Statistical Natural Language Parsing

Christopher Manning

Parsing examples

• Fed raises interest rates

Statistical parsing

• Over the last 15 years statistical parsing has succeeded wonderfully!
• NLP researchers have produced a range of (often free, open source) statistical parsers, which can parse any sentence and often get most of it correct
• These parsers are now a commodity component
• The parsers are still improving year-on-year.  
  • Collins (C) or Bikel reimplementation (Java)
  • Charniak or Johnson-Charniak parser (C++)
  • Stanford Parser (Java)
  • ...

Parsing in the early 1990s

• The parsers produced detailed, linguistically rich representations
• Parsers had uneven and usually rather poor coverage
• E.g., 30% of sentences received no analysis
• Even quite simple sentences had many possible analyses
• Parsers either had no method to choose between them or a very ad hoc treatment of parse preferences
• Parsers could not be learned from data
• Parser performance usually wasn’t or couldn’t be assessed quantitatively and the performance of different parsers was often incommensurable

Statistical parsing applications

• High precision question answering systems (Pasca and Harabagiu SIGIR 2001)
• Improving biological named entity extraction (Finkel et al. JNLPBA 2004):
• Syntactically based sentence compression (Lin and Wilbur Inf. Retr. 2007)
• Extracting people’s opinions about products (Bloom et al. NAACL 2007)
• Improved interaction in computer games (Gorniak and Roy, AAAI 2005)
• Helping linguists find data (Resnik et al. BLS 2005)

Ambiguity: natural languages vs. programming languages

• Programming languages have only local ambiguities, which a parser can resolve with lookahead (and conventions)
• Natural languages have global ambiguities
  • I saw that gasoline can explode
  • “Construe an else statement with which if makes most sense.”
Classical NLP Parsing

- Wrote symbolic grammar and lexicon
  - \( S \rightarrow NP \ VP \)
  - \( NP \rightarrow (DT) \ NN \)
  - \( NN \rightarrow interest \)
  - \( NP \rightarrow NN \ NNS \)
  - \( NNS \rightarrow rates \)
  - \( NP \rightarrow NNP \ VBP \)
  - \( VBP \rightarrow interest \)
  - ...
- Used proof systems to prove parses from words
- This scaled very badly and didn't give coverage
  - Minimal grammar on "Fed raises" sentence: 36 parses
  - Simple 10 rule grammar: 592 parses
  - Real-size broad-coverage grammar: millions of parses

The rise of annotated data: The Penn Treebank

Starting off, building a treebank seems a lot slower and less useful than building a grammar
- But a treebank gives us many things
  - Reusability of the labor
  - Broad coverage
  - Frequencies and distributional information
  - A way to evaluate systems

Two views of linguistic structure: 1. Constituency (phrase structure)

- Phrase structure organizes words into nested constituents.
- How do we know what is a constituent? (Not that linguists don't argue about some cases.)
  - Distribution: a constituent behaves as a unit that can appear in different places:
    - John talked [to the children] [about drugs].
    - John talked [about drugs] [to the children].
  - Substitution/expansion/pro-forms:
    - I sat [in the box/sight on top of the box/there].
  - Coordination, regular internal structure, no intrusion, fragments, semantics, ...

The rise of annotated data

Two views of linguistic structure: 2. Dependency structure

- Dependency structure shows which words depend on (modify or are arguments of) which other words.
Attachment ambiguities: Two possible PP attachments

- The key parsing decision: How do we ‘attach’ various kinds of constituents – PPs, adverbial or participial phrases, coordinations, etc.
- Prepositional phrase attachment:
  - I saw the man with a telescope
  - What does with a telescope modify?
  - The verb saw?
  - The noun man?
  - Is the problem ‘AI complete’? Yes, but …

Attachment ambiguities

- Proposed simple structural factors
  - Right association (Kimball 1973) = ‘low’ or ‘near’ attachment = ‘early closure’ (of NP)
  - Minimal attachment (Frazier 1978). Effects depend on grammar, but gave ‘high’ or ‘distant’ attachment = ‘late closure’ (of NP) under the assumed model
  - Which is right?
  - Such simple structural factors dominated in early psycholinguistics (and are still widely invoked).
  - In the V NP PP context, right attachment usually gets right 55–67% of cases.
  - But that means it gets wrong 33–45% of cases.

