The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2733. If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

**Operation for all encodings**

The description of LDM, LDMIA, LDMFD gives the operational pseudocode for this instruction.
F5.1.137  POP (single register)

Pop Single Register from Stack loads a single general-purpose register from the stack, loading from the address in SP, and updates SP to point just above the loaded data.

This instruction is an alias of the LDR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of LDR (immediate).
- The description of LDR (immediate) gives the operational pseudocode for this instruction.

**A1**

![Binary representation]

**Post-indexed variant**

`POP{<c>}{<q>} <single_register_list>`

is equivalent to

`LDR{<c>}{<q>} <Rt>, [SP], #4`

and is always the preferred disassembly.

**T4**

![Binary representation]

**Post-indexed variant**

`POP{<c>}{<q>} <single_register_list>`

is equivalent to

`LDR{<c>}{<q>} <Rt>, [SP], #4`

and is always the preferred disassembly.

**Assembler symbols**

- `<c>`  
  See Standard assembler syntax fields on page F2-2848.

- `<q>`  
  See Standard assembler syntax fields on page F2-2848.

- `<single_register_list>`
  Is the general-purpose register `<Rt>` to be loaded surrounded by `{ and `}`.

- `<Rt>`
  For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
For encoding T4: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.

**Operation for all encodings**

The description of LDR (immediate) gives the operational pseudocode for this instruction.
F5.1.138   PUSH

Push Multiple Registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2855.

T1

| 15 14 13 12| 11 10  9  8  7 |   0 |
| 1  0  1  1 | 0  1  0 | M | register_list |

T1 variant

PUSH{<c>}{<q>} <registers> // Preferred syntax
STMDB{<c>}{<q>} SP!, <registers> // Alternate syntax

Decode for this encoding

registers = '0':M:'000000':register_list; UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;

CONSTRANDED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

Notes for all encodings

For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<e> See Standard assembler syntax fields on page F2-2848.
<q> See Standard assembler syntax fields on page F2-2848.
<registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the LR. If the LR is in the list, the "M" field is set to 1, otherwise this field defaults to 0.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    address = SP - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == 13 && i != LowestSetBit(registers) then // Only possible for encoding A1
                MemA[address,4] = bits(32) UNKNOWN;
else
  if UnalignedAllowed then
    MemU[address,4] = R[i];
  else
    MemA[address,4] = R[i];
  address = address + 4;
if registers<15> == '1' then  // Only possible for encoding A1 or A2
  if UnalignedAllowed then
    MemU[address,4] = PCStoreValue();
  else
    MemA[address,4] = PCStoreValue();
  SP = SP - 4*BitCount(registers);
F5.1.139  PUSH (multiple registers)

Push multiple registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

This instruction is an alias of the STMDB, STMFD instruction. This means that:

- The encodings in this description are named to match the encodings of STMDB, STMFD.
- The description of STMDB, STMFD gives the operational pseudocode for this instruction.

#### T1 variant

PUSH{<c>}.W <registers> // All registers in R0-R7, LR

is equivalent to

STMDB{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount(M:register_list) > 1.

PUSH{<c>}{<q>} <registers>

is equivalent to

STMDB{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount(M:register_list) > 1.

### Assembler symbols

- `<c>`  See Standard assembler syntax fields on page F2-2848.
- `<q>`  See Standard assembler syntax fields on page F2-2848.
- `<registers>`  For encoding A1: is a list of two or more registers to be stored, separated by commas and surrounded by `{ `and `}`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2855.
The SP and PC can be in the list. However:

- ARM deprecates the use of instructions that include the PC in the list.
- If the SP is in the list, and it is not the lowest-numbered register in the list, the instruction stores an **UNKNOWN** value for the SP.

For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC on page F2-2855.*

The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

**Operation for all encodings**

The description of STMDB, STMFD gives the operational pseudocode for this instruction.
F5.1.140   PUSH (single register)

Push Single Register to Stack stores a single general-purpose register to the stack, storing to the 32-bit word below the address in SP, and updates SP to point to the start of the stored data.

This instruction is an alias of the STR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of STR (immediate).
- The description of STR (immediate) gives the operational pseudocode for this instruction.

<Rn>  Is the second general-purpose source register, encoded in the "Rn" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  (doubled, sat1) = SignedSatQ(2 * SInt(R[n]), 32);
(R[d], sat2) = SignedSatQ(SInt(R[m]) + SInt(doubled), 32);
if sat1 || sat2 then
    PSTATE.Q = '1';
F5.1.146  QDSUB

Saturating Double and Subtract subtracts a doubled register value from another register value, and writes the result to the destination register. Both the doubling and the subtraction have their results saturated to the 32-bit signed integer range \(-2^{31} \leq x \leq 2^{31} - 1\). If saturation occurs in either operation, it sets PSTATE.Q to 1.

<td></td>
</tr>
</tbody>
</table>

T2 variant

REVSH{<c>}.W <Rd>, <Rm> // <Rd>, <Rm> can be represented in T1
REVSH{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd);  m = UInt(Rm);  n = UInt(Rn);
if m != n || d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONstrained UNPREDICTABLE behavior

If m != n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
• The instruction executes with the additional decode: \( m = \text{UInt}(Rn); \).

• The instruction executes with the additional decode: \( m = \text{UInt}(Rm); \).

• The value in the destination register is \text{UNKNOWN}.

Notes for all encodings

For more information about the \text{CONSTRAINED UNPREDICTABLE} behavior of this instruction, see Appendix K1 \text{Architectural Constraints on UNPREDICTABLE behaviors}.

Assembler symbols

<
\text{See Standard assembler syntax fields on page F2-2848}.

>
\text{See Standard assembler syntax fields on page F2-2848}.

<Rd>
Is the general-purpose destination register, encoded in the "Rd" field.

<Rm>
For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field.

For encoding T2: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation for all encodings

\begin{verbatim}
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    result<31:8> = SignExtend(R[m]<7:0>, 24);
    result<7:0> = R[m]<15:8>;
    R[d] = result;
\end{verbatim}
F5.1.155 RFE, RFEDA, RFEDB, RFEIA, RFEIB

Return From Exception loads two consecutive memory locations using an address in a base register:

- The word loaded from the lower address is treated as an instruction address. The PE branches to it.
- The word loaded from the higher address is used to restore PSTATE. This word must be in the format of an SPSR.

An address adjusted by the size of the data loaded can optionally be written back to the base register.

The PE checks the value of the word loaded from the higher address for an illegal return event. See Illegal return events from AArch32 state on page G1-4361.

RFE is UNDEFINED in Hyp mode and CONSTRAINED UNPREDICTABLE in User mode.

\end{align*}
\]

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

IA

For encoding A1: is an optional suffix to indicate the Increment After variant.

For encoding T2: is an optional suffix for the Increment After form.

<c>

For encoding A1: see Standard assembler syntax fields on page F2-2848. <c> must be AL or omitted.

For encoding T1 and T2: see Standard assembler syntax fields on page F2-2848.

<q>

See Standard assembler syntax fields on page F2-2848.

<Rn>

Is the general-purpose base register, encoded in the "Rn" field.

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

RFEFA, RFEEA, RFEOF, and RFEED are pseudo-instructions for RFEDA, RFEDB, RFEIA, and RFEIB respectively, referring to their use for popping data from Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation for all encodings

\[
\begin{align*}
\text{if } \text{ConditionPassed()} \text{ then} \\
\text{EncodingSpecificOperations();} \\
\text{if } \text{PSTATE.EL} \text{ == EL2 then} \\
\text{UNDEFINED;} \\
\text{elsif } \text{PSTATE.EL} \text{ == EL0 then} \\
\text{UNPREDICTABLE; // UNDEFINED or NOP} \\
\text{else} \\
\text{address} = \text{if increment then R[n] else R[n]-8;} \\
\text{if wordhigher then address = address+4;} \\
\text{new\_pc\_value = MemA[address,4];} \\
\text{spsr = MemA[address+4,4];} \\
\text{if wback then R[n] = if increment then R[n]+8 else R[n]-8;} \\
\text{AArch32.ExceptionReturn(new\_pc\_value, spsr);} \\
\end{align*}
\]
CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
F5.1.156  ROR (immediate)

Rotate Right (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

A1

ROR{<c>}{<q>} {<Rd>,} <Rm>, #<imm>

is equivalent to
MOV{<c>}{<q>} <Rd>, <Rm>, ROR #<imm>

and is always the preferred disassembly.

T3

ROR{<c>}{<q>} {<Rd>,} <Rm>, #<imm>

is equivalent to
MOV{<c>}{<q>} <Rd>, <Rm>, ROR #<imm>

and is always the preferred disassembly.

Assembler symbols

- `<c>` See Standard assembler syntax fields on page F2-2848.
- `<p>` See Standard assembler syntax fields on page F2-2848.
- `<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
- `<Rm>` For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
- For encoding T3: is the general-purpose source register, encoded in the "Rm" field.
For encoding A1: is the shift amount, in the range 1 to 31, encoded in the "imm5" field.
For encoding T3: is the shift amount, in the range 1 to 31, encoded in the "imm3:imm2" field.

Operation for all encodings

The description of MOV, MOVV (register) gives the operational pseudocode for this instruction.
F5.1.157   ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

A1

Not flag setting variant

ROR{<c>}{<q>} {<Rd>,} <Rm>, <Rs>
is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>
and is always the preferred disassembly.

T1

Rotate right variant

ROR{<c>}{<q>} {<Rdm>,} <Rdm>, <Rs> // Inside IT block
is equivalent to

MOV{<c>}{<q>} <Rdm>, <Rdm>, ROR <Rs>
and is the preferred disassembly when InITBlock().

T2

Not flag setting variant

ROR{<c>}.W {<Rd>,} <Rm>, <Rs> // Inside IT block, and <Rd>, <Rm>, <type>, <Rs> can be represented in T1
is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>
ROR{<c>}{<q>} {<Rd>,} <Rm>, <Rs>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

**Assembler symbols**

- `<c>`: See *Standard assembler syntax fields* on page F2-2848.
- `<q>`: See *Standard assembler syntax fields* on page F2-2848.
- `<Rdm>`: Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.
- `<Rd>`: Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rm>`: Is the first general-purpose source register, encoded in the "Rm" field.
- `<Rs>`: Is the second general-purpose source register holding a rotate amount in its bottom 8 bits, encoded in the "Rs" field.

**Operation for all encodings**

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.
F5.1.158   RORS (Immediate)

Rotate Right, setting flags (Immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-4361.
- The instruction is UNEFIND in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field.

For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T3: is the general-purpose source register, encoded in the "Rm" field.

**Operation for all encodings**

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.
**F5.1.162 RSB, RSBS (immediate)**

Reverse Subtract (immediate) subtracts a register value from an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the RSBS variant of the instruction updates the condition flags based on the result.

The field descriptions for `<Rd>` identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSB variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2733.
- The RSBS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
  - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-4361.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

\(\langle c \rangle\)
See Standard assembler syntax fields on page F2-2848.

\(\langle p \rangle\)
See Standard assembler syntax fields on page F2-2848.

\(\langle R_d \rangle\)
For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(\langle R_n \rangle\). ARM deprecates using the PC as the destination register, but if the PC is used:

- For the RSB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
- For the RSBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_\_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(\langle R_n \rangle\).

\(\langle R_n \rangle\)
For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.
<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, '1');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```
F5.1.164   RSB, RSBS (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

Assembler symbols

- $<c>$  
  See Standard assembler syntax fields on page F2-2848.
- $<q>$  
  See Standard assembler syntax fields on page F2-2848.
- $<Rd>$  
  Is the general-purpose destination register, encoded in the "Rd" field.
- $<Rn>$  
  Is the first general-purpose source register, encoded in the "Rn" field.
- $<Rm>$  
  Is the second general-purpose source register, encoded in the "Rm" field.
- $<type>$  
  Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
  - LSL  when type = 00
  - LSR  when type = 01
  - ASR  when type = 10
  - ROR  when type = 11
- $<Rs>$  
  Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
F5.1.165 RSC, RSCS (immediate)

Reverse Subtract with Carry (immediate) subtracts a register value and the value of NOT (Carry flag) from an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the RSCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
- The RSCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-4361.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

### Flag setting variant

Applies when $S = 1$.

RSCS{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

### Not flag setting variant

Applies when $S = 0$.

RSC{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

### Decode for all variants of this encoding

\[
d = \text{UInt}(Rd); \quad n = \text{UInt}(Rn); \quad m = \text{UInt}(Rm); \quad s = \text{UInt}(Rs);
setflags = (S == '1'); \quad \text{shift}_t = \text{DecodeRegShift}(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
\]

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

### Assembler symbols

- `<c>`  
  See Standard assembler syntax fields on page F2-2848.
- `<q>`  
  See Standard assembler syntax fields on page F2-2848.
- `<Rd>`  
  Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>`  
  Is the first general-purpose source register, encoded in the "Rn" field.
- `<Rm>`  
  Is the second general-purpose source register, encoded in the "Rm" field.
- `<type>`  
  Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
  - LSL when type = 00
  - LSR when type = 01
  - ASR when type = 10
  - ROR when type = 11
- `<Rs>`  
  Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
SADD16

Signed Add 16 performs two 16-bit signed integer additions, and writes the results to the destination register. It sets PSTATE.GE according to the results of the additions.

PSTATE.GE<1:0> = if diff >= 0 then '11' else '00';  
PSTATE.GE<3:2> = if sum >= 0 then '11' else '00';
SBC, SBCS (immediate)

Subtract with Carry (immediate) subtracts an immediate value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SBCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The SBC variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
- The SBCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-4361.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<<>>  See Standard assembler syntax fields on page F2-2848.
<ap>  See Standard assembler syntax fields on page F2-2848.
<Rdn>  Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.
<Rd>  For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:
  • For the SBC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
  • For the SBCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.
For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
<Rn>  For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.
<Rm>  For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.
<shift>  Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
  LSL  when type = 00
  LSR  when type = 01
  ASR  when type = 10
  ROR  when type = 11
<amount>  For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzcv) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);

\]

setflags = (S == '1');  shift_t = DecodeRegShift(type);

if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

- \(<c>\)  See Standard assembler syntax fields on page F2-2848.
- \(<q>\)  See Standard assembler syntax fields on page F2-2848.
- \(<Rd>\)  Is the general-purpose destination register, encoded in the "Rd" field.
- \(<Rn>\)  Is the first general-purpose source register, encoded in the "Rn" field.
- \(<Rm>\)  Is the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{type}>\)  Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
  - LSL when type = 00
  - LSR when type = 01
  - ASR when type = 10
  - ROR when type = 11
- \(<\text{Rs}>\)  Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
F5.1.174   SBFX

Signed Bit Field Extract extracts any number of adjacent bits at any position from a register, sign-extends them to 32 bits, and writes the result to the destination register.

if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<> See Standard assembler syntax fields on page F2-2848.
<q> See Standard assembler syntax fields on page F2-2848.
<Rd> Is the general-purpose destination register, encoded in the "Rd" field.
<Rn> Is the general-purpose source register, encoded in the "Rn" field.
<lsb> For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.
For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.
<width> Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = SignExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;

CONSTRANGED UNPREDICTABLE behavior

If msbit > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.
F5.1.175   SDIV

Signed Divide divides a 32-bit signed integer register value by a 32-bit signed integer register value, and writes the result to the destination register. The condition flags are not affected.

A1

```
|31| 28|27|26|25|24|23|22|21|20|19|16|15|12|11| 8| 7| 6| 5| 4| 3| 0|

Ra |
```

**T1 variant**

SDIV{<c>}{<q>} {<Rd>,} <Rn>, <Rm>

**Decode for this encoding**

\[
d = \text{UInt}(Rd); \ n = \text{UInt}(Rn); \ m = \text{UInt}(Rm); \ a = \text{UInt}(Ra);
\]
\[
\text{if } d = 15 \text{ || } n = 15 \text{ || } m = 15 \text{ || } a \neq 15 \text{ then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If Ra != '1111', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes as described, and the register specified by Ra becomes UNKNOWN.
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

- `<c>` See Standard assembler syntax fields on page F2-2848.
- `<q>` See Standard assembler syntax fields on page F2-2848.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rn>` Is the first general-purpose source register holding the dividend, encoded in the "Rn" field.
- `<Rm>` Is the second general-purpose source register holding the divisor, encoded in the "Rm" field.

Overflow

If the signed integer division `0x80000000 / 0xFFFFFFFF` is performed, the pseudocode produces the intermediate integer result `+2^{31}`, that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to `<Rd>` must be the bottom 32 bits of the binary representation of `+2^{31}`. So the result of the division is `0x80000000`.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    if SInt(R[m]) == 0 then
        result = 0;
    else
        result = RoundTowardsZero(Real(SInt(R[n])) / Real(SInt(R[m])));
    R[d] = result<31:0>;
F5.1.176 SEL

Select Bytes selects each byte of its result from either its first operand or its second operand, according to the values of the PSTATE.GE flags.

F5.1.187   SMC

Secure Monitor Call causes a Secure Monitor Call exception. For more information see Secure Monitor Call (SMC) exception on page G1-4382.

SMC is available only for software executing at EL1 or higher. It is UNDEFINED in User mode.

If the values of HCR.TSC and SCR.SCD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception that is taken to EL3. When EL3 is using AArch32 this exception is taken to Monitor mode. When EL3 is using AArch64, it is the SCR_EL3.SMD bit, rather than the SCR.SCD bit, that can change the effect of executing an SMC instruction.

If the value of HCR.TSC is 1, execution of an SMC instruction in a Non-secure EL1 mode generates an exception that is taken to EL2, regardless of the value of SCR.SCD. When EL2 is using AArch32, this is a Hyp Trap exception that is taken to Hyp mode. For more information see Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-4434.

If the value of HCR.TSC is 0 and the value of SCR.SCD is 1, the SMC instruction is:

- UNDEFINED in Non-secure state.
- CONSTRAINED UNPREDICTABLE if executed in Secure state at EL1 or higher.

SMC{<c>}{<q>} {#}<imm4>

**Decode for this encoding**

// imm4 is for assembly/disassembly only and is ignored by hardware

if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-2848.
\(<q>\) See Standard assembler syntax fields on page F2-2848.
\(<\text{imm4}>\) Is a 4-bit unsigned immediate value, in the range 0 to 15, encoded in the "imm4" field. This is ignored by the PE. The Secure Monitor Call exception handler (Secure Monitor code) can use this value to determine what service is being requested, but ARM does not recommend this.

Operation for all encodings

if \(\text{ConditionPassed()}\) then
  \(\text{EncodingSpecificOperations()};\)
  if !\(\text{HaveEL(EL3)}\) || \(\text{PSTATE.EL} = \text{EL0}\) then
    \(\text{UNDEFINED};\)
  \(\text{AArch32.CheckForSMCTrap();}\)
  if !\(\text{ELUsingAArch32(EL3)}\) then
    if \(\text{SCR.EL3.SMD} = '1'\) then
      \(\text{/// SMC disabled.}\)
      \(\text{UNDEFINED};\)
  else
    if \(\text{SCR.SCD} = '1'\) then
      \(\text{/// SMC disabled}\)
      if \(\text{IsSecure()}\) then
        \(\text{// Executes either as a NOP or UNALLOCATED.}\)
        \(\text{c = ConstrainUnpredictable(Unpredictable_SMD);}\)
        \(\text{assert c IN \{Constraint_NOP, Constraint_UNDEF\};}\)
        if \(c = \text{Constraint_NOP}\) then \(\text{EndOfInstruction();}\)
        \(\text{UNDEFINED};\)
    if !\(\text{ELUsingAArch32(EL3)}\) then
      \(\text{AArch64.CallSecureMonitor(Zeros(16));}\)
    else
      \(\text{AArch32.TakeSMCException();}\)

CONstrained UNpREDICTABLE behavior

If \(\text{SCR.SCD} = '1' \&\& \text{IsSecure()}\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
F5.1.188   SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on
two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The
other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the
result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets PSTATE.Q to 1. It is not possible
for overflow to occur during the multiplication.

    result = SInt(R[n]) * SInt(R[m]) + SInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        PSTATE.N = result<63>;
        PSTATE.Z = IsZeroBit(result<63:0>);
        // PSTATE.C, PSTATE.V unchanged
```
SMLALBB, SMLALBT, SMLALTB, SMLALTT

Signed Multiply Accumulate Long (halfwords) multiplies two signed 16-bit values to produce a 32-bit value, and accumulates this with a 64-bit value. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is sign-extended and accumulated with a 64-bit accumulate value.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo 2^64.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    result = (SInt(R[a]) << 32) + SInt(R[n]) * SInt(R[m]);
    if round then result = result + 0x80000000;
    R[d] = result<63:32>;}
F5.1.197  SMMLS, SMMLSR

Signed Most Significant Word Multiply Subtract multiplies two signed 32-bit values, subtracts the result from a 32-bit accumulate value that is shifted left by 32 bits, and extracts the most significant 32 bits of the result of that subtraction.

Optionally, the instruction can specify that the result of the instruction is rounded instead of being truncated. In this case, the constant \(0x80000000\) is added to the result of the subtraction before the high word is extracted.

F5.1.199 SMUAD, SMUADX

Signed Dual Multiply Add performs two signed 16 x 16-bit multiplications. It adds the products together, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets PSTATE.Q to 1 if the addition overflows. The multiplications cannot overflow.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

\(<c>\)  
See *Standard assembler syntax fields* on page F2-2848.

\(<q>\)  
See *Standard assembler syntax fields* on page F2-2848.

\(<Rd>\)  
Is the general-purpose destination register, encoded in the "Rd" field.

\(<Rn>\)  
Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

\(<Rm>\)  
Is the second general-purpose source register holding the multiplier in the bottom or top half (selected by \(<y>\)), encoded in the "Rm" field.

Operation for all encodings

if *ConditionPassed()* then
  EncodingSpecificOperations();
  operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
  product = SInt(R[n]) * SInt(operand2);
  R[d] = product<47:16>;
  // Signed overflow cannot occur
F5.1.203   SMUSD, SMUSDX

Signed Multiply Subtract Dual performs two signed 16 x 16-bit multiplications. It subtracts one of the products from the other, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

Overflow cannot occur.

F5.1.204  SRS, SRSDA, SRSDB, SRSIA, SRSIB

Store Return State stores the LR_<current_mode> and SPSR_<current_mode> to the stack of a specified mode. For information about memory accesses see Memory accesses on page F2-2854.

SRS is UNDEFINED in Hyp mode.

SRS is CONSTRAINED UNPREDICTABLE if it is executed in User or System mode, or if the specified mode is any of the following:

- Not implemented.
- A mode that Table G1-5 on page G1-4322 does not show.
- Hyp mode.
- Monitor mode, if the SRS instruction is executed in Non-secure state.

If EL3 is using AArch64 and an SRS instruction that is executed in a Secure EL1 mode specifies Monitor mode, it is trapped to EL3.

See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1870.

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly SRS (T32) on page K1-6108 and SRS (A32) on page K1-6108.

Assembler symbols
IA
For encoding A1: is an optional suffix to indicate the Increment After variant.
For encoding T2: is an optional suffix for the Increment After form.

<>
For encoding A1: see Standard assembler syntax fields on page F2-2848. <> must be AL or omitted.
For encoding T1 and T2: see Standard assembler syntax fields on page F2-2848.

<op>
See Standard assembler syntax fields on page F2-2848.

!
The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<mode>
Is the number of the mode whose Banked SP is used as the base register, encoded in the "mode" field. For details of PE modes and their numbers see AArch32 PE mode descriptions on page G1-4322.

SRSFA, SRSEA, SRSFD, and SRSED are pseudo-instructions for SRSIB, SRSIA, SRSDB, and SRSDA respectively, referring to their use for pushing data onto Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

CONSTRANDED UNPREDICTABLE behavior
If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.

If mode == M32_Hyp, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.

If mode == M32_Monitor && (!HaveEL(EL3) || !IsSecure()), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.

If BadMode(mode), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
- The instruction stores to the stack of the mode in which it is executed.
- The instruction stores to an UNKNOWN address, and if the instruction specifies writeback then any general-purpose register that can be accessed from the current Exception level without a privilege violation becomes UNKNOWN.
F5.1.205  SSAT

Signed Saturate saturates an optionally-shifted signed value to a selectable signed range.

This instruction sets PSTATE.Q to 1 if the operation saturates.

A1

Arithmetic shift right variant
Applies when sh == 1.

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn>, ASR #<amount>

Logical shift left variant
Applies when sh == 0.

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, LSL #<amount>}

Decode for all variants of this encoding

if sh == '1' then SSAT16;
d = UInt(Rd); n = UInt(Rn); saturate_to = UInt(sat_imm)+1;
(shift_t, shift_n) = DecodedImmShift(sh:'0', imm5);
if d == 15 || n == 15 then UNPREDICTABLE;

T1

Arithmetic shift right variant
Applies when sh == 1 && !(imm3 == 000 && imm2 == 000).

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn>, ASR #<amount>

Logical shift left variant
Applies when sh == 0.

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, LSL #<amount>}

Decode for all variants of this encoding

if sh == '1' && (imm3:imm2) == '0000' then SEE SSAT16;
d = UInt(Rd); n = UInt(Rn); saturate_to = UInt(sat_imm)+1;
(shift_t, shift_n) = DecodedImmShift(sh:'0', imm3:imm2);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<> See *Standard assembler syntax fields on page F2-2848*.

<> See *Standard assembler syntax fields on page F2-2848*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<imm> Is the bit position for saturation, in the range 1 to 32, encoded in the "sat_imm" field as <imm>-1.

<Rn> Is the general-purpose source register, encoded in the "Rn" field.

<amount> For encoding A1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.

For encoding A1: is the shift amount, in the range 1 to 32 encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field.

For encoding T1: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as <amount>.

Operation for all encodings

```c
if ConditionPassed() then
  EncodingSpecificOperations();
  operand = Shift(R[n], shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
  (result, sat) = SignedSatQ(SInt(operand), saturate_to);
  R[d] = SignExtend(result, 32);
  if sat then
    PSTATE.Q = '1';
```
F5.1.206  SSAT16

Signed Saturate 16 saturates two signed 16-bit values to a selected signed range.

This instruction sets PSTATE.Q to 1 if the operation saturates.

A1

```

PSTATE.GE<3>  = if diff4 >= 0 then '1' else '0';
F5.2.10  STC

Store data to System register calculates an address from a base register value and an immediate offset, and stores a word from the DBGDTRRXint System register to memory. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses see Memory accesses on page F2-2854.

In an implementation that includes EL2, the permitted STC access to DBGDTRRXint can be trapped to Hyp mode, meaning that an attempt to execute an STC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see Trapping general Non-secure System register accesses to debug registers on page G1-4443.

For simplicity, the STC pseudocode does not show this possible trap to Hyp mode.

\]
\[
\text{if } n == 15 \&\& (\text{wback} || \text{CurrentInstrSet}() != \text{InstrSet_A32}) \text{ then UNPREDICTABLE;}
\]

CONstrained UNPredictable behavior
If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in Using R15 on page K1-6097.

Assembler symbols

<
See Standard assembler syntax fields on page F2-2848.

>
See Standard assembler syntax fields on page F2-2848.

<Rn>
For the offset or unindexed variant: is the general-purpose base register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For the offset, post-indexed or pre-indexed variant: is the general-purpose base register, encoded in the "Rn" field.

<option>
Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when \( U = 0 \)
+ when \( U = 1 \)

\(<imm>\) Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as \(<imm>/4\).

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CheckSystemAccess(cp, ThisInstr());
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];

    // System register read from DBGDTRRXint.
    MemA[address,4] = DBGDTR_EL0[];

    if wback then R[n] = offset_addr;
```

</tbody>
</table>

**Aborts and alignment**

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,4) then
        Memo[address, 4] = R[t];
```
R[d] = ZeroExtend('0');
else
R[d] = ZeroExtend('1');
F5.1.214   STLEXB

Store-Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to
the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was
performed.

The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release on page E2-2770.

For more information about support for shared memory see Synchronization and semaphores on page E2-2795. For
information about memory accesses see Memory accesses on page F2-2854.

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,1) then
        MemO[address, 1] = R[t]<7:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```
F5.1.215   STLEXD

Store-Release Exclusive Doubleword stores a doubleword from two registers to memory if the executing PE has
exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if
no store was performed.

The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release on page E2-2770.

For more information about support for shared memory see Synchronization and semaphores on page E2-2795. For
information about memory accesses see Memory accesses on page F2-2854.

A1

A1 variant

STLEXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

d = UInt(Rd);  t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);
if d == 15 || Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t || d == t2 then UNPREDICTABLE;

CONstrained UNPREDICTABLE behavior

If d == t, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The store instruction executes but the value stored is UNKNOWN.

If d == n, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction performs the store to an UNKNOWN address.

If Rt<0> == '1', then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes with the additional decode: Rt<0> = '0'.
• The instruction executes with the additional decode: t2 = t.
• The instruction executes as described, with no change to its behavior and no additional side effects.

If Rt = '1110', then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction is handled as described in Using R15 on page K1-6097.

**Decode for this encoding**

\[
d = \text{U} \text{Int}(Rd); \quad t = \text{U} \text{Int}(Rt); \quad t2 = \text{U} \text{Int}(Rt2); \quad n = \text{U} \text{Int}(Rn);
\]

\[
\text{if } d == 15 \text{ || } t == 15 \text{ || } t2 == 15 \text{ || } n == 15 \text{ then UNPREDICTABLE;}
\]

\[
\text{if } d == n \text{ || } d == t \text{ || } d == t2 \text{ then UNPREDICTABLE;}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If d == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If d == n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-2848.
- `<q>` See Standard assembler syntax fields on page F2-2848.
- `<Rd>` Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:
  - 0 If the operation updates memory.
  - 1 If the operation fails to update memory.
- `<Rt>` For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. `<Rt>` must be even-numbered and not R14.
  For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.
- `<Rt2>` For encoding A1: is the second general-purpose register to be transferred. `<Rt2>` must be `<R(t+1)>`.
  For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field.
**Aborts and alignment**

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    value = if BigEndian() then R[t]:R[t2] else R[t2]:R[t];
    if AArch32.ExclusiveMonitorsPass(address, 8) then
        MemO[address, 8] = value;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```
F5.1.216   STLEXH

Store-Release Exclusive Halfword stores a halfword from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2770.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2795. For information about memory accesses see *Memory accesses* on page F2-2854.

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.
If $\text{BitCount}(\text{registers}) == 1$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as $\text{NOP}$.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction operates as an $\text{STM}$ with the same addressing mode but targeting an unspecified set of registers. These registers might include $R15$.

If $\text{wback} \&\& \text{registers}<n> == 1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as $\text{NOP}$.
- The store instruction executes but the value stored for the base register is UNKNOWN.

If $\text{registers}<13> == 1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as $\text{NOP}$.
- The store instruction performs all of the stores using the specified addressing mode but the value of $R13$ is UNKNOWN.

If $\text{registers}<15> == 1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as $\text{NOP}$.
- The store instruction performs all of the stores using the specified addressing mode but the value of $R15$ is UNKNOWN.

If $n == 15 \&\& \text{wback}$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as $\text{NOP}$.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in Using $R15$ on page K1-6097.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

- IA Is an optional suffix for the Increment After form.
- $<c>$ See Standard assembler syntax fields on page F2-2848.
- $<q>$ See Standard assembler syntax fields on page F2-2848.
- $<Rn>$ Is the general-purpose base register, encoded in the "Rn" field.
- $!$ The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
For encoding A1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The PC can be in the list. However, ARM deprecates the use of instructions that include the PC in the list.

If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T2: is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Operation for all encodings

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations();
  address = R[n];
  for i = 0 to 14
    if registers<i> == '1' then
      if i == n && wback && i != LowestSetBit(registers) then
        MemA[address,4] = bits(32) UNKNOWN;  // Only possible for encodings T1 and A1
      else
        MemA[address,4] = R[i];
        address = address + 4;
    if registers<15> == '1' then  // Only possible for encoding A1
      MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

```
F5.1.219 STM (User registers)

In an EL1 mode other than System mode, Store Multiple (User registers) stores multiple User mode registers to consecutive memory locations using an address from a base register. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Store Multiple (User registers) is UNDEFINED in Hyp mode, and CONSTRAINED UNPREDICTABLE in User or System modes.

ARMv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see ARMv8.2-LSMAOC.

**A1 variant**

STM{<amode>}{<c>}{<q>} <Rn>, <registers>

**Decode for this encoding**

\[
\text{n} = \text{UInt}(\text{Rn}); \quad \text{registers} = \text{register_list}; \quad \text{increment} = (\text{U} == '1'); \quad \text{wordhigher} = (\text{P} == \text{U});
\]

if \(n == 15\) || BitCount(registers) < 1 then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

**Assembler symbols**

<amode> is one of:

- **DA** Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
- **ED** Empty Descending. For this instruction, a synonym for DA.
- **DB** Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
- **FD** Full Descending. For this instruction, a synonym for DB.
- **IA** Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
- **EA** Empty Ascending. For this instruction, a synonym for IA.
- **IB** Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
FA  Full Ascending. For this instruction, a synonym for IB.

See *Standard assembler syntax fields* on page F2-2848.

See *Standard assembler syntax fields* on page F2-2848.

<Rn>  Is the general-purpose base register, encoded in the "Rn" field.

<registers>  Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be stored by the STM instruction. The registers are stored with the lowest-numbered register to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2855.

**Operation**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;
    else
        length = 4*BitCount(registers);
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;
        for i = 0 to 14
            if registers<i> == '1' then  // Store User mode register
                MemA[address,4] = Rmode[i, M32_User];
                address = address + 4;
            if registers<15> == '1' then
                MemA[address,4] = PCStoreValue();
```

**CONSTRAINED UNPREDICTABLE behavior**

If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
F5.1.220  STMDA, STMED

Store Multiple Decrement After (Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. • The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If n == 15 && wback, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes without writeback of the base address.
• The instruction uses the addressing mode described in the equivalent immediate offset instruction.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

<c> See Standard assembler syntax fields on page F2-2848.

<q> See Standard assembler syntax fields on page F2-2848.
<Rn> Is the general-purpose base register, encoded in the "Rn" field.

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The PC can be in the list. However, ARM deprecates the use of instructions that include the PC in the list.

If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

**Operation**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers[i] == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;
            else
                MemA[address,4] = R[i];
                address = address + 4;
        if registers<15> == '1' then
            MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] - 4*BitCount(registers);
```
F5.1.221 STMDB, STMFD

Store Multiple Decrement Before (Full Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also Encoding of lists of general-purpose registers and the PC on page F2-2855.

ARMv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see ARMv8.2-LSMAOC. For details of related system instructions see STM (User registers).

This instruction is used by the alias PUSH (multiple registers). See Alias conditions on page F5-3505 for details of when each alias is preferred.

A1

```
|31|28|27|26|25|24|23|22|21|20|19|16|15|14|13|12|11|10| 9  | 8 | 7 | 6 | 5 | 4 | 3 | 0 |0  |0  |0  | W |0 |Rn | register_list |
```

A1 variant

STMDB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
STMFD{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack

Decode for this encoding

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == IS || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRANGED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

T1

```
|15|14|13|12|11|10| 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |15|14|13|12|11|10| 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |0  |0  |0  | W |0 |Rn | register_list |
```

T1 variant

STMDB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
STMFD{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack
Decode for this encoding

n = UInt(Rn);  registers = P:M:register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
if wback & registers<n> == '1' then UNPREDICTABLE;
if registers<13> == '1' then UNPREDICTABLE;
if registers<15> == '1' then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If wback & registers<n> == '1', then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The store instruction executes but the value stored for the base register is UNKNOWN.

If BitCount(registers) == 1, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes as described, with no change to its behavior and no additional side effects.
• The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If registers<13> == '1', then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes as described, with no change to its behavior and no additional side effects.
• The store instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

If registers<15> == '1', then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The store instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

<td>T4 (pre-indexed)</td>
<td>$Rn = '1101' &amp;&amp; U = '0' &amp;&amp; imm8 = '00000100'$</td>
</tr>
</tbody>
</table>

### Assembler symbols

- `<c>`  
  See Standard assembler syntax fields on page F2-2848.

- `<q>`  
  See Standard assembler syntax fields on page F2-2848.

- `<Rt>`  
  For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.
  
  For encoding T1, T2, T3 and T4: is the general-purpose register to be transferred, encoded in the "Rt" field.

- `<Rn>`  
  For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.
  
  For encoding T1, T3 and T4: is the general-purpose base register, encoded in the "Rn" field.

- `+/-`  
  Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  
  - when $U = 0$  
    - `-`
  - when $U = 1$  
    - `+`

- `<imm>`  
  For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
  
  For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as `<imm>/4`.
  
  For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as `<imm>/4`.
  
  For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
  
  For encoding T4: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

### Operation for all encodings

```plaintext
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,4] = if t == 15 then PCStoreValue() else R[t];
    if wback then R[n] = offset_addr;
  else
    if ConditionPassed() then
      EncodingSpecificOperations();
      offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
      address = if index then offset_addr else R[n];
      MemU[address,4] = R[t];
      if wback then R[n] = offset_addr;
```

### Aliases of variant is preferred when

- **PUSH (single register) A1 (pre-indexed)**  
  $P = '1' \&\& U = '0' \&\& W = '1' \&\& Rn = '1101' \&\& imm12 = '000000000100'$

- **PUSH (single register) T4 (pre-indexed)**  
  $Rn = '1101' \&\& U = '0' \&\& imm8 = '00000100'$
F5.1.224  STR (register)

Store Register (register) calculates an address from a base register value and an offset register value, stores a word from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see Memory accesses on page F2-2854.

A1

```
|   31  28  27  26  25  24  23  22  21  20  19  16  15  12  11  7  6  5  4  3  0 |

F5.1.227  STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see Memory accesses on page F2-2854.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

- The instruction is UNDEFINED.
- The instruction executes as \( \text{NOP} \).
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

\(<c>\) See Standard assembler syntax fields on page F2-2848.

\(<q>\) See Standard assembler syntax fields on page F2-2848.

\(<Rt>\) For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.

For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.

\(<Rt2>\) For encoding A1: is the second general-purpose register to be transferred. This register must be \( <R(t+1)> \).

For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.

\(<Rn>\) For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

\(|/-|\) Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when \( U = 0 \)
- when \( U = 1 \)

\(<\text{imm}>\) For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 if omitted, and encoded in the "imm8" field as \( <\text{imm}>/4 \).

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];

if d == 15 || t == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if d == n || d == t then UNPREDICTABLE;
CONSTRUINED UNPREDICATBLE behavior

If \( d = t \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes asNOP.
- The store instruction executes but the value stored is UNKNOWN.

If \( d = n \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes asNOP.
- The instruction performs the store to an UNKNOWN address.

Notes for all encodings

For more information about the CONSTRUINED UNPREDICATBLE behavior of this instruction, see Appendix K.1 Architectural Constraints on UNPREDICATBLE behaviors.

Assembler symbols

- **<c>** See Standard assembler syntax fields on page F2-2848.
- **<q>** See Standard assembler syntax fields on page F2-2848.
- **<Rd>** Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:
  - 0 If the operation updates memory.
  - 1 If the operation fails to update memory.
- **<Rt>** Is the general-purpose register to be transferred, encoded in the "Rt" field.
- **<Rn>** Is the general-purpose base register, encoded in the "Rn" field.
- **<imm>** For encoding A1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted.
  - For encoding T1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
if AArch32.ExclusiveMonitorsPass(address,4) then
    MemA[address,4] = R[t];
    R[d] = ZeroExtend('0');
else
    R[d] = ZeroExtend('1');

**CONSTRAINED UNPREDICTABLE behavior**

If \(d = t\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If \(d = n\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

If \(Rt<0> = '1'\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: \(Rt<0> = '0'\).
- The instruction executes with the additional decode: \(t2 = t\).
- The instruction executes as described, with no change to its behavior and no additional side effects.

If \(Rt == '1110'\), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in Using R15 on page K1-6097.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-2848.
- `<q>` See Standard assembler syntax fields on page F2-2848.
- `<Rd>` Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:
  - 0 If the operation updates memory.
  - 1 If the operation fails to update memory.
- `<Rd>` must not be the same as `<Rn>`, `<Rt>`, or `<Rt2>`.
- `<Rt>` For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. `<Rt>` must be even-numbered and not R14.
  - For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.
- `<Rt2>` For encoding A1: is the second general-purpose register to be transferred. `<Rt2>` must be \(R(t+1)\).
  - For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field.
Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- \(<Rd>\) is not updated.

A non doubleword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation for all encodings

if `ConditionPassed()` then
    EncodingSpecificOperations();
    address = R[n];
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    value = if BigEndian() then R[t]:R[t2] else R[t2]:R[t];
    if `AArch32.ExclusiveMonitorsPass(address,8)` then
        MemA[address,8] = value;  R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
F5.1.233   STREXH

Store Register Exclusive Halfword derives an address from a base register value, stores a halfword from a register to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see Synchronization and semaphores on page E2-2795. For information about memory accesses see Memory accesses on page F2-2854.

- The store instruction executes but the value stored is UNKNOWN.

