

Fusion Trees

Part One

Outline for Today

- ***Word-Level Parallelism***
 - Harnessing the intrinsic parallelism inside the processor.
- ***Word-Parallel Operations***
 - Comparing, tiling, and ranking numbers; adding and packing bits.
- ***The Sardine Tree***
 - Unconditionally beating a BST for very small integers.
- ***Most-Significant Bits***
 - Finding the most significant bit in $O(1)$ time/space.

Recap from Last Time

Our Machine Model

- We will assume we're working on a machine where memory is segmented into w -bit words.
 - Although on any one fixed machine w is a constant, in general, don't assume this is the case. 32-bit was the norm until fairly recently, and before that 16-bit was standard.
- We'll assume C integer operators work in constant time, and won't assume other integer operations (say, finding most significant bits, counting 1 bits set) are available.

+ - * / % << >> & | ^ = <=

Integer Ordered Dictionaries

- The ***y-Fast Trie*** is an ordered dictionary for integers where each operation takes $O(\log w)$ time, amortized/expected.
 - Note that when $\log n = \omega(\log w)$, this is better than a binary search tree!
- Space usage is $\Theta(n)$ words, where n is the number of elements in the trie.

New Stuff!

A Key Technique: ***Word-Level Parallelism***

Word-Level Parallelism

- On a standard computer, arithmetic and logical operations on a machine word take time $O(1)$.
- We can perform certain classes of operations (addition, shifts, etc.) on $\Theta(w)$ bits in time $O(1)$.
 - Think of this as a weak form of parallel computation, where we can work over multiple bits in parallel with a limited set of operations.
- With some creativity, we can harness these primitives to build operations that run in time $O(1)$ but work on $\omega(1)$ objects.
- Let's see a quick example...

Word-Level Parallelism

a_1	a_2	a_3	a_4	a_5	a_6	a_7	a_8
1101110	0101110	1111000	1001101	0101111	0001101	1110111	1100001
b_1	b_2	b_3	b_4	b_5	b_6	b_7	b_8
0011010	1000101	0010100	0100000	1010000	0100010	1000100	0001000

We've performed eight
logical additions with a
single add instruction!

The Landscape

- Preprocessing/runtime tradeoffs:
“Yes, we have to do a lot of work, but it’s a one-time cost and everything is cheaper after that.”
- Randomization:
“We might have to do a lot of work, but it’s unlikely that we’ll do so.”
- Amortization:
“Yes, we have to do a lot of work every once and a while, but only after a period of doing very little.”
- Word-level parallelism:
“We have to do a lot of work, but we don’t have to perform many operations to do it.”

Sardine Trees

These actually aren't called sardine trees. I couldn't find a name for them anywhere and thought that this title was appropriate. Let me know if there's a more proper name to associate with them!

The Setup

- Let w denote the machine word size.
- Imagine you want to store a collection of s -bit integers, where s is small compared to w .
 - For example, storing 7-bit integers on a 64-bit machine would have $s = 7$ and $w = 64$.
- Can we build an ordered dictionary that takes advantage of the small key size?

A Refresher: B-Trees

- A **B-tree** is a multiway tree with a tunable parameter b called the **order** of the tree.
- Each node stores $\Theta(b)$ keys. The height of the tree is $\Theta(\log_b n)$.
- Most operations (**lookup**, **insert**, **delete**, **successor**, **predecessor**, etc.) perform a top-down search of the tree, doing some amount of work per node.
- Runtime of each operation is $O(f(b) \log_b n)$, where $f(b)$ is the amount of work done per node.

B-Tree Traversals

- Most B-tree operations work by choosing some subtree to descend into, then descending there.
- **Claim:** The subtree we want is given by the number of keys in the current node less than or equal to the query key k . This quantity is the **rank** of k .
- For example, in the top node of the B-tree shown below:
 $\text{rank}(40) = 0$ $\text{rank}(74) = 2$ $\text{rank}(107) = 3$
- **Question:** How quickly can we determine the rank of a key in a B-tree node?

