaces = strspn(*strPtr, " ");
    *strPtr += numSpaces;
}

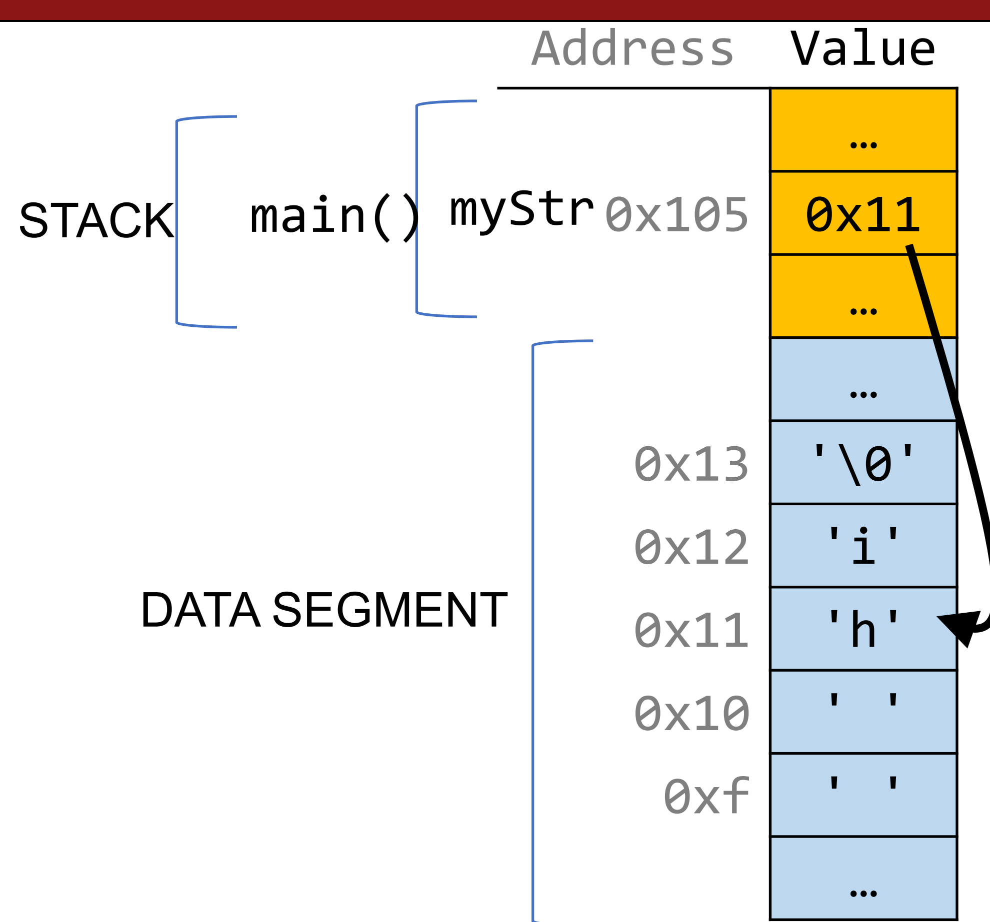
int main(int argc, char *argv[]) {
    char *myStr = "  hi";
    skipSpaces(&myStr);
    printf("%s\n", myStr);        // hi
    return 0;
}
```



Pointers to Strings

```
void skipSpaces(char **strPtr) {
    int numSpaces = strspn(*strPtr, " ");
    *strPtr += numSpaces;
}

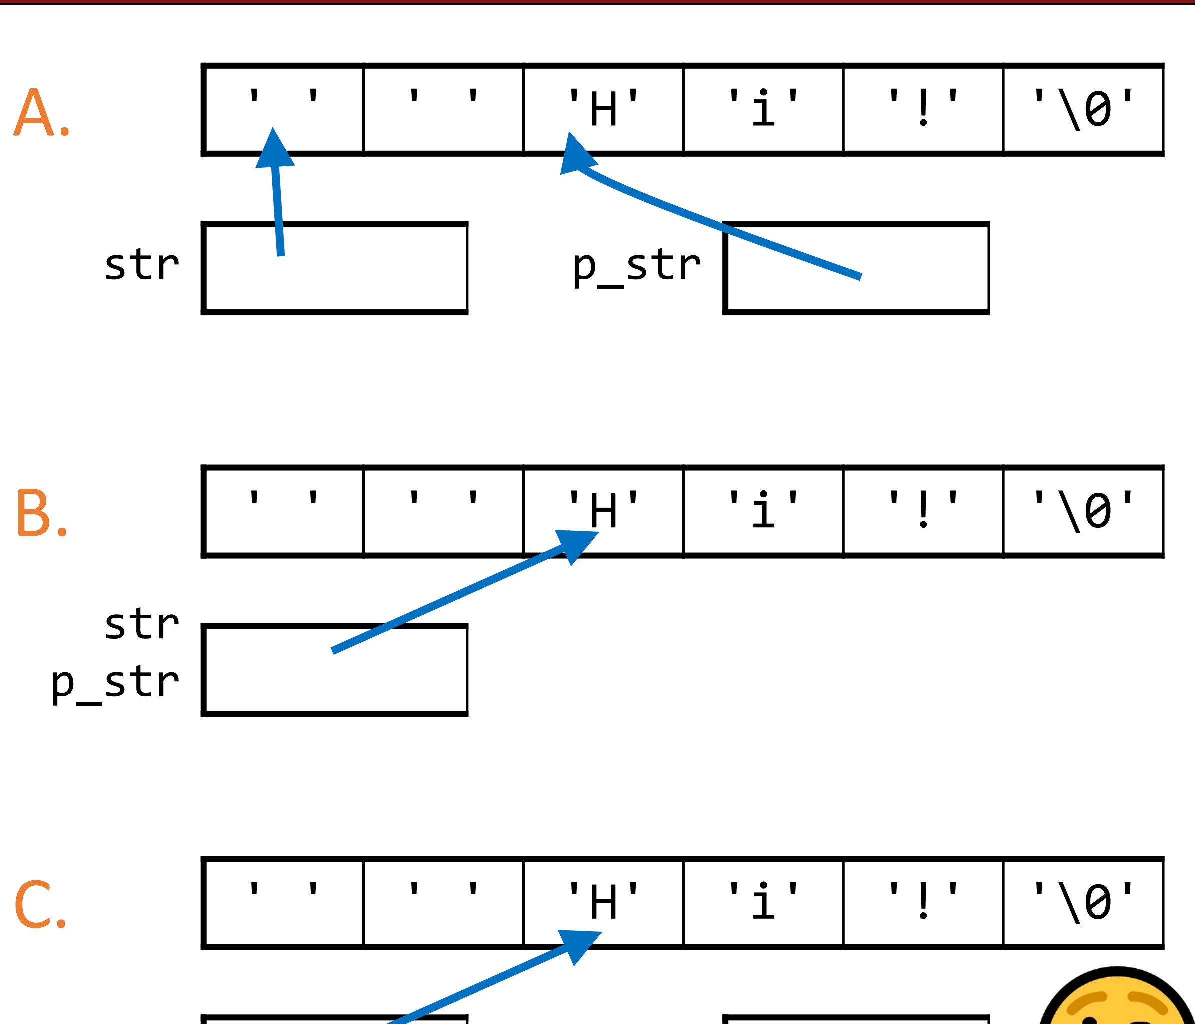
int main(int argc, char *argv[]) {
    char *myStr = "  hi";
    skipSpaces(&myStr);
    printf("%s\n", myStr);      // hi
    return 0;
}
```



Skip spaces

```
 1  void skip_spaces(char **p_str) {
 2    int num = strspn(*p_str, " ");
 3    *p_str = *p_str + num;
 4  }
 5  int main(int argc, char *argv[]){
 6    char *str = "  Hi!";
 7    skip_spaces(&str);
 8    printf("%s", str); // "Hi!"
 9    return 0;
10  }
```

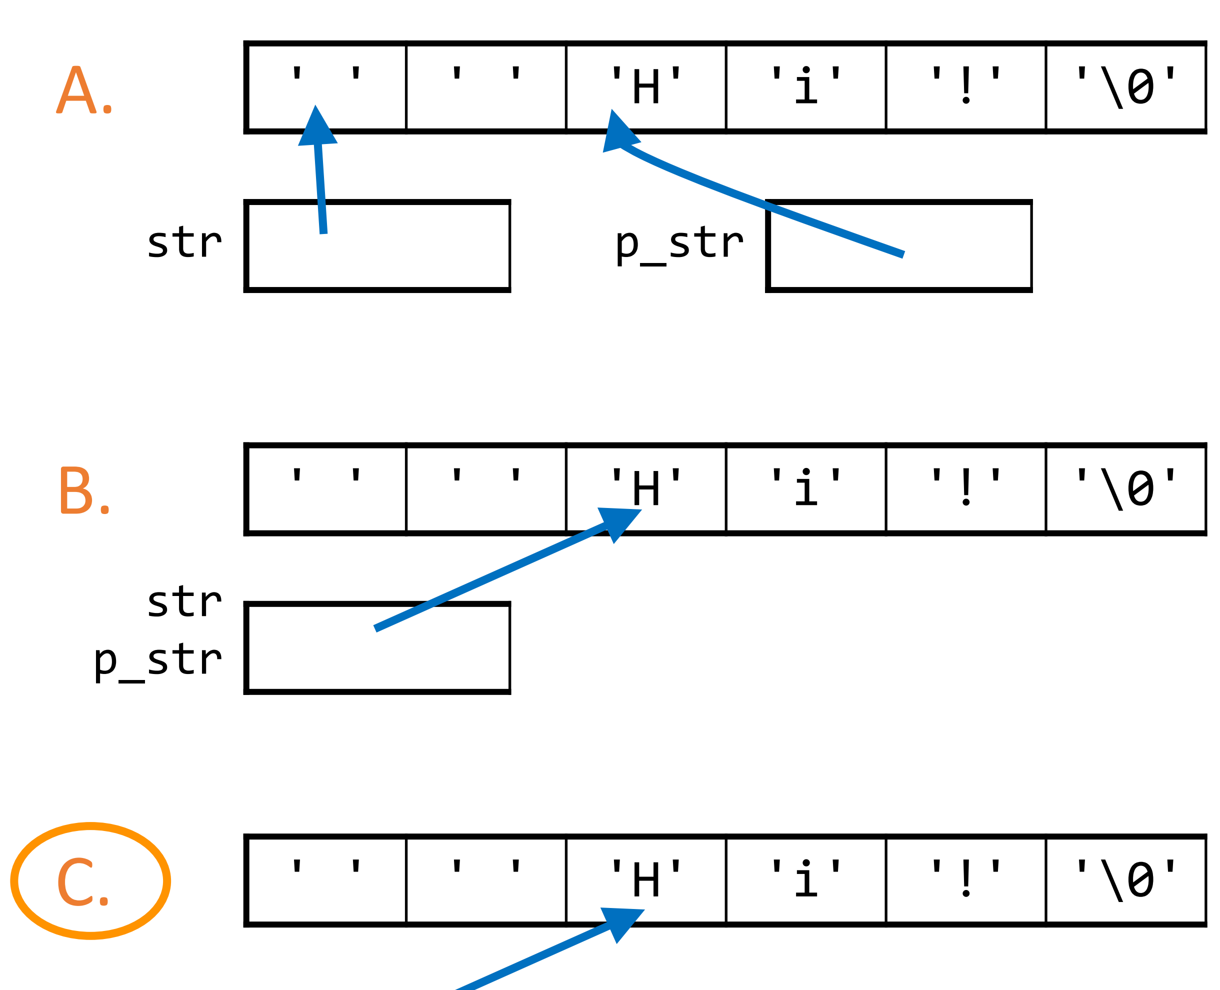
What diagram most accurately depicts program state at Line 4 (before skip_spaces returns to main)?



Skip spaces