If n == 15, then one of the following behaviors must occur:

- The instruction uses the addressing mode described in the equivalent immediate offset instruction.
A2

A2 variant

\[ \text{STRHT}\{<c>\}<q> <Rt>, [<Rn>], {+/-}<Rm> \]

**Decode for this encoding**

\[ t = \text{UInt}(Rt); \, n = \text{UInt}(Rn); \, m = \text{UInt}(Rm); \, \text{postindex} = \text{TRUE}; \, \text{add} = (U == '1'); \]
\[ \text{register form} = \text{TRUE}; \]
\[ \text{if } t == 15 || n == 15 || n == t || m == 15 \text{ then UNPREDICTABLE;} \]

**CONSTRAINED UNPREDICTABLE behavior**

If \( t == 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as \textit{NOP}.
- The store instruction performs the store using the specified addressing mode but the value corresponding to \( R15 \) is UNKNOWN.

If \( n == t \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as \textit{NOP}.
- The store instruction executes but the value stored is UNKNOWN.

If \( n == 15 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as \textit{NOP}.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

**T1 variant**

\[ \text{STRHT}\{<c>\}<q> <Rt>, [<Rn> \{, #{+}\}<imm>] \]

**Decode for this encoding**

if \( Rn == '1111' \) then UNDEFINED;
\[ t = \text{UInt}(Rt); \, n = \text{UInt}(Rn); \, \text{postindex} = \text{FALSE}; \, \text{add} = \text{TRUE}; \]
\[ \text{register form} = \text{FALSE}; \, \text{imm32} = \text{ZeroExtend}(\text{imm8}, 32); \]
\[ \text{if } t == 15 \text{ then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13} \]
**CONSTRAINED UNPREDICTABLE behavior**

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- See Standard assembler syntax fields on page F2-2848.
- See Standard assembler syntax fields on page F2-2848.
- Is the general-purpose register to be transferred, encoded in the "Rt" field.
- Is the general-purpose base register, encoded in the "Rn" field.
- For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - when U = 0
  - when U = 1
- For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - when U = 0
  - when U = 1
- Is the general-purpose index register, encoded in the "Rm" field.
- Specifies the offset is added to the base register.
- For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.
  - For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

**Operation for all encodings**

if ConditionPassed() then
  if PSTATE_EL == EL2 then UNPREDICTABLE; // Hyp mode
  EncodingSpecificOperations();
  offset = if register_form then R[m] else imm32;
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  MemU_unpriv[address,2] = R[t]<15:0>;
  if postindex then R[n] = offset_addr;

**CONSTRAINED UNPREDICTABLE behavior**

If PSTATE_EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes as STRH (immediate).
F5.1.237 STRT

Store Register Unprivileged stores a word from a register to memory. For information about memory accesses see *Memory accesses on page F2-2854.*

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

**STRT** is **UNPREDICTABLE** in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

t = UInt(Rt); n = UInt(Rn); postindex = FALSE; add = TRUE;
register_form = FALSE; imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRANDED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

Notes for all encodings

For more information about the CONSTRANDED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

See Standard assembler syntax fields on page F2-2848.
Operation for all encodings

if ConditionPassed() then
  if PSTATE.EL == EL2 then UNPREDICTABLE;            // Hyp mode
  EncodingSpecificOperations();
  offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  if t == 15 then // Only possible for encodings A1 and A2
    data = PCStoreValue();
  else
    data = R[t];
  MemU_unpriv[address,4] = data;
  if postindex then R[n] = offset_addr;

CONSTRANGED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The instruction executes as STR (immediate).
F5.1.238   SUB (immediate, from PC)

Subtract from PC subtracts an immediate value from the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. ARM recommends that, where possible, software avoids using this alias.

This instruction is an alias of the ADR instruction. This means that:

- The encodings in this description are named to match the encodings of ADR.
- The description of ADR gives the operational pseudocode for this instruction.

```

**A2 variant**

```
SUB{<c>}{<q>} <Rd>, PC, #<const>
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

and is the preferred disassembly when imm12 == '000000000000'.

**T2**

```
|15|14|13|12|11|10|9|8|7|6|5|4|3|2|1|0|15|14|12|11|8|7| |0|
|1|1|1|1|0|i|1|0|1|0|1|1|1|1|1|0|imm3|Rd|imm8|
```

**T2 variant**

```
SUB{<c>}{<q>} <Rd>, PC, #<imm12>
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

and is the preferred disassembly when i:imm3:imm8 == '000000000000'.

**Assembler symbols**

- `<>` See *Standard assembler syntax fields* on page F2-2848.
- `<q>` See *Standard assembler syntax fields* on page F2-2848.
- `<Rd>` For encoding A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2733.
  
  For encoding T2: is the general-purpose destination register, encoded in the "Rd" field.
- `<label>` For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.
  
  If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset.
If the offset is negative, encoding A2 is used, with \( \text{imm32} \) equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of \( \text{imm32} \).

Permitted values of the size of the offset are any of the constants described in Modified immediate constants in A32 instructions on page F2-2864.

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into \(<Rd>\). The assembler calculates the required value of the offset from the \( \text{Align(PC, 4)} \) value of the \( \text{ADR} \) instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into \(<Rd>\). The assembler calculates the required value of the offset from the \( \text{Align(PC, 4)} \) value of the \( \text{ADR} \) instruction to this label.

If the offset is zero or positive, encoding T3 is used, with \( \text{imm32} \) equal to the offset.

If the offset is negative, encoding T2 is used, with \( \text{imm32} \) equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of \( \text{imm32} \).

Permitted values of the size of the offset are 0-4095.

\(<\text{imm12}>\) Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

\(<\text{const}>\) An immediate value. See Modified immediate constants in A32 instructions on page F2-2864 for the range of values.

**Operation for all encodings**

The description of \( \text{ADR} \) gives the operational pseudocode for this instruction.
F5.1.239  SUB, SUBS (immediate)

Subtract (immediate) subtracts an immediate value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
- The SUBS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-4361.
  - The instruction is UNDEFINED in Hyp mode, except for encoding T5 with <imm8> set to zero, which is the encoding for the ERET instruction, see ERET.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```
F5.1.240 SUB, SUBS (register)

Subtract (register) subtracts an optionally-shifted register value from a register value, and writes the result to the
destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the
result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However,
when the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on
  the AArch32 general-purpose registers and the PC on page E1-2733.

- The SUBS variant of the instruction performs an exception return without the use of the stack. ARM
deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from
    AArch32 state on page G1-4361.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.
Assembler symbols

<c> See Standard assembler syntax fields on page F2-2848.

<q> See Standard assembler syntax fields on page F2-2848.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
- For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1 and T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. If the SP is used, see SUB, SUBS (SP minus register).

For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see SUB, SUBS (SP minus register).

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUEExceptionReturn(result);
        else
            ALUWritePC(result);
        else
            R[d] = result;
            if setflags then
                PSTATE.<N,Z,C,V> = nzcv;
F5.1.241   SUB, SUBS (register-shifted register)

Subtract (register-shifted register) subtracts a register-shifted register value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

\]

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1

* Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

\(<c>\) See Standard assembler syntax fields on page F2-2848.

\(<q>\) See Standard assembler syntax fields on page F2-2848.

\(<\text{imm7}>\) Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as \(<\text{imm7}>)/4.

\(<\text{Rd}>\) For encoding A1: is the general-purpose destination register, encoded in the "\text{Rd}" field. If omitted, this register is the SP. If the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation.

  This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. ARM deprecates use of this instruction unless <Rn> is the LR.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F2-2864 for the range of values.

For encoding T2: an immediate value. See Modified immediate constants in T32 instructions on page F2-2863 for the range of values.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(SP, NOT(imm32), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```
F5.1.243  SUB, SUBS (SP minus register)

Subtract from SP (register) subtracts an optionally-shifted register value from the SP value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
- The SUBS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See Illegal return events from AArch32 state on page G1-4361.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-2848.

\(<q>\) See Standard assembler syntax fields on page F2-2848.

\(<\text{Rd}>\) For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used:

\begin{itemize}
  \item For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733.
  \item For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR._current_mode_.
\end{itemize}

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

\(<\text{Rm}>\) For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.

<shift>  Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL  when type = 00
- LSR  when type = 01
- ASR  when type = 10
- ROR  when type = 11

<amount>  For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(SP, NOT(shifted), '1');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUEXceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;

F5.1.244  SVC

Supervisor Call causes a Supervisor Call exception. For more information, see Supervisor Call (SVC) exception on page G1-4380.

—— Note ————

SVC was previously called SWI, Software Interrupt, and this name is still found in some documentation.

Software can use this instruction as a call to an operating system to provide a service.

In the following cases, the Supervisor Call exception generated by the SVC instruction is taken to Hyp mode:

• If the SVC is executed in Hyp mode.

• If HCR.TGE is set to 1, and the SVC is executed in Non-secure User mode. For more information, see Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-4357

In these cases, the HSR identifies that the exception entry was caused by a Supervisor Call exception, EC value 0x11, see Use of the HSR on page G4-4677. The immediate field in the HSR:

• If the SVC is unconditional:
  — For the T32 instruction, is the zero-extended value of the imm8 field.
  — For the A32 instruction, is the least-significant 16 bits the imm24 field.

• If the SVC is conditional, is UNKNOWN.

<code>
<var>imm</var>

For encoding A1: is a 24-bit unsigned immediate, in the range 0 to 16777215, encoded in the "imm24" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm24 in software, for example to determine the required service.

For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm8 in software, for example to determine the required service.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CallSupervisor(imm32<15:0>);
```

F5.1.245  SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

```
F5.1.251   TBB, TBH

Table Branch Byte or Halfword causes a PC-relative forward branch using a table of single byte or halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value returned from the table.

**T1**

```
|15 14 13 12|11 10 9 8|7 6 5 4|3 0 |
|1 1 0 1 0 0 0 1 1 0 1| Rn |1|1|1|1|0|0|0|0|0|0|H | Rm |
```

**Byte variant**

Applies when \(H = 0\).

\[TBB\{<c>\}{<q>}\ [<Rn>, <Rm>] // Outside or last in IT block\]

**Halfword variant**

Applies when \(H = 1\).

\[TBH\{<c>\}{<q>\} [<Rn>, <Rm>, LSL #1] // Outside or last in IT block\]

**Decode for all variants of this encoding**

\[n = UInt(Rn); \quad m = UInt(Rm); \quad is_tbh = (H == '1');\]
\[\text{if } m == 15 \text{ then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13}\]
\[\text{if } InITBlock() \& \& \text{!LastInITBlock()} \text{ then UNPREDICTABLE;}\]

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields* on page F2-2848.
- `<q>` See *Standard assembler syntax fields* on page F2-2848.
- `<Rn>` Is the general-purpose base register holding the address of the table of branch lengths, encoded in the "Rn" field. The PC can be used. If it is, the table immediately follows this instruction.
- `<Rm>` For the byte variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.
  
  For the halfword variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

**Operation**

```
if ConditionPassed() then
  EncodingSpecificOperations();
  if is_tbh then
    halfwords = UInt(MemU[Rn]+LSL(Rm), 2));
  else
    halfwords = UInt(MemU[Rn]+R[m], 1));
  BranchWritePC(PC + 2*halfwords);
```
F5.1.252   TEQ (immediate)

Test Equivalence (immediate) performs a bitwise exclusive OR operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

**Assembler symbols**

\( <c> \)

See Standard assembler syntax fields on page F2-2848.
See *Standard assembler syntax fields on page F2-2848.*

For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1: is the second general-purpose source register, encoded in the "Rn" field.

Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```
F5.1.254   TEQ (register-shifted register)

Test Equivalence (register-shifted register) performs a bitwise exclusive OR operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

\langle Rn\rangle \quad \text{Is the general-purpose source register, encoded in the "Rn" field.}

\langle lsb\rangle \quad \text{For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.}

\text{For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.}

\langle width\rangle \quad \text{Is the width of the field, in the range 1 to 32-\langle lsb\rangle, encoded in the "widthm1" field as \langle width\rangle-1.}
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        $R[d] = \text{ZeroExtend}(R[n]<\text{msbit}:\text{lsbit}>\text{, 32});$
    else
        UNPREDICTABLE;

CONSTRANDED UNPREDICTABLE behavior

If msbit > 31, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• The value in the destination register is UNKNOWN.
F5.1.262  UDF

Permanently Undefined generates an Undefined Instruction exception.

The encodings for UDF used in this section are defined as permanently UNDEFINED in the ARMv8-A architecture. However:

- With the T32 instruction set, ARM deprecates using the UDF instruction in an IT block.
- In the A32 instruction set, UDF is not conditional.

A1

UDF{<c>}{<q>} {#}<imm>

Decode for this encoding

imm32 = ZeroExtend(imm4:imm12, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```
Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F2-2848. <c> must be AL or omitted.
For encoding T1 and T2: see Standard assembler syntax fields on page F2-2848. ARM deprecates using any <c> value other than AL.

<q> See Standard assembler syntax fields on page F2-2848.

<imm> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. The PE ignores the value of this constant.
For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. The PE ignores the value of this constant.
For encoding T2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. The PE ignores the value of this constant.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   UNDEFINED;
F5.1.263   UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

See Divide instructions on page F1-2819 for more information about this instruction.

<amount>
For encoding A1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.

For encoding A1: is the shift amount, in the range 1 to 32 encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field.

For encoding T1: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as <amount>.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
    (result, sat) = UnsignedSatQ(SInt(operand), saturate_to);
    R[d] = ZeroExtend(result, 32);
    if sat then
        PSTATE.Q = '1';
F5.1.282   USAT16

Unsigned Saturate 16 saturates two signed 16-bit values to a selected unsigned range.

This instruction sets PSTATE.Q to 1 if the operation saturates.

```

F5.1.292  WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a
wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any
PE in the multiprocessor system. For more information, see Wait For Event and Send Event on page G1-4403.

As described in Wait For Event and Send Event on page G1-4403, the execution of a WFE instruction that would
otherwise cause entry to a low-power state can be trapped to a higher Exception level, see:

•  Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-4421.
•  Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437.
•  Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on
  page G1-4447.

        WaitForInterrupt();
YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction see The Yield instruction on page F1-2825.

if ConditionPassed() then
    EncodingSpecificOperations();
    Hint_Yield();
F5.2 Encoding and use of Banked register transfer instructions

Software executing at EL1 or higher can use the MRS (Banked register) and MSR (Banked register) instructions to transfer values between the general-purpose registers and Special-purpose registers. One particular use of these instructions is for a hypervisor to save or restore the register values of a Guest OS. The following sections give more information about these instructions:

- Register arguments in the Banked register transfer instructions.
- Usage restrictions on the Banked register transfer instructions on page F5-3675.
- Encoding the register argument in the Banked register transfer instructions on page F5-3676.
- Pseudocode support for the Banked register transfer instructions on page F5-3677.

For descriptions of the instructions see MRS (Banked register) on page F5-3277 and MSR (Banked register) on page F5-3281.

F5.2.1 Register arguments in the Banked register transfer instructions

Figure F5-1 shows the Banked general-purpose registers and Special-purpose registers:

For the general-purpose registers, if no other register is shown, the current mode register is the _usr register. So, for example, the full set of current mode registers, including the registers that are not banked:

- For Hyp mode, is \{R0 usr - R12 usr, SP hyp, LR usr, SPSR hyp, ELR hyp\}.
- For Abort mode, is \{R0 usr - R12 usr, SP abt, LR abt, SPSR abt\}.

Figure F5-1 Banking of general-purpose and Special-purpose registers

Figure F5-1 is based on Figure G1-2 on page G1-4325, that shows the complete set of general-purpose registers and Special-purpose registers accessible in each mode.

---

**Note**

- System mode uses the same set of registers as User mode. Neither of these modes can access an SPSR, except that System mode can use the MRS (Banked register) and MSR (Banked register) instructions to access some SPSRs, as described in Usage restrictions on the Banked register transfer instructions on page F5-3675.

- General-purpose registers R0-R7, that are not Banked, cannot be accessed using the MRS (Banked register) and MSR (Banked register) instructions.

- In addition to the registers shown in Figure F5-1, the DLR and DSPSR are AArch32 System registers that map onto the AArch64 Special-purpose registers DLR_EL0 and DSPSR_EL0. However, DLR and DSPSR are not accessible using the MRS (Banked register) and MSR (Banked register) instructions.

---

Software using an MRS (Banked register) or MSR (Banked register) instruction specifies one of these registers using a name shown in Figure F5-1, or an alternative name for SP or LR. These registers can be grouped as follows:

R8-R12 Each of these registers has two Banked copies, _usr and _fiq, for example R8._usr and R8._fiq.
SP
There is a Banked copy of SP for every mode except System mode. For example, SP_svc is the SP for Supervisor mode.

LR
There is a Banked copy of LR for every mode except System mode and Hyp mode. For example, LR_svc is the LR for Supervisor mode.

SPSR
There is a Banked copy of SPSR for every mode except System mode and User mode.

ELR_hyp
Except for the operations provided by MRS (Banked register) and MSR (Banked register), ELR_hyp is accessible only from Hyp mode. It is not Banked.

F5.2.2 Usage restrictions on the Banked register transfer instructions

MRS (Banked register) and MSR (Banked register) instructions are CONSTRAINED UNPREDICTABLE if any of the following applies:

• The instruction is executed in User mode.
• The instruction accesses a Banked register that is not implemented, or that either:
  — Is not accessible from the current Privilege level and Security state.
  — Can be accessed from the current mode by using a different instruction.

MSR/MRS Banked registers on page K1-6117 describes the permitted CONSTRAINED UNPREDICTABLE behavior.

An MRS (Banked register) or an MSR (Banked register) executed:

• At Non-secure EL1 cannot access any Hyp mode Banked registers.
• At Non-secure EL1 or EL2 cannot access any Monitor mode Banked registers.
• In a Secure mode other than Monitor mode cannot access any Hyp Banked registers.

This means that the Banked registers that MRS (Banked register) and MSR (Banked register) instructions cannot access are:

From Monitor mode
• The current mode registers R8_usr-R12_usr, SP_mon, LR_mon, and SPSR_mon.

From Hyp mode
• The Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
• The current mode registers R8_usr-R12_usr, SP_hyp, LR_usr, and SPSR_hyp.

Note
MRS (Banked register) and MSR (Banked register) instructions can access the current mode register ELR_hyp.

From FIQ mode
• From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
• The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
• The current mode registers R8_fiq-R12_fiq, SP_fiq, LR_fiq, and SPSR_fiq.

From System mode
• From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
• The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
• The current mode registers R8_usr-R12_usr, SP_usr, and LR_usr.

From Supervisor mode, Abort mode, Undefined mode, and IRQ mode
• From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
• The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.
• The current mode registers R8_usr-R12_usr, SP_<current_mode>, LR_<current_mode>, and SPSR_<current_mode>.
If EL3 is using AArch64, all MRS (Banked register) and MSR (Banked register) accesses to the Monitor mode registers from Secure EL1 modes are trapped to EL3. See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1870.

For more information, see:
- Encoding the register argument in the Banked register transfer instructions.
- Pseudocode support for the Banked register transfer instructions on page F5-3677.
- MRS (Banked register) on page F5-3277.
- MSR (Banked register) on page F5-3281.

Note

CONSTRAINED UNPREDICTABLE behavior must not give access to registers that are not accessible from the current Privilege level and Security state.

F5.2.3 Encoding the register argument in the Banked register transfer instructions

The MRS (Banked register) and MSR (Banked register) instructions include a 5-bit field, SYSm, and an R bit, that together encode the register argument for the instruction.

When the R bit is set to 0, the argument is a register other than a Banked copy of the SPSR, and Table F5-1 shows how the SYSm field defines the required register argument. In this table, CONST. UNPREDICTABLE indicates that behavior is CONSTRAINED UNPREDICTABLE.

<table>
<thead>
<tr>
<th>SYSm&lt;2:0&gt;</th>
<th>SYSm&lt;4:3&gt;</th>
<th>0b00</th>
<th>0b01</th>
<th>0b10</th>
<th>0b11</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b000</td>
<td>R8_usr</td>
<td>R8_fiq</td>
<td>LR_irq</td>
<td>CONST. UNPREDICTABLE</td>
<td></td>
</tr>
<tr>
<td>0b001</td>
<td>R9_usr</td>
<td>R9_fiq</td>
<td>SP_irq</td>
<td>CONST. UNPREDICTABLE</td>
<td></td>
</tr>

</tr>
<tr>
<td>0b111</td>
<td>CONST. UNPREDICTABLE</td>
<td>CONST. UNPREDICTABLE</td>
<td>SP_und</td>
<td>SP_hyp</td>
<td></td>
</tr>
</tbody>
</table>

When the R bit is set to 1, the argument is a Banked copy of the SPSR, and Table F5-2 shows how the SYSm field defines the required register argument. In this table, CONST. UNPREDICTABLE indicates that behavior is CONSTRAINED UNPREDICTABLE.

<table>
<thead>
<tr>
<th>SYSm&lt;2:0&gt;</th>

</tbody>
</table>
F5.2.4 Pseudocode support for the Banked register transfer instructions

The pseudocode functions `BankedRegisterAccessValid()` and `SPSRaccessValid()` check the validity of MRS (Banked register) and MSR (Banked register) accesses. That is, they filter the accesses that are CONSTRAINED UNPREDICTABLE either because:

- They attempt to access a register that Usage restrictions on the Banked register transfer instructions on page F5-3675 shows is not accessible.

- They use an `SYSm<4:0>` encoding that Encoding the register argument in the Banked register transfer instructions on page F5-3676 shows as CONSTRAINED UNPREDICTABLE.

`BankedRegisterAccessValid()` applies to accesses to the banked general-purpose registers, or to ELR_hyp, and `SPSRaccessValid()` applies to accesses to the SPSRs.
F5 T32 and A32 Base Instruction Set Instruction Descriptions
F5.2 Encoding and use of Banked register transfer instructions
Chapter F6
T32 and A32 Advanced SIMD and floating-point Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

•  *Alphabetical list of floating-point and Advanced SIMD instructions on page F6-3680.*

Note

Some headings in this chapter use the term *floating-point register.* This is an abbreviated description, and means a register in the Advanced SIMD and floating-point register file.
F6.1 Alphabetical list of floating-point and Advanced SIMD instructions

This section lists every floating-point and Advanced SIMD instruction in the T32 and A32 instruction sets. For details of the format used see Format of instruction descriptions on page F2-2844.

This section is formatted so that each instruction description starts on a new page.
F6.1.1 AESD

AES single round decryption.

  EncodingSpecificOperations(); CheckCryptoEnabled32();
  \texttt{Q[d>>1] = AESMixColumns(Q[m>>1]);}
F6.1.5 FLDM*X (FLDMDBX, FLDMIAX)

FLDMDBX is the Decrement Before variant of this instruction, and FLDMIAX is the Increment After variant. FLDM*X loads multiple SIMD&FP registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

ARM deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-4413.

</tbody>
</table>
```

**Decrement Before variant**

Applies when \( P = 1 \) \&\& \( U = 0 \) \&\& \( W = 1 \).

FLDMDBX{<c>}{<q>} <Rn>!, <dreglist>

**Increment After variant**

Applies when \( P = 0 \) \&\& \( U = 1 \).

FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

**Decode for all variants of this encoding**

If \( P = '0' \) \&\& \( U = '0' \) \&\& \( W = '0' \) then SEE "Related encodings";

if \( P = '1' \) \&\& \( W = '0' \) then SEE VLDR;

if \( P = '1' \) \&\& \( W = '1' \) then UNDEFINED;

// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)

single_regs = FALSE; add = (U == '1'); wback = (W == '1');

\( d = \text{UInt}(D:Vd); \quad n = \text{UInt}(Rn); \quad \text{imm32} = \text{ZeroExtend}(\text{imm8}:00', 32);\)

\( \text{regs} = \text{UInt}(\text{imm8}) \div 2; \quad \text{If UInt(imm8)} \) is odd, see "FLDM*X".

if \( n == 15 \) \&\& (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;

if \( \text{regs} == 0 \) \&\& \( \text{regs} > 16 \) \&\& (d+regs) > 32 then UNPREDICTABLE;

if \( \text{imm8}<0> == '1' \) \&\& (d+regs) > 16 then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**

If \( \text{regs} == 0 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If \( \text{regs} > 16 \) \&\& (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

F6.1.17 VABA

Vector Absolute Difference and Accumulate subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand and result elements are all integers of the same length.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-2848.

<q>
See Standard assembler syntax fields on page F2-2848.

<dt>
Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:

- S8 when $U = 0$, $size = 00$
- S16 when $U = 0$, $size = 01$
- S32 when $U = 0$, $size = 10$
- U8 when $U = 1$, $size = 00$
- U16 when $U = 1$, $size = 01$
- U32 when $U = 1$, $size = 10$

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as $<Qd>*2$.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as $<Qn>*2$.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as $<Qm>*2$.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];
            op2 = Elem[Din[m+r],e,esize];
            absdiff = Abs(Int(op1,unsigned) - Int(op2,unsigned));
            if long_destination then
                Elem[D[d+1],e,2*esize] = Elem[Din[d+1],e,2*esize] + absdiff;
            else
                Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + absdiff;
```

F6.1.18   VABAL

Vector Absolute Difference and Accumulate Long subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

    end
F6.1.23   VACGE

Vector Absolute Compare Greater Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements are floating-point numbers. The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

This instruction is used by the pseudo-instruction VACLE. The pseudo-instruction is never the preferred disassembly.

<q>
See *Standard assembler syntax fields* on page F2-2848.

<dt>
Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:

- I8 when size = 00
- I16 when size = 01
- I32 when size = 10
- I64 when size = 11

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = Elem[D[n+r],e,esize] + Elem[D[m+r],e,esize];
```
F6.1.29 VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. For rounded results, see VRADDHN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

F6.1.32 VAND (immediate)

Vector bitwise AND (immediate) performs a bitwise AND between a register value and an immediate value, and returns the result into the destination vector.

This instruction is a pseudo-instruction of the VBIC (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of VBIC (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VBIC (immediate) gives the operational pseudocode for this instruction.

### A1

64-bit SIMD vector variant

Applies when Q == 0.

\[
\text{VAND}\{<c>\}{<q>}.I16 \{<Dd>,\} <Dd>, \#<imm>
\]

is equivalent to

\[
\text{VBIC}\{<c>\}{<q>}.I16 <Dd>, \#~<imm>
\]

and is never the preferred disassembly.

128-bit SIMD vector variant

Applies when Q == 1.

\[
\text{VAND}\{<c>\}{<q>}.I16 \{<Qd>,\} <Qd>, \#<imm>
\]

is equivalent to

\[
\text{VBIC}\{<c>\}{<q>}.I16 <Qd>, \#~<imm>
\]

and is never the preferred disassembly.

### A2

64-bit SIMD vector variant

Applies when Q == 0.

\[
\text{VAND}\{<c>\}{<q>}.I32 \{<Dd>,\} <Dd>, \#<imm>
\]

is equivalent to

\[
\text{VBIC}\{<c>\}{<q>}.I32 <Dd>, \#~<imm>
\]

and is never the preferred disassembly.
128-bit SIMD vector variant

Applies when \( Q = 1 \).

\[
\text{VAND\{<c>\}{<q>}.I32 \{<Qd>,\} \ <Qd>, \ #<imm>}
\]

is equivalent to

\[
\text{VBIC\{<c>\}{<q>}.I32 \ <Qd>, \ #<imm>}
\]

and is never the preferred disassembly.

T1

\[
\begin{array}{cccccccccccccccc}

\end{array}
\]

64-bit SIMD vector variant

Applies when \( Q = 0 \).

\[
\text{VAND\{<c>\}{<q>}.I16 \{<Dd>,\} \ <Dd>, \ #<imm>}
\]

is equivalent to

\[
\text{VBIC\{<c>\}{<q>}.I16 \ <Dd>, \ #<imm>}
\]

and is never the preferred disassembly.

128-bit SIMD vector variant

Applies when \( Q = 1 \).

\[
\text{VAND\{<c>\}{<q>}.I16 \{<Qd>,\} \ <Qd>, \ #<imm>}
\]

is equivalent to

\[
\text{VBIC\{<c>\}{<q>}.I16 \ <Qd>, \ #<imm>}
\]

and is never the preferred disassembly.

T2

\[
\begin{array}{cccccccccccccccc}
15 & 14 & 13 & 12 & 11 & 10 & 9 & 8 & 7 & 6 & 5 & 4 & 3 & 2 & 0 & 15 & 12 & 11 & 8 & 7 & 6 & 5 & 4 & 3 & 0 \\
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & D & 0 & 0 & 0 & \text{imm3} & \text{Vd} & 1 & 0 & x & 1 & 0 & Q & 1 & 1 & \text{imm4} & \text{cmode}
\end{array}
\]

64-bit SIMD vector variant

Applies when \( Q = 0 \).

\[
\text{VAND\{<c>\}{<q>}.I32 \{<Dd>,\} \ <Dd>, \ #<imm>}
\]

is equivalent to

\[
\text{VBIC\{<c>\}{<q>}.I32 \ <Dd>, \ #<imm>}
\]

and is never the preferred disassembly.

128-bit SIMD vector variant

Applies when \( Q = 1 \).
VAND{<c>}{<q>}.I32 {<Qd>,} <Qd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.I32 <Qd>, #~<imm>

and is never the preferred disassembly.

**Assembler symbols**

- `<c>` For encoding A1 and A2: see *Standard assembler syntax fields on page F2-2848*. This encoding must be unconditional.
  For encoding T1 and T2: see *Standard assembler syntax fields on page F2-2848*.

- `<q>` See *Standard assembler syntax fields on page F2-2848*.

- `<Qd>` Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<imm>` Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of `<imm>`, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-2865*.

**Operation for all encodings**

The description of VBIC (immediate) gives the operational pseudocode for this instruction.
F6.1.33   VAND (register)

Vector Bitwise AND (register) performs a bitwise AND operation between two registers, and places the result in
the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the
instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

VAND{<c>}{<q>}{.<dt>} {<Dd>,} <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VAND{<c>}{<q>}{.<dt>} {<Qd>,} <Qn>, <Qm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;

d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;

Assembler symbols

<> For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be
    unconditional.

    For encoding T1: see Standard assembler syntax fields on page F2-2848.
See Standard assembler syntax fields on page F2-2848.

An optional data type. It is ignored by assemblers, and does not affect the encoding.

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND D[m+r];
```
F6.1.34 VBIC (immediate)

Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be undefined, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

This instruction is used by the pseudo-instruction VAND (immediate). The pseudo-instruction is never the preferred disassembly.

```
F6.1.38 VBSL

Vector Bitwise Select sets each bit in the destination to the corresponding bit from the first source operand when the original destination bit was 1, otherwise from the second source operand.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-2848.

<q>
See Standard assembler syntax fields on page F2-2848.

<dt>
An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
enumeration VBitOps {VBitOps_VBIF, VBitOps_VBIT, VBitOps_VBSL};
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        case operation of
            when VBitOps_VBIF  D[d+r] = (D[d+r] AND D[m+r]) OR (D[n+r] AND NOT(D[m+r]));
            when VBitOps_VBIT  D[d+r] = (D[n+r] AND D[m+r]) OR (D[d+r] AND NOT(D[m+r]));
            when VBitOps_VBSL  D[d+r] = (D[n+r] AND D[d+r]) OR (D[m+r] AND NOT(D[d+r]));
```

```
F6.1.39 VCEQ (Immediate #0)

Vector Compare Equal to Zero takes each element in a vector, and compares it with zero. If it is equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

F6.1.46  VCLE (register)

Vector Compare Less Than or Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This instruction is a pseudo-instruction of the VCGE (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VCGE (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VCGE (register) gives the operational pseudocode for this instruction.

Assembler symbols

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<c> For encoding A1 and A2: see Standard assembler syntax fields on page F2-2848. This encoding
must be unconditional.
For encoding T1 and T2: see Standard assembler syntax fields on page F2-2848.

<q> See Standard assembler syntax fields on page F2-2848.

<dt> For encoding A1 and T1: is the data type for the elements of the operands, encoded in the "U:size"
field. It can have the following values:
S8 when U = 0, size = 00
S16 when U = 0, size = 01
S32 when U = 0, size = 10
U8 when U = 1, size = 00
U16 when U = 1, size = 01
U32 when U = 1, size = 10
For encoding A2 and T2: is the data type for the elements of the vectors, encoded in the "sz" field.
It can have the following values:
F32 when sz = 0
F16 when sz = 1

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Operation for all encodings

The description of VCGE (register) gives the operational pseudocode for this instruction.
F6.1.47 VCLS

Vector Count Leading Sign Bits counts the number of consecutive bits following the topmost bit, that are the same as the topmost bit, in each element in a vector, and places the results in a second vector. The count does not include the topmost bit itself.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit signed integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      if floating_point then
        bits(esize) zero = FPZero('0');
        test_passed = FPCompareGT(zero, Elem[D[m+r],e,esize], StandardFPSCRValue());
      else
        test_passed = (SInt(Elem[D[m+r],e,esize]) < 0);
        Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
F6.1.49 VCLT (register)

Vector Compare Less Than takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This instruction is a pseudo-instruction of the VCGT (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VCGT (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VCGT (register) gives the operational pseudocode for this instruction.

  • The instruction is UNDEFINED.
  • The instruction executes as if it passes the Condition code check.
  • The instruction executes as NOP. This means it behaves as if it fails the Condition code check.
Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1, Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

- `<c>` See Standard assembler syntax fields on page F2-2848.
- `<q>` See Standard assembler syntax fields on page F2-2848.
- `<Sd>` Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- `<Sm>` Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- `<Dm>` Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the FPSCR flags being set as N=0, Z=0, C=1 and V=1.

VMPF raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    case esize of
        when 16
            bits(16) op16 = if with_zero then FPZero('0') else S[m]<15:0>;
            FPSCR.<N,Z,C,V> = FPCompare(S[d]<15:0>, op16, quiet_nan_exc, FPSCR);
        when 32
            bits(32) op32 = if with_zero then FPZero('0') else S[m];
            FPSCR.<N,Z,C,V> = FPCompare(S[d], op32, quiet_nan_exc, FPSCR);
        when 64
            bits(64) op64 = if with_zero then FPZero('0') else D[m];
            FPSCR.<N,Z,C,V> = FPCompare(D[d], op64, quiet_nan_exc, FPSCR);
```
**F6.1.52  VCMPE**

Vector Compare, raising Invalid Operation on NaN compares two floating-point registers, or one floating-point register and zero. It writes the result to the FPSCR flags. These are normally transferred to the PSTATE, {N, Z, C, V} Condition flags by a subsequent VMRS instruction.

It raises an Invalid Operation exception if either operand is any type of NaN.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support on page G1-4413.*

Applies when size == 10.

VCMPE{<c>}{<q>}.F32 <Sd>, #0.0

### Double-precision scalar variant

Applies when size == 11.

VCMPE{<c>}{<q>}.F64 <Dd>, #0.0

### Decode for all variants of this encoding

if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
if size == '01' && InITBlock() then UNPREDICTABLE;
quiet_nan_exc = (E == '1'); with_zero = FALSE;
case size of
  when '01' esize = 16; d = UInt(Vd:D); m = UInt(Vm:M);
  when '10' esize = 32; d = UInt(Vd:D); m = UInt(Vm:M);
  when '11' esize = 64; d = UInt(D:Vd); m = UInt(M:Vm);

### CONstrained UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.
**Notes for all encodings**

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields* on page F2-2848.
- `<p>` See *Standard assembler syntax fields* on page F2-2848.
- `<sD>` Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- `<sM>` Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
- `<oD>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- `<oM>` Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**NANs**

The IEEE 754 standard specifies that the result of a comparison is precisely one of `<`, `==`, `>` or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the **FPSCR** flags being set as N=0, Z=0, C=1 and V=1.

**VOMPE** raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for `<`, `<=`, `>`, `>=`, and other predicates that raise an exception when the operands are unordered.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    case esize of
        when 16
            bits(16) op16 = if with_zero then FPZero('0') else S[m]<15:0>;
            FPSCR.<N,Z,C,V> = FPCompare(S[d]<15:0>, op16, quiet_nan_exc, FPSCR);
        when 32
            bits(32) op32 = if with_zero then FPZero('0') else S[m];
            FPSCR.<N,Z,C,V> = FPCompare(S[d], op32, quiet_nan_exc, FPSCR);
        when 64
            bits(64) op64 = if with_zero then FPZero('0') else D[m];
            FPSCR.<N,Z,C,V> = FPCompare(D[d], op64, quiet_nan_exc, FPSCR);
```

F6.1.53   VCNT

Vector Count Set Bits counts the number of bits that are one in each element in a vector, and places the results in a second vector.

The operand vector elements must be 8-bit fields.

The result vector elements are 8-bit integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

**CONSTRAINED UNPREDICTABLE behavior**

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Assembler symbols**

<
For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-2848.

<
See Standard assembler syntax fields on page F2-2848.

<dt1>
Is the data type for the elements of the destination vector, encoded in the "size:op" field. It can have the following values:

- F16 when size = 01, op = 0x
- S16 when size = 01, op = 10
- U16 when size = 01, op = 11
- F32 when size = 10, op = 0x
- S32 when size = 10, op = 10
- U32 when size = 10, op = 11

<dt2>
Is the data type for the elements of the source vector, encoded in the "size:op" field. It can have the following values:

- S16 when size = 01, op = 00
- U16 when size = 01, op = 01
- F16 when size = 01, op = 1x
- S32 when size = 10, op = 00
- U32 when size = 10, op = 01
- F32 when size = 10, op = 1x

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm>
Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm>
Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(esize) result;
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[m+r],e,esize];
            if to_integer then
                result = FPtoFixed(op1, 0, unsigned, StandardFPSCRValue(), FPRounding_ZERO);
            else
                result = FixedToFP(op1, 0, unsigned, StandardFPSCRValue(), FPRounding_TIEEVEN);
            Elem[D[r+D],e,esize] = result;
F6.1.57 VCVT (floating-point to integer, floating-point)

Convert floating-point to integer with Round towards Zero converts a value in a register from floating-point to a 32-bit integer, using the Round towards Zero rounding mode, and places the result in a second register.

VCVT (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

                    D[d] = FixedToFP(S[m], 0, unsigned, FPSCR, rounding);
F6.1.59 VCVT (between floating-point and fixed-point, Advanced SIMD)

Vector Convert between floating-point and fixed-point converts each element in a vector from floating-point to fixed-point, or from fixed-point to floating-point, and places the results in a second vector.

The vector elements are the same type, and are floating-point numbers or integers. Signed and unsigned integers are distinct.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

- **<Qm>** Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- **<Od>** Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- **<Om>** Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<fbits> The number of fraction bits in the fixed point number, in the range 1 to 32 for 32-bit elements, or in the range 1 to 16 for 16-bit elements:
- \((64 - \text{<fbits>})\) is encoded in imm6.

An assembler can permit an <fbits> value of 0. This is encoded as floating-point to integer or integer to floating-point instruction, see VCVT (between floating-point and integer, Advanced SIMD).

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(esize) result;
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[m+r],e,esize];
            if to_fixed then
                result = FPToFixed(op1, frac_bits, unsigned, StandardFPSCRValue(), FPRounding_ZERO);
            else
                result = FixedToFP(op1, frac_bits, unsigned, StandardFPSCRValue(), FPRounding_TIEEVEN);
            Elem[D[d+r],e,esize] = result;
```

F6.1.60   VCVT (between floating-point and fixed-point, floating-point)

Convert between floating-point and fixed-point converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

F6.1.64   VCVTM (Advanced SIMD)

Vector Convert floating-point to integer with Round towards -Infinity converts each element in a vector from
floating-point to integer using the Round towards -Infinity rounding mode, and places the results in a second vector.

The operand vector elements are floating-point numbers.

The result vector elements are 32-bit integers. Signed and unsigned integers are distinct.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in
which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp
mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

- **<dt>**
  - Is the data type for the elements of the destination, encoded in the "op" field. It can have the following values:
    - U32 when op = 0
    - S32 when op = 1
- **<Sd>**
  - Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- **<Sm>**
  - Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
- **<Dm>**
  - Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
case esize of
  when 16
    S[d] = FPToFixed(S[m]<15:0>, 0, unsigned, FPSCR, rounding);
  when 32
    S[d] = FPToFixed(S[m], 0, unsigned, FPSCR, rounding);
  when 64
    S[d] = FPToFixed(D[m], 0, unsigned, FPSCR, rounding);
F6.1.70   VCVTR

Convert floating-point to integer converts a value in a register from floating-point to a 32-bit integer, using the rounding mode specified by the FPSCR and places the result in a second register.

VCVTR (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

**Assembler symbols**

<q> For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-2848.

<q> See Standard assembler syntax fields on page F2-2848.

<size> The data size. It must be one of:
  8   Encoded as imm4<0> = '1'. imm4<3:1> encodes the index[x] of the scalar.
  16  Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index [x] of the scalar.
  32  Encoded as imm4<2:0> = '100'. imm4<3> encodes the index [x] of the scalar.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm[x]> The scalar. For details of how [x] is encoded, see the description of <size>.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  scalar = Elem[D[m],index,esize];
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = scalar;
F6.1.75  VEOR

Vector Bitwise Exclusive OR performs a bitwise Exclusive OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

F6.1.76  VEXT (byte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

The following figure shows the operation of VEXT doubleword operation for \( \text{imm} = 3 \).

