

Section Solutions 2

Problem One: Iteration Station

```
void iterateVec1(const Vector<int>& vals) {  
    for (int i = 0; i < vals.size(); i++) {  
        cout << vals[i] << endl;  
    }  
}
```

This one works just fine!

```
void iterateVec2(const Vector<int>& vals) {  
    for (int i: vals) {  
        cout << vals[i] << endl;  
    }  
}
```

This code will likely crash at runtime. The variable *i* here refers to a *value* in the *Vector*, not an *index* in the *Vector*, so using it as an index will jump to a spot that wasn't designed to be an index.

```
void iterateVec3(const Vector<int>& vals) {  
    for (int i: vals) {  
        cout << i << endl;  
    }  
}
```

This code works just fine!

```
void iterateSet1(const HashSet<int>& vals) {  
    for (int i = 0; i < vals.size(); i++) {  
        cout << vals[i] << endl;  
    }  
}
```

This code won't compile. You can't get individual elements of a *HashSet* by index using the square bracket operator.

```
void iterateSet2(const HashSet<int>& vals) {  
    for (int i: vals) {  
        cout << i << endl;  
    }  
}
```

This code works just fine!

```
void iterateStack1(const Stack<int>& s) {  
    for (int i = 0; i < s.size(); i++) {  
        cout << s.pop() << endl;  
    }  
}
```

This code won't compile. The *Stack* here is passed in by *const* reference, which means that it can't be modified. However, calling *.pop()* modifies the stack.

```
void iterateStack2(Stack<int> s) {  
    for (int i = 0; i < s.size(); i++) {  
        cout << s.pop() << endl;  
    }  
}
```

This one fails for a subtle reason. Each iteration of the loop decreases *s.size()* by one. Coupled with the fact that *i* is increasing by one at each point, this will only look at the first half of the stack.

```
void iterateStack3(Stack<int> s) {  
    while (!s.isEmpty()) {  
        cout << s.pop() << endl;  
    }  
}
```

This code works just fine! It does make a copy of the *Stack*, but that's okay given that the only way to see everything in a stack is to destructively modify it.

Problem Two: Debugging Deduplicating

There are three errors here:

1. Calling `.remove()` on the `Vector` while iterating over it doesn't work particularly nicely. Specifically, if you remove the element at index `i` and then increment `i` in the `for` loop, you'll skip over the element that shifted into the position you were previously in.
2. There's an off-by-one error here: when `i = vec.size() - 1`, the indexing `vec[i + 1]` reads off the end of the `Vector`.
3. The `Vector` is passed in by value, not by reference, so none of the changes made to it will persist to the caller.

Here's a corrected version of the code:

```
void deduplicate(Vector<string>& vec) {
    for (int i = 0; i < vec.size() - 1; ) {
        if (vec[i] == vec[i + 1]) {
            vec.remove(i);
        } else {
            i++;
        }
    }
}
```

Problem Three: References Available Upon Request

Topics: Reference parameters, range-based for loops

Here's the output from the program:

```
1 3 7
1 3 7
2 4 8
2 4 8
```

Here's a breakdown of where this comes from:

- The `maui` function takes its argument by value, so it's making changes to a copy of the original vector, not the vector itself. That means that the values are unchanged back in `main`.
- The `moana` function uses a range-based `for` loop to access the elements of the vector. This makes a *copy* of each element of the vector, so the changes made in the loop only change the temporary copy and not the elements of the vector. That makes that the values are unchanged back in `main`.
- `heihei`, on the other hand, uses `int&` as its type for the range-based `for` loop, so in a sense it's really iterating over the elements of the underlying vector. Therefore, its changes stick.
- The `teFiti` function creates and returns a new vector with a bunch of updated values, but the return value isn't captured back in `main`.

Problem Four: Another Way to Find the Maximum

You can think of what's being done here as staging an elimination tournament. We pair off all the elements of the original vector against one another, eliminating the smaller of the two elements. The elements of the winners vector are the elements that "won" their game. To find the maximum element of that vector, we then recursively use `maxOf` to find the biggest value.

There's an edge case that's handled in the for loop that accounts for the case where there's an odd number of elements in the vector. In that case, the last element is always promoted to the next round. (I guess it got a bye in the tournament?)