```
1  void skip_spaces(char **p_str) {
2    int num = strspn(*p_str, " ");
3    *p_str = *p_str + num;
4  }
5  int main(int argc, char *argv[]){
6    char *str = "  Hi!";
7    skip_spaces(&str);
8    printf("%s", str); // "Hi!"
9    return 0;
10 }
```

What diagram most accurately depicts program state at Line 4 (before `skip_spaces` returns to `main`)?

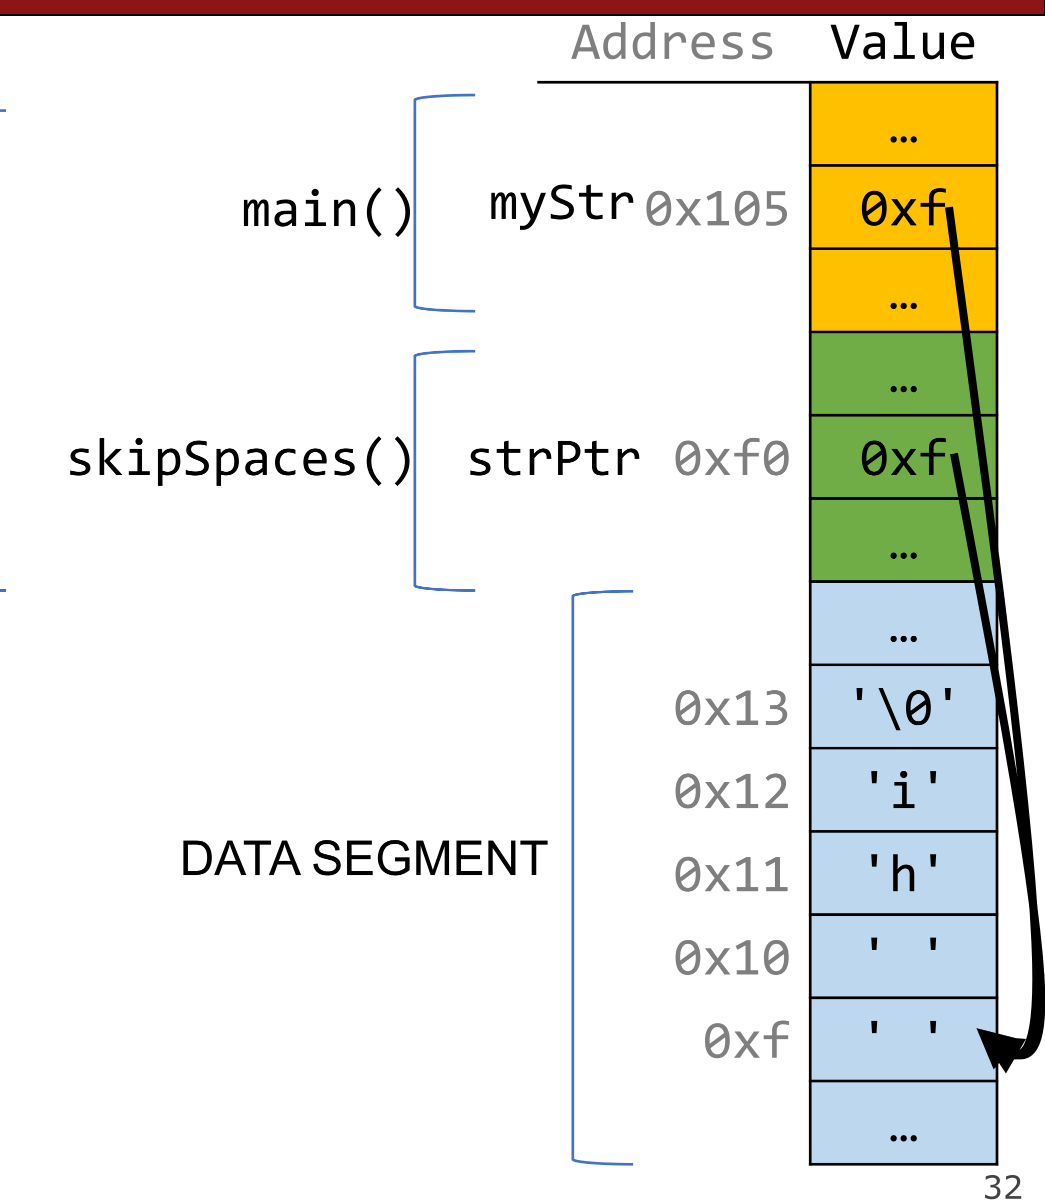


Beware: Making Copies

```
void skipSpaces(char *strPtr) {
    int numSpaces = strspn(strPtr, " ");
    strPtr += numSpaces;
}

int main(int argc, char *argv[]) {
    char *myStr = "  hi";
    skipSpaces(myStr);
    printf("%s\n", myStr);        //   hi
    return 0;
}
```

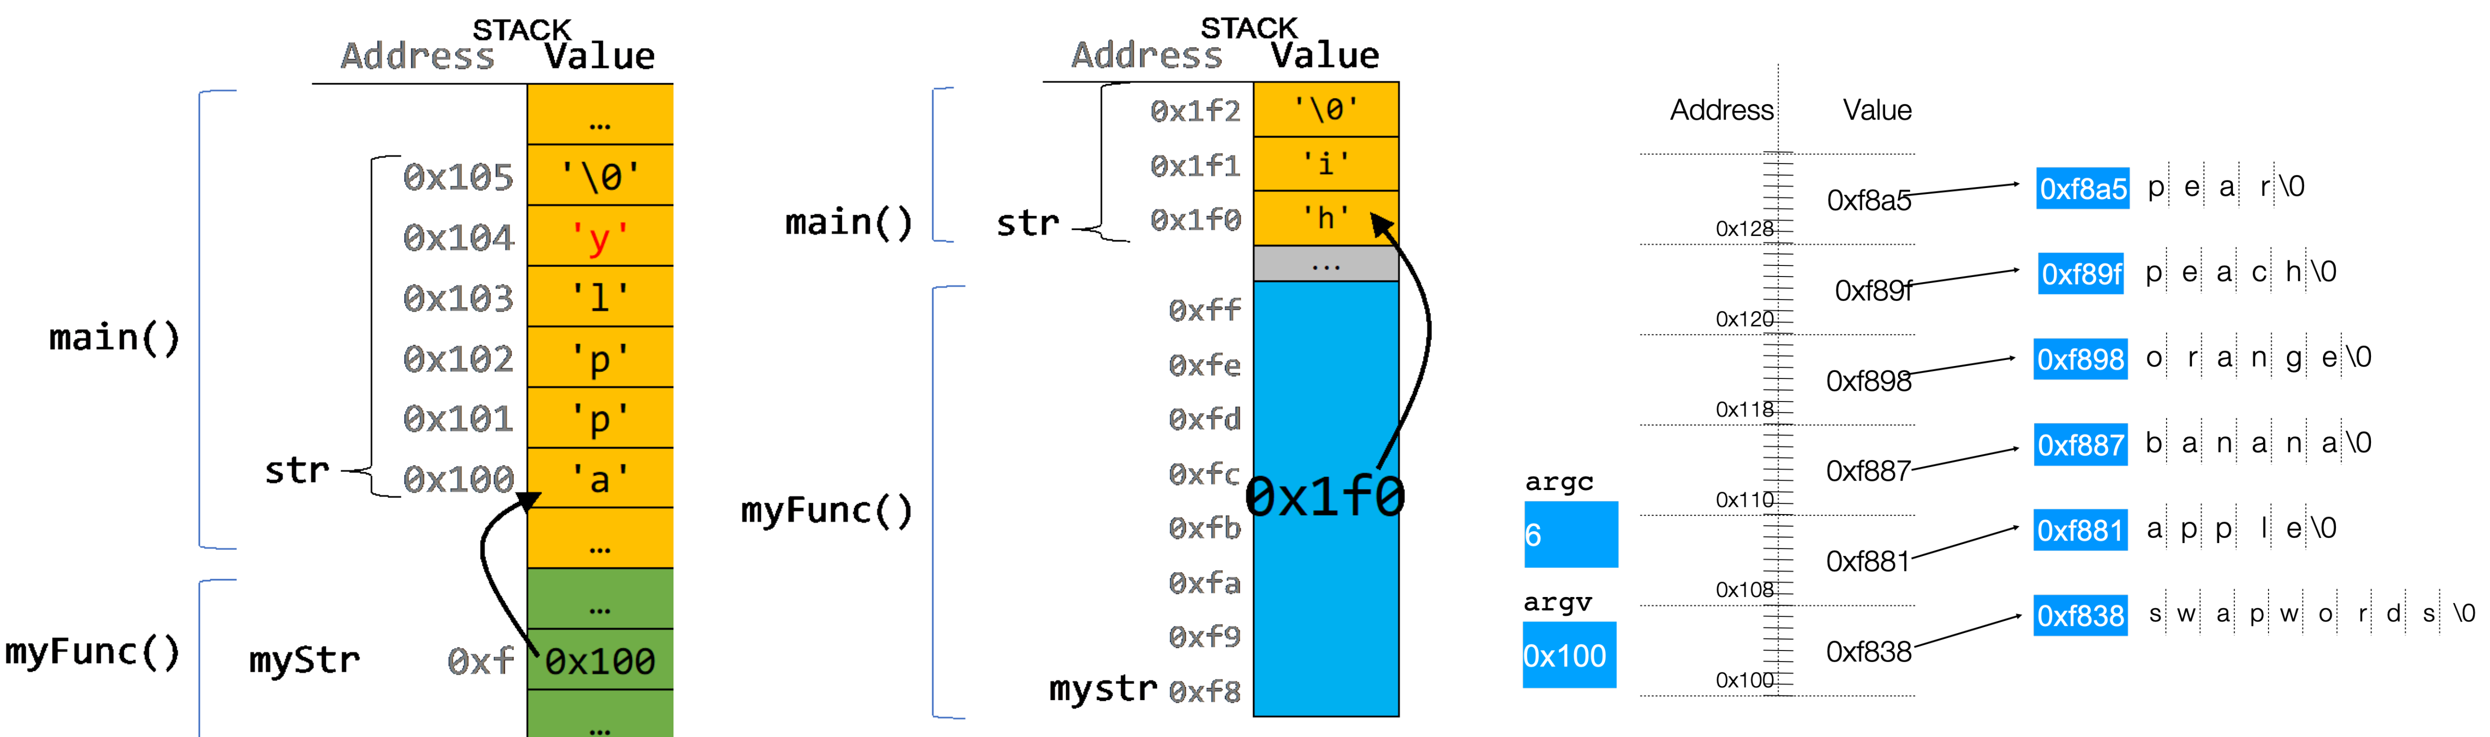
This advances skipSpace's own copy of the string pointer, not the instance in main.



Recap

Pointers let us store the addresses of data and pass them as parameters. We can use double pointers if we want to change the value of a pointer in another function.

How to draw memory diagrams?



Choose whatever style is convenient for you, keeping in mind that (1) memory is contiguous, and (2) C types are different sizes.

Lecture Plan

- Pointers, Parameters, & Memory
- **Arrays in Memory**
- Arrays of Pointers
- Pointer Arithmetic
- Other topics: const, struct and ternary

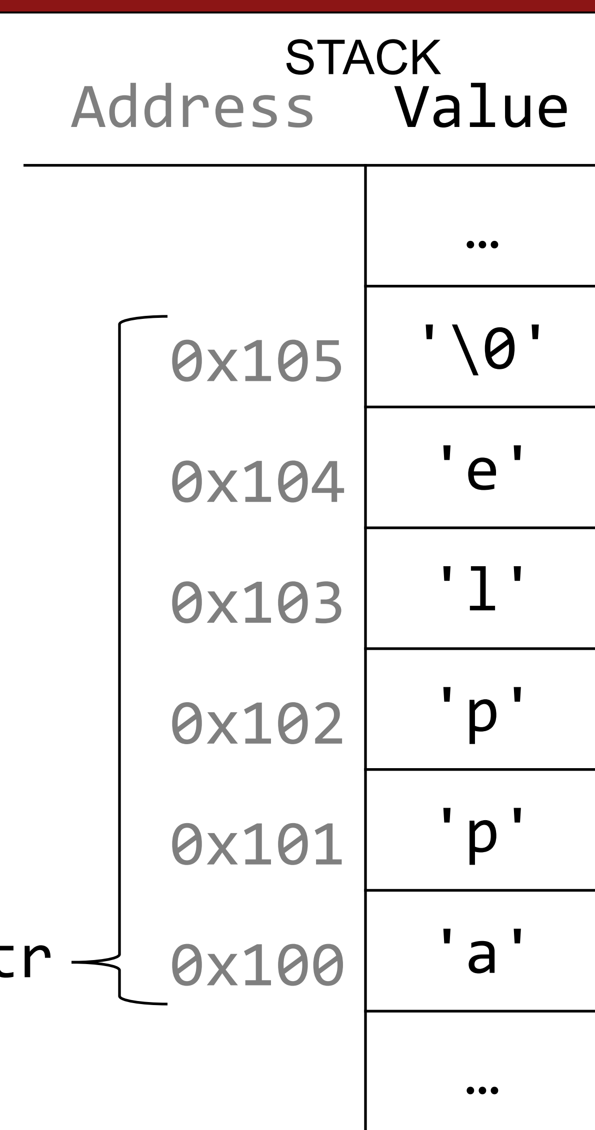
Arrays

When you declare an array, contiguous memory is allocated on the stack to store the contents of the entire array.