![Diagram of VEXT operation](image)

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

This instruction is used by the pseudo-instruction VEXT (multibyte elements). The pseudo-instruction is never the preferred disassembly.

F6.1.77 VEXT (multibyte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

This instruction is a pseudo-instruction of the VEXT (byte elements) instruction. This means that:

- The encodings in this description are named to match the encodings of VEXT (byte elements).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VEXT (byte elements) gives the operational pseudocode for this instruction.

F6.1.79   VFMS

Vector Fused Multiply Subtract negates the elements of one vector and multiplies them with the corresponding elements of another vector, adds the products to the corresponding elements of the destination vector, and places the results in the destination vector. The instruction does not round the result of the multiply before the addition.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

A1

64-bit SIMD vector variant

Applies when $Q == 0$.

      Elem[D+d+r],e,esize] = result<esize:1>;
F6.1.83 VHSUB

Vector Halving Subtract subtracts the elements of the second operand from the corresponding elements of the first operand, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated. There is no rounding version.

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 then UNPREDICTABLE;

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

**Assembler symbols**

- **<c>** For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
  For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-2848.

- **<q>** See Standard assembler syntax fields on page F2-2848.

- **<size>** Is the data size, encoded in the "size" field. It can have the following values:
  - 8 when size = 00
  - 16 when size = 01
  - 32 when size = 10

- **<list>** Is a list containing the single 64-bit name of the SIMD&FP register holding the element.
The list must be \{ <Dd>[<index>] \}.
The register <Dd> is encoded in the "D:Vd" field.
The permitted values and encoding of <index> depend on <size>:
  - <size> == 8  \(<index>\) is in the range 0 to 7, encoded in the "index_align<3:1>" field.
  - <size> == 16 \(<index>\) is in the range 0 to 3, encoded in the "index_align<3:2>" field.
  - <size> == 32 \(<index>\) is 0 or 1, encoded in the "index_align<3>" field.

- **<Rn>** Is the general-purpose base register, encoded in the "Rn" field.

- **<align>** When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.
Whenever `<align>` is omitted, the standard alignment is used, see *Unaligned data access on page E2-2777*, and the encoding depends on `<size>`:

- `<size>` == 8  
  Encoded in the "index_align<0>" field as 0.
- `<size>` == 16  
  Encoded in the "index_align<1:0>" field as 0b00.
- `<size>` == 32  
  Encoded in the "index_align<2:0>" field as 0b000.

Whenever `<align>` is present, the permitted values and encoding depend on `<size>`:

- `<size>` == 16  
  `<align>` is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01.
- `<size>` == 32  
  `<align>` is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011.

: is the preferred separator before the `<align>` value, but the alignment can be specified as @<align>, see *The Advanced SIMD addressing mode on page F2-2869*.

`<Rm>`  
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode on page F2-2869*.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d],index] = MemU[address,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;
    else
```

\]
\[
\text{if n} = 15 || d+regs > 32 \text{ then UNPREDICTABLE;}
\]

CONSTRUINED UNPREDICTABLE behavior
If \( d+\text{regs} > 32 \), then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings
For more information about the CONSTRUINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLDI (single element to all lanes) on page K1-6110.

Assembler symbols
\(<c>\)  For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-2848.

\(<q>\)  See Standard assembler syntax fields on page F2-2848.

\(<\text{size}>\)  Is the data size, encoded in the "size" field. It can have the following values:
- 8 when size = 00
- 16 when size = 01
- 32 when size = 10

The encoding size = 11 is reserved.

\(<\text{list}>\)  Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:
\[
\{ <Dd>[] \} \quad \text{Encoded in the "T" field as 0.} \]
The register <Dd> is encoded in the "D:Vd" field.

<rn>  Is the general-purpose base register, encoded in the "Rn" field.

<align>  When <size> == 8, <align> must be omitted, otherwise it is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and is encoded in the "a" field as 0.
Whenever <align> is present, the permitted values and encoding depend on <size>:
  <size> == 16  <align> is 16, meaning 16-bit alignment, encoded in the "a" field as 1.
  <size> == 32  <align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.
: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-2869.

<Rm>  Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-2869.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  address = R[n];  iswrite = FALSE;
  address = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  bits(64) replicated_element = Replicate(MemU[address,ebytes]);
  for r = 0 to regs-1
    D[d+r] = replicated_element;
    if wback then
      if register_index then
        R[n] = R[n] + R[m];
      else
        R[n] = R[n] + ebytes;
    else
      R[n] = R[n] + ebytes;
F6.1.87 VLD1 (multiple single elements)

Load multiple single 1-element structures to one, two, three, or four registers loads elements from memory into one, two, three, or four registers, without de-interleaving. Every element of each register is loaded. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

\text{if n} &= 15 \| d+\text{regs} > 32 \text{ then UNPREDICTABLE;}
\end{align*}
\]

**CONSTRAINED UNPREDICTABLE behavior**

If \( d+\text{regs} > 32 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLDI (multiple single elements) on page K1-6110.

Related encodings: See Advanced SIMD element or structure load/store on page F3-2922 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-2997 for the A32 instruction set.

**Assembler symbols**

\(<^c>\) For encoding A1, A2, A3 and A4: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1, T2, T3 and T4: see *Standard assembler syntax fields* on page F2-2848.

For encoding T1, T2, T3 and T4: see *Standard assembler syntax fields* on page F2-2848.

**<size>**
Is the data size, encoded in the "size" field. It can have the following values:

- 8 when size = 00
- 16 when size = 01
- 32 when size = 10
- 64 when size = 11

**<list>**
Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of:

- \{ <Dd> \} Single register. Selects the A1 and T1 encodings of the instruction.
- \{ <Dd>, <Dd+1> \} Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.
- \{ <Dd>, <Dd+1>, <Dd+2> \} Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.
- \{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> \} Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.

The register \(<Dd>\) is encoded in the "D:Vd" field.

**<Rn>**
Is the general-purpose base register, encoded in the "Rn" field.

**<align>**
Is the optional alignment. Whenever \(<align>\) is omitted, the standard alignment is used, see *Unaligned data access* on page E2-2777, and is encoded in the "align" field as \(0b00\).

Whenever \(<align>\) is present, the permitted values are:

- 64 64-bit alignment, encoded in the "align" field as \(0b01\).
- 128 128-bit alignment, encoded in the "align" field as \(0b10\). Available only if \(<list>\) contains two or four registers.
- 256 256-bit alignment, encoded in the "align" field as \(0b11\). Available only if \(<list>\) contains four registers.

: is the preferred separator before the \(<align>\) value, but the alignment can be specified as @<align>, see *The Advanced SIMD addressing mode* on page F2-2869.

**<Rm>**
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode* on page F2-2869.

**Operation for all encodings**

```plaintext

  if n == 15 || d2 > 31 then UNPREDICTABLE;

CONstrained unpredictable behavior

If d2 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONstrained unpredictable behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD2 (single 2-element structure to one lane) on page K1-6110.

Assembler symbols

- For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
- For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-2848.

For encoding A1, A2 and A3:

- <c>  See Standard assembler syntax fields on page F2-2848.
- <q>  See Standard assembler syntax fields on page F2-2848.
- <size>  Is the data size, encoded in the "size" field. It can have the following values:
  - 8  when size = 00
  - 16 when size = 01
  - 32 when size = 10
- <list>  Is a list containing the 64-bit names of the two SIMD&FP registers holding the element. The list must be one of:
  - \{ <Dd>[<index>], <Dd+1>[<index>] \}  Single-spaced registers, encoded as "spacing" = 0.
  - \{ <Dd>[<index>], <Dd+2>[<index>] \}  Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

- <size> == 16  "spacing" is encoded in the "index\_align<1>" field.
- <size> == 32  "spacing" is encoded in the "index\_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.
The permitted values and encoding of \(<\text{index}>\) depend on \(<\text{size}>\):

- \(<\text{size}> == 8\)  \(<\text{index}>\) is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- \(<\text{size}> == 16\) \(<\text{index}>\) is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- \(<\text{size}> == 32\) \(<\text{index}>\) is 0 or 1, encoded in the "index_align<3>" field.

\(<\text{Rn}>\)  Is the general-purpose base register, encoded in the "Rn" field.

\(<\text{align}>\)  Is the optional alignment.

Whenever \(<\text{align}>\) is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and the encoding depends on \(<\text{size}>\):

- \(<\text{size}> == 8\) \(\text{align}\) is 0, encoded in the "index_align<0>" field as 0.
- \(<\text{size}> == 16\) \(\text{align}\) is 0, encoded in the "index_align<0>" field as 0.
- \(<\text{size}> == 32\) \(\text{align}\) is 0, encoded in the "index_align<1:0>" field as 0b00.

Whenever \(<\text{align}>\) is present, the permitted values and encoding depend on \(<\text{size}>\):

- \(<\text{size}> == 8\) \(\text{align}\) is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1.
- \(<\text{size}> == 16\) \(\text{align}\) is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
- \(<\text{size}> == 32\) \(\text{align}\) is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01.

\(<\text{Rm}>\)  Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-2869.

**Operation for all encodings**

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R\[n\];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[0][d], index] = MemU[address,ebytes];
    Elem[0][d2],index] = MemU[address+ebytes,ebytes];
if wback then
    if register_index then
        R\[n\] = R\[n\] + R\[m\];
    else
        R\[n\] = R\[n\] + 2*ebytes;
```
### F6.1.89 VLD2 (single 2-element structure to all lanes)

Load single 2-element structure and replicate to all lanes of two registers. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

\end{align*}
\]

CONSTRAINED UNPREDICTABLE behavior
If \( d2 > 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD2 (single 2-element structure to all lanes) on page K1-6111.

Assembler symbols

\(<c>\) For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-2848.

\(<q>\) See Standard assembler syntax fields on page F2-2848.

\(<\text{size}>\) Is the data size, encoded in the "size" field. It can have the following values:

\[
\begin{align*}
8 & \text{ when size = 00} \\
16 & \text{ when size = 01} \\
32 & \text{ when size = 10} \\
\end{align*}
\]

The encoding size = 11 is reserved.

\(<\text{list}>\) Is a list containing the 64-bit names of two SIMD&FP registers.
The list must be one of:

\[
\{ \ <Dd>[], \ <Dd+1>[] \} \quad \text{Single-spaced registers, encoded in the "T" field as 0.}
\]
{ <Dd>[], <Dd+2>[]} Double-spaced registers, encoded in the "T" field as 1.
The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and is encoded in the "a" field as 0.
Whenever <align> is present, the permitted values and encoding depend on <size>:
\[
\begin{align*}
\text{<size> == 8} & : \text{<align> is 16, meaning 16-bit alignment, encoded in the "a" field as 1.} \\
\text{<size> == 16} & : \text{<align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.} \\
\text{<size> == 32} & : \text{<align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1.}
\end{align*}
\]
: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-2869.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.
For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-2869.

Operation for all encodings
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;
F6.1.90   VLD2 (multiple 2-element structures)

Load multiple 2-element structures to two or four registers loads multiple 2-element structures from memory into
two or four registers, with de-interleaving. For more information, see Element and structure load/store instructions
on page F1-2829. Every element of each register is loaded. For details of the addressing mode see The Advanced
SIMD addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the
instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

VLD2{<c>}{<q>}{<size>} <list>, [<Rn>{:<align}>], <Rm>

Decode for all variants of this encoding

regs = 1;  if align == '11' then UNDEFINED;  
if size == '11' then UNDEFINED;  
inc = if type == '1001' then 2 else 1;  
alignment = if align == '00' then 1 else 4 << UInt(align);  
ebytes = 1 << UInt(size);  elements = 8 DIV ebytes;  
d = UInt(D:Vd);  d2 = d + inc;  n = UInt(Rn);  m = UInt(Rm);  
wbback = (m != 15);  register_index = (m != 15 & m != 13);  
if n == 15 || d2+regs > 32 then UNPREDICTABLE;

CONSTRANDED UNPREDICTABLE behavior

If d2+regs > 32, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as NOP.
• One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, 
  the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T2

| 15 14 13 12|11 10 9 8 7 6 5 4 3 0 | 12|11 10 9 8 7 6 5 4 3 0 |

Post-indexed variant
Applies when Rm == 1101.

VLD2{<c>}{<q>}{<size>} <list>, [<Rn>{:<align}>]!

Post-indexed variant
Applies when Rm != 11x1.

VLD2{<c>}{<q>}{<size>} <list>, [<Rn>{:<align}>], <Rm>

Decode for all variants of this encoding

regs = 2;  inc = 2;  
if size == '11' then UNDEFINED;  
alignment = if align == '00' then 1 else 4 << UInt(align);  
ebytes = 1 << UInt(size);  elements = 8 DIV ebytes;  
d = UInt(D:Vd);  d2 = d + inc;  n = UInt(Rn);  m = UInt(Rm);  
wbback = (m != 15);  register_index = (m != 15 & m != 13);  
if n == 15 || d2+regs > 32 then UNPREDICTABLE;
CONSTRANGED UNPREDICTABLE behavior

If $d2+\text{regs} > 32$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRANGED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD2 (multiple 2-element structures) on page K1-6110.

Related encodings: See Advanced SIMD element or structure load/store on page F3-2922 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-2997 for the A32 instruction set.

Assembler symbols

- `<c>` For encoding A1 and A2: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
  For encoding T1 and T2: see Standard assembler syntax fields on page F2-2848.
- `<q>` See Standard assembler syntax fields on page F2-2848.
- `<size>` Is the data size, encoded in the "size" field. It can have the following values:
  - 8 when size = 00
  - 16 when size = 01
  - 32 when size = 10
  The encoding size = 11 is reserved.
- `<list>` Is a list containing the 64-bit names of the SIMD&FP registers.
  The list must be one of:
  - `{ <Dd>, <Dd+1> }` Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as 0b1000.
  - `{ <Dd>, <Dd+2> }` Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as 0b1001.
  - `{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }` Three single-spaced registers. Selects the A2 and T2 encodings of the instruction.
    The register <Dd> is encoded in the "D:Vd" field.
- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field.
- `<align>` Is the optional alignment.
  Whenever `<align>` is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and is encoded in the "align" field as 0b00.
  Whenever `<align>` is present, the permitted values are:
  - 64 64-bit alignment, encoded in the "align" field as 0b01.
  - 128 128-bit alignment, encoded in the "align" field as 0b10.
  - 256 256-bit alignment, encoded in the "align" field as 0b11. Available only if `<list>` contains four registers.
<align> is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-2869.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-2869.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  address = R[n];  iswrite = FALSE;
  address = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[d+r, e] = MemU[address, ebytes];
      Elem[d2+r, e] = MemU[address+ebytes, ebytes];
      address = address + 2*ebytes;
    if wback then
      if register_index then
        R[n] = R[n] + R[m];
      else
        R[n] = R[n] + 16*regs;
```

**F6.1.91 VLD3 (single 3-element structure to one lane)**

Load single 3-element structure to one lane of three registers loads one 3-element structure from memory into corresponding elements of three registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

- The instruction is UNDEFINED.
- The instruction executes as \( \text{NOP} \).
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly \( VLD3 \) (single 3-element structure to one lane) on page K1-6111.

**Assembler symbols**

- **<c>** For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
  For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-2848.

- **<q>** See Standard assembler syntax fields on page F2-2848.

- **<size>** Is the data size, encoded in the "size" field. It can have the following values:
  - 8 when \( \text{size} = 00 \)
  - 16 when \( \text{size} = 01 \)
  - 32 when \( \text{size} = 10 \)

- **<list>** Is a list containing the 64-bit names of the three SIMD&FP registers holding the element. The list must be one of:
  - \{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] \}
    Single-spaced registers, encoded as "spacing" = 0.
  - \{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] \}
    Double-spaced registers, encoded as "spacing" = 1. Not permitted when \( \text{size} == 8 \).

The encoding of "spacing" depends on \( \text{size} \):

- \( \text{size} == 8 \) "spacing" is encoded in the "index.Align<0>" field.
- \( \text{size} == 16 \) "spacing" is encoded in the "index.Align<1>" field, and "index.Align<0>" is set to 0.
- \( \text{size} == 32 \) "spacing" is encoded in the "index.Align<2>" field, and "index.Align<1:0>" is set to 0b00.
The register $D_d$ is encoded in the "$D:\text{Vd}$" field.

The permitted values and encoding of $\langle \text{index} \rangle$ depend on $\langle \text{size} \rangle$:

- $\langle \text{size} \rangle = 8$: $\langle \text{index} \rangle$ is in the range 0 to 7, encoded in the "$\text{index\_align<3:1>}$" field.
- $\langle \text{size} \rangle = 16$: $\langle \text{index} \rangle$ is in the range 0 to 3, encoded in the "$\text{index\_align<3:2>}$" field.
- $\langle \text{size} \rangle = 32$: $\langle \text{index} \rangle$ is 0 or 1, encoded in the "$\text{index\_align<3>}" field.

$\langle Rn \rangle$ is the general-purpose base register, encoded in the "$Rn$" field.

$\langle Rm \rangle$ is the general-purpose index register containing an offset applied after the access, encoded in the "$Rm$" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode on page F2-2869*.

**Alignment**

Standard alignment rules apply, see *Alignment support on page B2-102*.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();

  Is the data size, encoded in the "size" field. It can have the following values:

  - 8 when size = 00
  - 16 when size = 01
  - 32 when size = 10

  The encoding size = 11 is reserved.

- \(<list>\)  
  
  Is a list containing the 64-bit names of three SIMD&FP registers.

  The list must be one of:

  \[ \{ <Dd>[], <Dd+1>[], <Dd+2>[] \} \]

  Single-spaced registers, encoded in the "T" field as 0.
Double-spaced registers, encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:\Vd" field.

<?r?> Is the general-purpose base register, encoded in the "Rn" field.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode* on page F2-2869.

**Alignment**

Standard alignment rules apply, see *Alignment support on page B2-102.*

**Operation for all encodings**

if **ConditionPassed()** then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n];
  D[d] = Replicate(MemU[address,ebytes]);
  D[d2] = Replicate(MemU[address+ebytes,ebytes]);
  D[d3] = Replicate(MemU[address+2*ebytes,ebytes]);
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + 3*ebytes;
F6.1.93   VLD3 (multiple 3-element structures)

Load multiple 3-element structures to three registers loads multiple 3-element structures from memory into three
registers, with de-interleaving. For more information, see Element and structure load/store instructions on
page F1-2829. Every element of each register is loaded. For details of the addressing mode see The Advanced SIMD
addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the
instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly \text{VLD3 (multiple 3-element structures)} on page K1-6111.

Related encodings: See Advanced SIMD element or structure load/store on page F3-2922 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-2997 for the A32 instruction set.
Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-2848.

<q>
See Standard assembler syntax fields on page F2-2848.

<size>
Is the data size, encoded in the "size" field. It can have the following values:
- 8 when size = 00
- 16 when size = 01
- 32 when size = 10

The encoding size = 11 is reserved.

<list>
Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:
- \{ <Dd>, <Dd+1>, <Dd+2> \}  
  Single-spaced registers, encoded in the "type" field as 0b0100.
- \{ <Dd>, <Dd+2>, <Dd+4> \}  
  Double-spaced registers, encoded in the "type" field as 0b0101.

The register <Dd> is encoded in the "D:Vd" field.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

<align>
Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and is encoded in the "align" field as 0b00.

Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b1.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-2869.

<Rm>
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about <Rn>, !, and <Rm>, see The Advanced SIMD addressing mode on page F2-2869.

Operation for all encodings

**Decode for all variants of this encoding**

- if size == '11' then see VLD4 (single 4-element structure to all lanes);
- if index_align<1:0> == '11' then UNDEFINED;
- bytes = 4; index = UInt(index_align<3>);
- inc = if index_align<2> == '0' then 1 else 2;
- alignment = if index_align<1:0> == '00' then 1 else 4 << UInt(index_align<1:0>);
- d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; d4 = d3 + inc; n = UInt(Rn); m = UInt(Rm);
- wback = (m != 15); register_index = (m != 15 & & m != 13);
- if n == 15 || d4 > 31 then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD4 (single 4-element structure to one lane) on page K1-6111.

**Assembler symbols**

- `<c>`: For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
- For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-2848.
- `<q>`: See Standard assembler syntax fields on page F2-2848.
- `<size>`: Is the data size, encoded in the "size" field. It can have the following values:
  - 8 when size = 00
  - 16 when size = 01
  - 32 when size = 10
- `<list>`: Is a list containing the 64-bit names of the four SIMD&FP registers holding the element.
  The list must be one of:
  - `{<Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>]}`
    Single-spaced registers, encoded as "spacing" = 0.
  - `{<Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>]}`
    Double-spaced registers, encoded as "spacing" = 1. Not permitted when `<size>` == 8.
  The encoding of "spacing" depends on `<size>`:
  - `<size>` == 16 "spacing" is encoded in the "index_align<1>" field.
  - `<size>` == 32 "spacing" is encoded in the "index_align<2>" field.
  The register `<Dd>` is encoded in the "D:Vd" field.
The permitted values and encoding of `<index>` depend on `<size>`:

- `<size> == 8`  
  `<index>` is in the range 0 to 7, encoded in the "index_align<3:1>" field.

- `<size> == 16`  
  `<index>` is in the range 0 to 3, encoded in the "index_align<3:2>" field.

- `<size> == 32`  
  `<index>` is 0 or 1, encoded in the "index_align<3:3>" field.

**<Rn>**  
Is the general-purpose base register, encoded in the "Rn" field.

**<align>**  
Is the optional alignment.

Whenever `<align>` is omitted, the standard alignment is used, see *Unaligned data access on page E2-2777*, and the encoding depends on `<size>`:

- `<size> == 8`  
  Encoded in the "index_align<0>" field as 0.

- `<size> == 16`  
  Encoded in the "index_align<0>" field as 0.

- `<size> == 32`  
  Encoded in the "index_align<1:0>" field as 0b00.

Whenever `<align>` is present, the permitted values and encoding depend on `<size>`:

- `<size> == 8`  
  `<align>` is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.

- `<size> == 16`  
  `<align>` is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1.

- `<size> == 32`  
  `<align>` can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10.

`:` is the preferred separator before the `<align>` value, but the alignment can be specified as @<align>, see *The Advanced SIMD addressing mode on page F2-2869*.

**<Rm>**  
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *The Advanced SIMD addressing mode on page F2-2869*.

**Operation for all encodings**

```c
if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  address = R[n];  iswrite = FALSE;
  - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  Elem[D][d], index = MemU[address,ebytes];
  Elem[D][d2],index = MemU[address+ebytes,ebytes];
  Elem[D][d3],index = MemU[address+2*ebytes,ebytes];
  Elem[D][d4],index = MemU[address+3*ebytes,ebytes];
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + 4*ebytes;
```
F6.1.95  VLD4 (single 4-element structure to all lanes)

Load single 4-element structure and replicate to all lanes of four registers loads one 4-element structure from memory into all lanes of four registers. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

**Notes for all encodings**
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VLD4 (single 4-element structure to all lanes) on page K1-6112.

**Assembler symbols**

\(<c>\) 
For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-2848.
<p>See Standard assembler syntax fields on page F2-2848.</p>

<code><strong>&lt;size&gt;</strong></code>

Is the data size, encoded in the "size" field. It can have the following values:

- <strong>8</strong> when size = 00
- <strong>16</strong> when size = 01
- <strong>32</strong> when size = 1x

<code><strong>&lt;list&gt;</strong></code>

Is a list containing the 64-bit names of four SIMD&FP registers.

The list must be one of:

- `{ <Dd>[], <Dd+1>[], <Dd+2>[], <Dd+3>[] }`  
  Single-spaced registers, encoded in the "T" field as 0.
- `{ <Dd>[], <Dd+2>[], <Dd+4>[], <Dd+6>[] }`  
  Double-spaced registers, encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<code><strong>&lt;Rn&gt;</strong></code>

Is the general-purpose base register, encoded in the "Rn" field.

<code><strong>&lt;align&gt;</strong></code>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and is encoded in the "a" field as 0.

Whenever <align> is present, the permitted values and encoding depend on <size>:

- <strong>&lt;size&gt; == 8</strong>  
  <align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.
- <strong>&lt;size&gt; == 16</strong>  
  <align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1.
- <strong>&lt;size&gt; == 32</strong>  
  <align> can be 64 or 128. 64-bit alignment is encoded in the "a:size<0>" field as 0b10, and 128-bit alignment is encoded in the "a:size<0>" field as 0b11.

  : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-2869.

<code><strong>&lt;Rm&gt;</strong></code>

Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-2869.

**Operation for all encodings**

if ConditionPassed() then

  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n]; iswrite = FALSE;
  - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  D[d] = Replicate(MemU[address,ebytes]);
  D[d2] = Replicate(MemU[address+ebytes,ebytes]);
  D[d3] = Replicate(MemU[address+2*ebytes,ebytes]);
  D[d4] = Replicate(MemU[address+3*ebytes,ebytes]);
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + 4*ebytes;
  ...
F6.1.96   VLD4 (multiple 4-element structures)

Load multiple 4-element structures to four registers loads multiple 4-element structures from memory into four registers, with de-interleaving. For more information, see Element and structure load/store instructions on page F1-2829. Every element of each register is loaded. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

        if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
F6.1.98   VLDR (immediate)

Load SIMD&FP register (immediate) loads a single register from the Advanced SIMD and floating-point register file, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

imm32 = if esize == 16 then ZeroExtend(imm8:'0', 32) else ZeroExtend(imm8:'00', 32);
d = UInt(D:Vd); n = UInt(Rn);
```

**CONSTRAINED UNPREDICTABLE behavior**

If `size == '01' && InITBlock()` , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-2848.
- `<q>` See Standard assembler syntax fields on page F2-2848.
- `.64` Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- `.32` Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
- `<Sd>` Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- `<label>` The label of the literal data item to be loaded. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020.

- `+/` Specifies the offset is added to or subtracted from the base register, defaulting to `+` if omitted and encoded in the "U" field. It can have the following values:
  - `-` when `U = 0`
For encoding A1 or T1: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2.
For encoding A1, T1: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax on page F1-2809.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    case esize of
        when 16
            S[d] = Zeros(16) : MemA[address,2];
        when 32
            S[d] = MemA[address,4];
        when 64
            word1 = MemA[address,4]; word2 = MemA[address+4,4];
            // Combine the word-aligned words in the correct order for current endianness.
            D[d] = if BigEndian() then word1:word2 else word2:word1;
```

F6.1.100   VMAX (floating-point)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements are floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

**CONstrained Unpredictable** behavior

If sz == '1' & InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Assembler symbols**

- For encoding A1: see *Standard assembler syntax fields on page F2-2848*. This encoding must be unconditional.
- For encoding T1: see *Standard assembler syntax fields on page F2-2848*.
- See *Standard assembler syntax fields on page F2-2848*.

- Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
  - F32 when sz = 0
  - F16 when sz = 1
- Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Floating-point maximum and minimum**

- max(+0.0, -0.0) = +0.0
- If any input is a NaN, the corresponding result element is the default NaN.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize];  op2 = Elem[D[m+r],e,esize];
            if maximum then
                Elem[D[d+r],e,esize] = FPMax(op1, op2, StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRValue());
F6.1.101 VMAX (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

F6.1.102  VMAXNM

This instruction determines the floating-point maximum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMAX.

This instruction is not conditional.

  when '11' esize = 64; d = UINT(D:Vd); n = UINT(N:Vn); m = UINT(M:Vm);
```

### 64-bit SIMD vector variant

Applies when \( Q = 0 \).

\[
\text{VMAXNM} \{\langle op\rangle, \langle dt\rangle \} \langle 0d\rangle, \langle 0n\rangle, \langle 0m\rangle
\]

### 128-bit SIMD vector variant

Applies when \( Q = 1 \).

\[
\text{VMAXNM} \{\langle op\rangle, \langle dt\rangle \} \langle 0d\rangle, \langle 0n\rangle, \langle 0m\rangle
\]

### Decode for all variants of this encoding

```c
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
maximum = (op == '0');
advsimd = TRUE;
case sz of
  when '0' esize = 32; elements = 2;
  when '1' esize = 16; elements = 4;
  d = UINT(D:Vd); n = UINT(N:Vn); m = UINT(M:Vm); regs = if Q == '0' then 1 else 2;
  if InITBlock() then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()` is true, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### T2

|15|14|13|12|11|10|9|8|7|6|5|4|3|0|15|12|11|10|9|8|7|6|5|4|3|0|
|1|1|1|1|1|1|1|0|D|0|sz|Vn|Vd|1|1|1|1|N|Q|M|1|Vm|

### Half-precision scalar variant

Applies when \( size == 01 \).

\[
\text{VMAXNM} \{\langle op\rangle, F16 \} \langle 5d\rangle, \langle 5n\rangle, \langle 5m\rangle // Not permitted in IT block
\]
Single-precision scalar variant

Applies when size == 10.

\textit{VMAXN}m{q}.F32 <Sd>, <Sn>, <Sm> // Not permitted in IT block

Double-precision scalar variant

Applies when size == 11.

\textit{VMAXN}m{q}.F64 <Dd>, <Dn>, <Dm> // Not permitted in IT block

Decode for all variants of this encoding

\begin{verbatim}
if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
advsimd = FALSE;
maximum = (op == '0');
case size of
  when '01' esize = 16; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
  when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
  when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
if InITBlock() then UNPREDICTABLE;
\end{verbatim}

CONSTRANGED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Notes for all encodings

For more information about the CONSTRANGED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

- \textit{q} See Standard assembler syntax fields on page F2-2848.
- \textit{dt} Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
  - F32 when \( sz = 0 \)
  - F16 when \( sz = 1 \)
- \textit{Qd} Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \textit{Qd}*2.
- \textit{Qn} Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as \textit{Qn}*2.
- \textit{Qm} Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as \textit{Qm}*2.
- \textit{Dd} Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- \textit{Dn} Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- \textit{Dm} Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
- \textit{Sd} Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- \textit{Sn} Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
- \textit{Sm} Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.

            D[d] = FPMinNum(D[n], D[m], FPSCR);
F6.1.103 VMIN (floating-point)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements are floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

      result = if maximum then Max(op1,op2) else Min(op1,op2);
      Elem[D+d+r],e,esize] = result<esize-1:0>;
F6.1.105 VMINNM

This instruction determines the floating point minimum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMIN.

This instruction is not conditional.

        Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;
F6.1.110   VMLAL (by scalar)

Vector Multiply Accumulate Long multiplies elements of a vector by a scalar, and adds the products to corresponding elements of the destination vector. The destination vector elements are twice as long as the elements that are multiplied.

For more information about scalars see Advanced SIMD scalars on page F2-2874.

Depending on settings in the CPACR, NSACR, and HCPtr registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

**Notes for all encodings**

Related encodings: See Advanced SIMD data-processing on page F3-2904 for the T32 instruction set, or Advanced SIMD data-processing on page F4-2985 for the A32 instruction set.

**Assembler symbols**

<e> For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1: see *Standard assembler syntax fields* on page F2-2848.

See *Standard assembler syntax fields* on page F2-2848.

**dt**

Is the data type for the scalar and the elements of the operand vector, encoded in the "U:size" field. It can have the following values:

- S16 when $U = 0$, size = 01
- S32 when $U = 0$, size = 10
- U16 when $U = 1$, size = 01
- U32 when $U = 1$, size = 10

**Qd**

Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as $Qd\times2$.

**Dn**

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

**Dm[x]**

Is the 64-bit name of the second SIMD&FP source register holding the scalar. If $dt$ is S16 or U16, $Dm$ is restricted to D0-D7. $Dm$ is encoded in "Vm\times2", and $x$ is encoded in "M:Vm\times3". If $dt$ is S32 or U32, $Dm$ is restricted to D0-D15. $Dm$ is encoded in "Vm", and $x$ is encoded in "M".

    endfor
endfor
```
F6.1.111  **VMLS (floating-point)**

Vector Multiply Subtract multiplies corresponding elements in two vectors, subtracts the products from corresponding elements of the destination vector, and places the results in the destination vector.

---  **Note**  ---

ARM recommends that software does not use the **VMLS** instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPtr, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-4413.

**CONstrained UNPREDICTABLE behavior**

If F == '1' && size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Notes for all encodings**

Related encodings: See *Advanced SIMD data-processing* on page F3-2904 for the T32 instruction set, or *Advanced SIMD data-processing* on page F4-2985 for the A32 instruction set.

**Assembler symbols**

- For encoding A1: see *Standard assembler syntax fields* on page F2-2848. This encoding must be unconditional.

  For encoding T1: see *Standard assembler syntax fields* on page F2-2848.

- Is the data type for the scalar and the elements of the operand vector, encoded in the "F:size" field. It can have the following values:
  
  - I16 when F = 0, size = 01
  - I32 when F = 0, size = 10
  - F16 when F = 1, size = 01
  - F32 when F = 1, size = 10

- Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.

- Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

- Is the 64-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field.

- Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

- Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is I16 or F16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>" and x is encoded in "M:Vm<3>". If <dt> is I32 or F32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

single_register = FALSE; advsimd = TRUE; imm64 = AdvSIMDEncodeImm(op, cmode, i:imm3:imm4);
d = UInt(D:Vd); regs = if Q == '0' then 1 else 2;

**Notes for all encodings**

Related encodings: See *Advanced SIMD one register and modified immediate* on page F3-2912 for the T32 instruction set, or *Advanced SIMD one register and modified immediate* on page F4-2994 for the A32 instruction set.

**Assembler symbols**

- **<c>**
  - For encoding A1, A3, A4 and A5: see *Standard assembler syntax fields* on page F2-2848. This encoding must be unconditional.
  - For encoding A2, T1, T2, T3, T4 and T5: see *Standard assembler syntax fields* on page F2-2848.

- **<q>**
  - See *Standard assembler syntax fields* on page F2-2848.

- **<dt>**
  - The data type, encoded in the "cmode" field. It can have the following values:
    - I32 when cmode = 110x
    - I8 when cmode = 1110
    - F32 when cmode = 1111

- **<Qd>**
  - Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

- **<Dd>**
  - Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- **<Sd>**
  - Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

- **<imm>**
  - For encoding A1, A3, A4, A5, T1, T3, T4 and T5: is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions* on page F2-2865.
  - For encoding A2 and T2: is a signed floating-point constant with 3-bit exponent and normalized 4 bits of precision, encoded in "imm4H:imm4L". For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 floating-point instructions* on page F2-2866.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDOVFPEnabled(TRUE, advsimd);
    if single_register then
        S[d] = imm32;
    else
        for r = 0 to regs-1
            D[d+r] = imm64;
F6.1.119 VMOV (register)

Copy between FP registers copies the contents of one FP register to another.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

Assembler symbols

\(<c>\) See Standard assembler syntax fields on page F2-2848.
\(<q>\) See Standard assembler syntax fields on page F2-2848.
\(<S_d>\) Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
\(<S_m>\) Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
\(<D_d>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
\(<D_m>\) Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    if single_register then
        S[d] = S[m];
    else
        for r = 0 to regs-1
            D[d+r] = D[m+r];
```

F6.1.120  VMOV (register, SIMD)

Copy between SIMD registers copies the contents of one SIMD register to another.

This instruction is an alias of the VORR (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (register).
- The description of VORR (register) gives the operational pseudocode for this instruction.

### A1

| 31 30 29 28|27 26 25 24|23 22 21 20|19 16|15 12|11 10 9 8 |7 6 5 4 |3 0 |

#### 64-bit SIMD vector variant

Applies when Q == 0.

VMOV{<c>}{<q>}{.<dt>} <Dd>, <Dm>

is equivalent to

VORR{<c>}{<q>}{.<dt>} <Dd>, <Dm>, <Dm>

and is the preferred disassembly when N:Vn == M:Vm.

#### 128-bit SIMD vector variant

Applies when Q == 1.

VMOV{<c>}{<q>}{.<dt>} <Qd>, <Qm>
is equivalent to
\[ \text{VORR} \{c\} \{q\} \{.dt\} \ Qd, \ Qm \]
and is the preferred disassembly when \( N:Vn = M:Vm \).

**Assembler symbols**

- \( c \): For encoding A1: see *Standard assembler syntax fields on page F2-2848*. This encoding must be unconditional.
  - For encoding T1: see *Standard assembler syntax fields on page F2-2848*.
- \( q \): See *Standard assembler syntax fields on page F2-2848*.
- \( .dt \): An optional data type. \( .dt \) must not be F64, but it is otherwise ignored.
- \( Qd \): Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \( Qd * 2 \).
- \( Qm \): Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as \( Qm * 2 \).
- \( Dd \): Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- \( Dm \): Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

**Operation for all encodings**

The description of *VORR (register)* gives the operational pseudocode for this instruction.
F6.1.121   VMOV (general-purpose register to scalar)

Copy a general-purpose register to a vector element copies a byte, halfword, or word from a general-purpose register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see *Advanced SIMD scalars* on page F2-2874.

Depending on settings in the CPACR, NSACR, HCPTTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-4413.

    d = UInt(D:Vd);  t = UInt(Rt);
    if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors.*
Assembler symbols

<>  See Standard assembler syntax fields on page F2-2848.

<>  See Standard assembler syntax fields on page F2-2848.

<size> The data size. It must be one of:

8  Encoded as opc1<1> = 1. [x] is encoded in opc1<0>, opc2.<n>
16 Encoded as opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>.
32 Encoded as opc1<1> = 0, opc2<1> = 0b00. [x] is encoded in opc1<0>.

omitted Equivalent to 32.

<DD[x]> The scalar. The register <DD> is encoded in D:Vd. For details of how [x] is encoded, see the description of <size>.

<Rt> The source general-purpose register.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDOrVFPEncabled(TRUE, advsimd);
    Elem[DD[0], index, esize] = R[t]<esize-1:0>;
## F6.1.122 VMOV (between general-purpose register and single-precision)

Copy a general-purpose register to or from a 32-bit SIMD&FP register. This instruction transfers the value held in a 32-bit SIMD&FP register to a general-purpose register, or the value held in a general-purpose register to a 32-bit SIMD&FP register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see _Enabling Advanced SIMD and floating-point support_ on page G1-4413.

### A1

  else
    \(S[n] = R[t];\)
\end{verbatim}
F6.1.123 \textbf{VMOV (scalar to general-purpose register)}

Copy a vector element to a general-purpose register with sign or zero extension copies a byte, halfword, or word from an Advanced SIMD scalar to a general-purpose register. Bytes and halfwords can be either zero-extended or sign-extended.