B-Tree Traversals

- We can determine *rank*(k) with a linear search in each B-tree node for a total lookup cost of $O(b \cdot \log_b n)$.
- We can determine *rank*(k) with a binary search in each B-tree node for a total lookup cost of
$$O(\log_b n \cdot \log b) = O(\log n).$$
- **Claim:** If we can fit all the keys in a node into $O(1)$ machine words, we can determine *rank*(k) in time $O(1)$ for total lookup cost of $O(\log_b n)$.

How is this possible?

Warmup: Comparing Two Values

- Imagine we have two s -bit integers x and y and want to determine whether $x \geq y$.
- How might we do this?

Diagram illustrating the subtraction of 1011 from 1100 using the borrowing rule:

	0	1	
	1	1	0
	0	0	1
-	0	0	1
	1	0	0

$$\begin{array}{r}
 1010 \\
 - 1100 \\
 \hline
 11
 \end{array}$$

Warmup: Comparing Two Values

- Imagine we have two s -bit integers x and y and want to determine whether $x \geq y$.
- How might we do this?

Diagram illustrating the subtraction of two 5-bit integers. The top number is 11100 (with a red 0 above the first 1 and a red 1 above the second 1) and the bottom number is 00011. A red line indicates a borrow from the third bit of the top number to the second bit. The result is 11001.

		0	1		
	1	1	1	0	0
-	0	0	0	1	1
	1	1	0	0	1

Diagram illustrating the subtraction of two 5-bit integers. The top number is 10011 (with a red 0 above the first 1 and a red 1 above the second 0) and the bottom number is 01100. A red line indicates a borrow from the first bit of the top number to the second bit. The result is 00011.

		0	1		
	1	0	0	1	1
-	0	1	1	0	0
	0	0	0	1	1

Warmup: Comparing Two Values

- Imagine we have two s -bit integers x and y and want to determine whether $x \geq y$.
- How might we do this?

Comparing Multiple Values

- This technique can be extended to work on multiple values in parallel.
- For example, here's how we'd compare eight pairs of 7-bit numbers by doing a single 64-bit subtraction:

a_1 a_2 a_3 a_4 a_5 a_6 a_7 a_8

1101110 0101110 1111000 1001101 0101111 0001101 1110111 1100001

b_1 b_2 b_3 b_4 b_5 b_6 b_7 b_8

0011010 1000101 0010100 0100000 1010000 0100010 1000100 0001000

Comparing Multiple Values

- This technique can be extended to work on multiple values in parallel.
- For example, here's how we'd compare eight pairs of 7-bit numbers by doing a single 64-bit subtraction:

a_1 a_2 a_3 a_4 a_5 a_6 a_7 a_8

11101110 10101110 11111000 11001101 10101111 10001101 11110111 11100001

b_1 b_2 b_3 b_4 b_5 b_6 b_7 b_8

00011010 01000101 00010100 00100000 01010000 00100010 01000100 00001000

Comparing Multiple Values

- This technique can be extended to work on multiple values in parallel.
- For example, here's how we'd compare eight pairs of 7-bit numbers by doing a single 64-bit subtraction:

1	1	1	0	1	1	1	0	1	0	1	1	1	0	1	1	1	0	0	0	1	0	0	0	1	1	0	0	1	1	0	1	1	1	0	0	0	0	1		
-	0	0	0	1	1	0	1	0	1	0	0	1	0	1	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0		
1	1	0	1	0	1	0	0	0	1	1	0	0	1	0	0	1	1	0	0	1	0	0	1	0	0	1	1	0	0	1	0	1	1	1	1	0	1	0	0	1

Comparing Multiple Values

- This technique can be extended to work on multiple values in parallel.
- For example, here's how we'd compare eight pairs of 7-bit numbers by doing a single 64-bit subtraction:

1	1	1	0	1	1	1	0	1	0	1	1	1	0	1	1	1	0	0	0	1	0	0	0	1	1	0	0	1	1	0	1	1	1	0	0	0	1	1	1	0	0	0	0	1		
-	0	0	0	1	1	0	1	0	1	0	0	1	0	1	0	0	1	0	0	0	1	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
1	1	0	1	0	1	0	0	0	1	1	0	0	1	0	0	1	1	0	0	1	0	0	1	0	0	1	1	0	0	1	0	0	1	1	1	0	1	0	1	1	0	0	1	1	0	1

Comparing Multiple Values

- This technique can be extended to work on multiple values in parallel.
- For example, here's how we'd compare eight pairs of 7-bit numbers by doing a single 64-bit subtraction:

```
11101110 10101110 11111000 11001101 10101111 10001101 11110111 11100001
- 00011010 01000101 00010100 00100000 01010000 00100010 01000100 00001000
-----
11010100 01101001 11100100 10101101 01011111 01101011 10110011 11011001
```

This technique is used in practice, including *the glibc version of strlen*. Thanks to former CS166 student Jane Lange for pointing this out!

Fundamental Primitive: *Parallel Compare*

Input: Two machine words. The first holds an array $x_1, \dots, x_n$ with one bit of space between each number. The second holds an array $y_1, \dots, y_n$ with one bit of space between each number.

Output: A machine word with the result of $x_i \geq y_i$ encoded as a bit in the blank spaces between the numbers in the input array.

Procedure:

1. Use a bitwise OR to place 1s between the x_i 's.
2. Use a bitwise AND to place 0s between the y_i 's.
3. Compute $X - Y$. The bit preceding $x_i - y_i$ is 1 if $x_i \geq y_i$ and 0 otherwise.

Back to B-Trees

- **Recall:** The whole reason we're interested in making these comparisons is so that we can find how many keys in a B-tree node are less than or equal to a query key k .
- **Idea:** Store the (s -bit) keys in the B-tree node in a single (w -bit) machine word, with zeros interspersed:

y_1	y_2	y_3	y_4	y_5	y_6	y_7	y_8
41	93	103	106	107	109	110	127

Back to B-Trees

- **Recall:** The whole reason we're interested in making these comparisons is so that we can find how many keys in a B-tree node are less than or equal to a query key k .
- **Idea:** Store the (s -bit) keys in the B-tree node in a single (w -bit) machine word, with zeros interspersed:

y_1 y_2 y_3 y_4 y_5 y_6 y_7 y_8

00101001 01011101 01100111 01101010 01101011 01101101 01101110 01111111

Rank in $O(1)$

- To perform a lookup for the key k , form a number by replicating k multiple times with 1s interspersed.

Rank in $O(1)$

- To perform a lookup for the key k , form a number by replicating k multiple times with 1s interspersed.
- Subtract the B-tree key number from it to do a parallel comparison.

$$\begin{array}{r} \mathbf{11100111} \ \mathbf{11100111} \ \mathbf{11100111} \ \mathbf{11100111} \ \mathbf{11100111} \ \mathbf{11100111} \ \mathbf{11100111} \ \mathbf{11100111} \\ - \mathbf{00101001} \ \mathbf{01011101} \ \mathbf{01100111} \ \mathbf{01101010} \ \mathbf{01101011} \ \mathbf{01101101} \ \mathbf{01101110} \ \mathbf{01111111} \\ \hline \mathbf{10111110} \ \mathbf{10001010} \ \mathbf{10000000} \ \mathbf{01111101} \ \mathbf{01111100} \ \mathbf{01111010} \ \mathbf{01111001} \ \mathbf{01101000} \end{array}$$

Rank in $O(1)$

How do we
do this?