Problem Five: The New Org Chart

Here's one possible implementation:

```
/* Given a person and the map of the bosses, returns the CEO of the company
 * that the indicated person works for
 *
 * We've taken in person by value rather than by reference here because inside
 * the body of the function we need to change its value, but we don't want to
 * change the value back in the caller.
 */
string ceoOf(string person, const HashMap<string, string>& bosses) {
    while (bosses.containsKey(person)) {
        person = bosses[person];
    }
    return person;
}

bool areAtSameCompany(const string& p1,
                    const string& p2,
                    const HashMap<string, string>& bosses) {
    return ceoOf(p1, bosses) == ceoOf(p2, bosses);
}
```

Problem Six: Xzibit Words

One possible implementation is shown here:

```
string mostXzibitWord(const Lexicon& words) {
    /* Track the best string we've found so far and how many subwords it has. */
    string result;
    int numSubwords = 0;

    for (string word: words) {
        /* Store all the subwords we find. To avoid double-counting
         * words, we'll hold this in a Lexicon.
         */
        Lexicon ourSubwords;

        /* Consider all possible start positions. */
        for (int start = 0; start < word.length(); start++) {
            /* Consider all possible end positions. Note that we include
             * the string length itself, since that way we can consider
             * substrings that terminate at the end of the string.
             */
            for (int stop = start; stop <= word.length(); stop++) {
                /* Note the C++ way of getting a substring. */
                string candidate = word.substr(start, stop - start);

                /* As an optimization, if this isn't a prefix of any legal
                 * word, then there's no point in continuing to extend this
                 * substring.
                 */
                if (!words.containsPrefix(candidate)) break;

                /* If this is a word, then record it as a subword. */
                if (words.contains(candidate)) {
                    ourSubwords.add(candidate);
                }
            }
        }

        /* Having found all subwords, see if this is better than our
         * best guess so far.
         */
        if (numSubwords < ourSubwords.size()) {
            result = word;
            numSubwords = ourSubwords.size();
        }
    }

    return result;
}
```

In case you're curious, the most Xzibit word is “foreshadowers,” with 34 subwords!

Problem Seven: Jaccard Similarity

```
/* Given a Queue<string>, produces a string representing the k-grams it
 * contains. We take our parameter by value because the only way to read a queue
 * is to destructively modify it.
 */
string queueToString(Queue<string> kGram) {
    string result;
    while (!kGram.isEmpty()) {
        /* If we already had something before us, add a space. */
        if (result != "") result += " ";
        result += kGram.dequeue();
    }
    return result;
}

/* Returns a set of all the k-grams in the given input stream, represented as
 * strings.
 */
HashSet<string> kGramsIn(istream& input, int k) {
    /* Validate the input. */
    if (k <= 0) error("k must be positive.");

    TokenScanner scanner(input);
    scanner.addWordCharacters(""); // Not necessary, but nice!

    /* We're going to store the last k word tokens read in in this queue.
     * This makes it easy to shift in and shift out new words into our k-gram.
     */
    Queue<string> kGram;
    HashSet<string> result;

    while (scanner.hasMoreTokens()) {
        string token = scanner.next_token();
        if (scanner.getTokenType(token) == WORD) {
            kGram.enqueue(token);

            /* If this brought us up to size k, output what we have, then kick
             * out the oldest element so that we're down to size k - 1. The next
             * word token we find will then refresh us to capacity.
             */
            if (kGram.size() == k) {
                result.add(queueToString(kGram));
                (void) kGram.dequeue(); // Ignore return value
            }
        }
    }

    return result;
}

/* The set of all the words in the stream is just the set of 1-grams. Nifty! */
HashSet<string> wordsIn(istream& input) {
    return kGramsIn(input, 1);
}
```

```

/* Prompts the user for the size of a k-gram to use. */
int chooseKGramSize() {
    while (true) {
        int result = getInteger("Enter k: ");
        if (result > 0) return result;

        cout << "Please enter a positive integer." << endl;
    }
}

/* Prompts the user for a filename, then returns the k-grams in that file. */
HashSet<string> contentsOfUserFileChoice(int k) {
    ifstream input;
    promptUserForFilename(input, "Enter filename: ");
    return kGramsIn(input, k);
}

int main() {
    int k = chooseKGramSize();
    HashSet<string> s1 = contentsOfUserFileChoice(k);
    HashSet<string> s2 = contentsOfUserFileChoice(k);

    /* Compute |S1 n S2| and |S1 u S2| using the overloaded * and + operators. */
    double intersectSize = (s1 * s2).size();
    double unionSize     = (s1 + s2).size();

    cout << "Jaccard similarity: " << intersectSize / unionSize << endl;
    return 0;
}

```