On a Floating-point-only system, this instruction transfers one word from the upper or lower half of a double-precision floating-point register to a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see \textit{Advanced SIMD scalars on page F2-2874.}

Depending on settings in the CPACR, NSACR, HCPTR, and FPXEC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see \textit{Enabling Advanced SIMD and floating-point support on page G1-4413.}

if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
if InITBlock() then UNPREDICTABLE;
d = UInt(Vd:D); m = UInt(Vm:M);

CONSTRUANDED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as if it passes the Condition code check.
• The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler symbols

<q> See Standard assembler syntax fields on page F2-2848.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    S[d] = Zeros(16) : S[m]<31:16>;
```
F6.1.128   VMRS

Move SIMD&FP Special register to general-purpose register moves the value of an Advanced SIMD and
floating-point System register to a general-purpose register. When the specified System register is the FPSCR, a
form of the instruction transfers the FPSCR. {N, Z, C, V} condition flags to the APSR. {N, Z, C, V} condition flags.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in
which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp
mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

When these settings permit the execution of floating-point and Advanced SIMD instructions, if the specified
floating-point System register is not the FPSCR, the instruction is UNDEFINED if executed in User mode.

In an implementation that includes EL2, when HCR.TID0 is set to 1, any VMRS access to FPSID from a Non-secure
EL1 mode that would be permitted if HCR.TID0 was set to 0 generates a Hyp Trap exception. For more information,
see ID group 0, Primary device identification registers on page G1-4435.

For simplicity, the VMRS pseudocode does not show the possible trap to Hyp mode.

A1

VMRS{<c>}{<q>} <Rt>, <spec_reg>

Decode for this encoding

\[ t = \text{UInt}(Rt); \]
\[ \text{if } !(\text{reg IN '000x', '0101', '011x', '1000'}) \text{ then UNPREDICTABLE; } \]
\[ \text{if } t == 15 \&\& \text{reg != '0001'} \text{ then UNPREDICTABLE; } // \text{ ARMv8-A removes UNPREDICTABLE for R13} \]

CONSTRUANCED UNPREDICTABLE behavior

If !(\text{reg IN '000x', '0101', '011x', '1000'}), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value
  0b1111, the specified target register is the APSR. {N, Z, C, V} bits, and these bits become UNKNOWN.
  Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

T1

VMRS{<c>}{<q>} <Rt>, <spec_reg>
Decode for this encoding

t = UInt(Rt);
if !(reg IN {'000x', '0101', '011x', '1000'}) then UNPREDICTABLE;
if t == 15 && reg != '0001' then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRAINED UNPREDICTABLE behavior

If !(reg IN {'000x', '0101', '011x', '1000'}), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value \(0b1111\), the specified target register is the APSR.{N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

- See Standard assembler syntax fields on page F2-2848.
- See Standard assembler syntax fields on page F2-2848.
- Is the general-purpose destination register, encoded in the "Rt" field. Is one of:
  - General-purpose register.
  - Permitted only when <spec_reg> is FPSCR. Encoded as 0b1111. The instruction transfers the FPSCR.{N, Z, C, V} condition flags to the APSR.{N, Z, C, V} condition flags.
- Is the source Advanced SIMD and floating-point System register, encoded in the "reg" field. It can have the following values:
  - FPSID when reg = 0000
  - FPSCR when reg = 0001
  - MVFR2 when reg = 0101
  - MVFR1 when reg = 0110
  - MVFR0 when reg = 0111
  - FPEXC when reg = 1000

The following encodings are UNPREDICTABLE:

- reg = 001x.
- reg = 0100.
- reg = 1001.
- reg = 101x.
- reg = 11xx.

Operation for all encodings

end

  case reg of
    // Pseudocode does not consider possible HCR.TIDn Hyp Traps of Non-secure register reads
    when '0000'  R[t] = FPSID;
    when '0101'  R[t] = MVFR2;
    when '0110'  R[t] = MVFR1;
    when '0111'  R[t] = MVFR0;
    when '1000'  R[t] = FPEXC;
    otherwise    Unreachable();   // Dealt with above or in encoding-specific pseudocode
F6.1.129  VMSR

Move general-purpose register to SIMD&FP Special register moves the value of a general-purpose register to a floating-point System register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

When these settings permit the execution of floating-point and Advanced SIMD instructions:

- If the specified floating-point System register is not the FPSCR, the instruction is UNDEFINED if executed in User mode.
- If the specified floating-point System register is the FPEXC and the instruction is executed in a mode other than User mode the instruction is ignored.

---|---|---|---|---|---|---|---|---|
| !=1111| 1 1 1 0 1 1 1 0| reg | Rt | 1 0 1 0 (0)(0)(0) 1 (0)(0)(0)(0) |

A1 variant

VMSR{<c>}{<q>} <spec_reg>, <Rt>

Decode for this encoding

t = UInt(Rt);
if reg != '000x' && reg != '1000' then UNPREDICTABLE;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRANDED UNPREDICTABLE behavior

If reg != '000x' && reg != '1000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using VMSR at the same Exception level.

T1

|15 14 13 12|11 10 9 8|7 6 5 4 3 0 15|12|11 10 9 8|7 6 5 4 3 2 1 0 |

| 1 1 1 0 1 1 1 0 1 1 1 0| reg | Rt | 1 0 1 0 (0)(0)(0)(0) 1 (0)(0)(0)(0) |

T1 variant

VMSR{<c>}{<q>} <spec_reg>, <Rt>

Decode for this encoding

t = UInt(Rt);
if reg != '000x' && reg != '1000' then UNPREDICTABLE;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
**CONSTRAINED UNPREDICTABLE behavior**

If \( \text{reg} \neq '000x' \land \text{reg} \neq '1000' \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using **VMSR** at the same Exception level.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields* on page F2-2848.
- `<q>` See *Standard assembler syntax fields* on page F2-2848.
- `<spec_reg>` Is the destination Advanced SIMD and floating-point System register, encoded in the "reg" field. It can have the following values:
  - FPSID when \( \text{reg} = 0000 \)
  - FPSCR when \( \text{reg} = 0001 \)
  - FPEXC when \( \text{reg} = 1000 \)

  The following encodings are UNPREDICTABLE:
  - \( \text{reg} = 001x \)
  - \( \text{reg} = 01xx \)
  - \( \text{reg} = 1001 \)
  - \( \text{reg} = 101x \)
  - \( \text{reg} = 11xx \).

- `<Rt>` Is the general-purpose source register, encoded in the "Rt" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    if reg == '0001' then // FPSCR
        CheckVFPEnabled(TRUE);
        FPSCR = R[t];
    elsif PSTATE.EL == EL0 then
        UNDEFINED; // Non-FPSCR registers accessible only at PL1 or above
    else
        CheckVFPEnabled(FALSE); // Non-FPSCR registers are not affected by FPEXC.EN
    end
    case reg of
        when '0000' // VMSR access to FPSID is ignored
            when '1000' FPEXC = R[t];
            otherwise Unreachable(); // Dealt with above or in encoding-specific pseudocode
```

**CONSTRAINED UNPREDICTABLE behavior**

If op == '1' && size == '10' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Related encodings: See Advanced SIMD data-processing on page F3-2904 for the T32 instruction set, or Advanced SIMD data-processing on page F4-2985 for the A32 instruction set.

**Assembler symbols**

- `<c>` For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
  
  For encoding T1: see Standard assembler syntax fields on page F2-2848.

- `<q>` See Standard assembler syntax fields on page F2-2848.

- `<dt>` Is the data type for the elements of the operands, encoded in the "op:U:size" field. It can have the following values:
  
  | S8   | when op = 0, U = 0, size = 00 |
  | S16  | when op = 0, U = 0, size = 01 |
  | S32  | when op = 0, U = 0, size = 10 |
  | U8   | when op = 0, U = 1, size = 00 |
  | U16  | when op = 0, U = 1, size = 01 |
  | U32  | when op = 0, U = 1, size = 10 |
  | P8   | when op = 1, U = 0, size = 00 |
  | P64  | when op = 1, U = 0, size = 10 |

- `<Qd>` Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.`

- `<Dn>` Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

- `<Dm>` Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

**Notes for all encodings**

Related encodings: See *Advanced SIMD data-processing* on page F3-2904 for the T32 instruction set, or *Advanced SIMD data-processing* on page F4-2985 for the A32 instruction set.

**Assembler symbols**

<

For encoding A1: see *Standard assembler syntax fields* on page F2-2848. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields* on page F2-2848.
See *Standard assembler syntax fields* on page F2-2848.

**dt**

Is the data type for the scalar and the elements of the operand vector, encoded in the "U:size" field. It can have the following values:

- **S16** when \( U = 0 \), size = 01
- **S32** when \( U = 0 \), size = 10
- **U16** when \( U = 1 \), size = 01
- **U32** when \( U = 1 \), size = 10

**qd**

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

**dn**

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

**dm**

Is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16 or U16, otherwise the "Vm" field.

**index**

Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16 or U16, otherwise in range 0 to 1, encoded in the "M" field.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  op2 = Elem[Din[m],index,esize]; op2val = Int(op2, unsigned);
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = Elem[Din[n+r],e,esize]; op1val = Int(op1, unsigned);
      if floating_point then
        Elem[D[d+r],e,esize] = FPMul(op1, op2, StandardFPSCRValue());
      else
        if long_destination then
          Elem[D[d+r],e,2*esize] = (op1val*op2val]<2*esize-1:0>
        else
          Elem[D[d+r],e,esize] = (op1val*op2val]<esize-1:0>
```

F6.1.138 VNMLA

Vector Negate Multiply Accumulate multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

--- Note ---

ARM recommends that software does not use the VNMLA instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

F6.1.141 VORN (immediate)

Vector Bitwise OR NOT (immediate) performs a bitwise OR between a register value and the complement of an immediate value, and returns the result into the destination vector.

This instruction is a pseudo-instruction of the VORR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VORR (immediate) gives the operational pseudocode for this instruction.

A1

```

For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1: see *Standard assembler syntax fields on page F2-2848.*

<q>
See *Standard assembler syntax fields on page F2-2848.*
<dt>
An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR NOT(D[m+r]);
```
F6.1.143 VORR (immediate)

Vector Bitwise OR (immediate) performs a bitwise OR between a register value and an immediate value, and returns the result into the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

This instruction is used by the pseudo-instruction VORN (immediate). The pseudo-instruction is never the preferred disassembly.

Assembler symbols

For encoding A1 and A2: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1 and T2: see Standard assembler syntax fields on page F2-2848.

<q>
See Standard assembler syntax fields on page F2-2848.

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<imm> Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-2865.

The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

**Operation for all encodings**

```c
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    D[d+r] = D[d+r] OR imm64;
```
F6.1.144   VORR (register)

Vector bitwise OR (register) performs a bitwise OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

This instruction is used by the pseudo-instructions VMOV (register, SIMD), VRSHR (zero), and VSHR (zero). The pseudo-instruction is never the preferred disassembly.

    when '1' esize = 16; elements = 4;
    d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);

CONSTRAINED UNPREDICTABLE behavior

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.
Assembler symbols

For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-2848.

See Standard assembler syntax fields on page F2-2848.

Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
- F32 when \( sz = 0 \)
- F16 when \( sz = 1 \)

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```plaintext
if ConditionPassed() then
   EncodingSpecificOperations(); CheckAdvSIMDEnabled();
   bits(64) dest;
   h = elements DIV 2;
   for e = 0 to h-1
      Elem[dest,e,esize] = FPAdd(Elem[D[n],2*e,esize], Elem[D[n],2*e+1,esize], StandardFPSCRValue());
      Elem[dest,e+h,esize] = FPAdd(Elem[D[m],2*e,esize], Elem[D[m],2*e+1,esize], StandardFPSCRValue());
   D[d] = dest;
```
F6.1.147 VPADD (integer)

Vector Pairwise Add (integer) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements must all be the same type, and can be 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The following figure shows the operation of VPADD doubleword operation for data type I16.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

PU W Rn

Increment After variant

VPOP{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

Assembler symbols

- `<c>` See *Standard assembler syntax fields* on page F2-2848.
- `<q>` See *Standard assembler syntax fields* on page F2-2848.
- `<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
- `<sreglist>` Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
- `<dreglist>` Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

Operation for all encodings

The description of VLDM, VLMDB, VLMIA gives the operational pseudocode for this instruction.
F6.1.154   VPUSH

Push SIMD&FP registers to Stack stores multiple consecutive registers from the Advanced SIMD and floating-point register file to the stack

This instruction is an alias of the VSTM, VSTMDB, VSTMIA instruction. This means that:

- The encodings in this description are named to match the encodings of VSTM, VSTMDB, VSTMIA.
- The description of VSTM, VSTMDB, VSTMIA gives the operational pseudocode for this instruction.

Operation for all encodings

The description of VSTM, VSTMDB, VSTMIA gives the operational pseudocode for this instruction.
F6.1.155  VQABS

Vector Saturating Absolute takes the absolute value of each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-2731.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

**Notes for all encodings**

Related encodings: See *Advanced SIMD data-processing* on page F3-2904 for the T32 instruction set, or *Advanced SIMD data-processing* on page F4-2985 for the A32 instruction set.

**Assembler symbols**

- **<c>**
  For encoding A1 and A2: see *Standard assembler syntax fields* on page F2-2848. This encoding must be unconditional.
  For encoding T1 and T2: see *Standard assembler syntax fields* on page F2-2848.

- **<q>**
  See *Standard assembler syntax fields* on page F2-2848.

- **<dt>**
  Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
  
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>S16</td>
<td>when size = 01</td>
</tr>
<tr>
<td>S32</td>
<td>when size = 10</td>
</tr>
</tbody>
</table>

- **<Qd>**
  Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

- **<Dn>**
  Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

- **<Dm>**
  For encoding A1 and T1: is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
  For encoding A2 and T2: is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16, otherwise the "Vm" field.

- **<index>**
  Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16, otherwise in range 0 to 1, encoded in the "M" field.

        if sat1 || sat2 then FPSCR.QC = '1';
F6.1.159 VQDMULH

Vector Saturating Doubling Multiply Returning High Half multiplies corresponding elements in two vectors, doubles the results, and places the most significant half of the final results in the destination vector. The results are truncated, for rounded results see VQRDMLULH.

The second operand can be a scalar instead of a vector. For more information about scalars see Advanced SIMD scalars on page F2-2874.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-2731.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

        if sat then FPSCR.QC = '1';
F6.1.161 VQMOVN, VQMOVUN

Vector Saturating Move and Narrow copies each element of the operand vector to the corresponding element of the destination vector.

The operand is a quadword vector. The elements can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result is a doubleword vector. The elements are half the length of the operand vector elements. If the operand is unsigned, the results are unsigned. If the operand is signed, the results can be signed or unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-2731.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

This instruction is used by the pseudo-instructions VQSRHN (zero), VQSRHUN (zero), VQSHRN (zero), and VQSHRUN (zero). The pseudo-instruction is never the preferred disassembly.

Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-2848.

<q>
See Standard assembler syntax fields on page F2-2848.

<dt>
Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:

S8  when size = 00
S16 when size = 01
S32 when size = 10

The encoding size = 11 is reserved.

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm>
Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm>
Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = -SInt(Elem[D[m+r],e,esize]);
            (Elem[D[d+r],e,esize], sat) = SignedSatQ(result, esize);
            if sat then FPSCR.QC = '1';
### F6.1.163 VQRDMLAH

Vector Saturating Rounding Doubling Multiply Accumulate Returning High Half. This instruction multiplies the vector elements of the first source SIMD&FP register with either the corresponding vector elements of the second source SIMD&FP register or the value of a vector element of the second source SIMD&FP register, without saturating the multiply results, doubles the results, and accumulates the most significant half of the final results with the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode description of saturation* on page E1-2731.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-4413.

Notes for all encodings

Related encodings: See *Advanced SIMD data-processing on page F3-2904* for the T32 instruction set, or *Advanced SIMD data-processing on page F4-2985* for the A32 instruction set.

Assembler symbols

<
> For encoding A1 and A2: see *Standard assembler syntax fields on page F2-2848*. This encoding must be unconditional.

For encoding T1 and T2: see *Standard assembler syntax fields on page F2-2848*.

<
> See *Standard assembler syntax fields on page F2-2848*.

<dt>
Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:

- S16 when size = 01
- S32 when size = 10

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Do>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<On>
Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Qm[x]>
Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16, omit is restricted to D0-D7. Qm is encoded in "Vm<2:0>\text{\textasciitilde}x", and x is encoded in "M:Vm<3>\text{\textasciitilde}x". If <dt> is S32, Qm is restricted to D0-D15. Qm is encoded in "Vm", and x is encoded in "M".

<Qm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then

  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  round_const = 1 << (esize-1);

  if scalar_form then op2 = SInt(Elem[D[m],index,esize]);
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = SInt(Elem[D[n+r],e,esize]);
      if !scalar_form then op2 = SInt(Elem[D[m+r],e,esize]);
      (result, sat) = SignedSatQ((2*op1*op2 + round_const) >> esize, esize);
      Elem[D[d+r],e,esize] = result;
      if sat then FPSCR.QC = '1';

F6.1.166  VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see VQSHL (register).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-2731.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

F6.1.167 VQRSHRN (zero)

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the signed rounded results in a doubleword vector.

This instruction is a pseudo-instruction of the VQMOVN, VQMOVUN instruction. This means that:

- The encodings in this description are named to match the encodings of VQMOVN, VQMOVUN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.

A1

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 12|11 10 9 8|7 6 5 4|3 0]
1 1 1 1 0 0 1 1 | D 1 1 | size | 1 0 | Vd | 0 0 | 1 0 | 1 x | M | 0 | Vm
```

Signed result variant

VQRSHRN{<c>}{<q>}.<dt> <Db>, <Qm>, #0

is equivalent to

VQMOVN{<c>}{<q>}.<dt> <Db>, <Qm>

and is never the preferred disassembly.

T1

```
[15 14 13 12|11 10 9 8|7 6 5 4|3 2 1 0|15 12|11 10 9 8|7 6 5 4|3 0]
1 1 1 1 1 1 1 1 | D 1 1 | size | 1 0 | Vd | 0 0 | 1 0 | 1 x | M | 0 | Vm
```

Signed result variant

VQRSHRN{<c>}{<q>}.<dt> <Db>, <Qm>, #0

is equivalent to

VQMOVN{<c>}{<q>}.<dt> <Db>, <Qm>

and is never the preferred disassembly.

Assembler symbols

- `<c>`  
  For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
  For encoding T1: see Standard assembler syntax fields on page F2-2848.

- `<q>`
  See Standard assembler syntax fields on page F2-2848.

- `<dt>`
  Is the data type for the elements of the operand, encoded in the "op<0>:size" field. It can have the following values:
  - `S16` when `op<0> = 0`, `size = 00`
  - `S32` when `op<0> = 0`, `size = 01`
  - `S64` when `op<0> = 0`, `size = 10`
  - `U16` when `op<0> = 1`, `size = 00`
U32 when op<0> = 1, size = 01
U64 when op<0> = 1, size = 10

The following encodings are reserved:
• op<0> = 0, size = 11.
• op<0> = 1, size = 11.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation for all encodings

The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.
F6.1.168 VQRSHRN, VQRSHRUN

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the rounded results in a doubleword vector.

For truncated results, see VQSHL (register).

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-2731.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

**Notes for all encodings**

Related encodings: See Advanced SIMD one register and modified immediate on page F3-2912 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-2994 for the A32 instruction set.

**Assembler symbols**

<cf> For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-2848.

<op> See Standard assembler syntax fields on page F2-2848.

<type> Is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values:

S when U = 0
U when U = 1
<size> Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:

- 8 when \( L = 0 \), \( \text{imm}6<5:3> = 001 \)
- 16 when \( L = 0 \), \( \text{imm}6<5:3> = 01x \)
- 32 when \( L = 0 \), \( \text{imm}6<5:3> = 1xx \)
- 64 when \( L = 1 \), \( \text{imm}6<5:3> = xxx \)

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as \(<Qd>*2\).

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as \(<Qm>*2\).

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm> Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            operand = Int(Elem[D[m+r],e,esize], src_unsigned);
            (result, sat) = SatQ(operand << shift_amount, esize, dest_unsigned);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSCR.QC = '1';
```
F6.1.171 VQSHL (register)

Vector Saturating Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

The results are truncated. For rounded results, see VQRSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-2731.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

Assembler symbols

• For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
• For encoding T1: see Standard assembler syntax fields on page F2-2848.

• See Standard assembler syntax fields on page F2-2848.

• Is the data type for the elements of the operand, encoded in the "op<0>:size" field. It can have the following values:

| S16 | when op<0> = 0, size = 0 |
| S32 | when op<0> = 0, size = 0 |
| S64 | when op<0> = 0, size = 10 |
| U16 | when op<0> = 1, size = 0 |
U32 when \( \text{op} < 0 > = 1, \text{size} = 01 \)
U64 when \( \text{op} < 0 > = 1, \text{size} = 10 \)

The following encodings are reserved:

- \( \text{op} < 0 > = 0, \text{size} = 11 \).
- \( \text{op} < 0 > = 1, \text{size} = 11 \).

\(<D_d>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

\(<Q_m>\) Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as \(<Q_m> \times 2\).

**Operation for all encodings**

The description of **VQMOVN, VQMOVUN** gives the operational pseudocode for this instruction.
F6.1.173   VQSHRN, VQSHRUN

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the truncated results in a doubleword vector.

For rounded results, see VQRSHRN, VQRSHRUN.

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see Pseudocode description of saturation on page E1-2731.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

and is never the preferred disassembly.

#### Assembler symbols

- `<c>` For encoding A1: see *Standard assembler syntax fields on page F2-2848*. This encoding must be unconditional.
  
  For encoding T1: see *Standard assembler syntax fields on page F2-2848*.

- `<q>` See *Standard assembler syntax fields on page F2-2848*.

- `<dt>` Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:
  
  \[
  \begin{align*}
  S16 & \quad \text{when size} = 00 \\
  S32 & \quad \text{when size} = 01 \\
  S64 & \quad \text{when size} = 10
  \end{align*}
  \]

  The encoding size = 11 is reserved.
<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

**Operation for all encodings**

The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.
F6.1.175 VQSUB

Vector Saturating Subtract subtracts the elements of the second operand vector from the corresponding elements of the first operand vector, and places the results in the destination vector. Signed and unsigned operations are distinct.

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode description of saturation* on page E1-2731.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-4413.

      if sat then FPSCR.QC = '1';

F6.1.176   VRADDHN

Vector Rounding Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are rounded. For truncated results, see VADDHN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

Notes for all encodings

Related encodings: See Advanced SIMD data-processing on page F3-2904 for the T32 instruction set, or Advanced SIMD data-processing on page F4-2985 for the A32 instruction set.

Assembler symbols

For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1: see Standard assembler syntax fields on page F2-2848.

<sp>

See Standard assembler syntax fields on page F2-2848.
<dt>  Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
  I16   when size = 00
  I32   when size = 01
  I64   when size = 10

<dd>  Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qn>  Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>  Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize] + round_const;
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

F6.1.177   VRECPE

Vector Reciprocal Estimate finds an approximate reciprocal of each element in the operand vector, and places the results in the destination vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see Floating-point reciprocal square root estimate and step on page E1-2750.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

  D[d+r] = result;
F6.1.181 VREV64

Vector Reverse in doublewords reverses the order of 8-bit, 16-bit, or 32-bit elements in each doubleword of the vector, and places the result in the corresponding destination vector.

There is no distinction between data types, other than size.

The following figure shows the operation of VREV64 doubleword operations.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

                D[d+r] = result;
F6.1.182 VRHADD

Vector Rounding Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector.

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The results of the halving operations are rounded. For truncated results, see VHADD.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

F6.1.187  VRINTN (Advanced SIMD)

Vector Round floating-point to integer Nearest rounds a vector of floating-point values to integral floating-point values of the same size using the Round to Nearest rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

**Operation for all encodings**

EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
  for e = 0 to elements-1
    op1 = Elem[D[m+r],e,esize];
    result = FPRoundInt(op1, StandardFPSCRValue(), rounding, exact);
    Elem[D[d+r],e,esize] = result;
F6.1.193 VRINTX (floating-point)

Round floating-point to integer inexact rounds a floating-point value to an integral floating-point value of the same size, using the rounding mode specified in the FPSCR, and raises an Inexact exception when the result value is not numerically equal to the input value. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

F6.1.196 VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see VSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

      Elem[0][d+r,e,esize] = result-esize-1:0;
F6.1.198 VRSHR (zero)

Vector Rounding Shift Right copies the contents of one SIMD register to another. This instruction is a pseudo-instruction of the VORR (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VORR (register) gives the operational pseudocode for this instruction.

and is never the preferred disassembly.

**Assembler symbols**

- `<c>`
  For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.
  For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).

- `<q>`
  See [Standard assembler syntax fields on page F2-2848](#).

- `<dt>`
  Is the data type for the elements of the vectors, and must be one of: S8, S16, S32, S64, U8, U16, U32 or U64.

- `<Qd>`
  Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>∗2`.

- `<Qm>`
  Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as `<Qm>∗2`.

- `<Dd>`
  Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<Dm>`
  Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

**Operation for all encodings**

The description of VORR (register) gives the operational pseudocode for this instruction.
F6.1.199   VRSHRN

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see VSHRN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see "Enabling Advanced SIMD and floating-point support on page G1-4413."

**Notes for all encodings**

Related encodings: See Advanced SIMD one register and modified immediate on page F3-2912 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-2994 for the A32 instruction set.
Assembler symbols

<c> For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional. For encoding T1: see Standard assembler syntax fields on page F2-2848.

<q> See Standard assembler syntax fields on page F2-2848.

<size> Is the data size for the elements of the vectors, encoded in the "imm6<5:3>" field. It can have the following values:

- 16 when imm6<5:3> = 001
- 32 when imm6<5:3> = 01x
- 64 when imm6<5:3> = 1xx

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<imm> Is an immediate value, in the range 1 to <size>/2, encoded in the "imm6" field as <size>/2 - <imm>.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount-1);
    for e = 0 to elements-1
        result = LSR(Elem[Qin[m>>1],e,2*esize] + round_const, shift_amount);
        Elem[D[d],e,esize] = result<esize-1:0>;
F6.1.200 VRSHRN (zero)

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector.

This instruction is a pseudo-instruction of the VMOVN instruction. This means that:

- The encodings in this description are named to match the encodings of VMOVN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VMOVN gives the operational pseudocode for this instruction.

**Assembler symbols**

- `<c>`: For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
  
  For encoding T1: see Standard assembler syntax fields on page F2-2848.

- `<q>`: See Standard assembler syntax fields on page F2-2848.

- `<dt>`: Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:
  
  I16 when size = 00
  
  I32 when size = 01
  
  I64 when size = 10

  The encoding size = 11 is reserved.
<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

**Operation for all encodings**

The description of **VMOVN** gives the operational pseudocode for this instruction.
F6.1.201 VRSQRTE

Vector Reciprocal Square Root Estimate finds an approximate reciprocal square root of each element in a vector, and places the results in a second vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see Floating-point reciprocal estimate and step on page E1-2749.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

A1

64-bit SIMD vector variant

Applies when Q == 0.

\[\text{VRSQRTE}{<c>}{<q>}.<dt> <Dd>, <Dm>\]

128-bit SIMD vector variant

Applies when Q == 1.

\[\text{VRSQRTE}{<c>}{<q>}.<dt> <Qd>, <Qm>\]

Decode for all variants of this encoding

\[
\text{if } Q == '1' \&\& (Vd<0> == '1' || Vm<0> == '1') \text{ then UNDEFINED;}
\]

\[
\text{if } (\text{size} == '01' \&\& \!\text{HaveFP16Ext()}) || \text{size IN ('00', '11')} \text{ then UNDEFINED;}
\]

\[
\text{floating_point} = (F == '1');
\]

\[
\text{case size of}
\]

\[
\begin{align*}
\text{when '01' esize} & = 16; \text{ elements} = 4; \\
\text{when '10' esize} & = 32; \text{ elements} = 2;
\end{align*}
\]

\[
\text{d = UInt(D:Vd); m = UInt(M:Vm); } \text{regs} = \text{if } Q == '0' \text{ then 1 else 2;}
\]

T1

64-bit SIMD vector variant

Applies when Q == 0.

\[\text{VRSQRTE}{<c>}{<q>}.<dt> <Dd>, <Dm>\]

128-bit SIMD vector variant

Applies when Q == 1.

\[\text{VRSQRTE}{<c>}{<q>}.<dt> <Qd>, <Qm>\]
Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && !HaveFP16Ext()) || size IN {'00', '11'} then UNDEFINED;
if size == '01' && InITBlock() then UNPREDICTABLE;
floating_point = (F == '1');
case size of
  when '01' esize = 16; elements = 4;
  when '10' esize = 32; elements = 2;
  d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;

CONstrained UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as if it passes the Condition code check.
• The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-2848.

<q>
See Standard assembler syntax fields on page F2-2848.

<dt>
Is the data type for the elements of the vectors, encoded in the "F:size" field. It can have the following values:
U32 when F = 0, size = 10
F16 when F = 1, size = 01
F32 when F = 1, size = 10

<Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm>
Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm>
Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see Floating-point reciprocal estimate and step on page E1-2749.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                Elem[D[d+r],e,esize] = FPRSqrtEstimate(Elem[D[m+r],e,esize], StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = UnsignedRSqrtEstimate(Elem[D[m+r],e,esize]);

F6.1.202 VRSQRTS

Vector Reciprocal Square Root Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 3.0, divides these results by 2.0, and places the results into the elements of the destination vector.

The operand and result elements are floating-point numbers.

For details of the operation performed by this instruction see Floating-point reciprocal estimate and step on page E1-2749.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

    cond = cc:(cc<1> EOR cc<0>):'0';
    if InITBlock() then UNPREDICTABLE;
```

**CONstrained UNPREDICTABLE behavior**

If \( \text{InITBlock}() \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

**Assembler symbols**

- \(<Dd>\) Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- \(<Dn>\) Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

    S[d] = Zeros(16) : (if ConditionHolds(cond) then S[n] else S[m]<15:0>);
  when 32
    S[d] = if ConditionHolds(cond) then S[n] else S[m];
  when 64
    D[d] = if ConditionHolds(cond) then D[n] else D[m];
```
F6.1.206  VSHL (immediate)

Vector Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in the destination vector.

Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

instruction set, or Advanced SIMD one register and modified immediate on page F4-2994 for the A32 instruction
set.

Assembler symbols

<q>  For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be
      unconditional.
      For encoding T1: see Standard assembler syntax fields on page F2-2848.
<q>  See Standard assembler syntax fields on page F2-2848.
<size>  Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the
         following values:
         8        when L = 0, imm6<5:3> = 001
         16       when L = 0, imm6<5:3> = 01x
         32       when L = 0, imm6<5:3> = 1xx
         64       when L = 1, imm6<5:3> = xxx
<Qd>  Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>  Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Qd>  Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Qm>  Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<imm>  Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();  CheckAdvSIMDEnabled();
   for r = 0 to regs-1
      for e = 0 to elements-1
         Elem[D[r],e,esize] = LSL(Elem[D[r],e,esize], shift_amount);
F6.1.207 VSHL (register)

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

For a rounding shift, see VRSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

See Standard assembler syntax fields on page F2-2848.

The data type for the elements of the operand. It must be one of:
S   Signed. In encoding T1/A1, encoded as U = 0.
U   Unsigned. In encoding T1/A1, encoded as U = 1.
I   Untyped integer, Available only in encoding T2/A2.
<size> The data size for the elements of the operand. The following table shows the permitted values and their encodings:

<table>
<thead>
<tr>
<th>size</th>
<th>Encoding T1/A1</th>
<th>Encoding T2/A2</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Encoded as imm6&lt;5:3&gt; = 0b001</td>
<td>Encoded as size = 0b00</td>
</tr>
<tr>
<td>16</td>
<td>Encoded as imm6&lt;5:4&gt; = 0b01</td>
<td>Encoded as size = 0b01</td>
</tr>
<tr>
<td>32</td>
<td>Encoded as imm6&lt;5&gt; = 1</td>
<td>Encoded as size = 0b10</td>
</tr>
</tbody>
</table>

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm> The immediate value. <imm> must lie in the range 1 to <size>, and:
- If <size> == <imm>, the encoding is T2/A2.
- Otherwise, the encoding is T1/A1, and:
  - If <size> == 8, <imm> is encoded in imm6<2:0>.
  - If <size> == 16, <imm> is encoded in imm6<3:0>.
  - If <size> == 32, <imm> is encoded in imm6<4:0>.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned) << shift_amount;
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
F6.1.209   VSHR

Vector Shift Right takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see VRSHR.

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

      Elem[D[r],e,esize] = result<esize-1:0>;

F6.1.210  VSHR (zero)

Vector Shift Right copies the contents of one SIMD register to another

This instruction is a pseudo-instruction of the VORR (register) instruction. This means that:

- The encodings in this description are named to match the encodings of VORR (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VORR (register) gives the operational pseudocode for this instruction.

### 64-bit SIMD vector variant

Applies when \( Q == 0 \).

\[
\text{VSHR}\{<c>\}{<q>}.<dt> <Dd>, <Dm>, #0
\]

is equivalent to

\[
\text{VORR}\{<c>\}{<q>}{.<dt>} <Dd>, <Dm>, <Dm>
\]

and is never the preferred disassembly.

### 128-bit SIMD vector variant

Applies when \( Q == 1 \).

\[
\text{VSHR}\{<c>\}{<q>}.<dt> <Qd>, <Qm>, #0
\]

is equivalent to

\[
\text{VORR}\{<c>\}{<q>}{.<dt>} <Qd>, <Qm>, <Qm>
\]

and is never the preferred disassembly.

### T1

64-bit SIMD vector variant

Applies when \( Q == 0 \).

\[
\text{VSHR}\{<c>\}{<q>}.<dt> <Dd>, <Dm>, #0
\]

is equivalent to

\[
\text{VORR}\{<c>\}{<q>}{.<dt>} <Dd>, <Dm>, <Dm>
\]

and is never the preferred disassembly.

128-bit SIMD vector variant

Applies when \( Q == 1 \).
VSHR{<c>}{<q>}.{<dt>} <Qd>, <Qm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} <Qd>, <Qm>, <Qm>

and is never the preferred disassembly.

**Assembler symbols**

- `<c>`: For encoding A1: see *Standard assembler syntax fields on page F2-2848*. This encoding must be unconditional.
  
  For encoding T1: see *Standard assembler syntax fields on page F2-2848*.

- `<q>`: See *Standard assembler syntax fields on page F2-2848*.

- `<dt>`: Is the data type for the elements of the vectors, and must be one of: S8, S16, S32, S64, U8, U16, U32 or U64.

- `<Qd>`: Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

- `<Qm>`: Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as <Qm>*2.

- `<Dd>`: Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<Dm>`: Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

**Operation for all encodings**

The description of VORR (register) gives the operational pseudocode for this instruction.
F6.1.211 VSHRN

Vector Shift Right Narrow takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see VRSHRN.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

See *Standard assembler syntax fields* on page F2-2848.

<
See *Standard assembler syntax fields* on page F2-2848.

<Sd>
Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<Sm>
Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

<Od>
Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Od>
Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
case esize of
  when 16 S[d] = Zeros(16) : FPSqrt(S[m]<IS:0>, FPSCR);
  when 32 S[d] = FPSqrt(S[m], FPSCR);
  when 64 D[d] = FPSqrt(D[m], FPSCR);
F6.1.215 VSRA

Vector Shift Right and Accumulate takes each element in a vector, right shifts them by an immediate value, and accumulates the truncated results into the destination vector. For rounded results, see VRSRA.

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support on page G1-4413.*

Notes for all encodings

Related encodings: See Advanced SIMD one register and modified immediate on page F3-2912 for the T32 instruction set, or Advanced SIMD one register and modified immediate on page F4-2994 for the A32 instruction set.

Assembler symbols

- `<c>`
  - For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
  - For encoding T1: see Standard assembler syntax fields on page F2-2848.

- `<q>`
  - See Standard assembler syntax fields on page F2-2848.

- `<type>`
  - Is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values:
    - S when U = 0
    - U when U = 1

- `<size>`
  - Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:
    - 8 when L = 0, imm6<5:3> = 001
    - 16 when L = 0, imm6<5:3> = 01x
    - 32 when L = 0, imm6<5:3> = 1xx
    - 64 when L = 1, imm6<5:3> = xxx

- `<Qd>`
  - Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as `<Qd>*2.

- `<Qm>`
  - Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as `<Qm>*2.

- `<Dd>`
  - Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- `<Dm>`
  - Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

- `<imm>`
  - Is an immediate value, in the range 1 to `<size>`, encoded in the "imm6" field as `<size> - <imm>`.

Operation for all encodings

```c
if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      result = Int(Elem[D[m+r],e,esize], unsigned) >> shift_amount;
      Elem[D[d+r],e,esize] = Elem[D[d+r],e,esize] + result;
```
F6.1.216 VSRI

Vector Shift Right and Insert takes each element in the operand vector, right shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the right of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Assembler symbols

\(<c>\>
For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-2848.

\(<q>\>
See Standard assembler syntax fields on page F2-2848.

\(<size>\>
Is the data size, encoded in the "size" field. It can have the following values:
8 when size = 00
16 when size = 01
32 when size = 10

\(<list>\>
Is a list containing the single 64-bit name of the SIMD&FP register holding the element.
The list must be \{ <Dd>[<index>] \}.
The register <Dd> is encoded in the "D:Vd" field.
The permitted values and encoding of <index> depend on <size>:
\begin{align*}
&\text{if size == 8 then in the range 0 to 7, encoded in the "index_align<3:1>" field.} \\
&\text{if size == 16 then in the range 0 to 3, encoded in the "index_align<3:2>" field.} \\
&\text{if size == 32 then 0 or 1, encoded in the "index_align<3>" field.}
\end{align*}

\(<Rn>\>
Is the general-purpose base register, encoded in the "Rn" field.

\(<align>\>
When \( size == 8 \), <align> must be omitted, otherwise it is the optional alignment.
Whenever `<align>` is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and the encoding depends on `<size>`:

- `<size> == 8`  
  Encoded in the "index_align<0>" field as 0.
- `<size> == 16`  
  Encoded in the "index_align<1:0>" field as 0b00.
- `<size> == 32`  
  Encoded in the "index_align<2:0>" field as 0b000.

Whenever `<align>` is present, the permitted values and encoding depend on `<size>`:

- `<size> == 16`  
  `<align>` is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01.
- `<size> == 32`  
  `<align>` is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011.

`: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see The Advanced SIMD addressing mode on page F2-2869.

 `<Rm>`  
 Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-2869.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = TRUE;
    = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address,ebytes] = Elem[D[d],index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;
```

### F6.1.218  VST1 (multiple single elements)

Store multiple single elements from one, two, three, or four registers stores elements to memory from one, two, three, or four registers, without interleaving. Every element of each register is stored. For details of the addressing mode see *The Advanced SIMD addressing mode on page F2-2869.*

Depending on settings in the CPACR, NSACR, and HCPR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support on page G1-4413.*

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST1 (multiple single elements) on page K1-6112.
Related encodings: See Advanced SIMD element or structure load/store on page F3-2922 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-2997 for the A32 instruction set.

**Assembler symbols**

<>< For encoding A1, A2, A3 and A4: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1, T2, T3 and T4: see Standard assembler syntax fields on page F2-2848.

<q> See Standard assembler syntax fields on page F2-2848.

<size> Is the data size, encoded in the "size" field. It can have the following values:

8 when size = 00
16 when size = 01
32 when size = 10
64 when size = 11

<list> Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

{ <Dd> } Single register. Selects the A1 and T1 encodings of the instruction.

{ <Dd>, <Dd+1> } Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.

{ <Dd>, <Dd+1>, <Dd+2> } Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.

{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and is encoded in the "align" field as 0b00.

Whenever <align> is present, the permitted values are:

64 64-bit alignment, encoded in the "align" field as 0b01.
128 128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.
256 256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-2869.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about <Rn>, !, and <Rm>, see The Advanced SIMD addressing mode on page F2-2869.

**Operation for all encodings**

if ConditionPassed() then

  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  address = R[n]; iswrite = TRUE;
  - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
for r = 0 to regs-1
  for e = 0 to elements-1
    if ebytes != 8 then
      MemU[address,ebytes] = Elem[0][d+r],e];
    else
      - = AArch32.CheckAlignment(address, ebytes, AccType_NORMAL, iswrite);
      bits(64) data = Elem[0][d+r],e];
      MemU[address,4] = if BigEndian() then data<63:32> else data<31:0>;
      MemU[address+4,4] = if BigEndian() then data<31:0> else data<63:32>;
      address = address + ebytes;
    if wback then
      if register_index then
        R[n] = R[n] + R[m];
      else
        R[n] = R[n] + 8*regs;
F6.1.219  VST2 (single 2-element structure from one lane)

Store single 2-element structure from one lane of two registers stores one 2-element structure to memory from corresponding elements of two registers. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

\]

CONSTRUANED UNPREDICTABLE behavior
If \( d2 > 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as \text{NOP}.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become \text{UNKNOWN}. If the instruction specifies writeback, then that register becomes \text{UNKNOWN}. This behavior does not affect any other memory locations.

Notes for all encodings
For more information about the CONSTRUANED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST2 (single 2-element structure from one lane) on page K1-6113.

Assembler symbols
<>
For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-2848.

<q>
See Standard assembler syntax fields on page F2-2848.

<size>
Is the data size, encoded in the "size" field. It can have the following values:
- 8 when size = 00
- 16 when size = 01
- 32 when size = 10

<list>
Is a list containing the 64-bit names of the two SIMD&FP registers holding the element.
The list must be one of:
- \{ <Dd>[<index>], <Dd+1>[<index>] \}  
  Single-spaced registers, encoded as "spacing" = 0.
- \{ <Dd>[<index>], <Dd+2>[<index>] \}  
  Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.
The encoding of "spacing" depends on <size>:

- <size> == 16   "spacing" is encoded in the "index_align<1>" field.
- <size> == 32   "spacing" is encoded in the "index_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

- <size> == 8   <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- <size> == 16  <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- <size> == 32  <index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> is the general-purpose base register, encoded in the "Rn" field.

<align> is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and the encoding depends on <size>:

- <size> == 8   Encoded in the "index_align<0>" field as 0.
- <size> == 16  Encoded in the "index_align<0>" field as 0.
- <size> == 32  Encoded in the "index_align<1:0>" field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

- <size> == 8   <align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 16  <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 32  <align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-2869.

<Rm> is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-2869.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];  iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address, ebytes] = Elem[D[d], index];
    MemU[address+ebytes, ebytes] = Elem[D[d2], index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;
```
F6.1.220  VST2 (multiple 2-element structures)

Store multiple 2-element structures from two or four registers to memory, with interleaving. For more information, see Element and structure load/store instructions on page F1-2829. Every element of each register is saved. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTF registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

**Notes for all encodings**

For more information about the **CONSTRAINED UNPREDICTABLE behavior** of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly **VST2 (multiple 2-element structures)** on page K1-6112.

Related encodings: See *Advanced SIMD element or structure load/store* on page F3-2922 for the T32 instruction set, or *Advanced SIMD element or structure load/store* on page F4-2997 for the A32 instruction set.