```
char str[6];
strcpy(str, "apple");
```

The array variable (e.g. **str**) is not a pointer; it refers to the entire array contents. In fact, **sizeof** returns the size of the entire array!

```
int arrayBytes = sizeof(str);    // 6
```



Arrays

An array variable refers to an entire block of memory. You cannot reassign an existing array to be equal to a new array.

```
int nums[] = {1, 2, 3};
int nums2[] = {4, 5, 6, 7};
nums = nums2; // not allowed!
```

An array's size cannot be changed once you create it; you must create another new array instead.

Arrays as Parameters

When you pass an **array** as a parameter, C makes a *copy of the address of the first array element*, and passes it (a pointer) to the function.

```
void myFunc(char *myStr) {
      ...
}

int main(int argc, char *argv[]) {
      char str[3];
      strcpy(str, "hi");
      myFunc(str);
      ...
}
```

STACK

		Address	Value
main()	str	0x1f2	'\0'
		0x1f1	'i'
		0x1f0	'h'
			...
myFunc()		0xff	
		0xfe	
		0xfd	
		0xfc	
		0xfb	0x1f0
		0xfa	
		0xf9	
	mystr	0xf8	
			...

Arrays as Parameters

When you pass an **array** as a parameter, C makes a *copy of the address of the first array element and* passes it (a pointer) to the function.

```
void myFunc(char *myStr) {
	…
}

int main(int argc, char *argv[]) {
	char str[3];
	strcpy(str, "hi");
	// equivalent
	char *arrPtr = str;
	myFunc(arrPtr);
	...
}
```

STACK

		Address	Value
main()		0x1f2	'\0'
		0x1f1	'i'
	str	0x1f0	'h'
	arrPtr	0x1e8	0x1f0
			…
myFunc()	myStr	0x10	0x1f0
			…

Arrays as Parameters

This also means we can no longer get the full size of the array using **sizeof**, because now it is just a pointer.

```
void myFunc(char *myStr) {
	int size = sizeof(myStr); // 8
}

int main(int argc, char *argv[]) {
	char str[3];
	strcpy(str, "hi");
	int size = sizeof(str);   // 3
	myFunc(str);
	...
}
```

STACK

		Address	Value
main()		0x1f2	'\0'
		0x1f1	'i'
	str	0x1f0	'h'
			...
myFunc()		0xff	
		0xfe	
		0xfd	
		0xfc	0x1f0
		0xfb	
		0xfa	
		0xf9	
	mystr	0xf8	

`sizeof` returns:

1) If local to the array, its size in bytes

2) If a pointer, 8 bytes for the pointer.

Therefore, when we pass an array as a parameter, we can no longer use **`sizeof`** to get its full size.

What is size_t?

size_t is the unsigned integer type that C uses for sizes and counts of things in memory. It's what **sizeof** and **strlen** return.

```
size_t bytes = sizeof(int[10]);       // 40
size_t len   = strlen("swapwords");   // 9
```

It's guaranteed big enough to hold the size of **any** object that can exist in memory — so its width depends on the machine:

- on the myth machines (64-bit): 8 bytes
- on a 32-bit system: 4 bytes

The same source code compiles everywhere — but the underlying type changes. That flexibility is exactly why printf needs a dedicated format specifier…

size_t Across Platforms

The same **`size_t`**, four different machines:

Platform	Pointer width	size_t is	Width	SIZE_MAX
64-bit Linux / macOS (LP64)	64-bit	**`unsigned long`**	8 bytes	$2^{64} - 1$
64-bit Windows (LLP64)	64-bit	**`unsigned long long`**	8 bytes	$2^{64} - 1$
32-bit Linux / Windows (ILP32)	32-bit	`unsigned int`	4 bytes	$2^{32} - 1$
Arduino Uno (AVR 8-bit)	16-bit	`unsigned int (16-bit on AVR)`	2 bytes	65,535

Rows 1 vs 2: identical hardware, identical width — **different underlying type**. So `%lu` compiles and runs on Linux but is undefined behavior on Windows. Only `%zu` is correct on both.

Rows 3 vs 4: `size_t` tracks the platform's address space downward — and even `unsigned int` means something different (16 bits!) once you leave desktop ABIs. Never assume its width; ask `sizeof(size_t)`.

Why %zu?

printf reads its extra arguments off of raw memory. The format specifier is its **only** clue about how many bytes to read and how to interpret them.

```
size_t len = strlen("swapwords");
printf("%d\n",  len);  // ⚠ expects a 4-byte int – wrong size!
printf("%lu\n", len);  // ⚠ works here, breaks on 32-bit
printf("%zu\n", len);  // ✓ z means "a size_t, whatever it is"
```

The **z** length modifier tells printf “this argument is a **size_t**”

The compiler picks the right width on every platform. (**u** = unsigned.)

Beware: size_t is Unsigned!

`size_t` is **unsigned** — it can never be negative. Subtracting past zero wraps around to a huge number!

```
char *str = "hi";
for (size_t i = strlen(str) - 1; i >= 0; i--) {
    printf("%c", str[i]);
}
// i >= 0 is ALWAYS true for an unsigned type.
```

When **`i`** is 0 and we do **`i--`**, it wraps to 18,446,744,073,709,551,615 — and the loop marches off the end of the string. **Infinite loop + garbage reads!**

Fix: loop with a signed type (**`int`** or **`long`**), or restructure the loop to count up.

sizeof: Array vs. Pointer

sizeof only knows an array's full size in the scope where it was declared. Pass the array to a function and it decays to a pointer:

```
void printSize(int arr[]) {
    printf("%zu\n", sizeof(arr));   // 8  – just a pointer!
}
int main(int argc, char *argv[]) {
    int nums[] = {1, 2, 3};
    printf("%zu\n", sizeof(nums));  // 12 – 3 ints × 4 bytes
    printSize(nums);
    return 0;
}
```

A function can never recover an array's length on its own, pass the length as a separate parameter.

strlen on an int Array?

strlen doesn't know about types! It just walks memory one byte at a time, counting until it finds a zero byte ('\0').

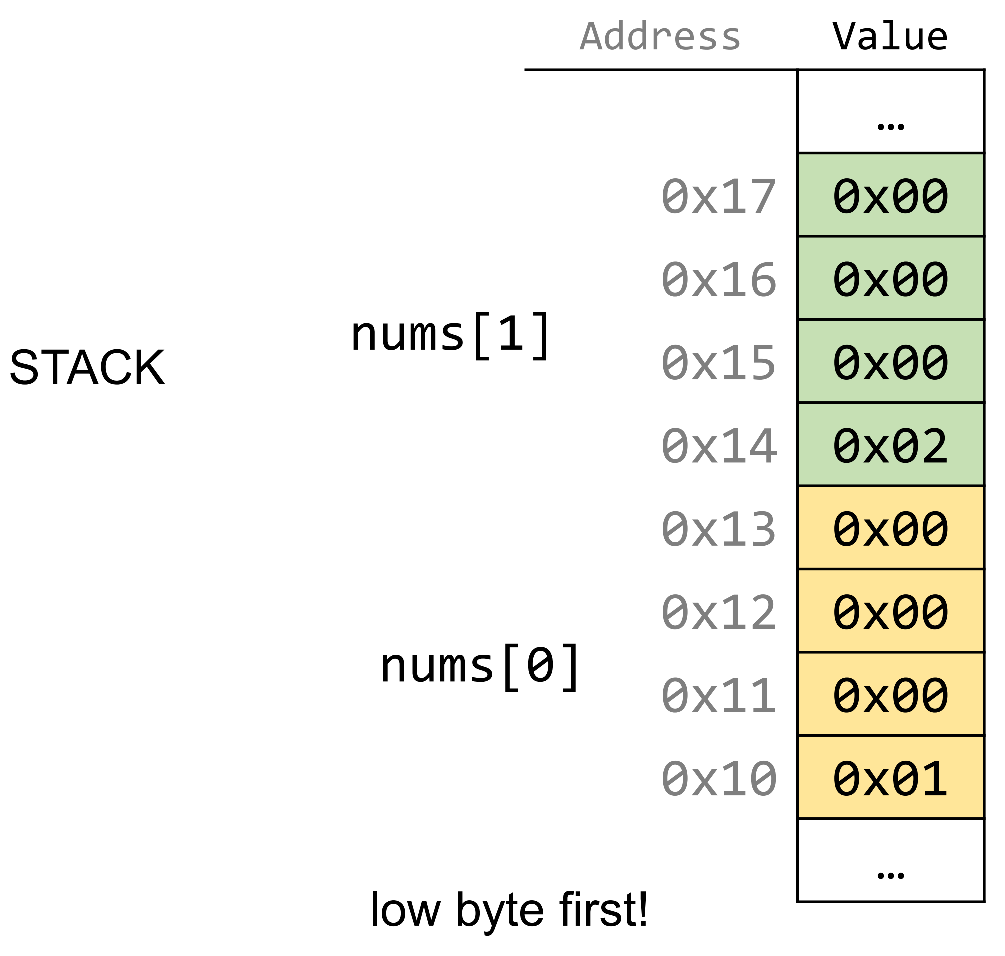
```
int nums[] = {1, 2, 3};
size_t len = strlen((char *)nums);
printf("%zu\n", len);   // what prints?
```

To strlen, nums is just 12 bytes of memory to scan. So… what do those 12 bytes actually look like?

An int is Full of Zero Bytes!