- To perform a lookup for the key k , form a number by replicating k multiple times with 1s interspersed.
- Subtract the B-tree key number from it to do a parallel comparison.
- Count up how many of the sentinel bits in the resulting number are equal to 1. This is the number of keys in the node less than or equal to k .

Or this?

11100111 11100111 11100111 11100111 11100111 11100111 11100111 11100111

How do we count
how many of these
bits are set?

Summing Up Flags

- After performing our subtraction, we're left with a number like this one, where the highlighted bits are “interesting” to us.
- **Goal:** Add up these “interesting” values using at most $O(1)$ total operations on words.

a00000000 **b**00000000 **c**00000000 **d**00000000

An Initial Idea

- To sum up the flags, we could extract each bit individually and add the result.
- ***The catch:*** This takes time $\Theta(r)$, where r is the number of times we tiled our value.
- Can we do better?

a00000000 **b**00000000 **c**00000000 **d**00000000

A Shifty Solution

- Given this number:

a00000000 **b**00000000 **c**00000000 **d**00000000

we want to compute **a** + **b** + **c** + **d**.

- We can't efficiently isolate **a**, **b**, **c**, and **d**.
- Claim:** We don't have to!

$$\begin{array}{r} d \\ c \\ b \\ + a \\ \hline \end{array}$$

A Shifty Solution

- Given this number:

a00000000 **b**00000000 **c**00000000 **d**00000000

we want to compute **a** + **b** + **c** + **d**.

- We can't efficiently isolate **a**, **b**, **c**, and **d**.
- Claim:** We don't have to!

	d
	c
	b
+	a

A Shifty Solution

???????? ???? sum ?????????? ?????????? ??????????

This is a series of shifts and adds. It's equivalent to multiplying our original number by some well-chosen spreader!

Fundamental Primitive: *Parallel Add*

Input: A machine word with “interesting” bits spaced evenly across the word.

Output: The sum of those “interesting” bits.

Procedure:

1. Perform a *parallel tile* with an appropriate multiplier to place all leading bits on top of one another.
2. Use a bitmask and bitshift to isolate those bits.

Computing Rank in $O(1)$

sum

Fundamental Primitive: *Parallel Rank*

Input: An array of integers packed into a machine word with one bit of space between integers, and a key k .

Output: How many elements of the array are less than or equal to k .

Procedure:

1. Perform a *parallel tile* to create n copies of the key k , prefixed by 1's.
2. Perform a *parallel compare* of the key k against values $x_1, \dots, x_n$.
3. Perform a *parallel add* to sum those values into some total t .
4. Return t .

The Sardine Tree

- Let w be the word size and s be some (much) smaller number of bits.
- A **sardine tree** is a B-tree of order $\Theta(w/s)$ where the keys in a node are packed into a single machine word.
 - Get it? The keys are “packed” tightly into a machine word! I’m funny.
- Each node is annotated with several values (the masks and multipliers from the preceding slide), which are updated in time $O(1)$ whenever a key is added or removed.
- Supports all ordered dictionary operations in time

$$O(\log_b n) = \mathbf{O(\log_{w/s} n)}.$$

The Scorecard

- Here's the performance breakdown for the sardine tree.
- Notice that the runtime performance is *strictly better* than that of a BST!
- Notice that the space usage is *sublinear*, since each node stores multiple keys!

The Sardine Tree

- **lookup**: $O(\log_{w/s} n)$
- **insert**: $O(\log_{w/s} n)$
- **delete**: $O(\log_{w/s} n)$
- **max**: $O(\log_{w/s} n)$
- **succ**: $O(\log_{w/s} n)$
- Space: $\Theta(n \cdot s/w)$ words

For Comparison

- It's helpful to compare the sardine tree against the y-fast trie.
- To make the comparison fair, I'm treating the y-fast trie as though the machine word size is s rather than w .