**Assembler symbols**

- `<c>` For encoding A1 and A2: see *Standard assembler syntax fields* on page F2-2848. This encoding must be unconditional. For encoding T1 and T2: see *Standard assembler syntax fields* on page F2-2848.
- `<q>` See *Standard assembler syntax fields* on page F2-2848.
- `<size>` Is the data size, encoded in the "size" field. It can have the following values:
  - 8 when `size = 00`
  - 16 when `size = 01`
  - 32 when `size = 10`
  - The encoding `size = 11` is reserved.
- `<list>` Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of:
  - `{ <Dd>, <Dd+1> }` Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as `0b1000`.
  - `{ <Dd>, <Dd+2> }` Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as `0b1001`.
  - `{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }` Three single-spaced registers. Selects the A2 and T2 encodings of the instruction.
  - The register `<Dd>` is encoded in the "D:Vd" field.
- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field.
- `<align>` Is the optional alignment. Whenever `<align>` is omitted, the standard alignment is used, see *Unaligned data access* on page E2-2777, and is encoded in the "align" field as `0b00`.
  - Whenever `<align>` is present, the permitted values are:
    - 64 64-bit alignment, encoded in the "align" field as `0b01`.
    - 128 128-bit alignment, encoded in the "align" field as `0b10`.
    - 256 256-bit alignment, encoded in the "align" field as `0b11`. Available only if `<list>` contains four registers.
is the preferred separator before the \texttt{<align>} value, but the alignment can be specified as @\texttt{<align>}, see \textit{The Advanced SIMD addressing mode on page F2-2869}.

\texttt{<Rm>}

Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see \textit{The Advanced SIMD addressing mode on page F2-2869}.

- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST3 (single 3-element structure from one lane) on page K1-6113.

**Assembler symbols**

- **<<** For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
  
  For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-2848.

- \(<a>\)** See Standard assembler syntax fields on page F2-2848.

- **<size>** Is the data size, encoded in the "size" field. It can have the following values:
  
  8 when size = 00
  
  16 when size = 01
  
  32 when size = 10

- **<list>** Is a list containing the 64-bit names of the three SIMD&FP registers holding the element.
  
  The list must be one of:
  
  \{ <Dd>[<index>], <Dd+2>[<index>] \}
  
  Single-spaced registers, encoded as "spacing" = 0.
  
  \{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] \}
  
  Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.
The encoding of "spacing" depends on <size>:

- <size> == 8  "spacing" is encoded in the "index_align<0>" field.
- <size> == 16  "spacing" is encoded in the "index_align<1>" field, and "index_align<0>" is set to 0.
- <size> == 32  "spacing" is encoded in the "index_align<2>" field, and "index_align<1:0>" is set to 0b00.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

- <size> == 8  <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- <size> == 16  <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- <size> == 32  <index> is 0 or 1, encoded in the "index_align<3>" field.

- <Rn>  Is the general-purpose base register, encoded in the "Rn" field.
- <Rm>  Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-2869.

**Alignment**

Standard alignment rules apply, see Alignment support on page B2-102.

**Operation for all encodings**

```c
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];
    MemU[address, ebytes] = Elem[D[d], index];
    MemU[address+ebytes, ebytes] = Elem[D[d2], index];
    MemU[address+2*bytes, ebytes] = Elem[D[d3], index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 3*bytes;
    else
        R[n] = R[n] + 3*bytes;
```

F6.1.222  VST3 (multiple 3-element structures)

Store multiple 3-element structures from three registers stores multiple 3-element structures to memory from three
registers, with interleaving. For more information, see Element and structure load/store instructions on
page F1-2829. Every element of each register is saved. For details of the addressing mode see The Advanced SIMD
addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the
instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For
more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

if n == 15 || d3 > 31 then UNPREDICTABLE;
```

**CONSTRAINED UNPREDICTABLE behavior**

If \( d_3 > 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST3 (multiple 3-element structures) on page K1-6113.

Related encodings: See Advanced SIMD element or structure load/store on page F3-2922 for the T32 instruction set, or Advanced SIMD element or structure load/store on page F4-2997 for the A32 instruction set.
Assembler symbols

<c>
For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-2848.

<q>
See Standard assembler syntax fields on page F2-2848.

<size>
Is the data size, encoded in the "size" field. It can have the following values:

<table>
<thead>
<tr>
<th>Size</th>
<th>Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>size = 00</td>
</tr>
<tr>
<td>16</td>
<td>size = 01</td>
</tr>
<tr>
<td>32</td>
<td>size = 10</td>
</tr>
</tbody>
</table>

The encoding size = 11 is reserved.

<list>
Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:

\{<Dd>, <Dd+1>, <Dd+2>\}
Single-spaced registers, encoded in the "type" field as 0b0100.

\{<Dd>, <Dd+2>, <Dd+4>\}
Double-spaced registers, encoded in the "type" field as 0b0101.
The register <Dd> is encoded in the "D:Vd" field.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

<align>
Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and is encoded in the "align" field as 0b00.
Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b10.
: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-2869.

<Rm>
Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-2869.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations(); CheckAdvSIMDEnabled();
   address = R[n]; iswrite = TRUE;
   - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
   for e = 0 to elements-1
      MemU[address, ebytes] = Elem[D[d], e];
      MemU[address+ebytes, ebytes] = Elem[D[d2], e];
      MemU[address+2*ebytes, ebytes] = Elem[D[d3], e];
      address = address + 3*ebytes;
   if wback then
      if register_index then
         R[n] = R[n] + R[m];
      else
         R[n] = R[n] + 24;

F6.1.223  VST4 (single 4-element structure from one lane)

Store single 4-element structure from one lane of four registers stores one 4-element structure to memory from corresponding elements of four registers. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

**Notes for all encodings**

For more information about the CONSTRANED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VST4 (single 4-element structure from one lane) on page K1-6113.

**Assembler symbols**

- `<c>` For encoding A1, A2 and A3: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.

For encoding T1, T2 and T3: see Standard assembler syntax fields on page F2-2848.

- `<q>` See Standard assembler syntax fields on page F2-2848.

- `<size>` Is the data size, encoded in the "size" field. It can have the following values:
  
  - 8 when size = 00
  - 16 when size = 01
  - 32 when size = 10

- `<list>` Is a list containing the 64-bit names of the four SIMD&FP registers holding the element.

The list must be one of:

{ "<Dd>[<index>], "<Dd+1>[<index>], "<Dd+2>[<index>], "<Dd+3>[<index>] } 

Single-spaced registers, encoded as "spacing" = 0.
{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] }  

Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:
- <size> == 16   "spacing" is encoded in the "index_align<1>" field.
- <size> == 32   "spacing" is encoded in the "index_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.
The permitted values and encoding of <index> depend on <size>:
- <size> == 8   <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
- <size> == 16  <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
- <size> == 32  <index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn>     Is the general-purpose base register, encoded in the "Rn" field.
<align>  Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-2777, and the encoding depends on <size>:
- <size> == 8   Encoded in the "index_align<0>" field as 0.
- <size> == 16  Encoded in the "index_align<0>" field as 0.
- <size> == 32  Encoded in the "index_align<1:0>" field as b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:
- <size> == 8   <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 16  <align> is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1.
- <size> == 32  <align> can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as b001, and 128-bit alignment is encoded in the "index_align<1:0>" field as b010.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-2869.

<Rm>     Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see The Advanced SIMD addressing mode on page F2-2869.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  address = R[n];  iswrite = TRUE;
  - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
  MemU[address, ebytes] = Elem[D[d], index];
  MemU[address+ebytes, ebytes] = Elem[D[d+2], index];
  MemU[address+2*ebytes, ebytes] = Elem[D[d+4], index];
  MemU[address+3*ebytes, ebytes] = Elem[D[d+6], index];
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + 4*ebytes;
F6.1.224  VST4 (multiple 4-element structures)

Store multiple 4-element structures from four registers stores multiple 4-element structures to memory from four registers, with interleaving. For more information, see Element and structure load/store instructions on page F1-2829. Every element of each register is saved. For details of the addressing mode see The Advanced SIMD addressing mode on page F2-2869.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

single_regs = TRUE;  add = (U == '1');  wback = (W == '1');  d = UInt(Vd:D);  n = UInt(Rn);
imm32 = ZeroExtend(imm8:'00', 32);  regs = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;

**CONSTRAINED UNPREDICTABLE behavior**

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If (d+regs) > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

**Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly VSTM on page K1-6113.

Related encodings: See Advanced SIMD and floating-point 64-bit move on page F3-2894 for the T32 instruction set, or Advanced SIMD and floating-point 64-bit move on page F4-2973 for the A32 instruction set.

**Alias conditions**

<table>

</tr>
</tbody>
</table>

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page F2-2848.
- `<q>` See Standard assembler syntax fields on page F2-2848.
- `<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
- `<Rn>` Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used. However, ARM deprecated use of the PC.
- `!` Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
- `<sreglist>` Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
- `<dreglist>` Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1

            MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
        if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
F6.1.226 VSTR

Store SIMD&FP register stores a single register from the Advanced SIMD and floating-point register file to memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;

Assembler symbols

<q> For encoding A1: see Standard assembler syntax fields on page F2-2848. This encoding must be unconditional.
For encoding T1: see Standard assembler syntax fields on page F2-2848.

<dt> Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
8     when size = 00
16    when size = 01
32    when size = 10

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      if !IsZero(Elem[D[n+r],e,esize] AND Elem[D[m+r],e,esize]) then
        Elem[D[d+r],e,esize] = Ones(esize);
      else
        Elem[D[d+r],e,esize] = Zeros(esize);
F6.1.236 VUZP

Vector Unzip de-interleaves the elements of two vectors.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows the operation of VUZP doubleword operation for data type 8.

```
<table>
<thead>
<tr>
<th>Register state before operation</th>
<th>Register state after operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dd A7 A6 A5 A4 A3 A2 A1 A0</td>
<td></td>
</tr>
<tr>
<td>Dm B7 B6 B5 B4 B3 B2 B1 B0</td>
<td></td>
</tr>
</tbody>
</table>
```

The following figure shows the operation of VUZP quadword operation for data type 32.