```
int nums[] = {1, 2, 3};
size_t len = strlen((char *)nums);
printf("%zu\n", len);   // prints 1!
```

myth is **little-endian**: the low byte of each int comes first in memory — and small ints are mostly zero bytes!



strlen starts at 0x10 and walks up: 0x01 → not zero, count it. Next byte at 0x11 is 0x00 → stop! It never even reaches nums[1].

Arrays vs. Pointers

- When you create an array, you are making space for each element in the array.
- When you create a pointer, you are making space for an 8 byte address.
- Arrays "***<u>decay to pointers</u>***" when you perform ***arithmetic*** or ***pass as parameter***.
- You can set a pointer equal to an array; that pointer will point to the array's first element
- &arr does nothing on arrays, but &ptr on pointers gets its address
- sizeof(arr) gets the size of an array in bytes, but sizeof(ptr) is always 8

Lecture Plan

- Pointers, Parameters, & Memory
- Arrays in Memory
- **Arrays of Pointers**
- Pointer Arithmetic
- Other topics: const, struct and ternary

Arrays Of Pointers

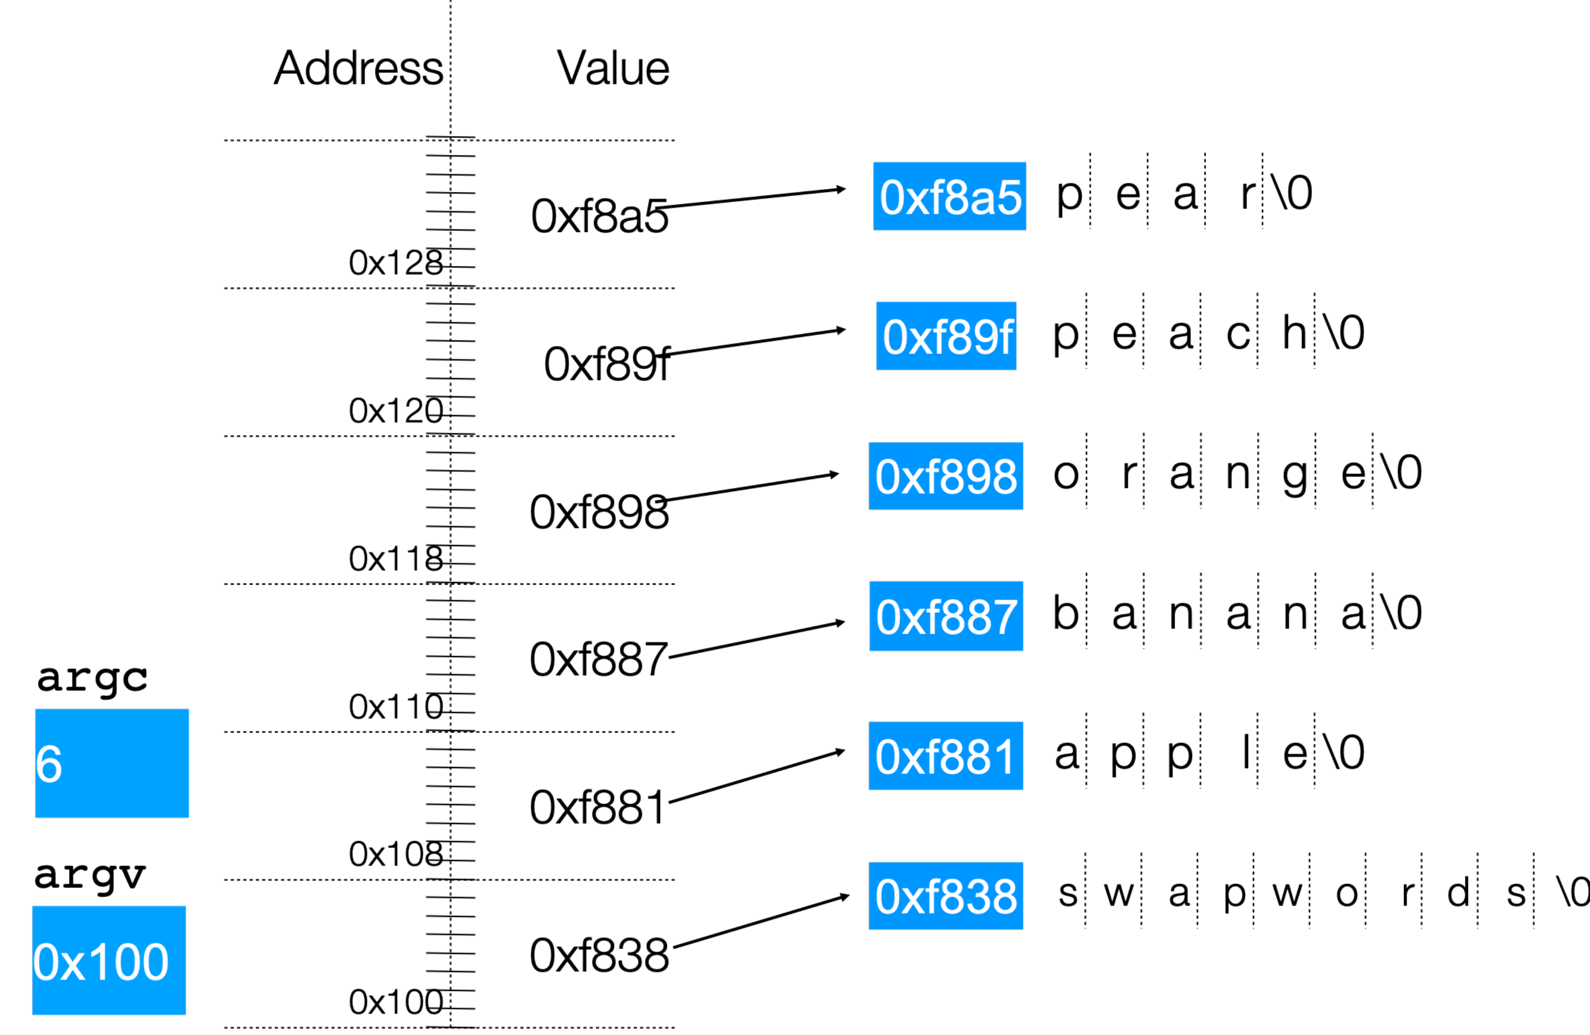
You can make an array of pointers to e.g. group multiple strings together:

```
char *stringArray[5];   // space to store 5 char *s
```

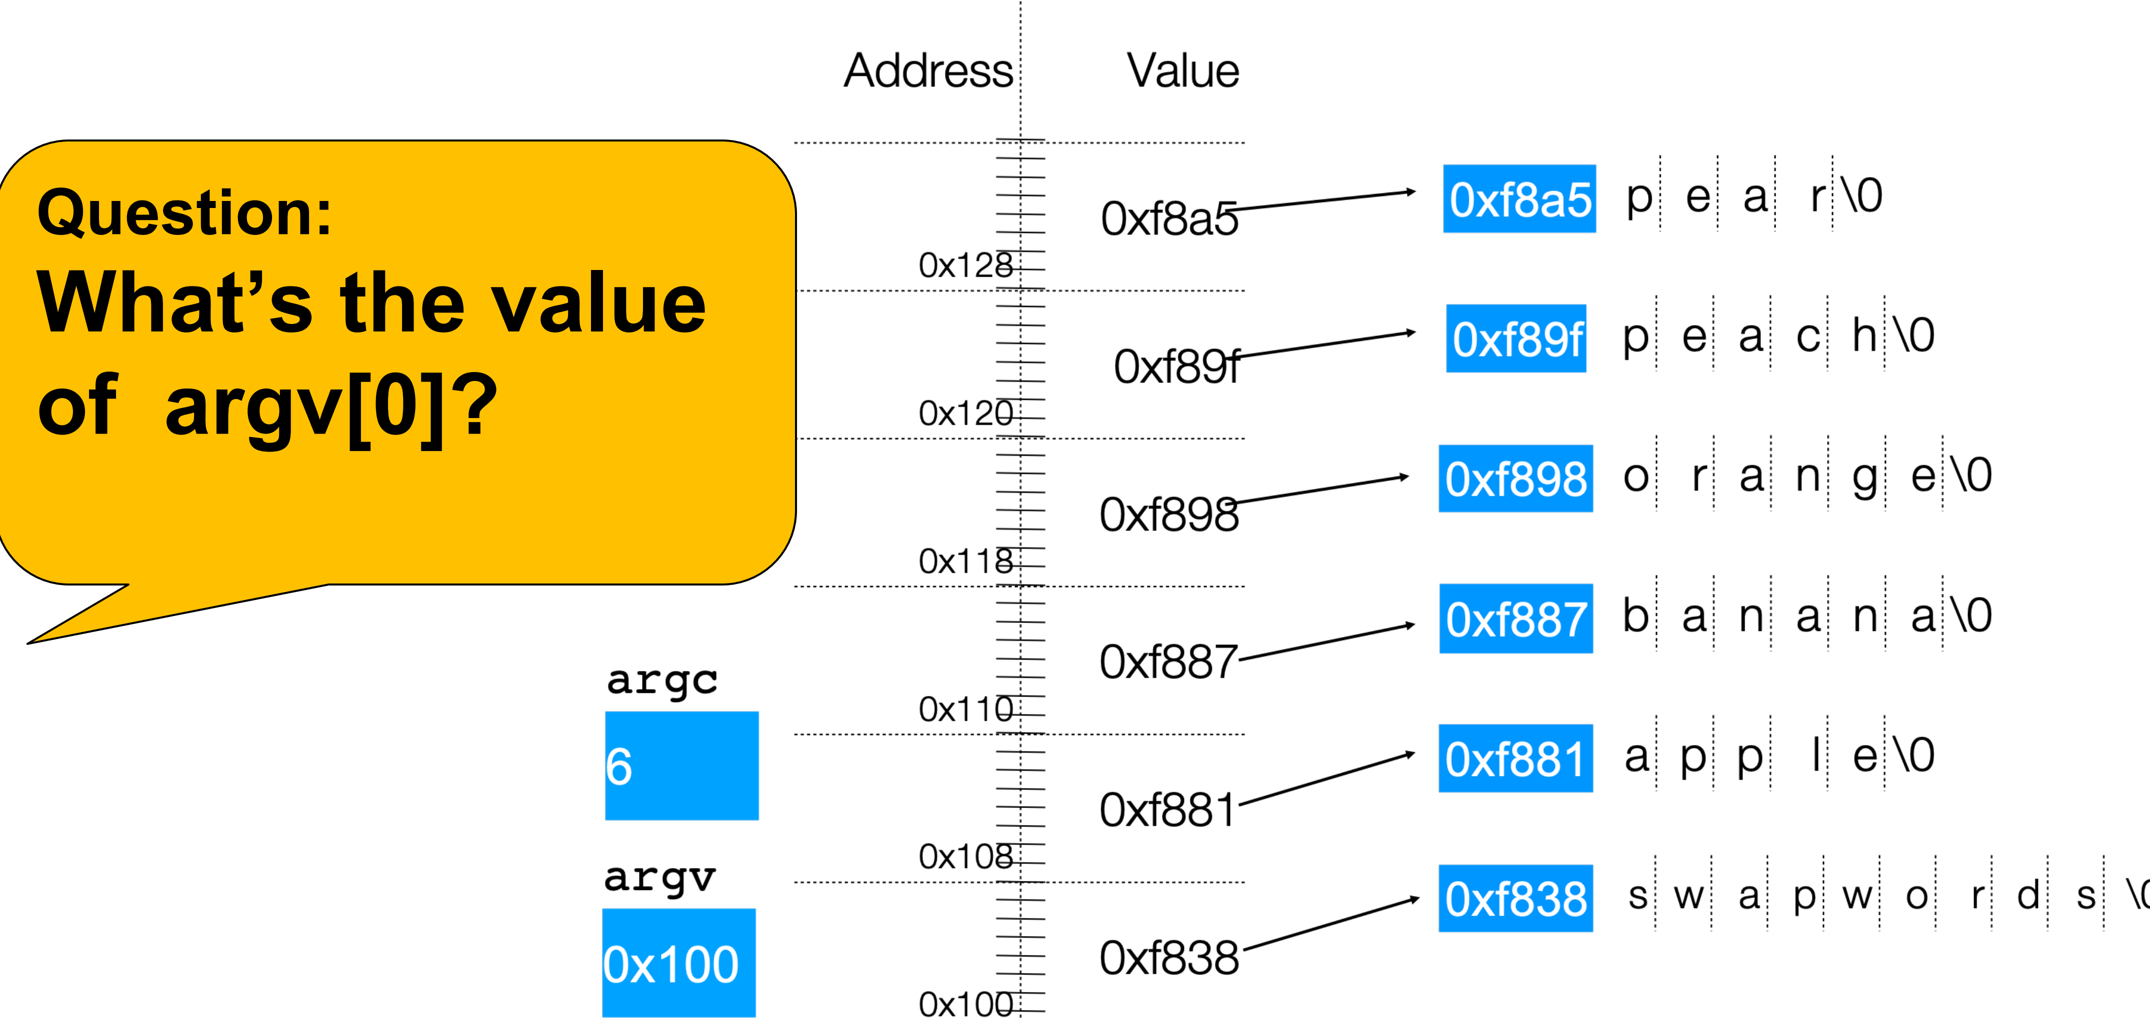
This stores 5 **char *s**, *not* all of the characters for 5 strings!

