First-Order Logic
Part Two
Recap from Last Time
**What is First-Order Logic?**

- **First-order logic** is a logical system for reasoning about properties of objects.
- Augments the logical connectives from propositional logic with
  - *predicates* that describe properties of objects,
  - *functions* that map objects to one another, and
  - *quantifiers* that allow us to reason about many objects at once.
Some muggle is intelligent.

\[ \exists m. \ (\text{Muggle}(m) \land \text{Intelligent}(m)) \]

\[ \exists \] is the **existential quantifier** and says “for some choice of \( m \), the following is true.”
New Stuff!
The Aristotelian Forms

“All As are Bs”
∀x. (A(x) → B(x))

“No As are Bs”
∀x. (A(x) → ¬B(x))

(Some As are Bs”
∃x. (A(x) ∧ B(x))

(“Some As aren’t Bs”
∃x. (A(x) ∧ ¬B(x))

It is worth committing these patterns to memory. We’ll be using them throughout the day and they form the backbone of many first-order logic translations.
The Art of Translation
Using the predicates

- *Person*(p), which states that *p* is a person, and
- *Loves*(x, y), which states that *x* loves *y*,

write a sentence in first-order logic that means “every person loves someone else.”
Every person loves someone else
Every person loves some other person
Every person $p$ loves some other person
Every person $p$ loves some other person

"All As are Bs"

$\forall x. (A(x) \rightarrow B(x))$
∀p. (Person(p) →
    p loves some other person
)

“All As are Bs”
∀x. (A(x) → B(x))
∀p. (Person(p) → p loves some other person)
\( \forall p. \ (Person(p) \rightarrow \text{there is some other person that } p \text{ loves}) \)
∀p. (\text{Person}(p) \rightarrow \text{there is a person other than } p \text{ that } p \text{ loves})
\[ \forall p. \ (\text{Person}(p) \rightarrow \text{there is a person q, other than p, where p loves q} ) \]
∀p. (Person(p) → 
\textit{there is a person q, other than p, where p loves q} 
)

\( \forall p. (\text{Person}(p) \rightarrow \text{there is a person } q, \text{ other than } p, \text{ where } p \text{ loves } q) \)

“Some As are Bs”

\( \exists x. (A(x) \land B(x)) \)
∀p. (Person(p) →
    ∃q. (Person(q) ∧, other than p, where
        p loves q
    )
)

“Some As are Bs”

∃x. (A(x) ∧ B(x))
∀p. (Person(p) \rightarrow
    \exists q. (Person(q) \land, other than p, where
               p loves q
            )
   )
)
∀p. (Person(p) → 
    ∃q. (Person(q) ∧ p ≠ q ∧ 
        p loves q 
    ) 
) 
)
∀p. (Person(p) → 
    ∃q. (Person(q) ∧ p ≠ q ∧ Loves(p, q) 
        ) 
    ) 
)
Using the predicates

- \textit{Person}(p), which states that \( p \) is a person, and
- \textit{Loves}(x, y), which states that \( x \) loves \( y \),

write a sentence in first-order logic that means "there is a person that everyone else loves."
There is a person that everyone else loves
There is a person $p$ where everyone else loves $p$
There is a person \( p \) where everyone else loves \( p \)

∃\( x \). (A(\( x \)) ∧ B(\( x \)))

“The As are Bs”
\(\exists p. (\text{Person}(p) \land \text{everyone else loves } p)\)

"Some As are Bs"

\(\exists x. (A(x) \land B(x))\)
\(\exists p. (\text{Person}(p) \land \text{everyone else loves } p)\)
\( \exists p. \ (\text{Person}(p) \land \text{every other person } q \text{ loves } p) \)
\( \exists p. (\text{Person}(p) \land \text{every person } q, \text{ other than } p, \text{ loves } p) \)
$\exists p. \ (\text{Person}(p) \land \text{every person } q, \text{ other than } p, \text{ loves } p)$

"All As are Bs"

$\forall x. \ (A(x) \rightarrow B(x))$
\[ \exists p. (\text{Person}(p) \land \\
\forall q. (\text{Person}(q) \land p \neq q \rightarrow \\
q \text{ loves } p) \\
) \]

“All As are Bs”
\[ \forall x. (A(x) \rightarrow B(x)) \]
∃p. (Person(p) ∧
   ∀q. (Person(q) ∧ p ≠ q →
       q loves p)
)
)
\[ \exists p. \ (\text{Person}(p) \land \forall q. \ (\text{Person}(q) \land p \neq q \rightarrow \text{Loves}(q, p)) \) \]
Combining Quantifiers

• Most interesting statements in first-order logic require a combination of quantifiers.

• Example: “Every person loves someone else”

\[
\forall p. \ (\text{Person}(p) \rightarrow \\
\exists q. \ (\text{Person}(q) \land p \neq q \land \\
\text{Loves}(p, q))
\]
Combining Quantifiers

• Most interesting statements in first-order logic require a combination of quantifiers.