The y-Fast Trie

- **lookup**: $O(\log s)$
 - **insert**: $O(\log s)^*$
 - **delete**: $O(\log s)^*$
 - **max**: $O(\log s)$
 - **succ**: $O(\log s)$
 - Space: $\Theta(n)$ words
- * Expected, amortized

What's Next

- **Question:** Can we get performance along these lines even if the keys fill full machine words?
- The strategy used in the sardine tree on its own won't get us there – but many of those same techniques will!
- We'll see how to do this next time. In the meantime, let's see some other cool tricks we can do with word-level parallelism.

Mystery Structure?

- ***lookup***: $O(\log_w n)$
- ***insert***: $O(\log_w n)$
- ***delete***: $O(\log_w n)$
- ***max***: $O(\log_w n)$
- ***succ***: $O(\log_w n)$
- Space: $\Theta(n)$

Word-Level Parallelism Tricks #2:
Most-Significant Bits

Most-Significant Bits

- The ***most-significant bit*** function, denoted ***msb(*n*)***, outputs the index of the highest 1 bit set in the binary representation of number *n*.
- Some examples:
$$\text{msb}(0110) = 2 \quad \text{msb}(010100) = 4 \quad \text{msb}(1111) = 3$$
- Note that $\text{msb}(0)$ is undefined.
- Mathematically, $\text{msb}(n)$ is the largest value of k such that $2^k \leq n$. (*Do you see why?*)

Most-Significant Bits

- Although we didn't have this name earlier in the quarter, you've seen a place where we needed to efficiently compute $\text{msb}(n)$.
- Do you remember where?
- **Answer:** In the sparse table RMQ structure, where computing $\text{RMQ}(i, j)$ requires computing the largest number k where $2^k \leq j - i + 1$.
- That's exactly the value of $\text{msb}(j - i + 1)$!

Most-Significant Bits

- On many architectures, there's a single assembly instruction that computes $\text{msb}(n)$.
 - on x86, it's **BSR** (**b**it **s**can **r**everse).
- On others, nothing like this exists.
 - Older versions of MIPS, for example.
- **Question:** How would we compute $\text{msb}(n)$ assuming we only have access to the regular C operators?

+ - * / % << >> & | ^ == <=

Computing msb

- In Problem Set 1, you (probably) computed $\text{msb}(n)$ by building a lookup table mapping each value of n to $\text{msb}(n)$.
- **The Good:** This takes time $O(1)$ to evaluate.
- **The Bad:** The preprocessing time, and space usage, is $\Theta(U)$, where U is the maximum value we'll be querying for.
- **The Ugly:** In the worst case $U = 2^w$.
- Can we do better?

Most-Significant Digits

- Can you compute most-significant digits
 - ... in time $O(w)$ using $O(1)$ space?
 - ... in time $O(\log w)$ using $O(1)$ space?
 - ... in time $O(1)$ using $O(1)$ space?
- Remember that the word size w is not a constant and that we can only use C-style operations.

Most-Significant Digits

Can you compute most-significant digits

- ... in time $O(w)$ using $O(1)$ space?
 - ... in time $O(\log w)$ using $O(1)$ space?
 - ... in time $O(1)$ using $O(1)$ space?

Remember that the word size w is not a constant and that we can only use C-style operations.

Most-Significant Bits

- There's a simple $O(w)$ -time algorithm for computing $\text{msb}(n)$ that just checks all the bits until a 1 is found:

```
for (uint8_t bit = 64; bit > 0; bit--) {  
    if (n & (uint64_t(1) << (bit - 1))) {  
        return bit;  
    }  
}  
flailAndPanic();
```

- Can we do better?

Computing msb

- We can improve this runtime to $O(\log w)$ by using a binary search:
 - Check if any bits in the upper half of the bits of n are set.
 - If so, recursively explore the upper half of n .
 - If not, recursively explore the lower half of n .
- We can test whether any bit in a range is set by ANDing with a mask of 1s and seeing if the result is nonzero:

	11011100	10111011	11000100	11010101	11100110	11110111	11000010	00110010
$\wedge$	11111111	11111111	11111111	11111111	00000000	00000000	00000000	00000000
	11011100	10111011	11000100	11010101	00000000	00000000	00000000	00000000

- Can we do better?