```
char *str0 = stringArray[0];     // first char *
// NOTE: This is the same as:
// char *str0 = *stringArray;
```

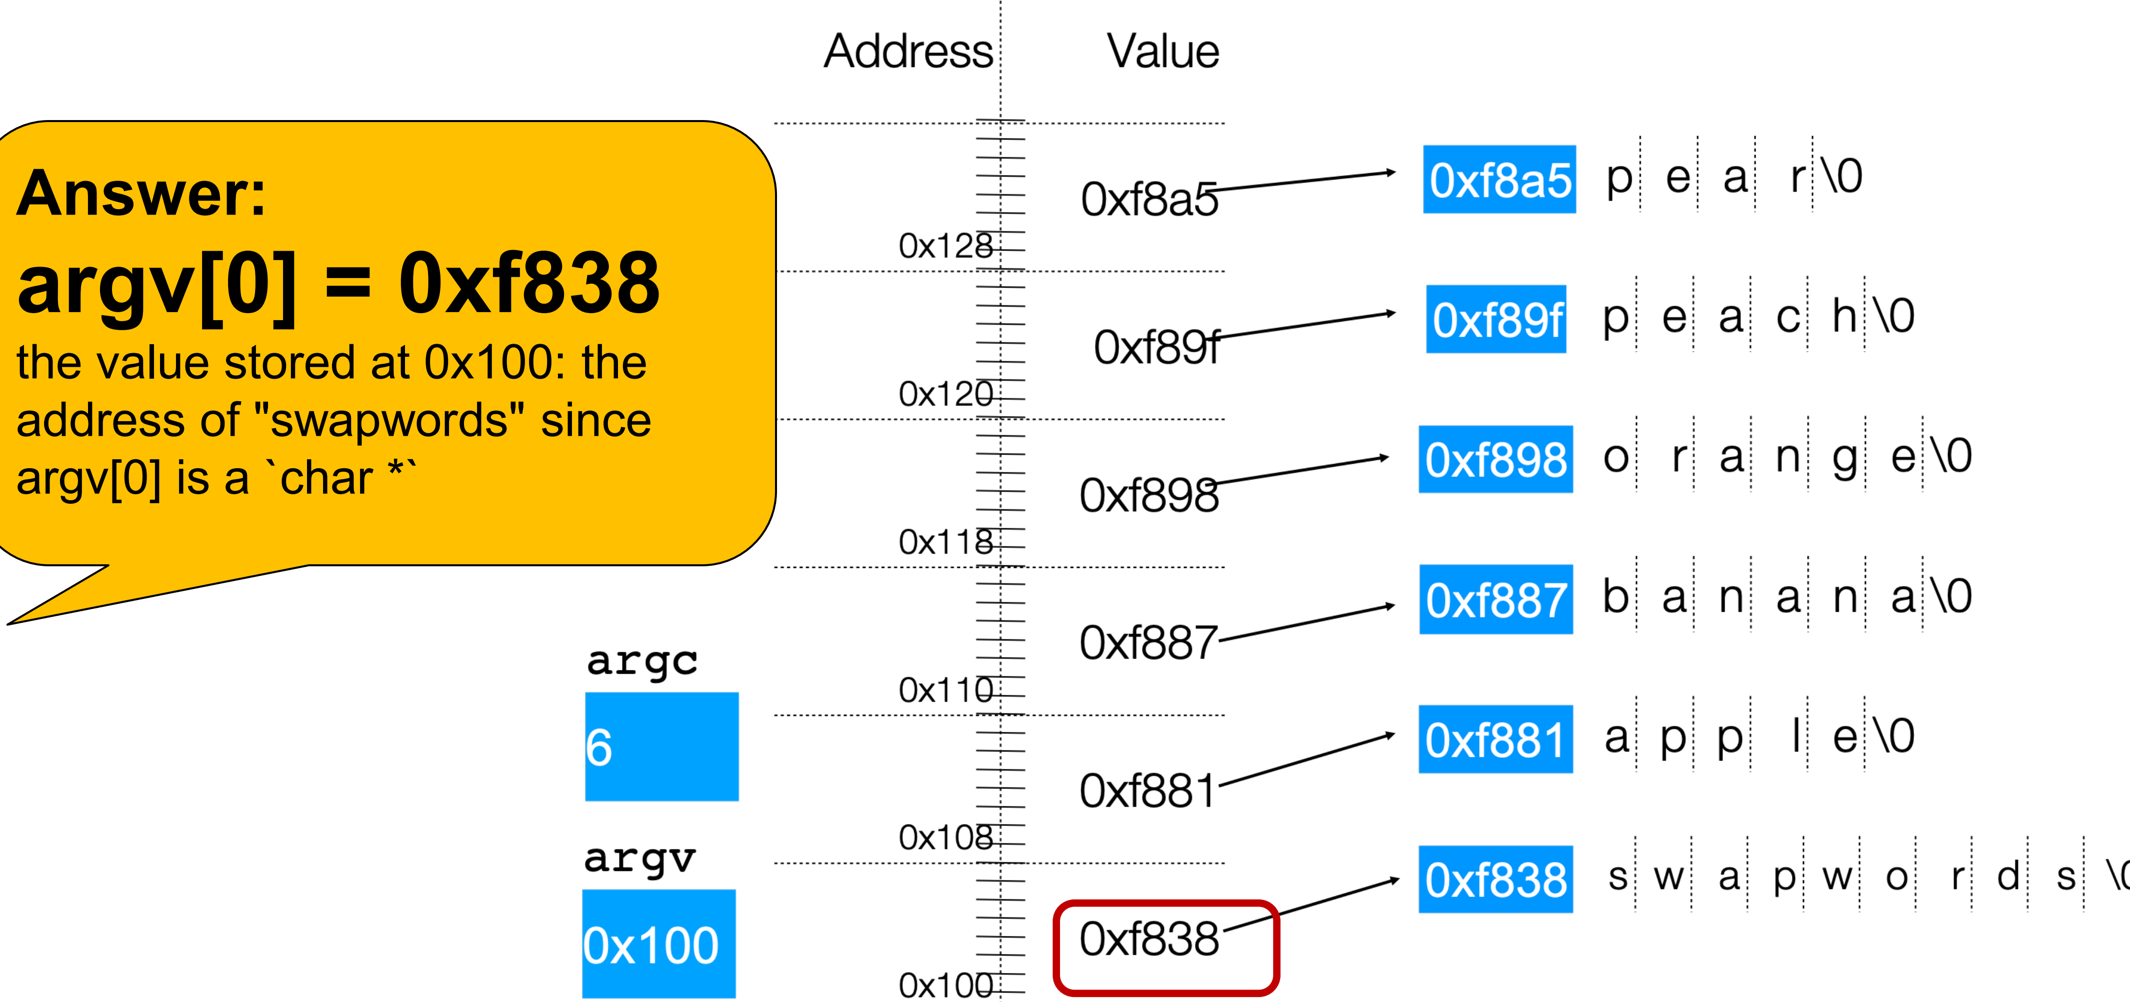
Visualizing Args



Visualizing Args



Visualizing Args



Lecture Plan

- Pointers, Parameters, & Memory
- Arrays in Memory
- Arrays of Pointers
- **Pointer Arithmetic**
- Other topics: const, struct and ternary

Pointer Arithmetic

When you do pointer arithmetic, you are adjusting the pointer by a certain *number of places* (e.g. characters).

```
char *str = "apple";    // e.g. 0xff0
char *str1 = str + 1;   // e.g. 0xff1
char *str3 = str + 3;   // e.g. 0xff3

printf("%s", str);      // apple
printf("%s", str1);     // pple
printf("%s", str3);     // le
```

DATA SEGMENT

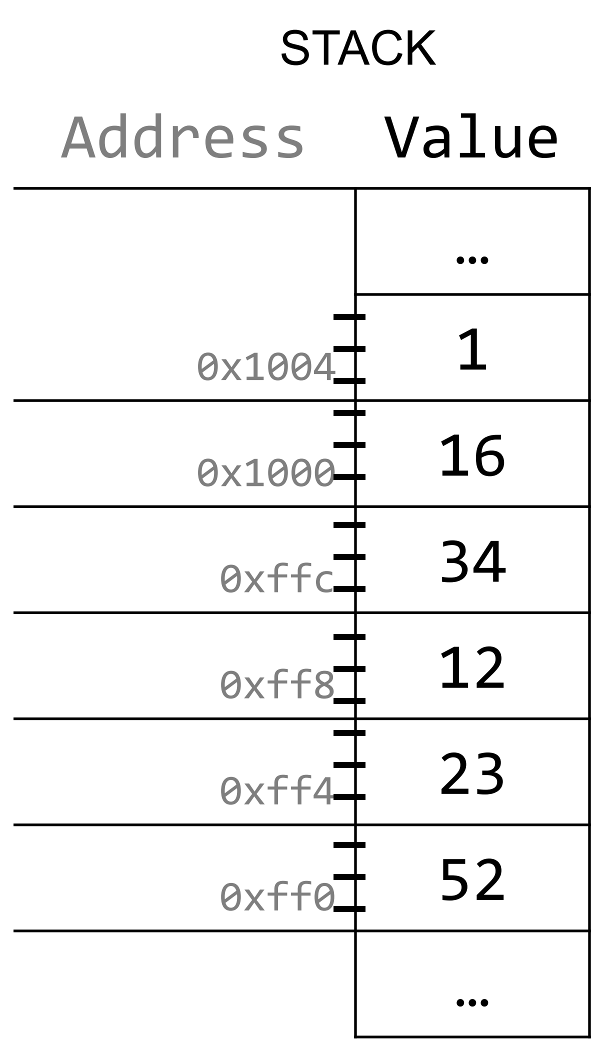
Address	Value
	…
0xff5	'\0'
0xff4	'e'
0xff3	'l'
0xff2	'p'
0xff1	'p'
0xff0	'a'
	…

Pointer Arithmetic

Pointer arithmetic does *not* work in bytes. Instead, it works in the *size of the type it points to*.