• Example: “There is someone everyone else loves.”

\[
\exists p. \ (\text{Person}(p) \land \\
\forall q. \ (\text{Person}(q) \land p \neq q \rightarrow \\
\text{Loves}(q, p))
\]
For every person...
... there is another person ...
... they love

There is a person...
... that everyone else ...
... loves.

\forall p. (\text{Person}(p) \rightarrow \exists q. (\text{Person}(q) \land p \neq q \land \text{Loves}(p, q))

\exists p. (\text{Person}(p) \land \forall q. (\text{Person}(q) \land p \neq q \rightarrow \text{Loves}(q, p))
Every Person Loves Someone Else
Every Person Loves Someone Else

No one here is universally loved.
There is Someone Everyone Else Loves
There is Someone Everyone Else Loves

This person does not love anyone else.
Every Person Loves Someone Else and There is Someone Everyone Else Loves
For every person...  
... there is another person ...  
... they love

and

There is a person...
... that everyone else ...
... loves.

\[ \forall p. \ (\text{Person}(p) \rightarrow \exists q. \ (\text{Person}(q) \land p \neq q \land \text{Loves}(p, q)) \) \]

\[ \land \]

\[ \exists p. \ (\text{Person}(p) \land \forall q. \ (\text{Person}(q) \land p \neq q \rightarrow \text{Loves}(q, p)) \) \]
Quantifier Ordering

• The statement

\[ \forall x. \exists y. P(x, y) \]

means “for any choice of \( x \), there's some choice of \( y \) where \( P(x, y) \) is true.”

• The choice of \( y \) can be different every time and can depend on \( x \).
Quantifier Ordering

• The statement

$$\exists x. \forall y. P(x, y)$$

means “there is some $$x$$ where for any choice of $$y$$, we get that $$P(x, y)$$ is true.”

• Since the inner part has to work for any choice of $$y$$, this places a lot of constraints on what $$x$$ can be.
Order matters when mixing existential and universal quantifiers!
Set Translations
Using the predicates

- $Set(S)$, which states that $S$ is a set, and
- $x \in y$, which states that $x$ is an element of $y$,

write a sentence in first-order logic that means “the empty set exists.”
Using the predicates

- \textit{Set}(S), which states that \( S \) is a set, and
- \( x \in y \), which states that \( x \) is an element of \( y \),

write a sentence in first-order logic that means “the empty set exists.”
The empty set exists.
There is some set $S$ that is empty.
\exists S. \ (Set(S) \land S \text{ is empty.})
\exists S. (\text{Set}(S) \land \\
\text{there are no elements in } S \\
)
\[ \exists S. \ (\text{Set}(S) \land \neg \text{there is an element in } S) \]
\[ \exists S. \ (Set(S) \land \neg \text{there is an element } x \text{ in } S) \]
\[ \exists S. \ (Set(S) \land \neg \exists x. \ x \in S) \]
∃S. (Set(S) ∧ ¬∃x. x ∈ S)
\( \exists S. (Set(S) \land \neg \exists x. x \in S) \)

\( \exists S. (Set(S) \land \\
\quad \text{there are no elements in } S \\
) \)
\[ \exists S. \ (Set(S) \land \neg \exists x. \ x \in S) \]

\[ \exists S. \ (Set(S) \land \neg \exists x. \ x \in S) \]

\[ \exists S. \ (Set(S) \land \\
    \text{every object does not belong to } S \\
) \]
\[ \exists S. (Set(S) \land \neg \exists x. x \in S) \]

\[ \exists S. (Set(S) \land \neg \exists x. x \in S) \]

\[ \exists S. (Set(S) \land \\
\text{every object } x \text{ does not belong to } S \]
\]
∃S. (Set(S) \land \neg \exists x. x \in S)

∃S. (Set(S) \land \\
    \forall x. x \notin S
)
\[ \exists S. (\text{Set}(S) \land \neg \exists x. \ x \in S) \]

\[ \exists S. (\text{Set}(S) \land \forall x. \ x \notin S) \]
Both of these translations are correct. Just like in propositional logic, there are many different equivalent ways of expressing the same statement in first-order logic.
\exists S. (Set(S) \land \neg \exists x. x \in S)

\exists S. (Set(S) \land \forall x. x \notin S)
\[\exists S. (\text{Set}(S) \land \neg \exists x. x \in S)\]

\[\exists S. (\text{Set}(S) \land \forall x. x \notin S)\]

Why can we switch which quantifier we’re using here?

</table>
Negating First-Order Statements

• Use the equivalences

\[ \neg \forall x. A \quad \text{is equivalent to} \quad \exists x. \neg A \]
\[ \neg \exists x. A \quad \text{is equivalent to} \quad \forall x. \neg A \]

to negate quantifiers.