Claim: For any machine word size w , there is an algorithm that uses $O(1)$ machine operations and $O(1)$ space – independently of w – and computes $\text{msb}(n)$.

This is not
obvious!

How is this possible?

Not Starting from Scratch

- We're not going into this problem blind. We've seen a bunch of useful techniques so far:
 - **Parallel compare:** We can compare a bunch of small numbers in parallel in $O(1)$ machine word operations.
 - **Parallel tile:** We can take a small number and “tile” it multiple times in $O(1)$ machine word operations.
 - **Parallel add:** If we have a bunch of “flag” bits spread out evenly, we can add them all up in $O(1)$ machine word operations.
 - **Parallel rank:** We can find the rank of a small number in an array of small numbers in $O(1)$ machine word operations.
- This is an impressive array of techniques. Let's see if we can reuse or adapt them.

Not Starting from Scratch

- We're not going into this problem blind. We've seen a bunch of useful techniques so far:

- This is an impressive array of techniques. Let's see if we can reuse or adapt them.

MSBs as Ranks

- **Recall:** $\text{msb}(n)$ is the largest value of k for which $2^k \leq n$.
- **Idea:** Imagine we have an array of all the powers of two that we can represent in a machine word. Then $\text{msb}(n)$ is the rank of n in that array!

00000000 00000000 00100000 00000010 00000000 00100000 00100001 00101111

2^0	2^1	2^2	2^3	2^4	2^5	2^6	...	2^{50}	2^{51}	2^{52}	2^{53}	2^{54}	2^{55}	2^{56}	2^{57}	2^{58}	...	2^{61}	2^{62}	2^{63}
-------	-------	-------	-------	-------	-------	-------	-----	----------	----------	----------	----------	----------	----------	----------	----------	----------	-----	----------	----------	----------

The Problem

- We can compute the rank of a value in an array assuming that all the array entries fit into a single machine word.
- This isn't the case here:
 - w total powers of two to write out.
 - Total bits needed: $\Theta(w^2)$, way too big to fit into a word.
- **Question:** Can we still harness the benefits of this parallel rank operation?

00000000 00000000 00100000 00000010 00000000 00100000 00100001 00101111

-------	-------	-------	-------	-------	-------	-------	-----	----------	----------	----------	----------	----------	----------	----------	----------	----------	-----	----------	----------	----------

A Nice Decomposition

- Imagine we want to compute the most-significant bit of a w -bit integer.
 - In what follows, we'll pick $w = 64$, but this works for any w .
- We ultimately want to be finding the MSB of numbers with way fewer than w bits.
- **Idea:** Split w into some number of blocks of size b . Then,
 - find the index of the highest block with at least one 1 bit set, then
 - find the index of the highest bit within that block.

A Nice Decomposition

- Imagine we want to compute the most-significant bit of a w -bit integer.
 - In what follows, we'll pick $w = 64$, but this works for any w .

A Nice Decomposition

- We will compute the MSB for w -bit integers by solving MSB for b and w/b -bit integers.
- What choice of b minimizes $\max\{b, w/b\}$?
- **Answer:** Pick $b = w^{1/2}$.
- So now we need to see how to
 - solve $\text{msb}(n)$ for integers with $w^{1/2}$ bits, and
 - replace each block with a bit indicating whether that block contains a 1.

A Nice Decomposition

MSB for $w^{1/2}$ Bits

- **Recall:** We can compute $\text{msb}(n)$ by counting how many powers of two are less than or equal to n .
- If our numbers have size $w^{1/2}$, there are $w^{1/2}$ powers of two to compare against.
- Each of those powers of two has $w^{1/2}$ bits, so all of those powers of two can be packed into a single machine word!
- **Idea:** Use our $O(1)$ -time rank algorithm!