```
// nums points to an int array
int *nums = …              // e.g. 0xff0
int *nums1 = nums + 1;  // e.g. 0xff4
int *nums3 = nums + 3;  // e.g. 0xffc

printf("%d", *nums);     // 52
printf("%d", *nums1);   // 23
printf("%d", *nums3);   // 34
```

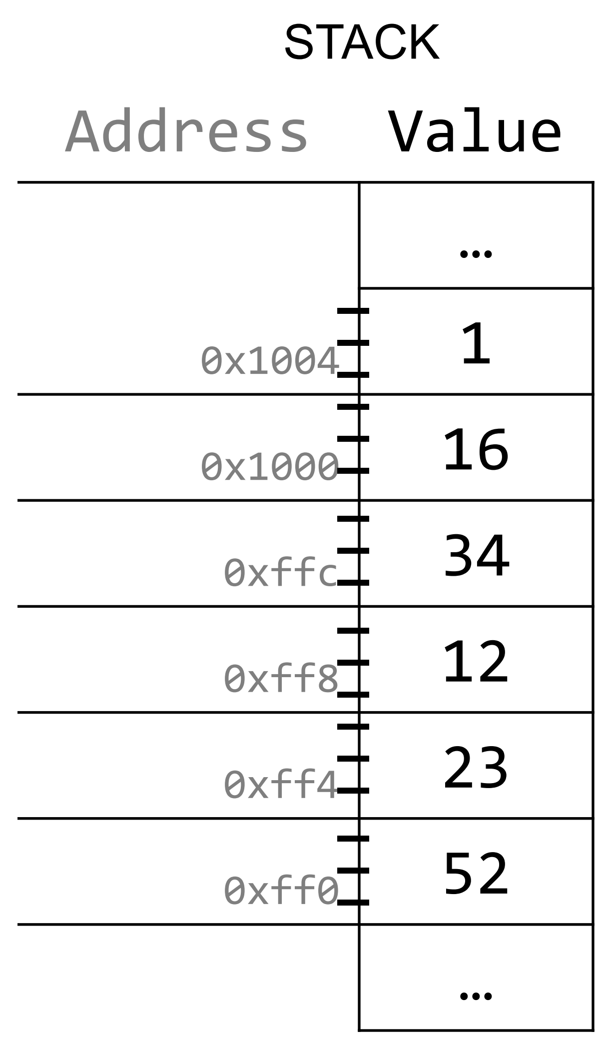


Pointer Arithmetic

Pointer arithmetic does *not* work in bytes. Instead, it works in the *size of the type it points to*.

```
// nums points to an int array
int *nums = …               // e.g. 0xff0
int *nums3 = nums + 3;  // e.g. 0xffc
int *nums2 = nums3 - 1; // e.g. 0xff8

printf("%d", *nums);    // 52
printf("%d", *nums2);   // 12
printf("%d", *nums3);   // 34
```



Pointer Arithmetic

When you use bracket notation with a pointer, you are actually *performing pointer arithmetic and dereferencing*:

```
char *str = "apple";    // e.g. 0xff0

// both of these add two places to str,
// and then dereference to get the char there.
// E.g. get memory at 0xff2.
char thirdLetter = str[2];         // 'p'
char thirdLetter = *(str + 2);    // 'p'
```

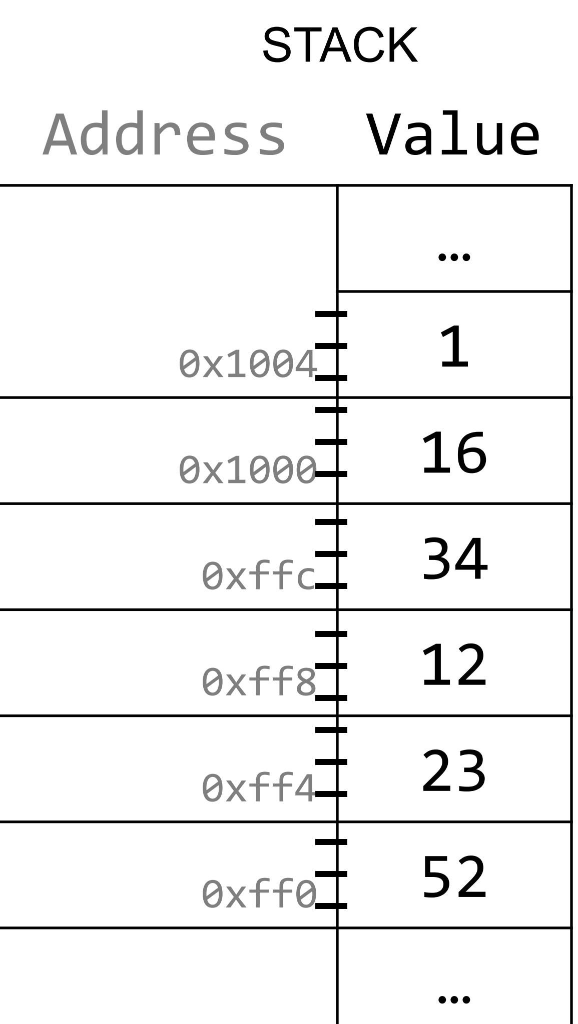
DATA SEGMENT

Address	Value
	…
0xff5	'\0'
0xff4	'e'
0xff3	'l'
0xff2	'p'
0xff1	'p'
0xff0	'a'
	…

Pointer Arithmetic

Pointer arithmetic with two pointers does *not* give the byte difference. Instead, it gives the number of *places* they differ by.

```
// nums points to an int array
int *nums = …                // e.g. 0xff0
int *nums3 = nums + 3;       // e.g. 0xffc
int diff = nums3 - nums;     // 3
```



Pointer Arithmetic

How does the code know how many bytes it should look at once it visits an address? At compile time, C can figure out the sizes of different data types, and the sizes of what they point to.

```
int x = 2;
int *xPtr = &x;         // e.g. 0xff0

// C knows to print out just the 4 bytes at xPtr
printf("%d", *xPtr);    // 2
```

Pointer Arithmetic

How does the code know how many bytes it should add when performing pointer arithmetic? At compile time, C can figure out the sizes of different data types, and the sizes of what they point to.

```
int nums[] = {1, 2, 3};

// C knows to add 4 bytes here
int *intPtr = nums + 1;

char str[6];
strcpy(str, "CS107");

// C knows to add 1 byte here
char *charPtr = str + 1;
```

Lecture Plan

- Pointers, Parameters, & Memory
- Arrays in Memory
- Arrays of Pointers
- Pointer Arithmetic
- **Other topics: const, struct and ternary**

Const

- Use **const** to declare global constants in your program. This indicates the variable cannot change after being created.

```
const double PI = 3.1415;
const int DAYS_IN_WEEK = 7;

int main(int argc, char *argv[]) {
    …
    if (x == DAYS_IN_WEEK) {
        …
    }
    …
}
```

Const

- Use **const** with pointers to indicate that the data that is pointed to cannot change.

```
char str[6];
strcpy(str, "Hello");
const char *s = str;

// Cannot use s to change characters it points to
s[0] = 'h';
```

Const

Sometimes we use **const** with pointer parameters to indicate that the function will not / should not change what it points to. The actual pointer can be changed, however.

```
// This function promises to not change str's characters

int countUppercase(const char *str) {
	int count = 0;
	for (int i = 0; i < strlen(str); i++) { if
		(isupper(str[i])) {
			count++;
		}
	}
	return count;
}
```

Const

By definition, C gets upset when you set a **non-const** pointer equal to a **const** pointer. You need to be consistent with **const** to reflect what you cannot modify.

```
// This function promises to not change str's characters
int countUppercase(const char *str) {
     // compiler warning and error
    char *strToModify = str;
    strToModify[0] = …
}
```

Const

By definition, C gets upset when you set a **non-const** pointer equal to a **const** pointer. You need to be consistent with **const** to reflect what you cannot modify. **Think of const as part of the variable type**.

```
// This function promises to not change str's characters
int countUppercase(const char *str) {
      const char *strToModify = str;
      strToModify[0] = …
}
```

Const

const can be confusing to interpret in some variable types.

```
// cannot modify this char
const char c = 'h';

// cannot modify chars pointed to by str
const char *str = …

// cannot modify chars pointed to by *strPtr
const char **strPtr = …
```

Const

```
// const LEFT of * → VALUE immutable (can't change the chars in the string)
const char *p;

const char **p

p ──────▶ inner_ptr ──────▶ "Hello"
(can modify) (can modify)   (cannot modify)

// const RIGHT of * → POINTER immutable (can't change where p points)
char * const p;

const char ** const p

p ──────▶ inner_ptr ──────▶ "Hello"
(cannot modify) (can modify) (cannot modify)
```

Const

```
// Create an array
char arr[14];
strcpy(arr, "Hello");

// Constant Data
// Pointer to constant data (modifiable pointer, non-modifiable data)
const char * str1 = arr;
// *str1 = 'h'; // This is not allowed

// Constant Pointer
// Constant pointer to data (non-modifiable pointer, modifiable data).
char * const str2 = arr;
// str2 = "New String"; // This is not allowed
str2[0] = 'h'; // This is allowed

// Constant Pointer to Constant Data
// Constant pointer to constant data (non-modifiable pointer, non-modifiable data).
const char * const str3 = arr;
// *str3 = 'h'; // This is not allowed
// str3 = "New String"; // This is not allowed
```

Const

```
                            pointer   pointer   chars
char **p1;                  // ✓ p1,   ✓ *p1,   ✓ **p1

const char **p2;            // ✓ p2,   ✓ *p2    ✗ **p2

char ** const p3;           // ✗ p3    ✓ *p3,   ✓ **p3

const char ** const p4;     // ✗ p4    ✓ *p4    ✗ **p4

char * const *p5;           // ✓ p5    ✗ *p5    ✓ **p5

const char * const *p6;     // ✓ p6    ✗ *p6    ✗ **p6

char * const * const p7;    // ✗ p7    ✗ *p7    ✓ **p7

const char * const * const p8; // ✗ p7    ✗ *p7    ✗ **p7
```

Const

```
// pointer to a pointer to a char
char **p1;
// pointer to a pointer to a const char (can change pointer not char)
const char **p2;

// const pointer to pointer to char (can’t change top level pointer)
char ** const p3;
// const pointer to pointer to const char (can’t change top level pointer or char)
const char ** const p4;

// pointer to const pointer to char (top level can change, but intermediary pointer cannot)
char * const *p5;
// pointer to const pointer to const char  (top level can change, but intermediary pointer and char cannot)
const char * const *p6;

// const pointer to const pointer to char (char is the only thing that can change)
char * const * const p7;
// const pointer to const pointer to const char (nothing can change)
const char * const * const p8;
```

const vs #define

```
#define THIRD_BIT 1 << 3

// cannot modify this char
const char c = 'h';