• Mechanically:
  • Push the negation across the quantifier.
  • Change the quantifier from \( \forall \) to \( \exists \) or vice-versa.
• Use techniques from propositional logic to negate connectives.
Taking a Negation

\[ \forall x. \exists y. \text{Loves}(x, y) \]
\[ ("Everyone loves someone.") \]

\[ \neg \forall x. \exists y. \text{Loves}(x, y) \]
\[ \exists x. \neg \exists y. \text{Loves}(x, y) \]
\[ \exists x. \forall y. \neg \text{Loves}(x, y) \]
\[ ("There's someone who doesn't love anyone.") \]
Two Useful Equivalences

- The following equivalences are useful when negating statements in first-order logic:
  \[-(p \land q) \text{ is equivalent to } p \rightarrow \neg q\]
  \[-(p \rightarrow q) \text{ is equivalent to } p \land \neg q\]

- These identities are useful when negating statements involving quantifiers.
  - \(\land\) is used in existentially-quantified statements.
  - \(\rightarrow\) is used in universally-quantified statements.
  
- When pushing negations across quantifiers, we strongly recommend using the above equivalences to keep \(\rightarrow\) with \(\forall\) and \(\land\) with \(\exists\).
Negating Quantifiers

• What is the negation of the following statement, which says “there is a cute puppy”?

\[ \exists x. \text{(Puppy}(x) \land \text{Cute}(x)) \]

• We can obtain it as follows:

\[ \neg \exists x. \text{(Puppy}(x) \land \text{Cute}(x)) \]
\[ \forall x. \neg \text{(Puppy}(x) \land \text{Cute}(x)) \]
\[ \forall x. \text{(Puppy}(x) \rightarrow \neg \text{Cute}(x)) \]

• This says “no puppy is cute.”

• Do you see why this is the negation of the original statement from both an intuitive and formal perspective?
\[ \exists S. (\text{Set}(S) \land \forall x. \neg (x \in S)) \]  
("There is a set with no elements.")

\[ \neg \exists S. (\text{Set}(S) \land \forall x. \neg (x \in S)) \]
\[ \forall S. \neg (\text{Set}(S) \land \forall x. \neg (x \in S)) \]
\[ \forall S. (\text{Set}(S) \rightarrow \neg \forall x. \neg (x \in S)) \]
\[ \forall S. (\text{Set}(S) \rightarrow \exists x. \neg \neg (x \in S)) \]
\[ \forall S. (\text{Set}(S) \rightarrow \exists x. x \in S) \]
("Every set contains at least one element.")
Restricted Quantifiers
Quantifying Over Sets

- The notation
  \[ \forall x \in S. \ P(x) \]
  means "for any element \( x \) of set \( S \), \( P(x) \) holds." (It’s vacuously true if \( S \) is empty.)

- The notation
  \[ \exists x \in S. \ P(x) \]
  means "there is an element \( x \) of set \( S \) where \( P(x) \) holds." (It’s false if \( S \) is empty.)
Quantifying Over Sets

• The syntax

\[ \forall x \in S. \ P(x) \]
\[ \exists x \in S. \ P(x) \]

is allowed for quantifying over sets.

• In CS103, feel free to use these restricted quantifiers, but please do not use variants of this syntax.

• For example, don't do things like this:

⚠ \[ \forall x \text{ with } P(x). \ Q(x) \] ⚠
⚠ \[ \forall y \text{ such that } P(y) \land Q(y). \ R(y). \] ⚠
⚠ \[ \exists P(x). \ Q(x) \] ⚠
Expressing Uniqueness
Using the predicate

- \textit{WayToFindOut}(w), which states that \(w\) is a way to find out,

write a sentence in first-order logic that means “there is only one way to find out.”
There is only one way to find out.
Something is a way to find out, and nothing else is.
Some thing w is a way to find out, and nothing else is.
Some thing $w$ is a way to find out, and nothing besides $w$ is a way to find out
\[ \exists w. \ (\text{WayToFindOut}(w) \land \text{nothing besides } w \text{ is way to find out}) \]
∃w. (WayToFindOut(w) ∧ anything that isn't w isn't a way to find out)
\[ \exists w.\ (\text{WayToFindOut}(w) \land \text{any thing } x \text{ that isn't } w \text{ isn't a way to find out}) \]
\( \exists w. \ (\text{WayToFindOut}(w) \land \ \\
\forall x. \ (x \neq w \rightarrow x \ isn't \ a \ way \ to \ find \ out) \) \)
\[ \exists w. \ (WayToFindOut(w) \land \\
\forall x. (x \neq w \rightarrow \neg WayToFindOut(x)) \]
∃w. (WayToFindOut(w) \land
    \forall x. (x \neq w \rightarrow \neg WayToFindOut(x)) )
$\exists w. \ (WayToFindOut(w) \land$

$\forall x. \ (WayToFindOut(x) \rightarrow x = w)$

)}
\[ \exists w. (WayToFindOut(w) \land \\
\forall x. (WayToFindOut(x) \rightarrow x = w) \) \]
Expressing Uniqueness

• To express the idea that there is exactly one object with some property, we write that
  • there exists at least one object with that property, and that
  • there are no other objects with that property.

• You sometimes see a special “uniqueness quantifier” used to express this:
  \( \exists!x. P(x) \)

• For the purposes of CS103, please do not use this quantifier. We want to give you more practice using the regular \( \forall \) and \( \exists \) quantifiers.