```
<table>
<thead>
<tr>
<th>Register state before operation</th>
<th>Register state after operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Qd A3 A2 A1 A0</td>
<td></td>
</tr>
<tr>
<td>Qm B3 B2 B1 B0</td>
<td></td>
</tr>
</tbody>
</table>
```

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support on page G1-4413.

Part G
The AArch32 System Level Architecture
Chapter G1
The AArch32 System Level Programmers’ Model

This chapter gives a system level description of the programmers’ model for execution in AArch32 state. It contains the following sections:

• About the AArch32 System level programmers’ model on page G1-4308.
• Exception levels on page G1-4309.
• Exception terminology on page G1-4310.
• Execution state on page G1-4312.
• Instruction Set state on page G1-4314.
• Security state on page G1-4315.
• Security state, Exception levels, and AArch32 execution privilege on page G1-4318.
• Virtualization on page G1-4320.
• AArch32 PE modes, and general-purpose and Special-purpose registers on page G1-4322.
• Process state, PSTATE on page G1-4332.
• Instruction set states on page G1-4338.
• Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340.
• Exception return to an Exception level using AArch32 on page G1-4360.
• Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365.
• AArch32 state exception descriptions on page G1-4376.
• Reset into AArch32 state on page G1-4399.
• Mechanisms for entering a low-power state on page G1-4403.
• The AArch32 System register interface on page G1-4408.
• Advanced SIMD and floating-point support on page G1-4412.
• Configurable instruction enables and disables, and trap controls on page G1-4418.
G1.1 About the AArch32 System level programmers’ model

An application programmer has only a restricted view of the system. The System level programmers’ model supports this application level view of the system, and includes features that are required for one or both of an operating system (OS) and a hypervisor to provide the programming environment seen by an application. This chapter describes the System level programmers’ model when executing at EL1 or higher in an Exception level that is using AArch32.

The system level programmers’ model includes all of the system features required to support operating systems and to handle hardware events.

The following sections give a system level introduction to the basic concepts of the ARM architecture AArch32 state, and the terminology that is used for describing the architecture when executing in this state:

- Exception levels on page G1-4309.
- Exception terminology on page G1-4310.
- Execution state on page G1-4312.
- Instruction Set state on page G1-4314.
- Security state on page G1-4315.
- Virtualization on page G1-4320.

The rest of this chapter describes the system level programmers’ model when executing in AArch32 state.

The other chapters in this part describe:

- The memory system architecture, as seen when executing in an Exception level that is using AArch32:
  - Chapter G3 The AArch32 System Level Memory Model describes the general features of the ARMv8 memory model, when executing in AArch32 state, that are not visible at the application level.

    ________ Note ________

    Chapter E2 The AArch32 Application Level Memory Model describes the application level view of the memory model.

    ________ Note ________

    Chapter G4 The AArch32 Virtual Memory System Architecture describes the Virtual Memory System Architecture (VMSA) used in AArch32 state.

- The AArch32 System Registers, see Chapter G6 AArch32 System Register Descriptions.

_______ Note _________

The T32 and A32 instruction sets include instructions that provide system level functionality, such as returning from an exception. See for example, ERET on page F5-3117.
G1.2 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If ELn is the Exception level, increased values of \( n \) indicate increased software execution privilege.
- Execution at EL0 is called unprivileged execution.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

Note
A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

The effect of implementation choices on the programmers’ model on page D1-1899 provides information on implementations.

When executing in AArch32 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the target Exception level of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

Exception levels exist within Security states. The ARMv8-A security model on page G1-4315 describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then because EL3 is only implemented in Secure state, execution at EL3 can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see Chapter G4 The AArch32 Virtual Memory System Architecture.

G1.2.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

- **EL0**: Applications.
- **EL1**: OS kernel and associated functions that are typically described as privileged.
- **EL2**: Hypervisor.
- **EL3**: Secure monitor.
G1.3 Exception terminology

The following subsections define the terms that are used when describing exceptions:

- Terminology for taking an exception.
- Terminology for returning from an exception.
- Exception levels.
- Definition of a precise exception.
- Definitions of synchronous and asynchronous exceptions on page G1-4311.

G1.3.1 Terminology for taking an exception

An exception is generated when the PE first responds to an exceptional condition. The PE state at this time is the state that the exception is taken from. The PE state immediately after taking the exception is the state that the exception is taken to.

G1.3.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception returns from. The PE state immediately after the execution of that instruction is the state that the exception returns to.

G1.3.3 Exception levels

An Exception level, EL_n, with a larger value of n than another Exception level, is described as being a higher Exception level than the other Exception level. For example, EL3 is a higher Exception level than EL1.

An Exception level with a smaller value of n than another Exception level is described as being a lower Exception level than the other Exception level. For example, EL0 is a lower Exception level than EL1.

An Exception level is described as:

- Using AArch64 when execution in that Exception level is in the AArch64 Execution state.
- Using AArch32 when execution in that Exception level is in the AArch32 Execution state.

G1.3.4 Definition of a precise exception

An exception is described as precise when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the SError interrupt all exceptions that are taken to AArch32 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch32 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by those instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address that is used by the instruction.

In AArch32 state, examples of instructions that perform more than one single-copy atomic memory access are the LDM and STM instructions.

--- Note ---

- For the definition of a single-copy atomic access, see Properties of single-copy atomic accesses on page E2-2759.
- The SError interrupt replaces the ARMv7 asynchronous abort.
G1.3.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about exceptions, see *Handling exceptions that are taken to an Exception level using AArch32* on page G1-4340.
G1.4 Execution state

The Execution states are:

- **AArch64** The 64-bit Execution state.
- **AArch32** The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

**Execution state** on page A1-34 gives more information about them.

Exception levels use Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

**Note**

- *Typical Exception level usage model* on page G1-4309 shows which Exception levels different software layers might typically use.
- *The effect of implementation choices on the programmers’ model* on page D1-1899 gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. *Interprocessing* on page D1-1887 describes this.

G1.4.1 About the AArch32 PE modes

AArch32 state provides a set of PE modes that support normal software execution and handle exceptions. The current mode determines the set of registers that are available, as described in *AArch32 general-purpose registers, the PC, and the Special-purpose registers* on page G1-4327.

The AArch32 modes are:

- Monitor mode. This mode always executes at Secure EL3.
- Hyp mode. This mode always executes at Non-secure EL2.
- System, Supervisor, Abort, Undefined, IRQ and FIQ modes. The Exception level these modes execute at depends on the Security state, as described in *Security state* on page G1-4315.
- User mode. This mode always executes at EL0.

**Note**

AArch64 state does not support modes. Modes are a concept that is specific to AArch32 state. Modes that execute at a particular Exception level are only implemented if that Exception level supports using AArch32.

For more information on modes see *AArch32 PE mode descriptions* on page G1-4322.

The mode in use immediately before an exception is taken is described as the mode the exception is *taken from*. The mode that is used on taking the exception is described as the mode the exception is *taken to*.

All of the following define the mode that an exception is taken to:

- The type of exception.
- The mode the exception is taken from.
- Configuration settings defined at EL2 and EL3.
Monitor mode and Hyp mode can create system traps that cause exceptions to EL3 or EL2 respectively. There is an
architected hierarchy where EL2 and EL3 configuration settings affect a common condition, for example interrupt
routing. When no traps are enabled for a particular condition, the AArch32 mode an exception is taken to is called
the default mode for that exception.

In AArch32 state, a number of different modes can exist at the same Exception level. All modes at a particular
Exception level have the execution privilege, meaning they have the same access rights for accesses to memory and
to System registers. However, the mapping of PE modes to Exception levels depends on the Security state, as
described in Security state on page G1-4315. Security state, Exception levels, and AArch32 execution privilege on
page G1-4318 gives more information about the PE modes, their associated execution privilege, and how this maps
onto the Exception levels.
G1.5 Instruction Set state

In AArch32 state, the Instruction Set state determines the instruction set that the PE is executing. In an implementation that follows the ARM recommendations, the available Instruction Set states are:

T32 state The PE is executing T32 instructions.
A32 state The PE is executing A32 instructions.

Note

In previous versions of the ARM architecture:
• The T32 instruction set was called the Thumb instruction set.
• The A32 instruction set was called the ARM instruction set.

For more information, see Process state, PSTATE on page E1-2734.
G1.6 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

Secure state When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.

Non-secure state When in this state, the PE:
- Can access only the Non-secure physical address space.
- Cannot access the Secure system control resources.

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see About VMSAv8-32 on page G4-4558.

G1.6.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If EL2 is implemented, it exists only in Non-secure state.
- If the implementation does not include EL3 it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
  - Non-secure state if the implementation includes EL2.

The AArch32 security model, and execution privilege

The Exception level hierarchy of four Exception levels, EL0, EL1, EL2, and EL3, applies to execution in both Execution states. This section describes the mapping between Exception levels, AArch32 modes, and execution privilege.

The AArch32 modes Monitor, System, Supervisor, Abort, Undefined, IRQ, and FIQ all have the same execution privilege.

In Secure state:

- Monitor mode executes only at EL3, and is accessible only when EL3 is using AArch32.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode all:
  - Execute at EL1 when EL3 is using AArch64.
  - Execute at EL3 when EL3 is using AArch32.

This means that there is a difference in the Secure state hierarchy that the PE is using, depending on which Execution state EL3 is using:

- If EL3 is using AArch64:
  - There is no support for Monitor mode.
  - If EL1 is using AArch32, System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL1.
- If EL3 is using AArch32:
  - Monitor mode is supported, and executes at Secure EL3
  - System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL3.
  - There is no support for a Secure EL1 Exception level.
See Security behavior in Exception levels using AArch32 when EL3 is using AArch64 on page G1-4352 for more information about operation in a Secure EL1 mode when EL3 is using AArch64.

In Non-secure state, the PL1 modes System, Supervisor, Abort, Undefined, IRQ, and FIQ always execute at EL1.

User mode always executes at EL0 and has the lowest possible execution privilege.

Hyp mode always executes in Non-secure state at EL2 and has higher execution privilege than all of:

- User mode.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode.

Limited use of Privilege level in ARMv8 AArch32 state on page G1-4319 describes how, in some contexts, the concept of Privilege levels can be used to represent the execution privilege hierarchy.

For more information about the modes see About the AArch32 PE modes on page G1-4312.

Figure G1-1 shows the security model when EL3 is using AArch32, and shows the expected use of the different Exception levels, and which modes execute at which Exception levels.

---

**Figure G1-1 ARMv8-A Security model when EL3 is using AArch32**

---

**Note**

For an overview of the Security models when EL3 is using AArch64:

- See Figure G1-2 on page G1-4325 for the case where EL2, EL1, and EL0 are all using AArch32. This figure shows the implementation of the PE modes.
- See Figure D1-1 on page D1-1781 for an overview of the set of possible implementations.

---
The AArch32 System Level Programmers' Model
G1.6 Security state

Figure G1-1 on page G1-4316 shows that when EL3 is using AArch32, the Exception levels and modes available in each Security state are as follows:

**Secure state**
- **EL0**: User mode.
- **EL3**: Any mode that is available in Secure state, other than User mode.

**Non-secure state**
- **EL0**: User mode.
- **EL1**: Any mode that is available in Non-secure state, other than Hyp mode and User mode.
- **EL2**: Hyp mode.

Execution at EL0 is described as *unprivileged execution*.

A mode associated with a particular Exception level, EL\(n\), is described as an EL\(n\) mode.

---
**Note**
The Exception level defines the ability to access resources in the current Security state, and does not imply anything about the ability to access resources in the other Security state.

---

When EL3 is using AArch32, many AArch32 System registers accessible at PL1 are *banked* between the Secure and Non-secure states.

When EL3 is using AArch64 and Secure EL1 is using AArch32, System registers accessible at PL1 are not banked between the Non-secure and Secure states. Software running at EL3 is expected to switch the content of the PL1-accessible System registers between the Secure and Non-secure context, in a similar manner to switching the contents of general purpose registers. For information on the relationship between AArch64 and AArch32 System registers in an interprocessing environment, see *Mapping of the System registers between the Execution states* on page D1-1890.

For more information on the System registers, see *The AArch32 System register interface* on page G1-4408.

The Secure Monitor Call (SMC) instruction provides software with a system call to EL3. When executing at a privileged Exception level, SMC instructions generates exceptions. For more information, see *Secure Monitor Call (SMC) exception* on page G1-4382 and *SMC* on page F5-3429.

---
**Note**
For more information about the Privilege level terminology, see *Security state, Exception levels, and AArch32 execution privilege* on page G1-4318.

---

**Changing from Secure state to Non-secure state**

Monitor mode is provided to support switching between Secure and Non-secure states. When executing in an Exception level that is using AArch32, except in Monitor mode and Hyp mode, the Security state is controlled:

- By the SCR.NS bit, when EL3 is using AArch32.
- By the SCR_EL3.NS bit, when EL3 is using AArch64.

The mapping of AArch32 privileged modes to the exception hierarchy means that it is possible when EL3 is using AArch32 to change from EL3 to Non-secure EL1 without an exception return. This can occur in one of the following ways:

- Using an MSR or CPS instruction to switch from Monitor mode to another privileged mode while SCR.NS is 1.
- Using an MCR instruction that writes SCR.NS to change from Secure to Non-secure state when in a privileged mode other than Monitor mode.

ARM strongly recommends that software executing at EL3 using AArch32 does not use either of these mechanisms to change from EL3 to Non-secure EL1 without an exception return. The use of both of these mechanisms is deprecated.
G1.7 Security state, Exception levels, and AArch32 execution privilege

In ARMv8, the hierarchy of software execution privilege, within a particular Security state, is defined by the Exception levels, with higher Exception level numbers indicating higher privilege. Table G1-1 shows this hierarchy for each Security state.

<table>
<thead>
<tr>
<th>Execution privilege</th>
<th>Secure state</th>
<th>Non-secure state</th>
<th>Typical use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highest</td>
<td>EL3</td>
<td>- a</td>
<td>Secure monitor</td>
</tr>
<tr>
<td>-</td>
<td>- a</td>
<td>EL2</td>
<td>Hypervisor</td>
</tr>
<tr>
<td>-</td>
<td>EL1</td>
<td>EL1</td>
<td>Secure or Non-secure OS</td>
</tr>
<tr>
<td>Lowest, Unprivileged</td>
<td>EL0</td>
<td>EL0</td>
<td>Secure or Non-secure application</td>
</tr>
</tbody>
</table>

a. EL2 is never implemented in Secure state, and EL3 is never implemented in Non-secure state.

When executing in AArch32 state, within a given Security state, the current PE state, including the execution privilege, is primarily indicated by the current PE mode. In Secure state, how the PE modes map onto the Exception levels depends on whether EL3 is using AArch32 or is using AArch64, and:

- Figure G1-1 on page G1-4316 shows this mapping when EL3 is using AArch32.
- Figure G1-2 on page G1-4325 shows this mapping when EL3 is using AArch64.

Table G1-2 shows this mapping. In interpreting this table:

- Monitor mode is implemented only in Secure state, and only if EL3 is using AArch32.
- Hyp mode is implemented only in Non-secure state, and only if EL2 is using AArch32.
- System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented:
  - In Secure state if either:
    - EL3 is using AArch32.
    - EL3 is using AArch64 and EL1 is using AArch32.
  - In Non-secure state if EL1 is using AArch32.
- User mode is implemented if EL0 is using AArch32.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>PE modes in the given Security state, and EL3 Execution state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure state, EL3 using AArch32</td>
<td>Secure state, EL3 using AArch64</td>
</tr>
<tr>
<td>EL3</td>
<td>Monitor, System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
</tr>
<tr>
<td>EL2</td>
<td>-</td>
</tr>
<tr>
<td>EL1</td>
<td>-</td>
</tr>
<tr>
<td>EL0</td>
<td>User</td>
</tr>
</tbody>
</table>

Because AArch32 behavior is described in terms of the PE modes, and transitions between PE modes, the Exception levels are implicit in most of the description of operation in AArch32 state.
### G1.7.1 Limited use of Privilege level in ARMv8 AArch32 state

As described in *The VMSAv8-32 translation regimes* on page G4-4560, a translation regime maps a virtual address (VA) to the corresponding physical address (PA). The VMSAv8-64 translation regimes are defined by the Exception levels that use them. However, because the mapping between PE modes and Exception levels in Secure state depends on whether EL3 is using AArch32 or is using AArch64, as shown in Table G1-2 on page G1-4318, the VMSAv8-32 translation regimes cannot be described simply in terms of either the Exception levels or the PE modes that use them.

To provide a consistent description of address translation as seen from AArch32 state, the VMSAv8-32 translation regimes are described in terms of the Privilege levels originally defined in the ARMv7 descriptions of AArch32 state. Table G1-3 shows how the PE modes map to these Privilege levels:

<table>
<thead>
<tr>
<th>Privilege level</th>
<th>Secure state</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL2</td>
<td>-</td>
<td>Hyp&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>PL1</td>
<td>Monitor&lt;sup&gt;b&lt;/sup&gt;, System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
<td>System, FIQ, IRQ, Supervisor, Abort, Undefined</td>
</tr>
<tr>
<td>PL0</td>
<td>User</td>
<td>User</td>
</tr>
</tbody>
</table>

<sup>a</sup> Implemented only in Non-secure state, and only if EL2 is using AArch32

<sup>b</sup> Implemented only in Secure state, and only if EL3 is using AArch32.

Comparing Table G1-3 with Table G1-2 on page G1-4318 shows that:

**In Non-secure state**

Each privilege level maps to the corresponding Exception level. For example PL1 maps to EL1.

**In Secure state**

- PL0 maps to EL0.
- The mapping of PL1 depends on the Execution state being used by EL3, as follows:
  - **EL3 using AArch64** Secure PL1 maps to Secure EL1. Monitor mode is not implemented.
  - **EL3 using AArch32** Secure PL1 maps to Secure EL3. Monitor mode is implemented as one of the Secure PL1 modes.
G1.8 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2. A PE is in *Hyp mode* when it is executing at EL2 in the AArch32 state. An exception return from Hyp mode to software running at EL1 or EL0 is performed using the `ERET` instruction.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between virtual machines. A virtual machine is comprised of Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems, that each run in Non-secure EL1, on a virtual machine.
- For each Guest operating system, applications, that usually run in Non-secure EL0, on a virtual machine.

*Note*

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a *virtual machine identifier* (VMID) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- Trap various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2.
- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

In Non-secure state:

- The implementation provides an independent *translation regime* for memory accesses from EL2.
- For the PL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the *virtual address* (VA) to an *intermediate physical address* (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the *physical address* (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see Chapter G4 *The AArch32 Virtual Memory System Architecture*.

G1.8.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. *EL2 configurable controls on page G1-4427*, describes these.
- All of the virtual interrupts:
  - Virtual SError.
  - Virtual IRQ.
  - Virtual FIQ.

HVC exceptions are always taken to EL2. All virtual interrupts are always taken to EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.
Each of the virtual interrupts has a corresponding physical interrupt. See \textit{Virtual interrupts}.

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3. For more information, see \textit{Asynchronous exception behavior for exceptions taken from AArch32 state} on page G1-4365.

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information see:
  - \textit{Routing exceptions from Non-secure EL0 to EL2} on page G1-4356.
  - \textit{Routing debug exceptions to EL2 using AArch32} on page G1-4358.

- Provides mechanisms to trap PE operations to EL2. See \textit{EL2 configurable controls} on page G1-4427.

When an operation is trapped to EL2, the hypervisor typically either:

- Emulates the required operation. The application running in the Guest OS is unaware of the trap.
- Returns an error to the Guest OS.

\section*{Virtual interrupts}

The virtual interrupts have names that correspond to the physical interrupts, as shown in Table G1-4.

\begin{table}[h]
\centering
\caption{The virtual interrupts}
\begin{tabular}{|c|c|}
\hline
\textbf{Physical interrupt} & \textbf{Corresponding virtual interrupt} \\
\hline
External SError & Virtual SError \\
\hline
IRQ & Virtual IRQ \\
\hline
FIQ & Virtual FIQ \\
\hline
\end{tabular}
\end{table}

Software executing at EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. \textbf{Example G1-1} shows a usage model for virtual interrupts.

\begin{example}
\textbf{Example G1-1 Virtual interrupt usage model}

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.

2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
   - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
   - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

Non-secure EL1 and Non-secure EL0 modes cannot distinguish a virtual interrupt from the corresponding physical interrupt.

For more information see \textit{Virtual exceptions when an implementation includes EL2} on page G1-4365.
\end{example}
### G1.9 AArch32 PE modes, and general-purpose and Special-purpose registers

The following sections describe the AArch32 PE modes and the general-purpose registers and the PC:

- **AArch32 PE mode descriptions.**
- **AArch32 general-purpose registers, the PC, and the Special-purpose registers** on page G1-4327.
- **Saved Program Status Registers (SPSRs)** on page G1-4329.
- **ELR_hyp** on page G1-4331.

---

#### Note

The PC is included in the scope of this section because, in AArch32 state, it is defined as being part of the same register file as the general-purpose registers. That is, the AArch32 register file R0-R15 comprises:

- The general-purpose registers R0-R14.
- The PC, that can be described as R15.

---

### G1.9.1 AArch32 PE mode descriptions

Table G1-5 shows the PE modes defined by the ARM architecture, for execution in AArch32 state. In this table:

- The **PE mode** column gives the name of each mode and the abbreviation used, for example, in the general-purpose register name suffixes used in **AArch32 general-purpose registers, the PC, and the Special-purpose registers** on page G1-4327.
- The **Security state** column gives the security state at which the mode can be entered.
- The **Exception level** column gives the Exception level at which the mode is implemented, including dependencies on the current Security state and on whether EL3 is using AArch32, see **Exception levels** on page G1-4309.
- Mode changes can be made under software control, or can be caused by an external or internal exception.

¹. EL3 if EL3 is using AArch32. EL1 if EL3 is using AArch64 and EL1 is using AArch32.

Mode changes can be made under software control, or can be caused by an external or internal exception.
Notes on the AArch32 PE modes

PE modes are defined only in AArch32 state. Because each mode is implemented as part of a particular Exception level that is using AArch32, the set of available modes depends on which Exception levels are implemented and using AArch32, as described in Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325.

This section gives more information about each of the modes, when it is implemented.

User mode
Software executing in User mode executes at EL0. Execution in User mode is sometimes described as unprivileged execution. Application programs normally execute in User mode, and any program executed in User mode:
- Makes only unprivileged accesses to system resources, meaning it cannot access protected system resources.
- Makes only unprivileged access to memory.
- Cannot change mode except by causing an exception, see Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340.

System mode
System mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325. System mode has the same registers available as User mode, and is not entered by any exception.

Supervisor mode
Supervisor mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325.

Supervisor mode is the default mode to which a Supervisor Call exception is taken. Executing a SVC (Supervisor Call) instruction generates a Supervisor Call exception.

In an implementation where the highest implemented Exception level is using AArch32, if that Exception level is EL3 or EL1, a PE enters Supervisor mode on Reset.

Abort mode
Abort mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325.

Abort mode is the default mode to which a Data Abort exception or Prefetch Abort exception is taken.

Undefined mode
Undefined mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325.

Undefined mode is the default mode to which an instruction-related exception, including any attempt to execute an UNDEFINED instruction, is taken.

FIQ mode
FIQ mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325.

FIQ mode is the default mode to which an FIQ interrupt is taken.

IRQ mode
IRQ mode is implemented at EL1 or EL3, see Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325.

IRQ mode is the default mode to which an IRQ interrupt is taken.

Hyp mode
Hyp mode is the Non-secure EL2 mode.

Hyp mode is entered on taking an exception from Non-secure state that must be taken to EL2.

In an implementation where the highest implemented Exception level is EL2 and EL2 uses AArch32 on reset, a PE enters Hyp mode on Reset.

The Hypervisor Call exception and Hyp Trap exception are implemented as part of EL2 and are always taken to Hyp mode.
Note
This means that Hypervisor Call and Hyp Trap exceptions cannot be taken from Secure state.

When the value of the Hypervisor Call enable bit, SCR.HCE, is 1, executing an HVC (Hypervisor Call) instruction in a Non-secure EL1 mode generates a Hypervisor Call exception.
For more information, see Hyp mode on page G1-4326.

Monitor mode
Monitor mode is the Secure EL3 mode. This means it is always in the Secure state, regardless of the value of the SCR.NS bit.
Monitor mode is the mode to which a Secure Monitor Call exception is taken. In a Non-secure EL1 mode, or a Secure EL3 mode, executing an SMC (Secure Monitor Call) instruction generates a Secure Monitor Call exception.
When EL3 is using AArch32, some exceptions that are taken to a different mode by default can be configured to be taken to EL3, see PE mode for taking exceptions on page G1-4350.
When EL3 is using AArch32, software executing in Monitor mode:
• Has access to both the Secure and Non-secure copies of System registers.
• Can perform an exception return to Secure state, or to Non-secure state.
This means that, when EL3 is using AArch32, Monitor mode provides the only recommended method of changing between the Secure and Non-secure Security states.

Secure and Non-secure modes
In an implementation that includes EL3, the names of most implemented modes can be qualified as Secure or Non-secure, to indicate whether the PE is also in Secure state or Non-secure state. For example:
• If a PE is in Supervisor mode and Secure state, it is in Secure Supervisor mode.
• If a PE is in User mode and Non-secure state, it is in Non-secure User mode.

Note
As indicated in the appropriate Mode descriptions:
• Monitor mode is a Secure mode, meaning it is always in the Secure state.
• Hyp mode is a Non-secure mode, meaning it is accessible only in Non-secure state.
Effect of the EL3 Execution state on the PE modes and Exception levels

Figure G1-1 on page G1-4316 shows the PE modes, Exception levels, and Security states, for an implementation that includes all of the Exception levels, when EL3 is using AArch32. Figure G1-2 shows how the implemented modes change when EL3 is using AArch64.

Comparing Figure G1-1 on page G1-4316 and Figure G1-2 shows how, in Secure state only, the implementation of System, FIQ, IRQ, Supervisor, Abort, and Undefined mode depends on the Execution state that EL3 is using. That is, these modes are implemented as follows:

Non-secure state

If Non-secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Non-secure state.

Secure state

The implementation of these modes depends on the Execution state that EL3 is using, as follows:

**EL3 using AArch64**

If Secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Secure state.

**EL3 using AArch32**

In Secure state, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL3, see Figure G1-1 on page G1-4316.

† When EL1 is using AArch64, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are not implemented
‡ When EL2 is using AArch64, Hyp mode is not implemented
Hyp mode

Hyp mode is the Non-secure EL2 mode. When EL2 is using AArch32, it provides the usual method of controlling the virtualization of Non-secure execution at EL1 and EL0.

--- Note ---

The alternative method of controlling this functionality is by accessing the EL2 controls from EL3 with the SCR_EL3.NS or SCR.NS bit set to 1.

This section summarizes how Hyp mode differs from the other modes, and references where this part of the manual describes the features of Hyp mode in more detail:

- Software executing in Hyp mode executes at EL2, see Figure G1-1 on page G1-4316.
- Hyp mode is accessible only in Non-secure state. In Secure state, an attempt by a CPS or an MSR instruction to change PSTATE.M to Hyp mode is an illegal change to PSTATE.M, as described in Illegal changes to PSTATE.M on page G1-4336.
- In Non-debug state, the only mechanisms for changing to Hyp mode are:
  - An exception taken from a Non-secure EL1 or EL0 mode.
  - When EL3 is using AArch32, an exception return from Secure Monitor mode.
  - When EL3 is using AArch64, an exception return from EL3.
- In Hyp mode, the only exception return is execution of an ERET instruction, see ERET on page F5-3117.
- In Hyp mode, the CPACR has no effect on the execution of:
  - System register access instructions.
  - Advanced SIMD and floating-point instructions.
  The HCPTR controls execution of these instructions in Hyp mode.
- If software running in Hyp mode executes an SVC instruction, the Supervisor Call exception generated by the instruction is taken to Hyp mode, see SVC on page F5-3575.
- An exception return with restored PSTATE specifying Hyp mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-4361, if any of the following applies:
  - EL3 is using AArch64 and the value of SCR_EL3.NS is 0.
  - EL3 is using AArch32 and the value of SCR.NS is 0.
  - The return is from a Non-secure EL1 mode.
- The instructions described in the following sections are UNDEFINED if executed in Hyp mode:
  - SRS. See SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-3464.
  - RFE. See RFE, RFEDA, RFEDB, RFIEA, RFIEB on page F5-3363.
  - LDM (exception return) on page F5-3148.
  - LDM (User registers) on page F5-3150.
  - STM (User registers) on page F5-3499.
  - The SUBS PC, LR forms of the instructions described in SUB, SUBS (immediate) on page F5-3560.
--- Note ---

In T32 state, ERET is encoded as SUBS PC, LR, #0, and therefore this is a valid instruction.

---

In addition, deprecated forms of the A32 ADCS, ADDS, ANDS, BICS, EORS, MOV5, MNS, ORRS, RSBS, RSCS, SBCS, and SUB5 instructions with the PC as the destination register are UNDEFINED if executed in Hyp mode. The instruction descriptions identify these UNDEFINED cases.
• The Load unprivileged and Store unprivileged instructions LDRT, LDRSHT, LDRHT, LDRBT, STRT, STRHT, and STRBT, are constrained unpredictable if executed in Hyp mode, see Execution of Load/Store unprivileged instructions in Hyp mode on page K1-6115.

In an implementation that includes EL3, from reset, the HVC instruction is undefined in Non-secure EL1 modes, meaning entry to Hyp mode is disabled by default. To permit entry to Hyp mode using the Hypervisor Call exception, Secure software must enable use of the HVC instruction:
• By setting the SCR_EL3.HCE bit to 1, if EL3 is using AArch64.
• By setting the SCR.HCE bit to 1, if EL3 is using AArch32.

When the HVC instruction is undefined in Non-secure EL1 modes because of the value of the SCR_EL3.HCE or SCR.HCE bit, HVC is constrained unpredictable in Hyp mode.

Pseudocode description of mode operations

The BadMode() function tests whether a 5-bit mode number corresponds to one of the permitted modes.

The BadMode() function is defined in Chapter 11 ARMv8 Pseudocode.

G1.9.2 AArch32 general-purpose registers, the PC, and the Special-purpose registers

The general-purpose registers, and the PC, in AArch32 state on page E1-2731 describes the application level view of the general-purpose registers, and the PC. This view provides:
• The general-purpose registers R0-R14, of which:
  — The preferred name for R13 is SP (stack pointer).
  — The preferred name for R14 is LR (link register).
• The PC (program counter), that can be described as R15.

These registers are selected from a larger set of registers, that includes Banked copies of some registers, with the current register selected by the execution mode. The implementation and banking of the general-purpose registers depends on whether or not the implementation includes EL2 and EL3, and whether those Exception levels are using AArch32. Figure G1-3 on page G1-4328 shows the full set of Banked general-purpose registers, and the Special-purpose registers:
• The Program Status Registers CPSR and SPSR.
• ELR_hyp.

—— Note ———

The architecture uses system level register names, such as R0_usr, R8_usr, and R8_fiq, when it must identify a specific register. The application level names refer to the registers for the current mode, and usually are sufficient to identify a register.
As described in PE mode for taking exceptions on page G1-4350, on taking an exception the PE changes mode, unless it is already in the mode to which it must take the exception. Each mode that the PE might enter in this way has:

- A Banked copy of the stack pointer, for example SP_irq and SP_hyp.
- A register that holds a preferred return address for the exception. This is:
  - For the EL2 mode, Hyp mode, the Special-purpose register ELR_hyp.
  - For the other privileged modes to which exceptions can be taken, a Banked copy of the link register, for example LR_und and LR_mon.
- A saved copy of PSTATE, made on exception entry, for example SPSR_irq and SPSR_fiq.

In addition FIQ mode has Banked copies of the general-purpose registers R8 to R12.

User mode and System mode share the same general-purpose registers.

User mode, System mode, and Hyp mode share the same LR.

For more information about the application level view of the SP, LR, and PC, and the alternative descriptions of them as R13, R14 and R15, see The general-purpose registers, and the PC, in AArch32 state on page E1-2731.

**AArch32 Special-purpose registers**

In AArch32 state, the Special-purpose registers are:

- The CPSR and its view as the APSR.
- The SPSR, including the banked copies SPSR_abt, SPSR_fiq, SPSR_hyp, SPSR_irq, SPSR_mon, SPSR_svc, and SPSR_und.
- The ELR_hyp.
Pseudocode description of general-purpose register and PC operations

The following pseudocode gives access to the general-purpose registers and the PC. These registers are an array, \( _R[] \), indexed by parameter \( n \). This array is common to AArch32 and AArch64 operation and therefore contains 31 64-bit registers. \( _PC \) is the program counter, and its definition is common to AArch32 and AArch64 operation and therefore its size is 64-bit.

\[ \text{LookUpRIndex()} \text{ looks up the index value, } n\text{, for the specified register number and PE mode, using RBankSelect()} \text{ to evaluates the result.} \]

\[ \text{R[]} \text{ accesses the specified general-purpose register in the current PE mode, using Rmode[]} \text{ to access the register, accessing } _R[] \text{ if necessary. SP accesses the stack pointer, LR accesses the link register, and } PC \text{ accesses the program counter. Each function has a non-assignment form for register reads and an assignment form for register writes, other than } PC, \text{ which has only a non-assignment form.} \]

\[ \text{BranchTo()} \text{ performs a branch to the specified address.} \]

The \( _R[], _PC, LR, SP, \text{LookUpRIndex()}, \text{ RBankSelect(), Rmode[]}, \text{ and BranchTo()} \text{ functions are defined in Chapter J1 ARMv8 Pseudocode.} \]

G1.9.3 Saved Program Status Registers (SPSRs)

The Saved Program Status Registers (SPSRs) are used to save PE state on taking exceptions. In AArch32 state, there is an SPSR for every mode that an exception can be taken to, as shown in Figure G1-3 on page G1-4328. For example, the SPSR for Monitor mode is called SPSR_mon.

--- Note ---
Exceptions cannot be taken to EL0.

---

When the PE takes an exception, PE state is saved from PSTATE in the SPSR for the mode the exception is taken to. For example, if the PE takes an exception to Monitor mode, PE state is saved in SPSR_mon. For more information on PSTATE, see Process state, PSTATE on page G1-4332.

--- Note ---
All PSTATE fields are saved, including those which have no direct read and write access.

---

Saving the PSTATE fields means the exception handler can:

- On return from the exception, restore the PE state to the values it had immediately before the exception was taken. When the PE returns from an exception, PE state is restored to the state stored in the SPSR of the mode the exception is returning from, if the exception return is made using one of:
  - ERET.
  - LDM.
  - The Exception return form of the instruction described in MOV, MOVS (register) on page F5-3260.
  - The Exception return form of the instruction described in SUB, SUBS (immediate) on page F5-3560.

  For example, on returning from Monitor mode, PE state is restored to the state stored in SPSR_mon. If the exception return is made using the RFE instruction, the PE restores the PE state from an SPSR valued read from memory.

- Examine the value that PSTATE had when the exception was taken, for example to determine the instruction set state and privilege level in which the instruction that caused an Undefined Instruction exception was executed.

The SPSRs are UNKNOWN on reset. Any operation in a Non-secure EL1 or EL0 mode makes SPSR_hyp UNKNOWN.
### SPSR format for exceptions taken to AArch32 state

The SPSR bit assignments are:

### N, Z, C, V, Q, GE[3:0], bits[31:27, 19:16]

- Shows the value of the PSTATE.\{N, Z, C, V, Q, GE\} flags immediately before the exception was taken.

### IT[1:0], J, IL, IT[7:2], E, T, bits[26:24, 20, 15:9, 5]

- Shows the values of the PSTATE.\{IT[7:0], J, IL, E, T\} PE state controls immediately before the exception was taken. The J bit is RES0.

### Bit[23]

- Reserved, RES0.

### Bit[22]

- In ARMv8.0, RES0.
- In ARMv8.1, PAN. Shows the value of the PSTATE.PAN state bit immediately before the exception was taken.

### Bit[21]

- Reserved, RES0.

### A, I, F, M, bits[8:6, 4:0]

- Shows the values of the PSTATE.\{A, I, F\} exception mask and PSTATE.M mode bits immediately before the exception was taken.

SPSR bits that are defined as RES0 on an exception taken from AArch32 state are ignored on any exception return to AArch32 state.

### Pseudocode description of SPSR operations

The following pseudocode gives access to the SPSRs.

The SPSR[] function accesses the current SPSR and is common to AArch32 and AArch64 operation.

The SPSRWriteByInstr() function is used by the MSR (register) and MSR (immediate) instructions to update the current SPSR.

The SPSR[] and SPSRWriteByInstr() functions are defined in Chapter J1 ARMv8 Pseudocode.
G1.9.4 ELR_hyp

Hyp mode does not provide its own Banked copy of LR. Instead, on taking an exception to Hyp mode, the preferred return address is stored in ELR_hyp, a 32-bit Special-purpose register implemented for this purpose.

ELR_hyp can be accessed explicitly only by executing:

- An \texttt{MRS} or \texttt{MSR} instruction that targets ELR_hyp, see:
  - \texttt{MRS (Banked register)} on page F5-3277.
  - \texttt{MSR (Banked register)} on page F5-3281.

The \texttt{ERET} instruction uses the value in ELR_hyp as the return address for the exception. For more information, see \texttt{ERET} on page F5-3117.

Software execution in any Non-secure EL1 or EL0 mode makes ELR_hyp UNKNOWN.
G1.10 Process state, PSTATE

In the ARMv8-A architecture, Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:
- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type ProcState. ProcState is defined in Chapter J1 ARMv8 Pseudocode.

The PSTATE fields that are meaningful in AArch32 state are:

**The Condition flags**
- **N**: Negative Condition flag.
- **Z**: Zero Condition flag.
- **C**: Carry Condition flag.
- **V**: Overflow Condition flag.

Process state, PSTATE on page E1-2734 gives more information about these.

**The overflow or saturation flag**
- **Q**: See Process state, PSTATE on page E1-2734.

**The greater than or equal flags**
- **GE[3:0]**: See Process state, PSTATE on page E1-2734.

**The PE state controls**
- **J, T**: Instruction set state. See Process state, PSTATE on page E1-2734. J is RES0. On a reset to AArch32 state, T is set to an IMPLEMENTATION DEFINED value. On taking an exception to:
  - A PL1 mode using AArch32, T is set to SCTLR.TE.
  - EL2 using AArch32, T is set to HSCTLR.TE.
- **IT[7:0]**: Instruction block state bits. See Process state, PSTATE on page E1-2734. On a reset or taking an exception to AArch32 state, these bits are set to 0.
- **E**: Endianness of data accesses. See Process state, PSTATE on page E1-2734. If an implementation provides both Big-endian and Little-endian support, then:
  - On a reset to AArch32 state this bit is set to the IMPLEMENTATION DEFINED reset value of:
    - SCTLR.EE if the highest implemented Exception level is not EL2.
    - HSCTLR.EE if the highest implemented Exception level is EL2.
  - On taking an exception to:
    - A PL1 mode using AArch32, this bit is set to SCTLR.EE.
    - EL2 using AArch32, this bit is set to HSCTLR.EE.
- **IL**: Illegal Execution state bit. See The Illegal Execution state exception on page G1-4363. On a reset or taking an exception to AArch32 state, this bit is set to 0.

For information on how the J, T, IT[7:0], E, and IL fields can be accessed, see Accessing the PE state controls and the Execution state bit on page G1-4335.

**The asynchronous exception mask bits**
- **A**: SError interrupt mask bit.
- **I**: IRQ interrupt mask bit.
- **F**: FIQ interrupt mask bit.
For each bit, the values are:

0 Exception not masked.
1 Exception masked.

On a reset to AArch32 state, these bits are set to 1.
On taking an exception to AArch32 state, one or more of these bits are set to 1.

For more information, see both:
- Asynchronous exception masking controls on page G1-4368.
- PE state on exception entry on page G1-4354.

The mode bits

M[4:0] Current mode of the PE. Table G1-5 on page G1-4322 lists the permitted values of this field. All other values are reserved. Illegal changes to PSTATE.M on page G1-4336 describes the effect of setting M[4:0] to a reserved value.
M[4] is:

M[4], Execution state
The current Execution state:
0 AArch64 state.
1 AArch32 state.

Note
This is consistent with the use of M[4:0] in previous versions of the architecture.

On a reset to AArch32 state, M[4:0] is set to:
- 0b10011, meaning Supervisor mode, if the highest implemented Exception level is not EL2.
- 0b11010, meaning Hyp mode, if the highest implemented Exception level is EL2.

On taking an exception to AArch32 state, M[4:0] is set to the target mode for the exception type.

For more information about the PE modes, see:
- AArch32 PE mode descriptions on page G1-4322.
- PE state on exception entry on page G1-4354.

Access control bits, from ARMv8.1

PAN Privileged Access Never (PAN) state bit, see About the PAN bit on page G4-4608.

G1.10.1 Accessing PSTATE fields

The PSTATE fields can be accessed as described in the following subsections:
- The Current Program Status Register, CPSR on page G1-4334.
- Accessing the PE state controls and the Execution state bit on page G1-4335.
- The CPS instruction on page G1-4335.
- The SETEND instruction on page G1-4336.
- The SETPAN instruction on page G1-4336.
The Current Program Status Register, CPSR

Some PSTATE fields can be accessed using the Special-purpose Current Program Status Register (CPSR). The CPSR can be directly read using the MRS instruction, and directly written using the MSR (register) and MSR (immediate) instructions.

The CPSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>N, Z, C, V</td>
</tr>
<tr>
<td>27</td>
<td>Q</td>
</tr>
<tr>
<td>26-24</td>
<td>Reserved: RAZ/SBZP</td>
</tr>
<tr>
<td>22</td>
<td>In ARMv8.0, Reserved, RES0. In ARMv8.1, Privileged Access Never (PAN) state bit, see About the PAN bit on page G4-4608.</td>
</tr>
<tr>
<td>19-16</td>
<td>GE[3:0]</td>
</tr>
<tr>
<td>9</td>
<td>E</td>
</tr>
<tr>
<td>8-6</td>
<td>A, I, F</td>
</tr>
<tr>
<td>0-4</td>
<td>M[4:0]</td>
</tr>
</tbody>
</table>

N, Z, C, V, bits [31:28]

The PSTATE Condition flags.

Q, bit [27]

The PSTATE overflow or saturation flag.

Bits[26:24]

Reserved, RAZ/SBZP. Software can use MSR instructions that write the top byte of the CPSR without using a read-modify-write sequence. If it does this, it must write zeros to bits[26:24].

Bits[23, 21:20, 15:10, 5]

Reserved, RES0.

Bit[22]

In ARMv8.0, Reserved, RES0.

In ARMv8.1, Privileged Access Never (PAN) state bit, see About the PAN bit on page G4-4608.

GE[3:0], bits [19:16]

The PSTATE greater than or equal flags.

E, bit [9]

The PSTATE endianness bit.

A, I, F, bits [8:6]

The PSTATE asynchronous exception mask bits.

M[4:0], bits [4:0]

The PSTATE mode bits.

The other PSTATE fields cannot be accessed by using the CPSR. For information on how to access them, see Accessing the PE state controls and the Execution state bit on page G1-4335.

The application level alias for the CPSR is the APSR. The APSR is a subset of the CPSR. See The Application Program Status Register, APSR on page E1-2736.

Writes to the CPSR have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the CPSR write. This means that they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.
The privilege level and address space of memory accesses associated with fetching instructions depend on the current Exception level and Security state. Writes to PSTATE.M can change one or both of the Exception level and Security state. The effect, on memory accesses associated with fetching instructions, of a change of Exception level or Security state is:

- Synchronous to the change of Exception level or Security state, if that change is caused by an exception entry or exception return.
- Guaranteed not to be visible to any memory access caused by fetching an earlier instruction in the execution stream.
- Guaranteed to be visible to any memory access caused by fetching any instruction after the next Context synchronization event in the execution stream.
- Might or might not affect memory accesses caused by fetching instructions between the mode change instruction and the point where the mode change is guaranteed to be visible.

See Exception return to an Exception level using AArch32 on page G1-4360 for the definition of exception return instructions.

### Accessing the PE state controls and the Execution state bit

The PE state controls are the PSTATE.{IL, IT[7:0], J, E, T} fields. Software can read or write these in an SPSR. In the CPSR:

- The PE state controls, other than PSTATE.E, are RAZ when read by an MRS instruction.
- Writes to the PE state controls, other than PSTATE.E, by MSR (register) or MSR (immediate), are ignored in all modes.

Instructions other than MRS, MSR (register), or MSR (immediate) that access the PE state controls can read and write them in any mode.

Unlike the other PSTATE PE state controls, PSTATE.E can be read by an MRS instruction and might be written by MSR (register) or MSR (immediate). However, ARM deprecates PSTATE.E having a different value from the equivalent System register EE bit, see Mixed-endian support on page G3-4524.

---

**Note**

To determine the current endianness, software can use an LDR instruction to load a word from memory with a known value that differs if the endianness is reversed. For example, using an LDR instruction to load a word whose four bytes are 0x01, 0x00, 0x00, and 0x00 in ascending order of memory address loads the destination register with:

- 0x00000001 if the current endianness is little-endian.
- 0x01000000 if the current endianness is big-endian.

The PSTATE.M[4] bit is the Execution state bit. When read by an MRS instruction in AArch32 state, this bit always reads as 1. When written by an MSR (register) instruction or MSR (immediate) instruction, writing a value other than 1 is an illegal change to the PSTATE.M field. See Illegal changes to PSTATE.M on page G1-4336.

### The CPS instruction

The A32 and T32 instruction sets both include an instruction to manipulate PSTATE.{A, I, F} and PSTATE.M:

CPSIE <iflags> {, #<mode>}

Sets the specified PSTATE.{A, I, F} exception masks to 0, enabling the exception, and optionally changes to the specified mode.

CPSID <iflags> {, #<mode>}

Sets the specified PSTATE.{A, I, F} exception masks to 1, disabling the exception, and optionally changes to the specified mode.

CPS #<mode>

Changes to the specified mode without affecting the PSTATE.{A, I, F} exception masks.
The CPS instruction is unconditional. For more information, see CPS, CPSID, CPSIE on page F5-3089.

**The SETEND instruction**

The A32 and T32 instruction sets both include an instruction to manipulate PSTATE.E:

- **SETEND BE** Sets PSTATE.E to 1, for big-endian operation.
- **SETEND LE** Sets PSTATE.E to 0, for little-endian operation.

The SETEND instruction is unconditional. For more information, see SETEND on page F5-3411. ARM deprecates use of the SETEND instruction.

**The SETPAN instruction**

ARMv8.1-PAN adds the SETPAN instruction to the A32 and T32 instruction sets, to manipulate PSTATE.PAN:

- **SETPAN #0** Sets PSTATE.PAN to 0, disabling Privileged access-never operation.
- **SETPAN #1** Sets PSTATE.PAN to 1, enabling Privileged access-never operation.

The SETPAN instruction is unconditional. For more information see:

- SETPAN on page F5-3412.
- About the PAN bit on page G4-4608.

**G1.10.2 The Saved Program Status Registers (SPSRs)**

On taking an exception, PSTATE is preserved in the SPSR of the mode to which the exception is taken. The SPSRs are described in Saved Program Status Registers (SPSRs) on page G1-4329.

**G1.10.3 Illegal changes to PSTATE.M**

In AArch32 PE modes other than User mode, MSR and CPS instructions can explicitly change PSTATE.M. The following changes to PSTATE.M by MSR or CPS instructions are illegal:

- A change to an encoding that Table G1-5 on page G1-4322 does not show.
- A change to a mode that is not implemented.
- A change to a mode that is not accessible from the context the MSR or CPS instruction is executed in, as follows:
  - A change to a mode that would cause entry to a higher Exception level.
  - When executing in Non-secure state, a change to Monitor mode.
  - When executing in Secure EL1, a change to Monitor mode when EL3 is using AArch64.
  - A change to Hyp mode from any other mode.
  - A change from Hyp mode to any other mode.
  - When the value of HCR.TGE is 1, attempting to change from Monitor mode to a Non-secure PL1 mode, see Trapping of general exceptions to Hyp mode on page K1-6116.

On executing an instruction that attempts an illegal change to PSTATE.M:

- PSTATE.M is unchanged, and the current mode remains unchanged.
- PSTATE.IL is set to 1.
- All other PSTATE fields are written to as normal.

**Note**

For the PSTATE fields that MSR and CPS instructions update, see the instruction descriptions:

- MSR (register) on page F5-3287.
- MSR (immediate) on page F5-3285.
When the value of PSTATE.IL is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See The Illegal Execution state exception on page G1-4363.

--- Note ---

- The PE ignores writes to PSTATE.M when executing at PL0.
- In ARMv7, an instruction that attempts to make an illegal change to PSTATE.M is UNPREDICTABLE.

### G1.10.4 Pseudocode description of PSTATE operations

The `CPSRWriteByInstr()` function is used by the MSR (register) and MSR (immediate) instructions to update PSTATE.

The `SetPSTATEFromPSR()` function updates PSTATE from a CPSR or SPSR.

Chapter J1 ARMv8 Pseudocode defines these functions.
G1.11 Instruction set states

The instruction set states are described in Chapter E2 The AArch32 Application Level Memory Model and application level operations on them are described there. This section supplies more information about how they interact with system level functionality, in the sections:

- Exceptions and instruction set state.
- Unimplemented instruction sets.

G1.11.1 Exceptions and instruction set state

If an exception is taken to an EL1 mode, the SCTLR.TE bit for the Security state the exception is taken to determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

If the exception is taken to Hyp mode, the HSCTLR.TE bit determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

On coming out of reset, if the highest implemented Exception level is using AArch32:

- If the highest implemented Exception level is EL2, the PE starts execution in Hyp mode, in the instruction set state determined by the reset value of HSCTLR.TE.
- Otherwise, the PE starts execution in Supervisor mode, in the instruction set state determined by the reset value of SCTLR.TE. If the implementation includes EL3, this execution is in Secure Supervisor mode.

For more information about exception entry, see Overview of exception entry on page G1-4347.

G1.11.2 Unimplemented instruction sets

The PSTATE.T bit defines the current instruction set state, see Process state, PSTATE on page E1-2734.

In the ARMv8 architecture there is no support for the hardware acceleration of Java bytecodes, and the Jazelle Instruction set state is obsolete. Every AArch32 implementation must support the Trivial Jazelle implementation described in Trivial implementation of the Jazelle extension.

--- Note ---

In previous versions of the ARM architecture, the PSTATE.{J, T} bits determined the Instruction set state. In ARMv8, PSTATE.J is RES0.

--- Trivial implementation of the Jazelle extension ---

ARMv8 requires that the implementation of AArch32 state includes the trivial Jazelle implementation.

In a trivial implementation of the Jazelle extension:

- At EL1, EL2, or EL3, if the Exception level is using AArch32:
  - The JMCR and JOSCR are RAZ/WI.
  - The JIDR is a RAZ read-only register.
- At EL0 when EL0 is using AArch32:
  - It is IMPLEMENTATION DEFINED whether the JMCR and JOSCR are RAZ/WI or UNDEFINED.
  - It is IMPLEMENTATION DEFINED whether JIDR is RAZ or UNDEFINED.
- The BXJ instruction behaves identically to the BX instruction in all circumstances.

--- Note ---

This is consistent with the JMCR.JE bit being RAZ, and means that the A32 and T32 instruction sets do not provide any mechanism for attempting to enter Jazelle state.
• Jazelle state, as defined in previous versions of the ARM architecture, is an unimplemented instruction set state.

These requirements ensure that operating systems that support an EJVM execute correctly. A trivial implementation is not required to extend the PC to 32 bits, that is, it can implement PC[0] as RAZ/WI.

——— Note ————
This is because the only way that PC[0] is visible in A32 or T32 state is as a result of an exception occurring during Jazelle state execution, and Jazelle state execution cannot occur on a trivial implementation.
G1.12 Handling exceptions that are taken to an Exception level using AArch32

An exception causes the PE to suspend program execution to handle an event, such as an externally generated interrupt or an attempt to execute an undefined instruction. Exceptions can be generated by internal and external sources.

Normally, when an exception is taken the PE state is preserved immediately, before handling the exception. This means that, when the event has been handled, the original state can be restored and program execution resumed from the point where the exception was taken.

More than one exception might be generated at the same time, and a new exception can be generated while the PE is handling an exception.

The following sections describe exception handling:
- Exception vectors and the exception base address.
- Exception prioritization for exceptions taken to AArch32 state on page G1-4344.