// cannot modify chars
pointed to by str
const char *str = …

// cannot modify chars
pointed to by *strPtr
const char **strPtr = …
```

#define is a hard-coded substitution that gcc will make when compiling your code.

Const signals that this variable (in this scope) should not be modified.

- In CS107, you often won't have to declare const variables, but you will be provided parameters or use functions that have it
- Const directly modifies the adjacent keyword

const

```
1  char buf[6];
2  strcpy(buf, "Hello");
3  const char *str = buf;
4  str[0] = 'M';
5  str = "Mello";
6  buf[0] = 'M';
```

Which lines (if any) above will cause an error due to violating const?
Remember that const char * means that the characters at the location it stores cannot be changed.

const

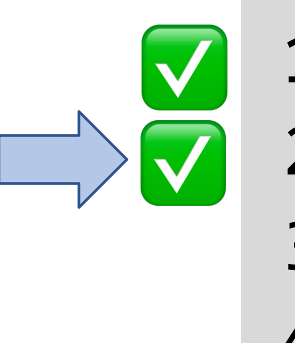
```
1   char buf[6];
2   strcpy(buf, "Hello");
3   const char *str = buf;
4   str[0] = 'M';
5   str = "Mello";
6   buf[0] = 'M';
```

Line 1 makes a typical modifiable character array of 6 characters.

Which lines (if any) above will cause an error due to violating const?

Remember that const char * means that the characters at the location it stores cannot be changed.

const

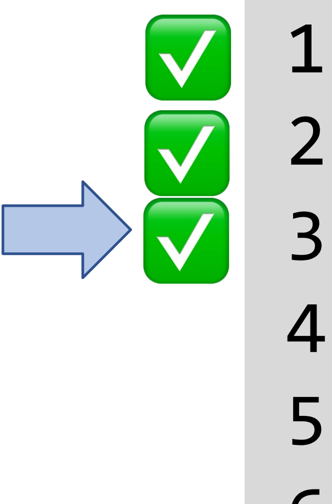


```
1    char buf[6];
2    strcpy(buf, "Hello");
3    const char *str = buf;
4    str[0] = 'M';
5    str = "Mello";
6    buf[0] = 'M';
```

Line 2 copies characters into this modifiable character array.

Which lines (if any) above will cause an error due to violating const?
Remember that const char * means that the characters at the location it stores cannot be changed.

const



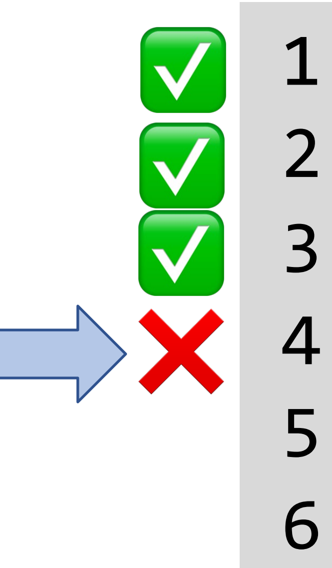
```
1   char buf[6];
2   strcpy(buf, "Hello");
3   const char *str = buf;
4   str[0] = 'M';
5   str = "Mello";
6   buf[0] = 'M';
```

Line 3 makes a const pointer that points to the first element of buf. We cannot use str to change the characters it points to because it is const.

Which lines (if any) above will cause an error due to violating const?

Remember that const char * means that the characters at the location it stores cannot be changed.

const

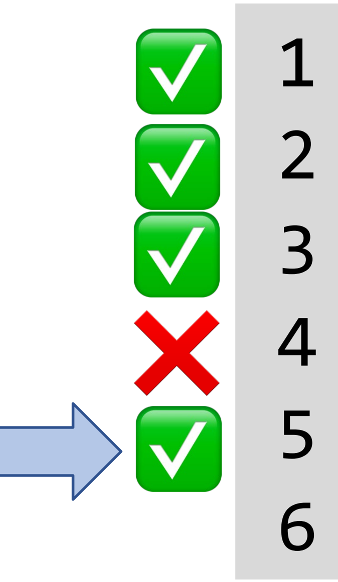


1	`char buf[6];`
2	`strcpy(buf, "Hello");`
3	`const char *str = buf;`
4	`str[0] = 'M';`
5	`str = "Mello";`
6	`buf[0] = 'M';`

Line 4 is not allowed – it attempts to use a const pointer to characters to modify those characters.

Which lines (if any) above will cause an error due to violating const?
Remember that const char * means that the characters at the location it stores cannot be changed.

const

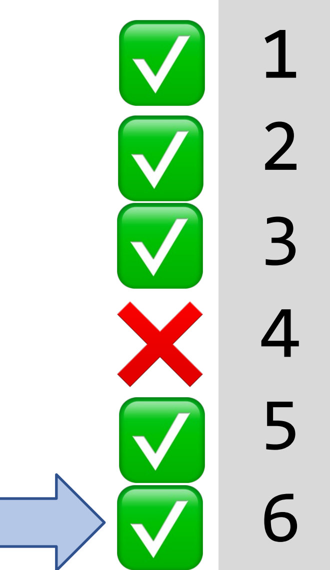


```
1    char buf[6];
2    strcpy(buf, "Hello");
3    const char *str = buf;
4    str[0] = 'M';
5    str = "Mello";
6    buf[0] = 'M';
```

Line 5 is ok – str's type means that while you cannot change the characters at which it points, you can change str itself to point somewhere else. **str** is not const – its characters are.

Which lines (if any) above will cause an error due to violating const? Remember that const char * means that the characters at the location it stores cannot be changed.

const



```
1  char buf[6];
2  strcpy(buf, "Hello");
3  const char *str = buf;
4  str[0] = 'M';
5  str = "Mello";
6  buf[0] = 'M';
```

Line 6 is ok – **buf** is a modifiable char array, and we can use it to change its characters.
Declaring str as const doesn't mean that place in memory is not modifiable at all – it just means that you cannot modify it using **str**.

Which lines (if any) above will cause an error due to violating const?
Remember that const char * means that the characters at the location it stores cannot be changed.

Structs

A *struct* is a way to define a new variable type that is a group of other variables.

```
struct date {              // declaring a struct type
    int month;
    int day;               // members of each date structure
};
…
struct date today;                          // construct structure instances
today.month = 1;
today.day = 28;
struct date new_years_eve = {12, 31};   // shorter initializer syntax
```

Structs

Wrap the struct definition in a **typedef** to avoid having to include the word **struct** every time you make a new variable of that type.

```
typedef struct date {
    int month;
    int day;
} date;
…

date today;
today.month = 1;
today.day = 28;

date new_years_eve = {12, 31};
```

Structs

If you pass a struct as a parameter, like for other parameters, C passes a **copy** of the entire struct.

```
void advance_day(date d) {
     d.day++;
}

int main(int argc, char *argv[]) {
     date my_date = {1, 28};
     advance_day(my_date);
     printf("%d", my_date.day); // 28
     return 0;
}
```

Structs

If you pass a struct as a parameter, like for other parameters, C passes a **copy** of the entire struct. **Use a pointer to modify a specific instance.**

```
void advance_day(date *d) {
	(*d).day++;
}

int main(int argc, char *argv[]) {
	date my_date = {1, 28};
	advance_day(&my_date);
	printf("%d", my_date.day); // 29
	return 0;
}
```

Structs

The **arrow** operator lets you access the field of a struct pointed to by a pointer.

```
void advance_day(date *d) {
      d->day++;  // equivalent to (*d).day++;
}

int main(int argc, char *argv[]) {
      date my_date = {1, 28};
      advance_day(&my_date);
      printf("%d", my_date.day); // 29
      return 0;
}
```

Structs

C allows you to return structs from functions as well.

It returns whatever is contained within the struct.

```
date create_new_years_date() {
      date d = {1, 1};
     return d;  // or return (date){1, 1};
}

int main(int argc, char *argv[]) {
      date my_date = create_new_years_date();
      printf("%d", my_date.day); // 1
      return 0;
}
```

Stack Safety

```
date create_new_years_date() {
     date d = {1, 1};
     return d; // or return (date){1, 1};
}

int main(int argc, char *argv[]) {
     date * my_date = &create_new_years_date(); // <- Error unsafe (compiler error)!
     printf("%d", my_date->day);
     return 0;
}

// More on this in the next lecture!
```

Stack Safety

```
char * sample_arr() {
    char arr[2048];
    strcpy(arr, "Hi");
    return arr; // <- Error unsafe! Can’t return stack array/memory
}

int main(int argc, char *argv[]) {
    char * ptr = sample_arr(); // <- Error unsafe (runtime error)!
    printf("%s", ptr);
    return 0;
}
// Most modern compilers will at least warn
// More on this in the next lecture!
```

Structs

sizeof gives you the entire size of a struct, which is the sum of the sizes of all its contents.

```
typedef struct date {
      int month;
      int day;
  } date;

int main(int argc, char *argv[]) {
      int size = sizeof(date);    // 8
      return 0;
}
```

Arrays of Structs

You can create arrays of structs just like any other variable type.

```
typedef struct my_struct {
	int x;
	char c;
} my_struct;

…

my_struct array_of_structs[5];
```

Arrays of Structs

To initialize an entry of the array, you must use this special syntax to confirm the type to C.

```
typedef struct my_struct {
    int x;
    char c;
} my_struct;

…

my_struct array_of_structs[5];
array_of_structs[0] = (my_struct){0, 'A'};
```

Arrays of Structs

You can also set each field individually.

```
typedef struct my_struct {
    int x;
    char c;
} my_struct;

…
my_struct array_of_structs[5];
array_of_structs[0].x = 2;
array_of_structs[0].c = 'A';
```

Ternary Operator

The ternary operator is a shorthand for using if/else to evaluate to a value.

```
condition ? expressionIfTrue : expressionIfFalse
```

```
int x;
if( argc > 1){
     x = 50;
} else {
     x = 0;
}
```

```
// equivalent to
int x = argc > 1 ? 50 : 0;
```

Is there a difference?