Attachment ambiguities

- Words are good predictors of attachment (even absent understanding)
  - The children ate the cake with a spoon
  - The children ate the cake with frosting
  - Moscow sent more than 100,000 soldiers into Afghanistan …
  - Sydney Water breached an agreement with NSW Health …

The importance of lexical factors

- Ford, Bresnan, and Kaplan (1982) [promoting ‘lexicalist’ linguistic theories] argued:
  - Order of grammatical rule processing [by a person] determines closure effects
  - Ordering is jointly determined by strengths of alternative lexical forms, strengths of alternative syntactic rewrite rules, and the sequences of hypotheses in the parsing process.
  - “It is quite evident, then, that the closure effects in these sentences are induced in some way by the choice of the lexical items.” (Psycholinguistic studies show that this is true independent of discourse context.)

A simple prediction

- Use a likelihood ratio:
  \[ \text{LR}(v,a,p) = \frac{P(p|v)}{P(p|a)} \]

- \( P(\text{with agreement}) = 0.15 \)
- \( P(\text{with breach}) = 0.02 \)
- \( \text{LR(} \text{breach, agreement, with) } = 0.13 \)
  \[ \rightarrow \text{Choose noun attachment} \]
A problematic example

- Chrysler confirmed that it would end its troubled venture with Maserati.
- Should be a noun attachment but got wrong answer:
  - $w \cdot C(w)$
  - end 5156 607
  - venture 1442 155
  - $P(w \text{ with } v) = \frac{607}{5156} \approx 0.118 > \frac{155}{1442} \approx 0.107$

A better predictor would use $n_2$ as well as $v, n_1, p$

Attachment ambiguities in a real sentence

What is parsing?

- We want to run a grammar backwards to find possible structures for a sentence
- Parsing can be viewed as a search problem
- Parsing is a hidden data problem
- For the moment, we want to examine all structures for a string of words
- We can do this bottom-up or top-down
  - This distinction is independent of depth-first or breadth-first search – we can do either both ways
  - We search by building a search tree which has its distinct from the parse tree

A phrase structure grammar

- $S \rightarrow NP \ VP$
- $NP \rightarrow e$
- $NP \rightarrow P \ PP$
- $VP \rightarrow V \ NP$
- $VP \rightarrow V \ NP \ PP$
- $NP \rightarrow NP \ PP$
- $NP \rightarrow N \ N$
- $NP \rightarrow N$
- $NP \rightarrow N$
- $VP \rightarrow V \ NP$
- $VP \rightarrow V \ NP$
Phrase structure grammars = context-free grammars

- $G = (T, N, S, R)$
- $T$ is set of terminals
- $N$ is set of nonterminals
  - For NLP, we usually distinguish out a set $P \subseteq N$ of preterminals, which always rewrite as terminals
  - $S$ is the start symbol (one of the nonterminals)
  - $R$ is rules/productions of the form $X \rightarrow \gamma$, where $X$ is a nonterminal and $\gamma$ is a sequence of terminals and nonterminals (possibly an empty sequence)
- A grammar $G$ generates a language $L$.

Soundness and completeness

- A parser is **sound** if every parse it returns is valid/correct
- A parser **terminates** if it is guaranteed to not go off into an infinite loop
- A parser is **complete** if for any given grammar and sentence, it is sound, produces every valid parse for that sentence, and terminates
  - (For many purposes, we settle for sound but incomplete parsers: e.g., probabilistic parsers that return a $k$-best list.)

Top-down parsing

- Top-down parsing is goal directed
- A top-down parser starts with a list of constituents to be built. The top-down parser rewrites the goals in the goal list by matching one against the LHS of the grammar rules, and expanding it with the RHS, attempting to match the sentence to be derived.
- If a goal can be rewritten in several ways, then there is a choice of which rule to apply (search problem)
- Can use depth-first or breadth-first search, and goal ordering.

Problems with top-down parsing

- Left recursive rules
- Will do badly if there are many rules for the same LHS.
  - Consider if there are 600 rules for $S$, 599 of which start with NP, but one of which starts with V, and the sentence starts with V.
- Useless work: expands things that are possible top-down but not there
- Top-down parsers do well if there is useful grammar-driven control: search is directed by the grammar
- Top-down is hopeless for rewriting parts of speech (preterminals) with words (terminals). In practice that is always done bottom-up as lexical lookup.
- Repeated work: anywhere there is common substructure

Bottom-up parsing

- Bottom-up parsing is data directed
- The initial goal list of a bottom-up parser is the string to be parsed. If a sequence in the goal list matches the RHS of a rule, then this sequence may be replaced by the LHS of the rule.
- Parsing is finished when the goal list contains just the start category.
- If the RHS of several rules match the goal list, then there is a choice of which rule to apply (search problem)
- Can use depth-first or breadth-first search, and goal ordering.
- The standard presentation is as *shift-reduce parsing.*
Shift-reduce parsing: one path

Problems with bottom-up parsing

• Unable to deal with empty categories: termination problem, unless rewriting empties as constituents is somehow restricted (but then it’s generally incomplete)
• Useless work: locally possible, but globally impossible.
• Inefficient when there is great lexical ambiguity (grammar-driven control might help here)
• Conversely, it is data-directed: it attempts to parse the words that are there.
• Repeated work: anywhere there is common substructure

What other search paths are there for parsing this sentence?