- Overview of exception entry on page G1-4347.
- PE mode for taking exceptions on page G1-4350.
- PE state on exception entry on page G1-4354.
- Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.
- Routing debug exceptions to EL2 using AArch32 on page G1-4358.
- Exception return to an Exception level using AArch32 on page G1-4360.

Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365 gives a full description of asynchronous exception handling, for exceptions taken asynchronously from AArch32 state.

Note
Because of the common model for handling exceptions, the current section requires some understanding of the asynchronous exception behaviors described in Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365.

AArch32 state exception descriptions on page G1-4376 then describes each exception.

G1.12.1 Exception vectors and the exception base address

When an exception is taken, PE execution is forced to an address that corresponds to the type of exception. This address is called the exception vector for that exception. The vectors for the different types of exception form a vector table.

Note
There are significant differences in the sets of exception vectors for exceptions taken to an Exception level that is using AArch32 and for exceptions taken to an Exception level that is using AArch64. This part of this manual describes only how exceptions are taken to an Exception level that is using AArch32. So, for example, when executing at EL1 or EL0, an exception might be generated that must be taken to EL3. In this case:

- If EL3 is using AArch32 then the exception is taken as described in this chapter, using the exception vectors described in this section.
- If EL3 is using AArch64 then the exception is taken as described in Chapter D1 The AArch64 System Level Programmers’ Model using the exception vectors described in Exception vectors on page D1-1800.

AArch32 state defines exception vector tables for exceptions taken to EL2 and EL3 when those Exception levels are using AArch32. Those vector tables are not used when the corresponding Exception levels are using AArch64.

A set of exception vectors for an Exception level that is using AArch32 comprises eight consecutive word-aligned memory addresses, starting at an exception base address. These eight vectors form an AArch32 vector table.
The number of possible exception base addresses, and therefore the number of vector tables, depends on the implemented Exception levels, as follows:

**Implementation that does not include EL3**

Any implementation that does not include EL3 must include the following AArch32 vector table if EL1 can use AArch32:

- An exception table for exceptions taken to EL1 modes other than System mode. This is the EL1 vector table, and is in the address space of the PL1&0 translation regime.

**Note**

Exceptions cannot be taken to System mode.

For this vector table, the VBAR holds the exception base address.

**Implementation that includes EL2**

Any implementation that includes EL2 must include the following additional AArch32 vector table if EL2 can use AArch32:

- An exception table for exceptions taken to Hyp mode. This is the Hyp vector table, and is in the address space of the Non-secure PL2 translation regime.

For this vector table, HVBAR holds the exception base address.

**Implementation that includes EL3**

Any implementation that includes EL3 must include the following AArch32 vector tables:

- If EL3 can use AArch32, a vector table for exceptions taken to Secure Monitor mode. This is the Monitor vector table, and is in the address space of the Secure PL1&0 translation regime.

For this vector table, MVBAR holds the exception base address.

- If Secure EL1 can use AArch32, a vector table for exceptions taken to Secure privileged modes other than Monitor mode and System mode. This is the Secure vector table, and is in the address space of the Secure PL1&0 translation regime.

For this vector table, the Secure VBAR holds the exception base address.

- If Non-secure EL1 can use AArch32, a vector table for exceptions taken to Non-secure PL1 modes. This is the Non-secure vector table, and is in the address space of the Non-secure PL1&0 translation regime.

For this vector table, the Non-secure VBAR holds the exception base address.

The following subsections give more information:

- *The vector tables and exception offsets.*
- *Pseudocode determination of the exception base address on page G1-4344.*

**The vector tables and exception offsets**

Table G1-6 on page G1-4342 defines the AArch32 vector table entries. In this table:

- The *Hyp mode* column defines the vector table entries for exceptions taken to Hyp mode.
- The *Monitor mode* column defines the vector table entries for exceptions taken to Monitor mode.
- The *Secure* and *Non-secure* columns define the Secure and Non-secure vector table entries, that are used for exceptions taken to modes other than Monitor mode, Hyp mode, System mode, and User mode. Table G1-7 on page G1-4342 shows the mode to which each of these exceptions is taken. Each of these modes is described as the *default* mode for taking the corresponding exception.

**Note**

Exceptions cannot be taken to System mode or User mode.
For more information about determining the mode to which an exception is taken, see *PE mode for taking exceptions on page G1-4350*.

When EL2 is using AArch32, it provides a number of additional exceptions, some of which are not shown explicitly in the vector tables. For more information, see *interrupt Offsets of AArch32 exceptions provided by EL2 on page G1-4343*.

a. Non-secure state only. Implemented only if the implementation includes EL2 and EL2 can use AArch32.
b. Secure state only. Implemented only if the implementation includes EL3 and EL3 can use AArch32.
c. If the implementation does not include EL3 then there is a single vector table for exceptions taken to EL1 when EL1 is using AArch32. That table holds the vectors shown in the Secure column of this table.
d. In previous versions of the architecture, this entry has been used for the Reset vector, meaning the address at which execution starts on coming out of reset. In ARMv8, the AArch32 Reset vector is IMPLEMENTATION DEFINED. An implementation might use this vector table entry to hold the Reset vector.
e. See *Use of offset 0x14 in the Hyp vector table on page G1-4343*.

For more information about use of the vector tables see *Overview of exception entry on page G1-4347*. 
Interrupt Offsets of AArch32 exceptions provided by EL2

EL2 provides the following exceptions. When EL2 is using AArch32, these exceptions are taken to Hyp mode, and the PE enters the handlers for these exceptions using the following vector table entries shown in Table G1-6 on page G1-4342:

**Hypervisor Call**

If taken from Hyp mode, shown explicitly in the Hyp mode vector table. Otherwise, see *Use of offset 0x14 in the Hyp vector table*.

**Hyp Trap**

Shown explicitly in the Hyp mode vector table.

**Virtual Abort**

Entered through the Data Abort vector in the Non-secure vector table.

**Virtual IRQ**

Entered through the IRQ vector in the Non-secure vector table.

**Virtual FIQ**

Entered through the FIQ vector in the Non-secure vector table.

---

**Note**

*Virtual exceptions when an implementation includes EL2* on page G1-4365 gives more information about the virtual exceptions.

---

Use of offset 0x14 in the Hyp vector table

The vector at offset 0x14 in the Hyp vector table is used for exceptions that cause entry to Hyp mode. This means it is:

- Always used for the Hyp Trap exception.
- Used for any Hypervisor Call exception that is taken from a mode other than Hyp mode.
- Used for any Supervisor Call exception that is taken from Non-secure User mode when the value of HCR.TGE is 1.
- Used for any Undefined Instruction that is taken from Non-secure User mode when the value of HCR.TGE is 1.
- Used for any Prefetch Abort exception that is:
  - Taken from Non-secure User mode when the value of HCR.TGE is 1.
  - Generated by a Debug exception from Non-secure state when the value of HDCR.TDE is 1.
  - Generated by a stage 2 abort on an address translation instruction.
- Used for any Data Abort exception that is:
  - Taken from Non-secure User mode when the value of HCR.TGE is 1.
  - Generated by an SError interrupt from Non-secure state when the value of HCR.AMO is 1.
  - Generated by a Watchpoint exception from Non-secure state when the value of HDCR.TDE is 1.
  - Generated by a stage 2 abort on an address translation operation.

---

**Note**

Offset 0x14 is never used for the following exceptions:

- IRQ exceptions.
- Virtual IRQ exceptions.
- FIQ exceptions.
- Virtual FIQ exceptions.

Virtual exceptions are never taken to Hyp mode.

---

For more information, see *PE mode for taking exceptions* on page G1-4350.
Pseudocode determination of the exception base address

For an exception taken to a PL1 mode, the `ExcVectorBase()` function determines the exception base address.

The `ExcVectorBase()` function is defined in Chapter J1 ARMv8 Pseudocode.

--- Note ---

The PL1 modes to which exceptions can be taken are Supervisor mode, Undefined mode, Abort mode, IRQ mode, and FIQ mode. In Non-secure state, and in Secure state when EL3 is using AArch64, these are EL1 modes.
However, in Secure state when EL3 is using AArch32, these are EL3 modes. For more information see Security state, Exception levels, and AArch32 execution privilege on page G1-4318.

G1.12.2 Exception prioritization for exceptions taken to AArch32 state

The following sections describe the ARMv8 requirements for the prioritization of synchronous exceptions, and the limits on when asynchronous exceptions can be taken:

- Synchronous exception prioritization for exceptions taken to AArch32 state.
- Architectural requirements for taking asynchronous exceptions on page G1-4346.

See also:

- AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660, for information about:
  - The prioritization of aborts on a single memory access in a VMSA implementation.
  - The prioritization of exceptions generated during address translation.
- Debug state entry and debug event prioritization on page H2-5437 for information about the relative prioritization of exceptions and the debug events that cause entry to Debug state.

Synchronous exception prioritization for exceptions taken to AArch32 state

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. This section describes the prioritization of such exceptions when they are taken to an Exception level that is using AArch32.

--- Note ---

- An exception that is taken to an Exception level that is using AArch32 must have been taken from an Exception level that is using AArch32.
- The priority numbering in this list only shows the relative priorities of exceptions taken to an Exception level that is using AArch32. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827.

For an exception that is taken to an Exception level that is using AArch32, exceptions are prioritized as follows, where 1 is the highest priority.

1. PC alignment fault exceptions. A PC alignment fault exception can only be taken to an Exception level that is using AArch32 as a result of:
   - The CONSTRAINED UNPREDICTABLE handling of a branch to an unaligned address, see Branching to an unaligned PC on page K1-6098.
   - Exiting from Debug state to AArch32 specifying an unaligned PC value, see Exiting Debug state on page H2-5471.

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, see Prefetch Abort exception reporting a PC alignment fault exception on page G1-4385.
2. Prefetch Abort exceptions. See Prefetch Abort exception on page G1-4384 and AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660.

3. Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
   • Breakpoint exceptions on page G2-4470.
   • Vector Catch exceptions on page G2-4510.

   **Note**

   An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in this section. This means that it does not have its own entry in this list.

4. Illegal Execution state exceptions. See The Illegal Execution state exception on page G1-4363.

5. Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
   • HSTR.Tn.
   • HCR.TIDCP.

6. Undefined Instruction exceptions that occur as a result of one or more of the following:
   • An attempt to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
   • An attempt to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
   • Debug state execution of an instruction encoding that is unallocated in Debug state.
   • Non-debug state execution of an instruction encoding that is unallocated in Non-debug state.
   • Execution of an HVC instruction, when HVC instructions are disabled by SCR.HCE or HCR.HCD.
   • Execution of an HLT instruction when HLT instructions are disabled by EDSCR.HDE.
   • In Debug state:
     — Execution of a DCPS1 instruction in Non-secure EL0 when HCR.TGE is 1.
     — Execution of a DCPS2 instruction in EL1 or EL0 when SCR.NS is 0 or when EL2 is not implemented.
     — Execution of a DCPS3 instruction when EDSCR.SDD is 1 or when EL3 is not implemented.
     — When the value of EDSCR.SDD is 1, execution in EL2, EL1, or EL0 of an instruction that is trapped to EL3.
   • Execution of an instruction that is UNDEFINED as a result of any of:
     — Being in an IT block when SCTLR.ITD is 1, or when HSCTLR.ITD is 1.
     — Executing a SETEND instruction when SCTLR.SED is 1, or when HSCTLR.SED is 1.
     — Executing a CP15DMB, CP15DSB, or CP15ISB barrier instruction when SCTLR.CP15BEN is 0, or when HSCTLR.CP15BEN is 0.
     
     See Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality on page G1-4421 and Disabling or enabling EL2 use of AArch32 deprecated functionality on page G1-4430.
   • Execution of an instruction that is UNDEFINED because at least one of FPSCR.\{Stride, Len\} is nonzero, when programming these bits to nonzero values is supported. See Floating-point exception traps on page G1-4416.

7. Exceptions taken to EL1, or taken to EL2 because the value of HCR.TGE is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 1-6.

8. Exceptions taken from EL0 to EL2 because of one of the following configuration settings:
   • HSTR.Tn.
   • HCR.TIDCP.

9. Exceptions taken to EL2 because of configuration settings in the HCPTR.
10. Exceptions taken to EL2 because of one of the following configuration settings:
   • Any setting in HCR, other than the TIDCP bit.
   • Any setting in CNTHCTL.
   • Any setting in HDCR.

11. Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 1-10.

12. Exceptions caused by the SMC instruction being UNDEFINED because the value of SCR.SCD is 1.

13. Exceptions caused by the execution of an Exception generating instruction, SVC, HVC, SMC, or BKPT.

14. Exceptions taken to EL3 because of configuration settings in the SDCR. These might be taken from EL0, EL1, or EL2.

15. Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities 1-14.

16. Trapped floating-point exceptions, if supported. See Floating-point exception traps on page G1-4416.

17. Data Abort exceptions other than a Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk. That is, any Data Abort exception that is not covered by item 19. See Data Abort exception on page G1-4387 and AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660. It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item 19.

18. Watchpoint exceptions. See Watchpoint exceptions on page G2-4496.

19. Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk, see External aborts on page G3-4550. It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item 17.

For items 17-19, if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

Note
Exceptions generated by a translation table walk are reported and prioritized as either a Prefetch Abort exception, priority 2 in this list, or a Data Abort exception, priority 17 in this list. See also AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660.

Architectural requirements for taking asynchronous exceptions
The ARM architecture does not define when asynchronous exceptions are taken. The prioritization of asynchronous exceptions, including virtual asynchronous exceptions, is IMPLEMENTATION DEFINED.

An asynchronous exception that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event completes its execution, provided that the pending asynchronous event is not masked:
• Execution of an ISB instruction that does not fail its Condition code check.
• Exception entry.
• Exception return.
• Exit from Debug state.
G1 The AArch32 System Level Programmers’ Model
G1.12 Handling exceptions that are taken to an Exception level using AArch32

--- Note ---

• If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define the order in which that synchronous exception and the asynchronous exception are taken.
• The ISR identifies any pending asynchronous exceptions.
• Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronizing events does not include the DCPS and DRPS instructions.

In the absence of a specific requirement to take an asynchronous exception, the only requirement of the architecture is that an unmasked asynchronous exception is taken in finite time.

--- Note ---

The taking of an unmasked asynchronous exception in finite time must occur with all code sequences, including with a sequence that consists of unconditional loops.

If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits the interrupt to be taken, but does not require this to happen. If the interrupt is taken then it must be taken before the first Context synchronization event after the interrupt was changed to not pending.

PSTATE includes a mask bit for each type of asynchronous exception. Setting one of these bits to 1 can prevent the corresponding asynchronous exception from being taken, although when the PE is in Non-secure state other controls can modify the effect of these bits. For more information, see Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365.

Taking an exception sets an exception-dependent subset of these mask bits.

--- Note ---

In some contexts, the PSTATE.A, I, F} bits mask the taking of asynchronous exceptions. The way these are set on exception entry, described in PSTATE.\{A, I, F, M\} values on exception entry on page G1-4355, can prevent an exception handler being interrupted by an asynchronous exception.

G1.12.3 Overview of exception entry

There are some significant differences between the handling of exceptions taken to Hyp mode and exceptions taken to other modes. Because Hyp mode is the EL2 mode, this means that the following descriptions sometimes distinguish between the EL2 mode and the non-EL2 modes.

On taking an exception to an Exception level that is using AArch32:

1. The hardware determines the mode to which the exception must be taken, see PE mode for taking exceptions on page G1-4350.
2. A link value, indicating the preferred return address for the exception, is saved. This is a possible return address for the exception handler, and depends on:
   • The exception type.
   • Whether the exception is taken to the EL2 mode or to a non-EL2 mode.
   • For some exceptions taken to non-EL2 modes, the instruction set state when the exception was taken.
   Where the link value is saved depends on whether the exception is taken to the EL2 mode.
   For more information see Link values saved on exception entry on page G1-4349.
3. The value of PSTATE is saved in the SPSR for the mode to which the exception must be taken. The value saved in SPSR.IT[7:0] is always correct for the preferred return address.
4. In an implementation that includes EL3, when EL3 is using AArch32:
   • If the exception is taken from Monitor mode, SCR.NS is cleared to 0.
   • Otherwise, taking the exception leaves SCR.NS unchanged.

When EL3 is using AArch64, Monitor mode is not available.

5. PSTATE is updated with new context information for the exception handler. This includes:
   • Setting PSTATE.M to the PE mode to which the exception is taken.
   • Setting the appropriate PSTATE mask bits. This can disable the corresponding exceptions, preventing uncontrolled nesting of exception handlers.
   • Setting the instruction set state to the state required for exception entry.
   • Setting the endianness to the required value for exception entry.
   • Clearing the PSTATE.IT[7:0] bits to 0.

For more information, see PE state on exception entry on page G1-4354.

6. The appropriate exception vector is loaded into the PC, see Exception vectors and the exception base address on page G1-4340.

7. Execution continues from the address held in the PC.

For an exception taken to a non-EL2 mode, on exception entry, the exception handler can use the SRS instruction to store the return state onto the stack of any mode at the same Exception level and in the same Security state, and can use the CPS instruction to change mode. For more information about the instructions, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-3464 and CPS, CPSID, CPSIE on page F5-3089.

Later sections of this chapter describe each of the possible exceptions, and each of these descriptions includes a pseudocode description of the PE state changes on taking that exception. Table G1-8 gives an index to these descriptions:

</tbody>
</table>
The following sections give more information about the PE state changes, for different architecture implementations. However, you must refer to the pseudocode for a full description of the state changes:

- **PE mode for taking exceptions** on page G1-4350.
- **PE state on exception entry** on page G1-4354.

### Link values saved on exception entry

On exception entry, a link value for use on return from the exception, is saved. This link value is based on the *preferred return address* for the exception, as shown in Table G1-9:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Preferred return address</th>
<th>Taken to a mode at</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined Instruction</td>
<td>Address of the UNDEFINED instruction</td>
<td>Non-EL2(^a), or EL2(^c)</td>
</tr>
<tr>
<td>Hyp Trap</td>
<td>Address of the trapped instruction</td>
<td>EL2 only(^c)</td>
</tr>
<tr>
<td>Monitor Trap</td>
<td>Address of the trapped instruction</td>
<td>EL3 only</td>
</tr>
<tr>
<td>Supervisor Call</td>
<td>Address of the instruction after the SVC</td>
<td>Non-EL2(^a) or EL2(^c)</td>
</tr>
<tr>
<td>Secure Monitor Call</td>
<td>Address of the instruction after the SMC</td>
<td>EL3(^b), and only in Secure state</td>
</tr>
<tr>
<td>Hypervisor Call</td>
<td>Address of the instruction after the HVC</td>
<td>EL2 only(^c)</td>
</tr>
<tr>
<td>Prefetch Abort</td>
<td>Address of aborted instruction fetch</td>
<td>Non-EL2(^a) or EL2(^c)</td>
</tr>
<tr>
<td>Data Abort</td>
<td>Address of instruction that generated the abort</td>
<td>Non-EL2(^a) or EL2(^c)</td>
</tr>
<tr>
<td>Virtual Abort</td>
<td>Address of next instruction to execute</td>
<td>EL1, and only in Non-secure state</td>
</tr>
<tr>
<td>IRQ or FIQ</td>
<td>Address of next instruction to execute</td>
<td>Non-EL2(^a) or EL2(^c)</td>
</tr>
<tr>
<td>Virtual IRQ or Virtual FIQ</td>
<td>Address of next instruction to execute</td>
<td>EL1, and only in Non-secure state</td>
</tr>
</tbody>
</table>

---

**Note**

- Although Reset is described as an exception, it differs significantly from other exceptions. The architecture has no concept of a return from a Reset and therefore it is not listed in this section.
- For each exception, the preferred return address is not affected by the Exception level from which the exception was taken.

---

\(^a\) EL1 if the exception is taken to a Non-secure mode, or is taken to a Secure mode when EL3 is using AArch64. EL3 if the exception is taken to a Secure mode when EL3 is using AArch64.

\(^b\) A Secure Monitor Call exception is taken to EL3, and therefore is taken to AArch32 state only if EL3 is using AArch32, in which case it is taken to Monitor mode.

\(^c\) EL2 is implemented only in Non-secure state. Therefore, an exception can be taken to EL2 mode only if it is taken from Non-secure state.
The link value saved, and where it is saved, depend on whether the exception is taken to a non-EL2 mode, or to an EL2 mode, as follows:

**Exception taken to a non-EL2 mode**

The link value is saved in the LR for the mode to which the exception is taken.

The saved link value is the preferred return address for the exception, plus an offset that depends on the instruction set state when the exception was taken, as Table G1-10 shows:

**Table G1-10 Offsets applied to Link value for exceptions taken to non-EL2 modes**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Offset, for PE state of:</th>
</tr>

<td>+8</td>
</tr>
<tr>
<td>IRQ or FIQ</td>
<td>+4</td>
</tr>
<tr>
<td>Virtual IRQ or Virtual FIQ</td>
<td>+4</td>
</tr>
</tbody>
</table>

**Exception taken to an EL2 mode**

The link value is saved in the ELR_hyp Special-purpose register.

The saved link value is the preferred return address for the exception, as shown in Table G1-9 on page G1-4349, with no offset.

**G1.12.4 PE mode for taking exceptions**

The following principles determine the Exception level to which an exception is taken, and if that Exception level is using AArch32, the PE mode to which the exception is taken:

- An exception cannot be taken to the EL0 mode.

- An exception is taken either:
  - To the Exception level at which the PE was executing when it took the exception.
  - To a higher Exception level.

This means that, in Secure state:

- When EL3 is using AArch32, an exception is always taken to an EL3 mode.
- When EL3 is using AArch64, an exception that is taken to AArch32 state is taken to an EL1 mode.

- Configuration options and other features provided by EL2 and EL3 can determine the mode to which some exceptions are taken, as follows:
  **In an implementation that does not include EL2 or EL3**
  An exception is always taken to the default mode for that exception.
In an implementation that includes EL3

A Secure Monitor Call exception is always taken to EL3. This means:

- If EL3 is using AArch32 the exception is taken to Secure Monitor mode.
- If EL3 is using AArch64 then executing the instruction generates an exception that is taken to EL3, see Execution of an SMC instruction from a privileged Exception level that is using AArch32 on page G1-4352.

IRQ, FIQ, and External abort exceptions can be configured to be taken to EL3. Therefore, if EL3 is using AArch32 the exceptions are taken to Secure Monitor mode.

When EL3 is using AArch32, a Monitor Trap exception is taken to Secure Monitor mode.

Any exception taken from Secure state that is not taken to Secure Monitor mode is taken to Secure state in the default mode for that exception. As described in Security state, Exception levels, and AArch32 execution privilege on page G1-4318, this means it is taken to:

- An EL3 mode other than Monitor mode if EL3 is using AArch32.
- An EL1 mode if EL3 is using AArch64.

If the implementation does not include EL2, any exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state to the default mode for that exception. The default mode will be an EL1 mode.

In an implementation that includes EL2

An exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state and:

- If the exception is taken from Hyp mode then it is taken to Hyp mode.
- Otherwise, the exception is either taken to Hyp mode, as described in Exceptions taken to Hyp mode on page G1-4352, or taken to the default mode for the exception.

Note

- Hyp mode is the EL2 mode. The other modes to which an exception can be taken in Non-secure state are EL1 modes.
- EL2 has no effect on the handling of exceptions taken from Secure state.

Table G1-7 on page G1-4342 shows the default mode to which each exception is taken.

Asynchronous exception routing controls on page G1-4367 describes the exception routing controls provided by EL2 and EL3.

Routing of aborts taken to AArch32 state on page G4-4649 gives more information about the modes to which memory aborts are taken.

The possible modes for taking each exception on page G1-4353 shows all modes to which each exception might be taken, in any implementation. That is, it applies to implementations:

- That include neither EL2 nor EL3.
- That include EL2 but not EL3
- That do not include EL2 but include EL3
- That include both EL2 and EL3.
Exceptions taken to Hyp mode

In an implementation that includes EL2 and EL3, when EL2 is using AArch32:

- Any exception taken from Hyp mode, that is not routed to EL3 by the controls described in Asynchronous exception routing controls on page G1-4367, is taken to Hyp mode.

- The following exceptions, if taken from Non-secure state, are taken to Hyp mode:
  - An abort that Routing of aborts taken to AArch32 state on page G4-4649 identifies as taken to Hyp mode.
  - A Hyp Trap exception, see EL2 configurable controls on page G1-4427.
  - A Hypervisor Call exception. This is generated by executing an HVC instruction in a Non-secure mode.
  - An SError interrupt exception, IRQ exception or FIQ exception that is not routed to EL3 but is explicitly routed to Hyp mode, as described in Asynchronous exception routing controls on page G1-4367.
  - A synchronous external abort, Alignment fault, Undefined Instruction exception, or Supervisor Call exception taken from the Non-secure EL0 mode and explicitly routed to Hyp mode, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.

  — Note ——
  A synchronous external abort can be routed to Hyp mode only if it is not routed to EL3.

  — Note ——
  The virtual exceptions cannot be taken to Hyp mode. They are always taken to a Non-secure EL1 mode.

Security behavior in Exception levels using AArch32 when EL3 is using AArch64

As described in The ARMv8-A security model on page G1-4315, when EL3 is using AArch64, lower Exception levels, in either Security state, can be using AArch32. This means software executing in those Exception levels might try to access AArch32 security features that are not available. The following subsections describe the associated behaviors:

- Execution of an SMC instruction from a privileged Exception level that is using AArch32
- Non-secure reads of the NSACR
- Secure EL1 operations when Secure EL1 is using AArch32 on page G1-4353

Execution of an SMC instruction from a privileged Exception level that is using AArch32

When EL3 is using AArch64, an SMC instruction executed from Secure or Non-secure EL1 using AArch32, or from Non-secure EL2 using AArch32 when the value of HCR.TSC is 0, generates an exception that is taken to EL3. The exception syndrome is reported with an EC value of 0x13, SMC instruction executed in AArch32 state, see Exception from SMC instruction execution in AArch32 state on page D1-1809.

Non-secure reads of the NSACR

The NSACR is defined as being RO from Non-secure PE modes other than User mode. When EL3 is using AArch64, a read of the NSACR returns a fixed value of 0x00000C00 in the following cases:

- If the read is from a Non-secure EL1 mode when EL1 is using AArch32.
- If the read is from Hyp mode when EL2 is using AArch32.
Secure EL1 operations when Secure EL1 is using AArch32

When Secure EL1 is using AArch32 and EL3 is using AArch64:

- Any of the following operations performed in a Secure EL1 mode is trapped to Secure EL3:
  - A read or write of any of the SCR, NSACR, MVBAR, and SDCR.
  - Executing any of the ATS12NSO** instructions.
  - Executing an SRS instruction that would use SP_mon, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-3464.
  - Executing an MRS (Banked register) or MSR (Banked register) instruction that would access SPSR_mon, SP_mon, or LR_mon, see MRS (Banked register) on page F5-3277 and MSR (Banked register) on page F5-3281.

For more information about these traps, including the associated exception syndromes, see Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1870.

- Writes to the CNTFRQ register are UNDEFINED.

- Any attempt to move into Monitor mode, either by an exception return or by executing a CPS or MSR instruction, is treated as an illegal operation and is handled as described in Illegal return events from AArch32 state on page G1-4361.

--- Note ---

This functionality supports a usage model where:

- EL3 uses AArch64.
- Secure software executed in Secure EL1 using AArch32 and Secure EL0 using AArch32.
- The Non-secure state uses AArch64.

The possible modes for taking each exception

Each of the exception descriptions in AArch32 state exception descriptions on page G1-4376 includes a subsection that describes the modes to which each exception can be taken. Those subsections are:

- The PE mode to which the Undefined Instruction exception is taken on page G1-4377.
- The PE mode to which the Hyp Trap exception is taken on page G1-4380.
- The PE mode to which the Monitor Trap exception is taken on page G1-4379.
- The PE mode to which the Supervisor Call exception is taken on page G1-4381.
- The PE mode to which the Secure Monitor Call exception is taken on page G1-4382.
- The PE mode to which the Hypervisor Call exception is taken on page G1-4383.
- The PE mode to which the Prefetch Abort exception is taken on page G1-4386.
- The PE mode to which the Data Abort exception is taken on page G1-4389.
- The PE mode to which the Virtual SError interrupt exception is taken on page G1-4392.
- The PE mode to which the physical IRQ exception is taken on page G1-4393.
- The PE mode to which the Virtual IRQ exception is taken on page G1-4394.
- The PE mode to which the physical FIQ exception is taken on page G1-4396.
- The PE mode to which the Virtual FIQ exception is taken on page G1-4397.

These descriptions also show the vector offset for the exception entry for each mode. These descriptions assume that all Exception levels are using AArch32, meaning:

- HCR, rather than HCR_EL2, controls the routing of exceptions to EL2.
- SCR, rather than SCR_EL3, controls the routing of exceptions to EL3.
For more information about:

- Vector offsets, see *Exception vectors and the exception base address* on page G1-4340.
- The routing of synchronous external aborts or SError, IRQ, and FIQ interrupt exceptions, and the virtual exceptions, see *Asynchronous exception routing controls* on page G1-4367.

**UNPREDICTABLE cases when the value of HCR.TGE is 1**

When the value of HCR.TGE is 1, exceptions that would otherwise be taken to EL1 are, instead, routed to EL2, see *Routing exceptions from Non-secure EL0 to EL2* on page G1-4356. Related to this, when the value of HCR.TGE is 1, execution in a Non-secure EL1 mode is UNPREDICTABLE. ARMv8 does not constrain this UNPREDICTABLE behavior, but in ARMv8 software that follows the ARM recommendations cannot get to this state. When following the ARM recommendations, any attempt to move to a Non-secure EL1 mode when the value of HCR.TGE is 1 is either:

- An illegal exception return, see *Illegal return events from AArch32 state* on page G1-4361.
- An illegal PE mode change, see *Illegal changes to PSTATE.M* on page G1-4336.

**G1.12.5 PE state on exception entry**

The description of each exception includes a pseudocode description of entry to that exception, as *Table G1-8* on page G1-4348 shows. The following sections describe the PE state changes on entering an exception, for different implementations and operating states. However, you must always see the exception entry pseudocode for a full description of the state changes on exception entry:

- *Instruction set state on exception entry."
- *PSTATE.E value on exception entry* on page G1-4355.
- *PSTATE.{A, I, F, M} values on exception entry* on page G1-4355.

--- **Note** ---

The descriptions in these sections assume that EL2 and EL3, that control some aspects of the routing of exceptions taken from EL1 or EL0, are both using AArch32. If this is not the case:

- If EL2 is using AArch64:
  - Controls shown as provided by the HSCTLR are provided by the SCTLR_EL2.
  - Controls shown as provided by the HCR are provided by the HCR_EL2.
- If EL3 is using AArch64, controls shown as provided by the SCR are provided by the SCR_EL3.

---

**Instruction set state on exception entry**

Exception handlers can execute in either T32 state or A32 state. On exception entry, PSTATE.T is set to the required value, as determined by SCTLR.TE or HSCTLR.TE, depending on the mode the exception is taken to. *Table G1-11* shows this:

<table>
<thead>
<tr>
<th>Mode to which exception is taken</th>
<th>HSCTLR.TE</th>
<th>SCTLR.TE</th>
<th>PSTATE.T</th>
<th>Exception handler state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not Hyp mode</td>
<td>x</td>
<td>0</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>1</td>
<td>T32</td>
</tr>
<tr>
<td>Hyp mode</td>
<td>0</td>
<td>x</td>
<td>0</td>
<td>A32</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>x</td>
<td>T32</td>
</tr>
</tbody>
</table>
When an implementation includes EL3 and EL3 is using AArch32, SCTLR is Banked for Secure and Non-secure states, and therefore the TE bit value might be different for Secure and Non-secure states. For an exception taken to a PE mode other than Hyp mode, the SCTLR.TE bit for the Security state to which the exception is taken determines the instruction set state for the exception handler. This means the instruction set state in which an exception handler might depending on the Security state to which the exception is taken.

**PSTATE.E value on exception entry**

PSTATE.E controls the load and store endianness for data handling. Table G1-12 show the value to which this bit is set on exception entry:

![Table G1-12 PSTATE.E value on exception entry](image)

For more information, see the bit description in *SPSR format for exceptions taken to AArch32 state* on page G1-4330.

**PSTATE.{A, I, F, M} values on exception entry**

On exception entry, PSTATE.M is set to the value for the mode to which the exception is taken, as described in *PE mode for taking exceptions* on page G1-4350.

Table G1-13 shows the cases where PSTATE.{A, I, F} bits are set to 1 on an exception entry, and how this depends on the mode and Security state to which an exception is taken. If the table entry for a particular mode and Security state does not define a value for a PSTATE.{A, I, F} bit then that bit is unchanged by the exception entry. In this table:

- The Exception mode column is the mode to which the exception is taken.
- The Non-secure, EL2 not implemented column applies to exceptions taken to Non-secure state in an implementation that includes EL3 but does not include EL2.
- The All others column applies to:
  - Exceptions taken to Secure state.
  - Implementations that do not include the EL3.
  - Exceptions taken to Non-secure state in an implementation that includes EL2.

![Table G1-13 PSTATE.{A, I, F} values on exception entry](image)
Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365 describes how, in some situations, the PSTATE.{A, I, F} bits mask the taking of SError interrupts, IRQ interrupts, and FIQ interrupts.

### G1.12.6 Routing exceptions from Non-secure EL0 to EL2

#### Note

The routing control described in this section permits a Non-secure state usage model where applications execute in User mode under a hypervisor, that executes in Hyp mode, without a Guest OS running at Non-secure EL1. This control applies when the PE is executing in Non-secure EL0 using AArch32 and either:
- EL2 is using AArch32 and the value of HCR.TGE is 1.
- EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

In general, this section describes only the handling and reporting of exceptions that are taken to EL2 using AArch32 because the value of HCR.TGE is 1. Exception entry on page D1-1799 describes the handling of exceptions that are taken to EL2 using AArch64 because the value of HCR_EL2.TGE is 1.

If the PE is in Non-secure User mode, any exception that would otherwise be taken to Non-secure EL1 is taken to EL2 if either:
- EL2 is using AArch32 and the value of HCR.TGE is 1.
- EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

In this case the exception is taken to Hyp mode, instead of to the default Non-secure mode for handling the exception. For more information see Exception reporting when HCR.TGE routes an exception to EL2 using AArch32 on page G1-4357.

Any exception that is routed to Secure Monitor mode or to EL3 using AArch64 is unaffected by the value of HCR.TGE or HCR_EL2.TGE.

When the value of HCR.TGE is 1, meaning TGE routing from Non-secure EL0 using AArch32 to EL2 using AArch32 applies:
- The SCTLR.M bit is treated as 0 for all purposes other than a direct read of the SCTLR register.
- Each of the HCR.{FMO, IMO, AMO} bits is treated as 1 for all purposes other than a direct read of the HCR register.
- Each of the HDCR.{TDE, TDA, TDRA, TDOSA} bits is treated as 1 for all purposes other than a direct read of the HDCR register.
- An exception return to Non-secure EL1 is treated as an illegal exception return, see Illegal return events from AArch32 state on page G1-4361.
• All virtual interrupts, including any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts, are disabled.

**Exception reporting when HCR.TGE routes an exception to EL2 using AArch32**

The following sections give more information about the behavior of synchronous exceptions that are routed to Hyp mode because the value of HCR.TGE is 1:

- **Undefined Instruction exception, when the value of HCR.TGE is 1.**
- **Supervisor Call exception, when the value of HCR.TGE is 1.**
- **Abort exceptions, when the value of HCR.TGE is 1.**
- **Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1 on page G1-4358.**

**Undefined Instruction exception, when the value of HCR.TGE is 1**

When HCR.TGE is set to 1, if the PE is executing in Non-secure User mode and attempts to execute an UNDEFINED instruction, it takes the Hyp Trap exception, instead of an Undefined Instruction exception. On taking the Hyp Trap exception, the HSR reports an unknown reason for the exception, using the EC value 0x00. For more information see [Use of the HSR on page G4-4677](#).

**Supervisor Call exception, when the value of HCR.TGE is 1**

When HCR.TGE is set to 1, if the PE executes an SVC instruction in Non-secure User mode, the Supervisor Call exception generated by the instruction is taken to Hyp mode.

The HSR reports that entry to Hyp mode was because of a Supervisor Call exception, and:

- If the SVC is unconditional, takes for the imm16 value in the HSR:
  - A zero-extended 8-bit immediate value for the T32 SVC instruction.
  - The only T32 encoding for SVC is a 16-bit instruction encoding.
  - The bottom16 bits of the immediate value for the A32 SVC instruction.
- If the SVC is conditional, the imm16 value in the HSR is UNKNOWN.

If the SVC is conditional, the PE takes the exception only if the instruction passes its Condition code check.

The HSR reports the exception as a Supervisor Call exception taken to Hyp mode, using the EC value 0x11. For more information, see [Use of the HSR on page G4-4677](#).

**Note**

The effect of setting HCR.TGE to 1 is to route the Supervisor Call exception to Hyp mode, not to trap the execution of the SVC instruction. This means that the preferred return address for the exception, when routed to Hyp mode in this way, is the instruction after the SVC instruction.

**Abort exceptions, when the value of HCR.TGE is 1**

When the value of HCR.TGE is 1, if the PE is executing in Non-secure User mode then any abort exception that is not routed to Secure Monitor mode or to EL3 using AArch64 generates an exception that is taken as a Hyp Trap exception. Where an attempt to execute an instruction causes an abort, on taking the Hyp Trap exception, the HSR indicates whether a Data Abort exception or a Prefetch Abort exception caused the Hyp Trap exception entry, and presents a valid syndrome in the HSR.

When SCR.EA is set to 1, external aborts and SError interrupts are routed to EL3, and this routing takes priority over the HCR.TGE routing. For more information, see [Asynchronous exception routing controls on page G1-4367](#). The SCR.EA control described in that section applies to both synchronous external aborts and asynchronous SError interrupts.

An SError interrupt that is routed to Hyp mode because the value of HCR.TGE is 1 is reported as a Data Abort exception routed to Hyp mode.
The HSR reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information about the exception reporting, see Use of the HSR on page G4-4677.

**Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1**

PL1 configurable controls on page G1-4419 describes controls that, when the value of HCR.TGE is 0, can generate exceptions that are taken from Non-secure EL0 to EL1. When EL2 is using AArch32 and the value of HCR.TGE is 1, the exceptions generated by these controls are routed to Hyp mode. Table G1-14 shows how these exceptions are then reported in the HSR.

<table>

a. T indicates a trap control, E indicates an instruction enable, and D indicates an instruction disable. For the definition of these terms, see the list that begins with Instruction enables and instruction disables on page G1-4418.

**G1.12.7 Routing debug exceptions to EL2 using AArch32**

When the value of HDCR.TDE is 1, if the PE is executing in a Non-secure mode other than Hyp mode, any Debug exception is routed to Hyp mode. This means it generates a Hyp Trap exception. This applies to:

- Debug exceptions associated with an instruction fetch, that would otherwise generate a Prefetch Abort exception. These are the Breakpoint, Breakpoint Instruction, and Vector Catch exception, see Chapter G2 AArch32 Self-hosted Debug.

- Watchpoint exceptions associated with data accesses, that would otherwise generate a Data Abort exception. See Watchpoint exceptions on page G2-4496.

When the value of HDCR.TDE is 1, each of the HDCR.{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than reading the HDCR register.
Note

- A Breakpoint or Watchpoint debug event that generates entry to Debug state cannot be trapped to Hyp mode. See *Breakpoint and Watchpoint debug events* on page H2-5436.

- When HCR.TDE is set to 1, the Hyp Trap exception is generated instead of the Prefetch Abort exception or Data Abort exception that is otherwise generated by the Debug exception.

- Debug exceptions, other than Breakpoint Instruction exceptions, are never generated in Hyp mode.

When a Hyp Trap exception is generated because the value of HCR.TDE is 1, the HSR reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information see *Use of the HSR* on page G4-4677.
G1.13 Exception return to an Exception level using AArch32

In the ARM architecture, exception return to an Exception level that is using AArch32 requires the simultaneous restoration of the PC and PSTATE to values that are consistent with the desired state of execution on returning from the exception. Typically, exception return involves returning to one of:

- The instruction after the instruction boundary at which an asynchronous exception was taken.
- The instruction following an SVC, SMC, or HMC instruction, for an exception generated by one of those instructions.
- The instruction that caused the exception, after the reason for the exception has been removed.
- The subsequent instruction, if the instruction that caused the exception has been emulated in the exception handler.

The ARM architecture defines a preferred return address for each exception other than Reset, see Link values saved on exception entry on page G1-4349. The values of the SPSR.IT[7:0] bits generated on exception entry are always correct for this preferred return address, but might require adjustment by the exception handler if returning elsewhere.

In some cases, to calculate the appropriate preferred return address for a return to an Exception level that is using AArch32, a subtraction must be performed on the link value saved on taking the exception. The description of each exception includes any value that must be subtracted from the link value, and other information about the required exception return.

On an exception return, the PSTATE takes either:

- The value loaded by the RFE instruction.
- If the exception return is not performed by executing an RFE instruction, the value of the current SPSR at the time of the exception return.

Illegal return events from AArch32 state on page G1-4361 describes the behavior if the restored PE state would not be valid for the Exception level, PE mode, and Security state targeted by the exception return.

G1.13.1 Exception return instructions

The instructions that an exception handler can use to return from an exception depend on whether the exception was taken to an EL1 mode, or in an EL2 mode, see:

- Return from an exception taken to a PE mode other than Hyp mode.
- Return from an exception taken to Hyp mode on page G1-4361.

Return from an exception taken to a PE mode other than Hyp mode

For an exception taken to a PE mode other than Hyp mode, the ARM AArch32 architecture provides the following exception return instructions:

- From privileged modes other than System mode, the ERET instruction. After the exception return, execution resumes from the address held in the LR (R14) for the mode in which ERET is executed. See ERET on page F5-3117.
- Data-processing instructions with the S bit set and the PC as a destination, see MOV, MOVS (register) on page F5-3260 and SUB, SUBS (immediate) on page F5-3560.

Note

The A32 instruction set includes other instructions that can be used for an exception return, but ARM deprecates any use of those instructions.
Typically:
— A return where no subtraction is required uses SUBS with an operand of 0, or the equivalent MOVS instruction.
— A return requiring subtraction uses SUBS with a nonzero operand.

• The RFE instruction, see RFE, RFEDA, RFEDB, RFEIA, RFEIB on page F5-3363. If a subtraction is required, typically it is performed before saving the LR value to memory. After the exception return, execution resumes from the address held in the memory location indicated by the base register specified by the RFE instruction.

• In A32 state, a form of the LDM instruction in which the PC is one of the registers loaded, see LDM (exception return) on page F5-3148. If a subtraction is required, typically it is performed before saving the LR value to memory.

Return from an exception taken to Hyp mode

For an exception taken to Hyp mode, the ARM architecture provides the ERET instruction, see ERET on page F5-3117. An exception handler executing in Hyp mode must return using the ERET instruction.

Both Hyp mode and the ERET instruction are implemented only as part of EL2.

G1.13.2 Alignment of exception returns

The T bit of the value transferred to the PSTATE by an exception return controls the target instruction set of that return. The behavior of the hardware for exception returns for different values of the T bit is as follows:

T == 0 The target instruction set state is A32 state. Bits[1:0] of the address transferred to the PC are ignored by the hardware.

T == 1 The target instruction set state is T32 state:
• Bit[0] of the address transferred to the PC is ignored by the hardware.
• Bit[1] of the address transferred to the PC is part of the instruction address.

Note

In previous versions of the ARM architecture, the PSTATE.{J, T} bits determined the Instruction set state. In ARMv8, PSTATE.J is RES0.

ARM deprecates any dependence on the requirements that the hardware ignores bits of the address. ARM recommends that the address transferred to the PC for an exception return is correctly aligned for the target instruction set.

After an exception entry other than Reset, the LR value has the correct alignment for the instruction set indicated by the SPSR.T bit. This means that if exception return instructions are used with the LR and SPSR values produced by such an exception entry, the only precaution software needs to take to ensure correct alignment is that any subtraction is of a multiple of four if returning to A32 state, or a multiple of two if returning to T32 state.

G1.13.3 Illegal return events from AArch32 state

Throughout this section:

Return In AArch32 state, refers to any of:
• Execution of any exception return instruction.
• Execution of a DRPS instruction in Debug state.
• Exit from Debug state.

If an exception or debug return from an Exception level using AArch32 triggers an illegal exception return, then bit[1] of the PC is either:
• Zero.
• The value of bit[1] of the return address for the exception or debug return.
The choice between these two alternatives is made by the implementation, and might differ from instance to instance of an illegal exception return.

--- Note ---

This means software must support both alternatives.

Saved process state value

In AArch32 state, refers to any of:

- The value held in the SPSR for any exception return other than an exception return made by executing an RFE instruction.
- The value read from memory that is to be restored to PSTATE by the execution of an RFE instruction.
- The value held in the SPSR for the execution of a DRPS instruction in Debug state.
- The value held in the DSPSR for a Debug state exit.

Link address

In AArch32 state, refers to any of:

- The address held in the link register for any exception return other than an exception return made by executing an ERET, LDM, or RFE instruction.
- The address held in ELR_hyp for any exception return made by executing an ERET instruction.
- The address read from memory that is to be restored to the PC by the execution of an LDM or RFE instruction.
- The address held in the DLR for Debug state exit.

Configured from reset

Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling exception or debug returns to a mode or state that is illegal. In AArch32 state, this can occur as a result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the mode being returned to is not implemented. For example:
  - A return to Hyp mode when EL2 is not implemented.
  - A return to Monitor mode, when EL3 is either not implemented or using AArch64 state.
- A return to EL2 when:
  - EL3 is implemented and using AArch64, and the value of the SCR_EL3.NS bit is 0.
  - EL3 is implemented and using AArch32, and the value of the SCR.NS bit is 0.
- A return to Non-secure EL1 when:
  - EL2 is implemented and using AArch64, and the value of the HCR_EL2.TGE bit is 1.
  - EL2 is implemented and using AArch32, and the value of the HCR.TGE bit is 1.
- A return where the value of the saved process state M[4:0] field is not a valid AArch32 PE mode for the implementation. Table G1-5 on page G1-4322 shows the valid M[4:0] values for AArch32 PE modes.

In these cases:

- PSTATE.IL is set to 1, to indicate an illegal return.
- PSTATE.M is unchanged. This means the PE mode does not change.
- The SS bit is handled in the same way as any other exception or debug return, see Software Step exceptions on page D2-1956.
• The following PSTATE bits are restored from the saved process state value:
  — The Q Overflow or saturation flag.
  — The GE Greater than or Equal flags.
  — The E Endianness mapping bit.
  — The A, I, F exception mask bits.

• The PSTATE.{IT, T} bits are each either:
  — Set to 0.
  — Copied from the saved process state in the SPSR for the PE mode in which the exception is handled.

The choice between these two options is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

• The PC is restored from the link address, unless the illegal return is the execution of a DRPS instruction in Debug state.

When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See "The Illegal Execution state exception."

All aspects of the illegal return, other than the effects described in this section, are the same as for a legal return.

G1.13.4 Legal returns that set PSTATE.IL to 1

In this section, return, saved process state value, and link address have the meaning that is defined in "Illegal return events from AArch32 state on page G1-4361."

If the IL bit in the saved process state value is 1, then it is copied to PSTATE meaning that PSTATE.IL is set to 1. In this case, the PSTATE.{IT, T} bits are each either:

• Set to 0.
• Copied from the SPSR, or loaded from memory if the exception return was performed by executing an RFE instruction.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. This means software must regard each value as being an UNKNOWN choice between the two permitted values.

Because the return sets the PSTATE.IL bit to 1, any attempt to execute any instruction results in an Illegal Execution state exception. See "The Illegal Execution state exception."

G1.13.5 The Illegal Execution state exception

When the value of the PSTATE.IL bit is 1, any attempt to execute an instruction generates an Illegal Execution state exception. In AArch32 state, the PSTATE.IL bit can be set to 1 by one of the following:

• An illegal return, as described in "Illegal return events from AArch32 state on page G1-4361."
• An illegal change to PSTATE.M, as described in "Illegal changes to PSTATE.M on page G1-4336."
• A legal return that sets PSTATE.IL to 1, as described in "Legal returns that set PSTATE.IL to 1."

An Illegal Execution state exception is taken in the same way as an Undefined Instruction exception in the current Exception level. If the current Exception level is EL2 using AArch32 state, the HSR provides additional syndrome information for the exception, see "Use of the HSR on page G4-4677."

An Illegal Execution state exception has priority over any other Undefined Instruction exception that might arise from instruction execution.
Note

This section only describes the handling of an Illegal Execution state exception that is taken to an Exception level that is using AArch32 state. The Illegal Execution state exception on page D1-1818 describes the cases where an Illegal Execution state exception is taken to an Exception level that is using AArch64 state.

On taking any exception to an Exception level that is using AArch32 state:

1. The value of the PSTATE.IL bit is 1 and this is copied to the SPSR.IL bit for the PE mode to which the exception is taken.
2. The PSTATE.IL bit is cleared to 0.

Note

This means that it is not possible for software to observe the value of PSTATE.IL.

Pseudocode description of exception return

The AArch32.ExceptionReturn() function transfers the return address to the PC and restores PSTATE to its saved value.

This function uses the function SetPSTATEFromPSR().

The IllegalExceptionReturn() function checks for an Illegal Execution state exception.

Chapter J1 ARMv8 Pseudocode includes the definitions of these functions.
G1.14 Asynchronous exception behavior for exceptions taken from AArch32 state

In an implementation that does not include EL2 or EL3, the asynchronous exceptions behave as follows when EL1 and EL0 are both using AArch32:

- An SError interrupt is taken to Abort mode.
- An IRQ exception is taken to IRQ mode.
- An FIQ exception is taken to FIQ mode.

These are the default PE modes for taking these exceptions.

Note

The SError interrupt replaces the ARMv7 asynchronous abort. The new name better describes the nature of the exception.

However, the PSTATE.\{A, I, F\} bits mask the asynchronous exceptions, meaning that when the value of one of these PSTATE bits is 1, the corresponding exception is not taken.

If a masked asynchronous exceptions remains signaled, then the exception remains pending unless the value of the PSTATE bit is changed to 0.

EL2 and EL3 provide controls that affect:

- The routing of these exceptions, see Asynchronous exception routing controls on page G1-4367.
- Masking of these exceptions in Non-secure state, see Asynchronous exception masking controls on page G1-4368.

Similar register control bits are provided regardless of whether EL2 and EL3 are using AArch32 or AArch64:

- The EL2 controls are provided by the HCR when EL2 is using AArch32, and by the HCR_EL2 when EL2 is using AArch64.
- The EL3 controls are provided by the SCR when EL3 is using AArch32, and by the SCR_EL3 when EL3 is using AArch64.

Therefore, most references to the HCR or SCR in this section are to entries in Table K11-1 on page K11-6282, that disambiguates between AArch32 registers and AArch64 registers. However, the Execution states used by EL2 and EL3 do affect some aspects of the routing and masking of the asynchronous exceptions, see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-4370.

G1.14.1 Virtual exceptions when an implementation includes EL2

When implemented, EL2 provides the following virtual exceptions, that correspond to the physical asynchronous exceptions:

- Virtual SError, that corresponds to a physical external SError interrupt.
- Virtual IRQ, that corresponds to a physical IRQ.