```
size_t get_total_strlen(char *strs[], size_t num) {
    …
}
```

Intent: `strs` is an array of strings

```
void *skip_spaces(char **p_str) {
    …
}
```

Intent: `p_str` is a pointer to a string

No difference to the compiler—it's char**!
But it clarifies the ***intent*** of a function/a parameter ***for the programmer***.

Pointer arithmetic

Array indexing is "syntactic sugar" for pointer arithmetic:

```
ptr + i          &ptr[i]
*(ptr + i)       ptr[i]
```

⚠️ Pointer arithmetic **does not work in bytes**; it works on the type it points to. On `int*` addresses scale by `sizeof(int)`, on `char*` scale by `sizeof(char)`.

- This means too-large/negative subscripts will compile

```
arr[99]   arr[-1]
```

NOTE: Compile, but the behavior is undefined behavior when out of bound

- You can use either syntax on either pointer or array.

Extra Practice

Translating C into English

*
If **declaration**: “pointer”
ex: `int *` is "pointer to an int”
If **operation**: "dereference/the value at address”
ex: `*num` is "the value at address num"

& “address of”

<ptr name> address

<arr name> address (except sizeof)

```
int arr[] = {3, 4, -1, 2};    // initializes stack array
                              // with 4 ints

int *ptr0 =   arr;
int *elt0 =   *arr;
int elt   =   *(arr + 3);
int **ptr1=.  &ptr;
```

Translating C into English

`*`

If **declaration**: “pointer”

ex: `int *` is "pointer to an int”

If **operation**: "dereference/the value at address”

ex: `*num` is "the value at address num"

`&` “address of”

`<ptr name>` address

`<arr name>` address (except sizeof)

```
int arr[] = {3, 4, -1, 2}; // initializes stack array
                           // with 4 ints

int *ptr0 =    arr;
int *elt0 =    *arr;
int elt   =    *(arr + 3);
int **ptr1=.   &ptr;
```

Address arr

Value at address arr

The value at address 3 ints after address arr

address of ptr

2. char* vs char[ ] exercises

Suppose we use a variable str as follows:

```
  // initialize as below
A str = str + 1;
B str[1] = 'u';
C printf("%s", str)
```

For each of the following initializations:

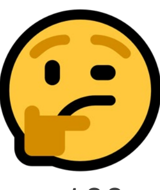
- Will there be a compile error/segfault?
- If no errors, what is printed?

1.
```
char str[7];
strcpy(str, "Hello1");
```

2.
```
char *str = "Hello2";
```

3.
```
char arr[7];
strcpy(arr, "Hello3");
char *str = arr;
```

4.
```
char *ptr = "Hello4";
char *str = ptr;
```



2. char* vs char[ ] exercises

Suppose we use a variable str as follows:

```
   // initialize as below
A  str = str + 1;
B  str[1] = 'u';
C  printf("%s", str)
```

For each of the following initializations:

- Will there be a compile error/segfault?
- If no errors, what is printed?

1.
```
char str[7];
strcpy(str, "Hello1");
```

Line A: Compile error (cannot reassign array)

2.
```
char *str = "Hello2";
```

Line B: Segmentation fault (string literal)

3.
```
char arr[7];
strcpy(arr, "Hello3");
char *str = arr;
```

Prints eulo3

4.
```
char *ptr = "Hello4";
char *str = ptr;
```

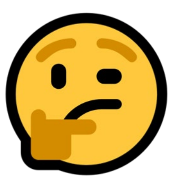
Line B: Segmentation fault (string literal)

3. Bonus: Tricky addresses

```
1   void tricky_addresses() {
2     char buf[] = "Local";
3     char *ptr1 = buf;
4     char **double_ptr = &ptr1;
5     printf("ptr1's value:     %p\n", ptr1);
6     printf("ptr1’s deref    : %c\n", *ptr1);
7     printf("       address:   %p\n", &ptr1);
8     printf("double_ptr value: %p\n", double_ptr);
9     printf("buf's address:    %p\n", &buf);

10    char *ptr2 = &buf;
11    printf("ptr2's value:     %s\n", ptr2);
12  }
```

What is stored in each variable?



3. Bonus: Tricky addresses

```
1   void tricky_addresses() {
2     char buf[] = "Local";
3     char *ptr1 = buf;
4     char **double_ptr = &ptr1;
5     printf("ptr1's value:     %p\n", ptr1);
6     printf("ptr1’s deref    : %c\n", *ptr1);
7     printf("       address:   %p\n", &ptr1);
8     printf("double_ptr value: %p\n", double_ptr);
9     printf("buf's address:    %p\n", &buf);

10    char *ptr2 = &buf;
11    printf("ptr2's value:     %s\n", ptr2);
12  }
```

	0x28	0x29	0x2a	0x2b	0x2c	0x2d
buf	'L'	'o'	'c'	'a'	'l'	'\0'

	0x10
ptr1	

	0x18
double_ptr	

	0x20
ptr2	

While Line 10 raises a compiler warning, functionally it will still work—because pointers are **addresses**.

3. Bonus: Tricky addresses

```
1  void tricky_addresses() {
2    char buf[] = "Local";
3    char *ptr1 = buf;
4    char **double_ptr = &ptr1;
5    printf("ptr1's value:     %p\n", ptr1);
6    printf("ptr1's deref    : %c\n", *ptr1);
7    printf("       address:   %p\n", &ptr1);
8    printf("double_ptr value: %p\n", double_ptr);
9    printf("buf's address:    %p\n", &buf);

10   char *ptr2 = &buf;
11   printf("ptr2's value:     %s\n", ptr2);
12 }
```

	0x28	0x29	0x2a	0x2b	0x2c	0x2d
buf	'L'	'o'	'c'	'a'	'l'	'\0'

	Address	Value
ptr1	0x10	0x28
double_ptr	0x18	0x10
ptr2	0x20	0x28

While Line 10 raises a compiler warning, functionally it will still work—because pointers are **addresses**.

Pen and paper: A * Wars Story

```
1 void binky() {
2       int a = 10;
3       int b = 20;
4       int *p = &a;
5       int *q = &b;
6
7       *p = *q;
8       p = q;
9 }
```

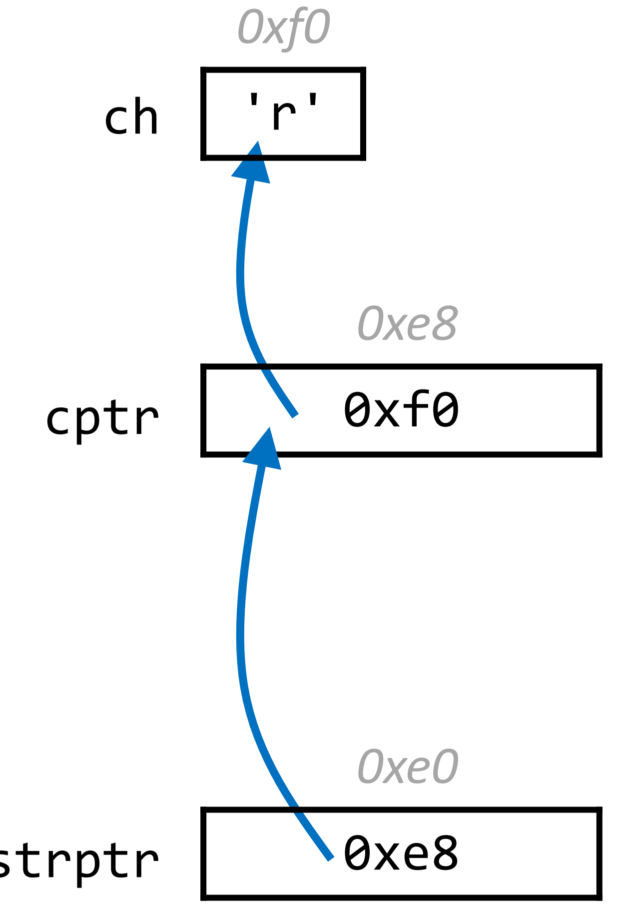
* Wars: Episode I (of 2)

In variable **declaration**, * creates a **pointer**.

`char ch = 'r';` — ch stores a char

`char *cptr = &ch;` — cptr stores an address of a char (**points to** a char)

`char **strptr = &cptr;` — strptr stores an address of a char * (**points to** a char *)



* Wars: Episode II (of 2)

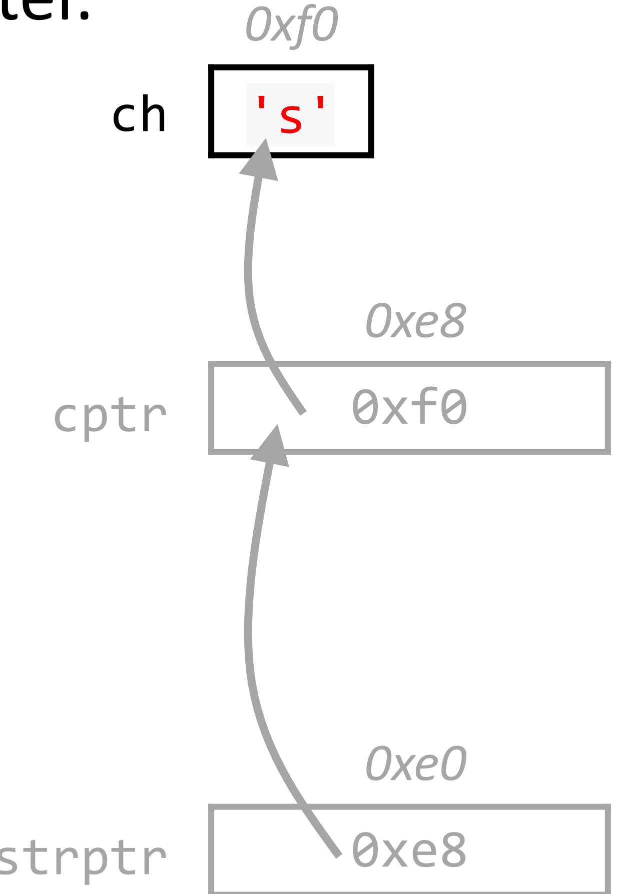
In **reading values from/storing values**, * **dereferences** a pointer.

```
char ch = 'r';
ch = ch + 1;
```

Increment value stored in ch

```
char *cptr = &ch;
```

```
char **strptr = &cptr;
```



* Wars: Episode II (of 2)

In **reading values from/storing values**, * **dereferences** a pointer.

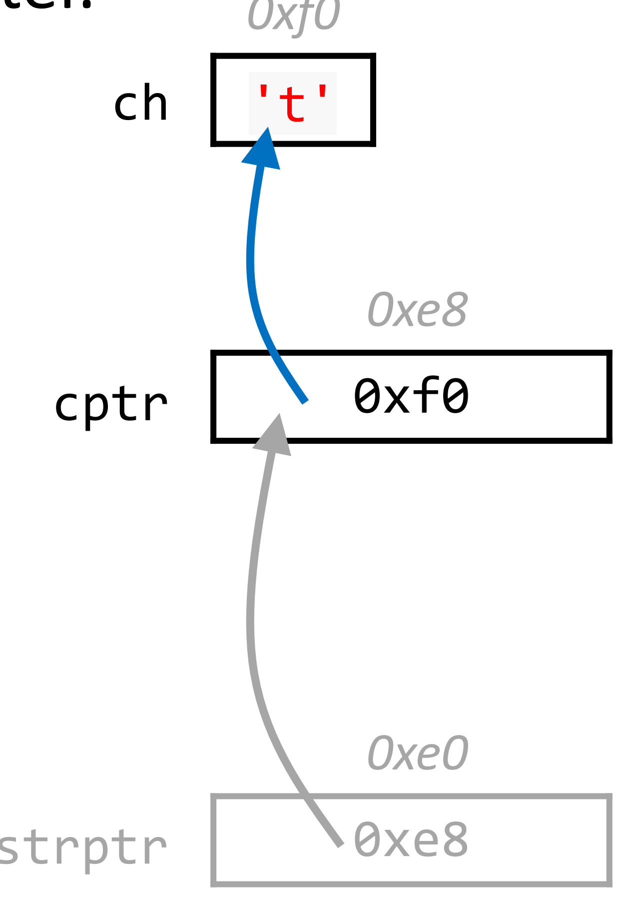
```
char ch = 'r';
ch = ch + 1;
```

Increment value stored in ch

```
char *cptr = &ch;
*cptr = *cptr + 1;
```

Increment value stored at memory address in cptr (increment char **pointed to**)

```
char **strptr = &cptr;
```



* Wars: Episode II (of 2)

In **reading values from/storing values**, * **dereferences** a pointer.

```
char ch = 'r';
ch = ch + 1;
```

Increment value stored in ch

```
char *cptr = &ch;
*cptr = *cptr + 1;
```

Increment value stored at memory address in cptr (increment char **pointed to**)

```
char **strptr = &cptr;
*strptr = *strptr + 1;
```

Increment value stored at memory address in cptr (increment address **pointed to**)