Repeated work...

Principles for success: take 1

• If you are going to do parsing-as-search with a grammar as is:
  • Left recursive structures must be found, not predicted
  • Empty categories must be predicted, not found
• Doing these things doesn’t fix the repeated work problem:
  • Both TD (LL) and BU (LR) parsers can (and frequently do) do work exponential in the sentence length on NLP problems.

Principles for success: take 2

• Grammar transformations can fix both left-recursion and epsilon productions
• Then you parse the same language but with different trees
• Linguists tend to hate you
  • But this is a misconception: they shouldn’t
  • You can fix the trees post hoc:
    • The transform-parse-detransform paradigm
• But the big problem is the global ambiguities leading to exponentially many parses

Principles for success: take 3

• Rather than doing parsing-as-search, we do parsing as dynamic programming
• This is the most standard way to do things
  • E.g., CKY parsing
• It solves the problem of doing repeated work
• But there are also other ways of solving the problem of doing repeated work
  • Memoization (remembering solved subproblems)
  • Doing graph-search rather than tree-search.
Quiz Question!

- How many distinct parses does the following sentence have due to PP attachment ambiguities?
  - A PP can attach to any preceding V or N, subject only to the parse still being a tree (which is equivalent to there being no crossing dependencies)

  John wrote the book with a pen in the room.

Human parsing

- Humans often do ambiguity maintenance
  - Have the police ... eaten their supper?
  - come in and look around.
  - taken out and shot.

- But humans also commit early and are “garden pathed”:
  - The man who hunts ducks out on weekends.
  - The cotton shirts are made from grows in Mississippi.
  - The horse raced past the barn fell.

Probabilistic or stochastic context-free grammars (PCFGs)

- G = (T, N, S, R, P)
  - T is set of terminals
  - N is set of nonterminals
    - For NLP, we usually distinguish out a set P ⊂ N of preterminals, which always rewrite as terminals
    - S is the start symbol (one of the nonterminals)
    - R is rules/productions of the form X → γ, where X is a nonterminal and γ is a sequence of terminals and nonterminals (possibly an empty sequence)
    - P(R) gives the probability of each rule.
  - A grammar G generates a language model L.

PCFGs – Notation

- w₁ⁿ = w₁ ... wₙ = the word sequence from 1 to n (sentence of length n)
- wₐᵇ = the subsequence wₐ ... wᵇ
- Nₐᵇ = the nonterminal N dominating wₐ ... wᵇ

The probability of trees and strings

- P(t) -- The probability of tree is the product of the probabilities of the rules used to generate it.
- P(w₁ⁿ) -- The probability of the string is the sum of the probabilities of the trees which have that string as their yield

  \[ P(w₁ⁿ) = \sum P(t) \]

A Simple PCFG (in CNF)

- \[ S \rightarrow NP \quad 1.0 \quad NP \rightarrow VP \quad 0.4 \]
- \[ VP \rightarrow V \quad 0.7 \quad NP \rightarrow astronomers \quad 0.1 \]
- \[ VP \rightarrow VP \quad 0.3 \quad NP \rightarrow ears \quad 0.18 \]
- \[ PP \rightarrow P \quad 1.0 \quad NP \rightarrow saw \quad 0.04 \]
- \[ P \rightarrow with \quad 1.0 \quad NP \rightarrow stars \quad 0.18 \]
- \[ V \rightarrow saw \quad 1.0 \quad NP \rightarrow telescopes \quad 0.1 \]
Tree and String Probabilities

- \( w_{15} = \text{astronomers saw stars with ears} \)
- \( P(t_1) = 1.0 \times 0.1 \times 0.7 \times 1.0 \times 0.4 \times 0.18 \times 1.0 \times 1.0 \times 0.18 = 0.0009072 \)
- \( P(t_2) = 1.0 \times 0.1 \times 0.3 \times 0.7 \times 1.0 \times 0.18 \times 1.0 \times 1.0 \times 0.18 = 0.0006804 \)
- \( P(w_{15}) = P(t_1) + P(t_2) = 0.0009072 + 0.0006804 = 0.0015876 \)