00000001 00000010 00000100 00001000 00010000 00100000 01000000 10000000

MSB for $w^{1/2}$ Bits

- If our numbers have size $w^{1/2}$, there are $w^{1/2}$ powers of two to compare against, each of which has $w^{1/2}$ bits.
- Our parallel comparison prepends an extra bit to each number to compare.

00000001 00000010 00000100 00001000 00010000 00100000 01000000 10000000

MSB for $w^{1/2}$ Bits

- If our numbers have size $w^{1/2}$, there are $w^{1/2}$ powers of two to compare against, each of which has $w^{1/2}$ bits.
- Our parallel comparison prepends an extra bit to each number to compare.
- That's barely – just barely – too many bits to fit into a machine word.

00000000100000001000000010000000100000001000000010000000100000001000000010000000

MSB for $w^{1/2}$ Bits

- **Claim:** This is an engineering problem at this point.
- **Option 1:** Split the powers of two into two different machine words and do two rank calculations.
- **Option 2:** Special-case the most-significant bit to reduce the number of bits to check.
- Either way, we find that the work done here is $O(1)$ machine operations, with no dependency on the word size w !

000000001000000010000000100000001000000010000000010000000010000000010000000010000000

High bit set?

Observation: A block contains a 1 bit if its first bit is 1 or its lower 7 bits contain a 1.

Identifying Active Blocks

- We now have a word holding flags telling us which blocks have a 1 bit set.
- We need to find the highest set flag.
- There are only $w^{1/2}$ flags. If we could compact them into $w^{1/2}$ adjacent bits, we could use our earlier algorithm to find the highest one set!

[illegible]

Identifying Active Blocks

- **Idea:** Adapt the shifting technique we used to compute ranks.
- Instead of shifting the bits on top of one another, shift the bits next to one another:

a0000000b0000000c0000000d0000000

+

a

Fundamental Primitive: *Parallel Pack*

Input: A machine word containing several “interesting” bits that are evenly spaced apart.

Output: A machine word with those “interesting” bits placed adjacent to one another at the low end of the word.

Procedure:

1. Perform a *parallel tile* with an appropriate multiplier to place all leading bits adjacent to one another.
2. Use a bitmask and bitshift to isolate those bits.

Putting It All Together

- Use a bitmask to identify all blocks whose high bit is set.
- Use a *parallel tile* and a *parallel compare* to identify all blocks with a 1 bit aside from the first.
- Use a *parallel pack* to pack those bits together.
- Use a *parallel rank* to determine the highest of those bits set, which gives the block index.
- Use a *parallel rank* to determine the highest bit set within that block.

The Finished Product

- I've posted a link to a working implementation of this algorithm for 64-bit integers on the course website.
- Feel free to check it out – it's really magical seeing all the techniques come together!

What We Covered

- We can use bit-parallel tricks to
 - compare multiple values in parallel,
 - tile a number across a word,
 - sum up evenly-spaced bits in a word,
 - compute ranks in an array,
 - compact evenly-spaced bits in a word, andall in $O(1)$ machine word operations!
- Using these techniques, we can modify a B-tree to work strictly faster than a conventional BST, provided that we store tiny keys.
- Using these techniques, can we compute the most-significant bit of a machine word in time $O(1)$, independent of the machine word size.
- And all of this flows from one source: ***word-level parallelism*** inside of the processor!

What's Next

- Can we build a data structure for integers that is *strictly better* than a binary search tree?
- The answer is **yes**, and it's called a fusion tree.
- Today's exploration provides the techniques we'll use to build the fusion tree. We just need a few more insights to get us there!

Next Time

- ***Patricia Codes***
 - Compressing a small number of big integers into a small number of small integers.
- ***Fusion Trees***
 - Combining all these techniques together!