- Virtual FIQ, that corresponds to a physical FIQ.

When the value of HCR.TGE is 0 and the value of an HCR.\{AMO, IMO, FMO\} routing control bit is 1, the corresponding virtual interrupt is enabled and a virtual exception is generated either:

- By setting the corresponding virtual interrupt pending bit, HCR.\{VA, VI, VF\}, to 1.
- For a Virtual IRQ or Virtual FIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the ARM Generic Interrupt Controller Architecture Specification.

When the value of HCR_EL2.TGE is 1 all virtual interrupts are disabled.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the ISR.
In AArch32 state, a virtual exception is taken only from a Non-secure EL1 or EL0 mode. In any other mode, if the exception is generated it is not taken.

A virtual exception is taken in Non-secure state to the default mode for the corresponding physical exception. This means:
- A Virtual SError is taken to Non-secure Abort mode.
- A Virtual IRQ is taken to Non-secure IRQ mode.
- A Virtual FIQ is taken to Non-secure FIQ mode.

Table G1-15 summarizes the HCR bits that route asynchronous exceptions to EL2, and the bits that generate the virtual exceptions.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Routing the physical exception to EL2</th>
<th>Generating the virtual exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>SError</td>
<td>HCR.AMO</td>
<td>HCR.VA</td>
</tr>
<tr>
<td>IRQ</td>
<td>HCR.IMO</td>
<td>HCR.VI</td>
</tr>
<tr>
<td>FIQ</td>
<td>HCR.FMO</td>
<td>HCR.VF</td>
</tr>
</tbody>
</table>

The HCR.\{VA, VI, VF\} bits generate a virtual exception only if set to 1 when the value of the corresponding HCR.\{AMO, IMO, FMO\} is 1.

Similarly, if the implementation also includes EL3, the HCR.\{AMO, IMO, FMO\} bits route the corresponding physical exception to Hyp mode only if the physical exception is not routed to Monitor mode by the SCR.\{EA, IRQ, FIQ\} bit. For more information, see Asynchronous exception routing controls on page G1-4367.

When the value of an HCR.\{AMO, IMO, FMO\} control bit is 1, the corresponding mask bit in PSTATE:
- Does not mask the physical exception.
- Masks the virtual exception when the PE is executing in a Non-secure EL1 or EL0 mode.

Taking a Virtual Abort exception clears HCR.VA to zero. Taking a Virtual IRQ exception or a Virtual FIQ exception does not affect the value of HCR.VI or HCR.VF.

--- Note ---
This means that the exception handler for a Virtual IRQ exception or a Virtual FIQ exception must cause software that is executing at EL2 or EL3 to update the HCR to clear the appropriate virtual exception bit to 0.

--- Note ---
A hypervisor can use virtual exceptions to signal exceptions to the current Guest OS. The Guest OS takes a virtual exception exactly as it would take the corresponding physical exception, and is unaware of any distinction between virtual exception and the corresponding physical exception.

Effects of the HCR.\{AMO, IMO, FMO\} bits
As described in this section, the HCR.\{AMO, IMO, FMO\} bits are part of the mechanism for enabling the virtual exceptions. In addition, for exceptions generated in Non-secure state:
- As mentioned in this section, affect the routing of the exceptions. See Asynchronous exception routing controls on page G1-4367.
- Affect the masking of the exceptions. See Asynchronous exception masking controls on page G1-4368.
G1.14.2 Asynchronous exception routing controls

This section describes the behavior when all Exception levels are using AArch32. For the differences when this is not the case see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-4370.

In an implementation that includes EL3 the following bits in the SCR control the routing of asynchronous exceptions, and also the routing of synchronous external aborts:

SCR.EA  When the value of this bit is 1, any synchronous external abort or SError interrupt is taken to EL3.

Note
- Although this section describes the asynchronous exception routing controls, SCR.EA controls the routing of both synchronous external aborts and asynchronous SError interrupts.
- The other classes of abort cannot be routed to EL3. For more information about the classification of aborts, see VMSAv8-32 memory aborts on page G4-4649.

SCR.FIQ  When the value of this bit is 1, any FIQ exception is taken to EL3.

SCR.IRQ  When the value of this bit is 1, any IRQ exception is taken to EL3.

When EL3 is using AArch32 and the value of one of the SCR.{EA, FIQ, IRQ} bits is 1, the exception is taken to Monitor mode.

Only Secure software can change the values of these bits.

In an implementation that includes EL2, the following bits in the HCR route asynchronous exceptions to EL2, for exceptions that are both:

- Taken from a Non-secure EL1 or EL0 mode.
- If the implementation also includes EL3, not configured, by the SCR.{EA, FIQ, IRQ} controls, to be taken to EL3.

HCR.AMO  When the value of this bit is 1, an SError interrupt exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure Abort mode. If the implementation also includes EL3, this control applies only if the value of SCR.EA is 0. When the value of SCR.EA is 1, the value of the AMO bit is ignored.

HCR.FMO  When the value of this bit is 1, an FIQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure FIQ mode. If the implementation also includes EL3, this control applies only if the value of SCR.FIQ is 0. When the value of SCR.FIQ is 1, the value of the FMO bit is ignored.

HCR.IMO  When the value of this bit is 1, an IRQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure IRQ mode. If the implementation also includes EL3, this control applies only if the value of SCR.IRQ is 0. When the value of SCR.IRQ is 1, the value of the IMO bit is ignored.

When EL2 is using AArch32 and the value of one of the HCR.{AMO, FMO, IMO} bits is 1, the exception is taken to Hyp mode.

Only software executing in Hyp mode, or Secure software executing at EL3 with SCR.NS set to 1, can change the values of these bits. If EL3 is using AArch32, this requires the Secure software to be executing in Monitor mode.

The HCR.{AMO, FMO, IMO} bits also affect the masking of asynchronous exceptions in Non-secure state, as described in Asynchronous exception masking controls on page G1-4368.

The SCR.{EA, FIQ, IRQ} and HCR.{AMO, FMO, IMO} bits have no effect on the routing of Virtual Abort, Virtual FIQ, and Virtual IRQ exceptions.
G1 The AArch32 System Level Programmers' Model

G1.14 Asynchronous exception behavior for exceptions taken from AArch32 state

Note
When the PE is in Hyp mode:
• Physical asynchronous exceptions that are not routed to Monitor mode are taken to Hyp mode.
• Virtual exceptions are not signaled to the PE.

See also Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365.

G1.14.3 Asynchronous exception masking controls

Note
This section describes the behavior when all Exception levels are using AArch32. For the differences when this is not the case see Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-4370.

The PSTATE.{A, I, F} bits can mask the taking of the corresponding exceptions from AArch32 state, as follows:
• PSTATE.A can mask SError interrupt exceptions.
• PSTATE.I can mask IRQ exceptions.
• PSTATE.F can mask FIQ exceptions.

In an implementation that does not include either of EL2 and EL3, setting one of these bits to 1 masks the corresponding exception, meaning the exception cannot be taken.

In an implementation that includes EL2, the HCR.{AMO, IMO, FMO} bits modify the masking of exceptions taken from Non-secure state.

Similarly, in an implementation that includes EL3, the SCR.{AW, FW} bits modify the masking of exceptions taken from Non-secure state by the PSTATE.{A, F} bits.

An implementation that includes only EL1 and EL0 does not provide any masking of the PSTATE.{A, I, F} bits. The following subsections describe the masking of these bits in other implementations:
• Asynchronous exception masking in an implementation that includes EL2 but not EL3.
• Asynchronous exception masking in an implementation that includes EL3 but not EL2.
• Asynchronous exception masking in an implementation that includes both EL2 and EL3 on page G1-4369.
• Summary of the asynchronous exception masking controls on page G1-4369.

Asynchronous exception masking in an implementation that includes EL2 but not EL3

The HCR.{AMO, IMO, FMO} bits modify the effect of the PSTATE.{A, I, F} bits. When the value of an HCR.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding PSTATE.{A, I, F} bit is ignored when the exception is taken from a Non-secure mode other than Hyp mode.

Asynchronous exception masking in an implementation that includes EL3 but not EL2

The SCR.{AW, FW} bits modify the effect of the PSTATE.{A, F} bits. When the value of one of the SCR.{AW, FW} bits is 0, the corresponding PSTATE bit is ignored when both of the follow apply:
• The corresponding exception is taken from Non-secure state.
• The value of the corresponding SCR.{EA, FIQ} bit is 1, routing the exception to EL3. This means the exception is routed to Monitor mode if EL3 is using AArch32.

Note
Whenever the value of PSTATE.I is 1, IRQ exceptions are masked and cannot be taken.
Asynchronous exception masking in an implementation that includes both EL2 and EL3

When the value of an HCR.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding PSTATE.{A, I, F} bit is ignored when both of the following apply:

- The exception is taken from Non-secure state.
- Either:
  - The corresponding SCR.{EA, IRQ, FIQ} bit routes the exception to Monitor mode.
  - The exception is taken from a Non-secure mode other than Hyp mode.

In addition, when the value of an SCR.{AW, FW} bit is 0, the value of the corresponding PSTATE.{A, F} bit is ignored when all of the following apply:

- The exception is taken from Non-secure state.
- The corresponding SCR.{EA, FIQ} bit routes the exception to Monitor mode.
- The corresponding HCR.{AMO, FMO} mask override bit is set to 0.

Summary of the asynchronous exception masking controls

The tables in this section show the masking controls for each of the PSTATE.{A, I, F} bits. For an implementation that does not include all of the Exception levels:

If the implementation includes only EL1 and EL0

The PSTATE bits cannot be masked. The behavior is as shown in the Secure row of the tables.

If the implementation includes EL2 but not EL3

The behavior is as shown in the Non-secure table rows when the control bits in the SCR are both 0.

If the implementation includes EL3 but not EL2

The behavior is as shown in the table rows where the control bit in the HCR is 0.

Table G1-16 shows the controls of the masking of SError interrupt exceptions by PSTATE.A.

G1.14.4 Asynchronous exception routing and masking with higher Exception levels using AArch64

Asynchronous exception routing controls on page G1-4367 and Asynchronous exception masking controls on page G1-4368 give full descriptions of the routing and masking of the asynchronous exceptions when all Exception levels are using AArch32. However, when EL0 and EL1 are using AArch32:

- As already described, the SCR and HCR controls might be from Exception levels that are using AArch64.
- If EL3 is using AArch64, or EL2 is using AArch64, there are some changes to the asynchronous exception behaviors.

Therefore, the following sections summarize the asynchronous exception behaviors, taking account of the Execution state being used at EL2 and EL3:

- Summary of physical interrupt routing.
- Summary of physical interrupt masking on page G1-4372.

Summary of physical interrupt routing

The following tables show the routing of physical interrupts. Table G1-19 on page G1-4371 shows the routing of physical FIQ interrupts, Table G1-20 on page G1-4371 shows the routing of physical IRQ interrupts, and Table G1-21 on page G1-4372 shows the routing of physical SError interrupts.
In these tables, for exceptions that must be taken to an Exception level that is using AArch32, the table shows the target Exception level and PE mode. In these entries, Mon indicates Monitor mode, and Abt indicates Abort mode.

- **HCR.TGE**: When the value of HCR.TGE is 1, the effective value of this bit is 1.
- **IMO <sup>b</sup>**: When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
- **SCR_EL3.RW**: When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.
The following tables show the masking of physical interrupts. Table G1-22 on page G1-4373 shows the masking of physical FIQ interrupts, Table G1-23 on page G1-4373 shows the masking of physical IRQ interrupts, and Table G1-24 on page G1-4374 shows the masking of physical SError interrupts. In these tables:

**M** Indicates that the exception is masked when the value of the PSTATE mask bit is 1.

**T** Indicates that the exception is taken, regardless of the value of the PSTATE mask bit.

**P** Indicates that the exception is not taken but remains pending. The value of the PSTATE mask bit has no effect on this behavior.

**Summary of physical interrupt masking**

**G1.14.5 Taking an interrupt or other exception during a multiple-register load or store**

In AArch32 state in ARMv8.0 and ARMv8.1, an interrupt cannot be taken during a sequence of memory accesses caused by a single load or store instruction.

When ARMv8.2-LSMAOC is implemented, an interrupt is permitted during a sequence of memory accesses generated by a LDM or STM instruction. Two control bits are added to HSCTLR and SCTLR to control this behavior. These are:

- **The LSMAOE bit.** This indicates that LDM and STM are permitted to be reordered or interrupted in any memory type.
- **The nTLSMD bit.** This causes LDM and STM instructions accessing Device memory to cause an Alignment fault.
When the LSMAOE bit is 0, if an interrupt is taken within the sequence of memory accesses generated by an LDM or STM instruction, then:

- For a load, any register being loaded by the instruction other than ones used in the generation of the address by the instruction, or PC, can contain a **UNKNOWN** value. Registers used in the generation of the address are restored to their initial value and the LR is set on the interrupt to a value consistent with returning to the instruction.

- For a store, any data location being stored to by the instruction can contain a **UNKNOWN** value.

- For either a load or store, if the instruction specifies writeback of the base address, then that register is restored to its initial value.
Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340 gives general information about exception handling. This section describes each of the exceptions, in the following subsections:

- Undefined Instruction exception.
- Monitor Trap exception on page G1-4379.
- Hyp Trap exception on page G1-4379.
- Supervisor Call (SVC) exception on page G1-4380.
- Secure Monitor Call (SMC) exception on page G1-4382.
- Hypervisor Call (HVC) exception on page G1-4383.
- Prefetch Abort exception on page G1-4384.
- Data Abort exception on page G1-4387.
- Virtual SError interrupt exception on page G1-4391.
- IRQ exception on page G1-4392.
- Virtual IRQ exception on page G1-4394.
- FIQ exception on page G1-4395.
- Virtual FIQ exception on page G1-4397.

Additional pseudocode functions for exception handling on page G1-4398 gives additional pseudocode that is used in the pseudocode descriptions of a number of the exceptions.

### G1.15.1 Undefined Instruction exception

An Undefined Instruction exception might be caused by:

- A System register access, floating-point, or Advanced SIMD instruction that is not accessible because of the settings in one or more of the CPACR, NSACR, HCPTR, and DBGDSCRext.
- A System register access, floating-point, or Advanced SIMD instruction that is not implemented.
- A System register access, floating-point, or Advanced SIMD instruction that causes an exception during execution. This includes:
  - Trapped floating-point exceptions that are taken to AArch32, if an implementation supports these traps. See Floating-point exceptions and exception traps on page E1-2743.
  - Execution of certain floating-point instructions when one or both of the FPSCR.{Stride, Len} fields in nonzero, in an implementation in which those fields are RW. The description of FPEXC specifies the instructions to which this applies.
- An instruction that is UNDEFINED.

The Undefined Instruction exception is taken using offset 0x04 in the Hyp, Secure, or Non-secure vector table. In the Monitor vector table this offset is used for the Monitor Trap exception. See Monitor Trap exception on page G1-4379 and The vector tables and exception offsets on page G1-4341.

By default, an Undefined Instruction exception is taken to Undefined mode, but an Undefined Instruction exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see The PE mode to which the Undefined Instruction exception is taken on page G1-4377.

The Undefined Instruction exception can provide:
- Signaling of an illegal instruction execution.
- Lazy context switching of System registers.
The preferred return address for an Undefined Instruction exception is the address of the instruction that generated the exception. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from Secure or Non-secure Undefined mode, the exception return uses the SPSR and LR_und values generated by the exception entry, as follows:
  - If SPSR.T is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
  - If SPSR.T is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.
- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see *Exception return to an Exception level using AArch32* on page G1-4360.

**Note**

If handling the Undefined Instruction exception requires instruction emulation, followed by return to the next instruction after the instruction that caused the exception, the instruction emulator must use the instruction length to calculate the correct return address, and to calculate the updated values of the IT bits if necessary.

**The PE mode to which the Undefined Instruction exception is taken**

*Figure G1-4* shows how the implementation, state, and configuration options determine the PE mode to which an Undefined Instruction exception is taken, when the exception is taken to an Exception level that is using AArch32.

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-4354.
Pseudocode description of taking the Undefined Instruction exception

The AArch32.UndefinedFault() pseudocode procedure determines whether the Undefined Instruction exception is taken to AArch32 state. If it is taken to AArch32 state, the AArch32.TakeUndefInstrException() pseudocode procedure describes how the PE takes the exception.

An Undefined Instruction exception is taken to an Exception level using AArch64 if either:
- It is generated in User mode when EL1 is using AArch64.
- It is generated in Non-secure User mode when EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

Conditional execution of undefined instructions

The conditional execution rules described in Conditional execution on page F2-2849 apply to all instructions. This includes undefined instructions and other instructions that would cause entry to the Undefined Instruction exception.

If such an instruction fails its condition check, the behavior depends on the potential cause of entry to the Undefined Instruction exception, as follows:
- If the potential cause is the execution of the instruction itself and depends on data values used by the instruction, the instruction executes as a NOP and does not cause an Undefined Instruction exception.
- In the following cases, it is IMPLEMENTATION DEFINED whether the instruction executes as a NOP or causes an Undefined Instruction exception:
  - The potential cause is the execution of an earlier System register access instruction, floating-point instruction, or Advanced SIMD instruction.
  - The potential cause is the execution of the instruction itself without dependence on the data values used by the instruction.

An implementation must handle all such cases in the same way.

Note

Before ARMv7, all implementations executed any instruction that failed its condition check as a NOP, even if it would otherwise have caused an Undefined Instruction exception. An Undefined Instruction handler written for these implementations might assume without checking that the undefined instruction passed its condition check. Such an Undefined Instruction handler is likely to need rewriting, to check the condition is passed, before it functions correctly on all AArch32 implementations.

Interaction of UNDEFINED instruction behavior with UNPREDICTABLE or CONSTRAINED UNPREDICTABLE instruction behavior

If this manual describes an instruction as both:
- UNPREDICTABLE and UNDEFINED then the instruction is UNPREDICTABLE.
- CONSTRAINED UNPREDICTABLE and UNDEFINED then the instruction is CONSTRAINED UNPREDICTABLE.

Note

An example of this is where both:
- An instruction, or instruction class, is made UNDEFINED by some general principle, or by a configuration field.
- A particular encoding of that instruction or instruction class is specified as CONSTRAINED UNPREDICTABLE.
G1.15.2  Monitor Trap exception

The Monitor Trap exception is implemented only as part of EL3, and can be generated only if EL3 is using AArch32.

--- Note ---

The Monitor Trap exception is taken using offset 0x04 in the Monitor vector table. In the other vector tables, this offset is used for the Undefined Instruction exception. See Undefined Instruction exception on page G1-4376 and The vector tables and exception offsets on page G1-4341.

A Monitor Trap exception is generated if the PE is running in a mode other than Monitor mode, and commits for execution a WFI or WFE instruction that would otherwise cause suspension of execution when:

• In the case of the WFI instruction, the value of the SCR.TWI bit is 1.
• In the case of the WFE instruction, the value of the SCR.TWE bit is 1.

--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The preferred return address for a Monitor Trap exception is the address of the instruction that generated the exception. The exception return uses the SPSR and LR_mon values generated by the exception entry, as follows:

• If SPSR.T is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
• If SPSR.T is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.

For more information, see Exception return to an Exception level using AArch32 on page G1-4360.

The PE mode to which the Monitor Trap exception is taken

When EL3 is using AArch32, a Monitor Trap exception is taken to Monitor mode, using a vector offset of 0x04 from the Monitor exception base address.

Pseudocode description of taking the Monitor Trap exception

The AArch32.TakeMonitorTrapException() pseudocode procedure describes how the PE takes the exception.

G1.15.3  Hyp Trap exception

The Hyp Trap exception provides the standard mechanism for trapping Guest OS functions to the hypervisor.

The Hyp Trap exception is implemented only as part of EL2 and can be generated only if EL2 is using AArch32.

A Hyp Trap exception is generated if the PE is running in a Non-secure mode other than Hyp mode, and commits for execution an instruction that is trapped to Hyp mode. Instruction traps are enabled by setting bits to 1 in the HCR, HCPTTR, HDCR, or HSTR. For more information see EL2 configurable controls on page G1-4427.

Traps to Hyp mode never apply in Secure state, regardless of the value of the SCR.NS bit.

The preferred return address for a Hyp Trap exception is the address of the trapped instruction. The exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.
Note

The SPSR and ELR_hyp values generated on exception entry can be used, without modification, for an exception return to re-execute the trapped instruction. If the exception handler emulates the trapped instruction, and must return to the following instruction, the emulation of the instruction must include modifying ELR_hyp, and possibly updating SPSR_hyp.

When the PE enters the handler for a Hyp Trap exception, the HSR holds syndrome information for the exception. For more information see Use of the HSR on page G4-4677.

The PE mode to which the Hyp Trap exception is taken

A Hyp Trap exception is taken to Hyp mode, using a vector offset of 0x14 from the Hyp exception base address.

Pseudocode description of taking the Hyp Trap exception

The AArch32.TakeHypTrapException() pseudocode procedure describes how the PE takes the exception.

G1.15.4 Supervisor Call (SVC) exception

The Supervisor Call instruction, SVC, requests a supervisor function, typically to request an operating system function. When EL1 is using AArch32, executing an SVC instruction causes the PE to enter Supervisor mode. For more information, see SVC on page F5-3575.

Note

In an implementation that includes EL2, when EL2 is using AArch32:

- When an SVC instruction is executed in Hyp mode, the Supervisor Call exception is taken to Hyp mode. For more information see SVC on page F5-3575.
- When the HCR.TGE bit is set to 1, the Supervisor Call exception generated by execution of an SVC instruction in Non-secure User mode is routed to Hyp mode. For more information, see Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-4357.

By default, a Supervisor Call exception that is taken to AArch32 state is taken to Supervisor mode, but a Supervisor Call exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see The PE mode to which the Supervisor Call exception is taken on page G1-4381.

The preferred return address for a Supervisor Call exception is the address of the next instruction after the SVC instruction. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from Secure or Non-secure Supervisor mode, the exception return uses the SPSR and LR_svc values generated by the exception entry, in an exception return instruction without subtraction.
- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see Exception return to an Exception level using AArch32 on page G1-4360.
The PE mode to which the Supervisor Call exception is taken

Figure G1-5 shows how the implementation, state, and configuration options determine the PE mode to which a Supervisor Call exception is taken, when the exception is taken to an Exception level that is using AArch32.

![Figure G1-5 The PE mode the Supervisor Call exception is taken to in AArch32 state](attachment:figure.png)

See also **UNPREDICTABLE cases when the value of HCR.TGE is 1** on page G1-4354.

Pseudocode description of taking the Supervisor Call exception

The `AArch32.CallSupervisor()` pseudocode procedure determines whether the Supervisor Call exception is taken to AArch32 state. If it is taken to AArch32 state, the `AArch32.TakeSVException()` pseudocode procedure describes how the PE takes the exception.

An Supervisor Call exception is taken to an Exception level using AArch64 if either:

- It is generated by executing an SVC instruction in User mode when EL1 is using AArch64.
- It is generated by executing an SVC instruction in Non-secure User mode when EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.
G1.15.5 Secure Monitor Call (SMC) exception

The Secure Monitor Call exception is implemented only as part of EL3. When EL3 is using AArch32, the exception is taken to Monitor mode.

The Secure Monitor Call instruction, SMC, requests a Secure Monitor function. When EL3 is using AArch32, executing an SMC instruction causes the PE to enter Monitor mode. For more information, see SMC on page F5-3429.

--- Note ---

• In an implementation that includes EL2, execution of an SMC instruction in a Non-secure EL1 mode can be trapped to EL2. When EL2 is using AArch32, this means that when HCR.TSC 1, execution of an SMC instruction in a Non-secure EL1 mode generates a Hyp Trap Exception that is taken to Hyp mode. For more information see Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-4434.

• The Operation pseudocode in the description of the AArch32 SMC instruction, in SMC on page F5-3429, identifies cases where execution of the instruction generates an exception that is taken to EL3 using AArch64.

The preferred return address for a Secure Monitor Call exception is the address of the next instruction after the SMC instruction. For an exception taken to AArch32 state, this return is performed using the SPSR and LR_mon values generated by the exception entry, using an exception return instruction without a subtraction.

For more information, see Exception return to an Exception level using AArch32 on page G1-4360.

--- Note ---

For an exception taken to AArch32 state, the exception handler can return to the SMC instruction itself by returning using a subtraction of 4, without any adjustment to the SPSR.IT[7:0] bits. If it does this, the return occurs, then asynchronous exceptions might occur and be handled, then the SMC instruction is re-executed and another Secure Monitor Call exception occurs.

This relies on:

• The SMC instruction being used correctly, either outside an IT block or as the last instruction in an IT block, so that the SPSR.IT[7:0] bits indicate unconditional execution.

• The Secure Monitor Call handler not changing the result of the original conditional execution test for the SMC instruction.

The PE mode to which the Secure Monitor Call exception is taken

The Secure Monitor Call exception is supported only as part of EL3. When EL3 is using AArch32, a Secure Monitor Call exception is taken to Monitor mode, using vector offset 0x08 from the Monitor exception base address.

--- Note ---

• An SMC instruction that is trapped to Hyp mode because HCR.TSC is set to 1 generates a Hyp Trap exception, see The PE mode to which the Hyp Trap exception is taken on page G1-4380.

• If EL3 is using AArch64 then Security behavior in Exception levels using AArch32 when EL3 is using AArch64 on page G1-4352 describes the effect of executing an SMC instruction at an Exception level that is using EL1.

Pseudocode description of taking the Secure Monitor Call exception

The AArch32.TakeSMCEXception() pseudocode procedure describes how the PE takes the exception when the exception is taken to an Exception level that is using AArch32.
G1.15.6 Hypervisor Call (HVC) exception

The Hypervisor Call exception is implemented only as part of EL2.

The Hypervisor Call instruction, HVC, requests a hypervisor function. When EL2 is using AArch32, executing an HVC instruction generates a Hypervisor Call exception that is taken to Hyp mode. For more information, see HVC on page F5-3123.

--- Note ---

- Execution of HVC instructions is disabled when the value of SCR.HCE is 0. Descriptions of HVC instruction execution elsewhere in this section assume the Effective value of SCR.HCE is 1.

- When EL2 is using AArch64 an HVC instruction executed in a Non-secure EL1 mode generates an exception that is taken to EL2 using AArch64. Exception classes and the ESR_ELx syndrome registers on page D1-1801 describes how this exception is reported in ESR_EL2.

The preferred return address for a Hypervisor Call exception is the address of the next instruction after the HVC instruction. The exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see Exception return to an Exception level using AArch32 on page G1-4360.

When EL2 is using AArch32, executing an HVC instruction transfers the immediate argument of the instruction to the HSR. The exception handler retrieves the argument from the HSR, and therefore does not have to access the original HVC instruction. For more information see Use of the HSR on page G4-4677.

The PE mode to which the Hypervisor Call exception is taken

The Hypervisor Call exception is supported only as part of EL2. When EL2 is using AArch32, a Hypervisor Call exception is taken to Hyp mode, using a vector offset that depends on the mode from which the exception is taken, as Figure G1-6 shows. This offset is from the Hyp exception base address.

![Figure G1-6 The PE mode the Hypervisor Call exception is taken to in AArch32 state](image_url)

Pseudocode description of taking the Hypervisor Call exception

The AArch32.CallHypervisor() pseudocode procedure determines whether the valid execution of an HVC instruction in AArch32 state generates an exception that is taken to EL2 using AArch64, or generates a Hypervisor Call exception taken to Hyp mode. The AArch32.TakeHVCException() pseudocode procedure describes how the PE takes a Hypervisor Call exception.
G1.15.7  Prefetch Abort exception

A Prefetch Abort exception can be generated by:

- A synchronous memory abort on an instruction fetch.

  **Note**
  Asynchronous external aborts on instruction fetches are reported as SError interrupts using the Data Abort exception, see Data Abort exception on page G1-4387.

  A Prefetch Abort exception entry is synchronous to the instruction whose fetch aborted.
  For more information about memory aborts see VMSAv8-32 memory aborts on page G4-4649.

- A Breakpoint, Vector Catch or Breakpoint Instruction exception, see Chapter G2 AArch32 Self-hosted Debug.

  **Note**
  If an implementation fetches instructions speculatively, it must handle a synchronous abort on such an instruction fetch by:

  - Generating a Prefetch Abort exception only if the instruction would be executed in a simple sequential execution of the program.
  - Ignoring the abort if the instruction would not be executed in a simple sequential execution of the program.

By default, when EL1 is using AArch32, a Prefetch Abort exception is taken to Abort mode, but a Prefetch Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the Prefetch Abort exception is taken to an Exception level that is using AArch32, see The PE mode to which the Prefetch Abort exception is taken on page G1-4386.
- About cases where the Prefetch Abort generates an exception that is taken to an Exception level that is using AArch64, see Pseudocode description of taking the Prefetch Abort exception on page G1-4387.

The preferred return address for a Prefetch Abort exception is the address of the aborted instruction. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_abt and LR_abt if returning from Abort mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.

- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information about the handling of Prefetch Abort exceptions in AArch32 state see Exception return to an Exception level using AArch32 on page G1-4360.
Prefetch Abort exception reporting a PC alignment fault exception

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, and:

If the exception is taken to EL1 using AArch32 or EL3 using AArch32

- The IFSR indicates the cause of the exception:
  - If the value of TTBCR.EAE is 0, IFSR.FS takes the value \texttt{0b00001}.
  - If the value of TTBCR.EAE is 1, IFSR.STATUS takes the value \texttt{0b100001}.
- IFAR holds the value of the address that faulted, including the misaligned low order bit or bits.
- R14_abt holds the address that faulted, including the misaligned low order bit or bits, with the standard offset for a Prefetch Abort exception.

If the exception is taken to EL2 using AArch32

- HSR.EC takes the value \texttt{0b100010}.
- HSR.IL is \texttt{UNKNOWN}.
- HSR.ISS is \texttt{RES0}.
- HIFAR and ELR_hyp each hold the value of the address that faulted, including the misaligned low order bit or bits.

For a PC alignment fault exception taken to an Exception level that is using AArch32:

- If the exception occurred because of the CONSTRAINED UNPREDICTABLE behavior of a branch to an unaligned PC value, as described in Branching to an unaligned PC on page K1-6098, then bit[0] of the faulting address is forced to zero, and therefore the misalignment is because the value of bit[1] of this address is 1.
- If the exception occurred on an exit from Debug state, as described in Exiting Debug state on page H2-5471, then it is CONSTRAINED UNPREDICTABLE whether bit[0] of the faulting address is forced to zero.
The PE mode to which the Prefetch Abort exception is taken

Figure G1-7 shows how the implementation, state, and configuration options determine the PE mode to which a Prefetch Abort exception is taken, when the exception is taken to an Exception level that is using AArch32.

Figure G1-7 The PE mode the Prefetch Abort exception is taken to in AArch32 state

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-4354.
Pseudocode description of taking the Prefetch Abort exception

The \texttt{AArch32.Abort()} pseudocode function determines whether the Prefetch Abort condition generates an exception that is taken to an Exception level that is using AArch64, or generates a Prefetch Abort exception that is taken in AArch32 state. When the exception is taken in AArch32 state, the \texttt{AArch32.TakePrefetchAbortException()} pseudocode procedure describes how the PE takes the exception.

The exception is taken to an Exception level using AArch64 if one of the following applies:

- The exception is generated in User mode when EL1 is using AArch64.
- The implementation includes EL2, EL2 is using AArch64, and one of the following applies:
  - The value of HCR\_EL2.TGE is 1 and the exception is generated in Non-secure User mode.
  - The value of MDCR\_EL2.TDE is 1 and the exception is generated by a Debug exception in a Non-secure EL1 or Non-secure EL0 mode.
  - The exception is generated by a stage 2 fault during a stage 1 translation table walk using the AArch32 Non-secure EL1\&0 translation regime.
- The implementation includes EL3, EL3 is using AArch64, the value of SCR\_EL3.EA is 1, and the exception is generated by an external abort in AArch32 state.

### G1.15.8 Data Abort exception

In AArch32 state, a Data Abort exception can be generated by:

- A synchronous abort on a data read or write memory access. Exception entry is synchronous to the instruction that generated the memory access.
- An SError interrupt. The SError interrupt might be caused by an external abort on a memory access, which can be any of:
  - A data read or write access.
  - An instruction fetch.
  - In a VMSA memory system, a translation table access.

Exception entry occurs asynchronously.

As described in \textit{Asynchronous exception masking controls} on page G1-4368, SError interrupts can be masked. When this happens, a generated SError interrupt is not taken until it is not masked.

- A watchpoint, see \textit{Watchpoint exceptions} on page G2-4496.

By default, when EL1 is using AArch32 a Data Abort exception is taken to Abort mode, but a Data Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the Data Abort exception is taken to an Exception level that is using AArch32 see \textit{The PE mode to which the Data Abort exception is taken} on page G1-4389.
- About memory aborts in AArch32 state see \textit{VMSAv8-32 memory aborts} on page G4-4649.
- About cases where the Data Abort generates an exception that is taken to an Exception level that is using AArch64 see \textit{Pseudocode description of taking the Data Abort exception} on page G1-4390.
The preferred return address for a Data Abort exception is the address of the instruction that generated the aborting memory access, or the address of the instruction following the instruction boundary at which an SError interrupt exception was taken. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 8. This means using:
  - SPSR_abt and LR_abt if returning from Abort mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information about the handling of Data Abort exceptions in AArch32 state see Exception return to an Exception level using AArch32 on page G1-4360.
The PE mode to which the Data Abort exception is taken

Figure G1-8 shows the determination of the mode to which a Data Abort exception is taken when the exception is taken to an Exception level that is using AArch32.

See also UNPREDICTABLE cases when the value of HCR.TGE is 1 on page G1-4354.
Pseudocode description of taking the Data Abort exception

The `AArch32.Abort()` pseudocode function determines whether the Data Abort condition generates an exception that is taken to an Exception level that is using AArch64, or generates a Data Abort exception that is taken in AArch32 state. When the exception is taken in AArch32 state, the `AArch32.TakeDataAbortException()` pseudocode procedure describes how the PE takes the exception.

The exception is taken to an Exception level using AArch64 if one of the following applies:

- The exception is generated in User mode when EL1 is using AArch64.
- The implementation includes EL2, EL2 is using AArch64, and one of the following applies:
  - The value of `HCR_EL2.TGE` is 1 and the exception is generated in Non-secure User mode.
  - The value of `MDCR_EL2.TDE` is 1 and the exception is generated by a Debug exception in a Non-secure EL1 or Non-secure EL0 mode.
  - The exception is generated by a stage 2 fault during a stage 1 translation table walk using the AArch32 Non-secure EL1&0 translation regime.
- The implementation includes EL3, EL3 is using AArch64, the value of `SCR_EL3.EA` is 1, and the exception is generated by an external abort in AArch32 state.

Effects of data-aborted instructions

An instruction that accesses data memory can modify memory by storing one or more values. If the execution of such an instruction generates a Data Abort exception, or causes Debug state entry because of a watchpoint set on the instruction, the value of each memory location that the instruction stores to is:

- Unchanged for any location for which one of the following applies:
  - An MMU fault is generated.
  - A Watchpoint is generated.
  - An external abort is generated, if that external abort is taken synchronously.
- **UNKNOWN** for any location for which no exception and no debug event is generated.

If the access to a memory location generates an external abort that is taken asynchronously, it is outside the scope of the architecture to define the effect of the store on that memory location, because this depends on the system-specific nature of the external abort. However, in general, ARM recommends that such locations are unchanged.

For external aborts and Watchpoints, where in principle faulting could be identified at byte or halfword granularity, the size of a location in this definition is the size for which a memory access is single-copy atomic.

In AArch32 state, instructions that access data memory can modify registers in the following ways:

- By loading values into one or more of the general-purpose registers. The registers loaded can include the PC.
- By loading values into one or more of the registers in the Advanced SIMD and floating-point register file.
- By specifying base register writeback, in which the base register used in the address calculation has a modified value written to it. All instructions that support base register writeback have constrained unpredictable results if base register writeback is specified with the PC as the base register. Only general-purpose registers can be modified reliably in this way.
- By a direct or indirect write to one or more System registers, for example:
  - An LDC instruction that writes to `DBGDTRTXint` using a value read from memory is a direct write to the System register `DBGDTRTXint`.
  - An STC instruction that reads `DBGDTRRXint` makes an indirect write to `DBGDSCRint.RXfull`.
- By modifying PSTATE.
If the execution of such an instruction generates a synchronous Data Abort exception, the following rules determine the values left in these registers:

- On entry to the Data Abort exception handler:
  - The PC value is the Data Abort vector address, see Exception vectors and the exception base address on page G1-4340.
  - The LR_abt value is determined from the address of the aborted instruction. Neither value is affected by the results of any load specified by the instruction.
- The base register is restored to its original value if either:
  - The aborted instruction is a load and the list of registers to be loaded includes the base register.
  - The base register is being written back.
- If the instruction only loads one general-purpose register the value in that register is unchanged.
- If the instruction loads more than one general-purpose register, **UNKNOWN** values are left in destination registers other than the PC and the base register of the instruction.
- If the instruction affects any registers in the Advanced SIMD and floating-point register file, **UNKNOWN** values are left in the registers that are affected.
- **PSTATE** bits that are not defined as updated on exception entry retain their current value.
- If the instruction is a **STREX**, **STREXB**, **STREXH**, or **STREXD**, **<Rd>** is not updated.

After taking a Data Abort exception, the state of the Exclusives monitors is **UNKNOWN**. Therefore, ARM strongly recommends that the abort handler performs a **CLREX** instruction, or a dummy **STREX** instruction, to clear the Exclusives monitor state.

### The ARM abort model

The abort model used by an ARM PE is described as a Base Restored Abort Model. This means that if a synchronous Data Abort exception is generated by executing an instruction that specifies base register writeback, the value in the base register is unchanged.

The abort model applies uniformly across all instructions.

### G1.15.9 Virtual SError interrupt exception

The Virtual SError interrupt exception is implemented only as part of EL2.

A Virtual SError interrupt exception is generated in AArch32 state if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of **PSTATE.A** is 0.
- Either:
  - EL2 is using AArch32 and the values of the HCR_{TGE, AMO, VA} bits are \{0, 1, 1\}.
  - EL2 is using AArch64 and the values of the HCR_EL2_{TGE, AMO, VA} bits are \{0, 1, 1\}.

The conditions for generating a Virtual SError interrupt exception in AArch32 state mean the exception is:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure Abort mode if EL1 is using AArch32.
- Taken to Non-secure EL1 using AArch64 if Non-secure EL0 is using AArch32 and Non-secure EL1 is using AArch64.

For more information see Virtual exceptions when an implementation includes EL2 on page G1-4365.
Note
Because a Virtual SError interrupt exception taken to AArch32 state is always taken to Non-secure Abort mode, on exception entry the preferred return address is always saved to LR_abt.

The preferred return address for a Virtual SError interrupt exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state, this return is performed using the SPSR and LR_abt values generated by the exception entry, using an exception return instruction without subtraction.

The PE mode to which the Virtual SError interrupt exception is taken
The Virtual SError interrupt exception is supported only as part of EL2. A Virtual SError interrupt exception is taken from a Non-secure EL1 or EL0 mode, and when taken to AArch32 state is taken to Non-secure Abort mode, using a vector offset of 0x10 from the Non-secure exception base address.

For more information about this exception see Virtual exceptions when an implementation includes EL2 on page G1-4365.

Pseudocode description of taking the Virtual SError interrupt exception
The AArch32.TakeVirtualSErrorException() pseudocode procedure describes how the PE takes the exception. This procedure includes the case where in Non-secure state EL0 is using AArch32 and EL1 is using AArch64, and the exception is taken to EL1 using AArch64.

Note
This is the only case where the exception is taken from an Exception level using AArch32 to an Exception level using AArch64.

G1.15.10 IRQ exception

The IRQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an IRQ interrupt request input to the PE.

When an IRQ exception is taken, exception entry is precise to an instruction boundary.

As described in Asynchronous exception masking controls on page G1-4368, IRQ exceptions can be masked. When this happens, a generated IRQ exception is not taken until it is not masked.

By default, when EL1 is using AArch32, an IRQ exception is taken to IRQ mode, but an IRQ exception can be taken to:
- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:
- About cases where the exception is taken to an Exception level using AArch32 see The PE mode to which the physical IRQ exception is taken on page G1-4393.
- About cases where the exception is taken to an Exception level using AArch64 see Pseudocode description of taking the physical IRQ exception on page G1-4394.
The preferred return address for an IRQ exception is the address of the instruction following the instruction boundary at which the exception was taken. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_irq and LR_irq if returning from IRQ mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information, see Exception return to an Exception level using AArch32 on page G1-4360.

**The PE mode to which the physical IRQ exception is taken**

Figure G1-9 shows how the implementation, state, and configuration options determine the mode to which an IRQ exception is taken when the exception is taken to an Exception level that is using AArch32.
Pseudocode description of taking the physical IRQ exception

The `AArch32.TakePhysicalIRQException()` pseudocode procedure describes how the PE takes the exception. This procedure includes the case where the exception is taken to an Exception level that is using AArch64. This happens if one of the following applies:

- The exception is taken from User mode and EL1 is using AArch64. The Exception is taken to EL1 using AArch64.
- The exception is taken from Non-secure User mode, EL2 is implemented and using AArch64, and the value of HCR_EL2.TGE is 1. The Exception is taken to EL2 using AArch64, in Non-secure state.
- The exception is taken from a Non-secure EL0 or EL1 mode, EL2 is implemented and using AArch64, and the value of HCR_EL2.IMO is 1. The Exception is taken to EL2 using AArch64, in Non-secure state.
- The exception is taken from a PE mode other than Monitor mode, EL3 is implemented and using AArch64, and the value of SCR_EL3.IRQ is 1. The Exception is taken to EL3 using AArch64.

G1.15.11 Virtual IRQ exception

The Virtual IRQ exception is implemented only as part of EL2.

A Virtual IRQ exception is generated in AArch32 state if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of PSTATE.I is 0.
- Either:
  - EL2 is using AArch32 and the value of HCR.{TGE, IMO} is {0, 1}.
  - EL2 is using AArch64 and the value of HCR_EL2.{TGE, IMO} is {0, 1}.
- One of the following applies:
  - EL2 is using AArch32 and the value of HCR.VI is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.VI is 1.
  - A Virtual IRQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual IRQ exception in AArch32 state mean the exception is:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure IRQ mode if EL1 is using AArch32.
- Taken to Non-secure EL1 using AArch64 if Non-secure EL0 is using AArch32 and Non-secure EL1 is using AArch64.

For more information see Virtual exceptions when an implementation includes EL2 on page G1-4365.

The preferred return address for a Virtual IRQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state this return is performed using the SPSR and LR_irq values generated by the exception entry, using an exception return instruction with a subtraction of 4.

The PE mode to which the Virtual IRQ exception is taken

The Virtual IRQ exception is supported only as part of EL2. A Virtual IRQ exception is taken from a Non-secure EL1 or EL0 mode, and when taken to AArch32 state is taken to Non-secure IRQ mode, using a vector offset of 0x18 from the Non-secure exception base address.

For more information about this exception see Virtual exceptions when an implementation includes EL2 on page G1-4365.
Pseudocode description of taking the Virtual IRQ exception

The `AArch32.TakeVirtualIRQException()` pseudocode procedure describes how the PE takes the exception. This procedure includes the case where, in Non-secure state, EL0 is using AArch32 and EL1 is using AArch64, and the exception is taken to Non-secure EL1 using AArch64.

--- Note ---

This is the only case where the exception is taken from an Exception level using AArch32 to an Exception level using AArch64.

G1.15.12 FIQ exception

The FIQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an FIQ interrupt request input to the PE.

When an FIQ exception is taken, exception entry is precise to an instruction boundary.

As described in *Asynchronous exception masking controls on page G1-4368*, FIQ exceptions can be masked. When this happens, a generated FIQ exception is not taken until it is not masked.

By default, an FIQ exception is taken to FIQ mode, but an FIQ exception can be taken to:

• EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
• EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

• About cases where the exception is taken to an Exception level using AArch32 see *The PE mode to which the physical FIQ exception is taken on page G1-4396*.
• About cases where the exception is taken to an Exception level using AArch64 see *Pseudocode description of taking the FIQ exception on page G1-4396*.

The preferred return address for an FIQ exception is the address of the instruction following the instruction boundary at which the exception was taken. For an exception taken to AArch32 state this return is performed as follows:

• If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  — `SPSR_fiq` and `LR_fiq` if returning from FIQ mode.
  — `SPSR_mon` and `LR_mon` if returning from Monitor mode.
• If returning from Hyp mode, using the `SPSR_hyp` and `ELR_hyp` values generated by the exception entry, using an `ERESET` instruction.

For more information see *Exception return to an Exception level using AArch32 on page G1-4360*. 
The PE mode to which the physical FIQ exception is taken

Figure G1-9 on page G1-4393 shows how the implementation, state, and configuration options determine the PE mode to which an FIQ exception is taken when the exception is taken to an Exception level that is using AArch32.

![Diagram of the PE mode to which the physical FIQ exception is taken](image)

**Figure G1-10 The PE mode the FIQ exception is taken to in AArch32 state**

Pseudocode description of taking the FIQ exception

The `AArch32.TakePhysicalFIQException()` pseudocode procedure describes how the PE takes the exception. This procedure includes the case where the exception is taken to an Exception level that is using AArch64. This happens if one of the following applies:

- The exception is taken from User mode and EL1 is using AArch64. The Exception is taken to EL1 using AArch64.
- The exception is taken from Non-secure User mode, EL2 is implemented and using AArch64, and the value of `HCR_EL2.TGE` is 1. The Exception is taken to EL2 using AArch64, in Non-secure state.
- The exception is taken from a Non-secure EL0 or EL1 mode, EL2 is implemented and using AArch64, and the value of `HCR_EL2.FMO` is 1. The Exception is taken to EL2 using AArch64, in Non-secure state.
- The exception is taken from a PE mode other than Monitor mode, EL3 is implemented and using AArch64, and the value of `SCR_EL3.FIQ` is 1. The Exception is taken to EL3 using AArch64.
G1.15.13 Virtual FIQ exception

The Virtual FIQ exception is implemented only as part of EL2.

A Virtual FIQ exception is generated in AArch32 state if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of PSTATE.F is 0.
- Either:
  - EL2 is using AArch32 and the value of HCR.{TGE, FMO} is {0, 1}.
  - EL2 is using AArch64 and the value of HCR_EL2.{TGE, FMO} is {0, 1}.
- One of the following applies:
  - EL2 is using AArch32 and the value of HCR.VF is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.VF is 1.
  - A Virtual FIQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual FIQ exception in AArch32 state mean the exception is:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure FIQ mode if EL1 is using AArch32.
- Taken to Non-secure EL1 using AArch64 if Non-secure EL0 is using AArch32 and Non-secure EL1 is using AArch64.

For more information see Virtual exceptions when an implementation includes EL2 on page G1-4365.

The preferred return address for a Virtual FIQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state this return is performed using the SPSR and LR_irq values generated by the exception entry, using an exception return instruction with a subtraction of 4.

The PE mode to which the Virtual FIQ exception is taken

The Virtual FIQ exception is supported only as part of EL2. A Virtual FIQ exception is taken from a Non-secure EL1 or EL0 mode, and when taken to AArch32 state is taken to Non-secure FIQ mode, using a vector offset of 0x1C from the Non-secure exception base address.

For more information about this exception see Virtual exceptions when an implementation includes EL2 on page G1-4365.

Pseudocode description of taking the Virtual FIQ exception

The AArch32.TakeVirtualFIQException() pseudocode procedure describes how the PE takes the exception. This procedure includes the case where, in Non-secure state, EL0 is using AArch32 and EL1 is using AArch64, and the exception is taken to Non-secure EL1 using AArch64.

Note

This is the only case where the exception is taken from an Exception level using AArch32 to an Exception level using AArch64.
G1.15.14 Additional pseudocode functions for exception handling

The `AArch32.EnterMonitorMode()` pseudocode function changes the PE mode to Monitor mode, with the required state changes.

The `AArch32.EnterHypMode()` pseudocode function changes the PE mode to Hyp mode, with the required state changes.

The `AArch32.EnterMode()` pseudocode function changes the PE mode to a PL1 mode, with the required state changes. It is used for all exceptions that are not routed to Hyp mode or Monitor mode.

The `AArch32.EnterMonitorMode()`, `AArch32.EnterHypMode()`, and `AArch32.EnterMode()` functions are described in Chapter J1 ARMv8 Pseudocode.
Reset into AArch32 state

Reset on page D1-1795 describes the ARMv8 reset model, including the defined levels of reset. When reset is deasserted, the PE starts executing instructions in the highest implemented Exception level. If that Exception level is using AArch32, then it starts execution:

- In Secure state, if the implementation includes EL3.
- With interrupts disabled:
  - In Hyp mode, if the highest implemented Exception level is EL2.
  - In Supervisor mode, otherwise.

Note

- This section describes the architectural requirements for a reset into AArch32 state. It takes no account of whether ARM licenses any particular combination of Exception levels and Execution state. For more information about the licensed combinations see Support for Exception levels and Execution states on page D1-1900.
- The Execution state in which the highest implemented Execution level starts executing instructions on coming out of reset might be determined by a configuration input signal.

Reset returns some PE state to architecturally-defined or IMPLEMENTATION DEFINED values, and makes other state UNKNOWN, as described in PE state on reset into AArch32 state on page G1-4400. For more information about behavior when resetting into an Exception level using AArch32, see:

- Behavior of caches at reset on page G3-4531.
- Enabling stages of address translation on page G4-4569.
- TLB behavior at reset on page G4-4629.
- Reset and debug on page H6-5545.

When reset is deasserted, if the PE resets into an Exception level that is using AArch32, it is IMPLEMENTATION DEFINED whether execution starts:

- From an IMPLEMENTATION DEFINED address.
- If reset is into EL3 or EL1, from the low or high reset vector address, as determined by the reset value of the SCTLR.V bit. This reset value can be determined by an IMPLEMENTATION DEFINED configuration input signal.

Note

This option might be implemented for compatibility with earlier versions of the architecture.

Software might be able to identify the reset address:

- If reset is into EL3, by reading the reset value of MVBAR. That is, after coming out of reset, by reading MVBAR before the boot software has updated it. It is IMPLEMENTATION DEFINED whether this discovery mechanism is supported.
- If reset is into EL2 or EL1, by reading RVBAR. RVBAR can only be implemented at the highest implemented Exception level, and only if that Exception level is not EL3.

If RVBAR is not implemented, and at all Exception levels other than the highest implemented Exception level, the encoding for RVBAR is UNDEFINED.

The ARM architecture does not define any way of returning to a previous Execution state from a reset.
G1.16.1 PE state on reset into AArch32 state

Note
See the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0 for the reset requirements for GIC System registers.

Immediately after a reset, much of the PE state is unknown. However, some of the PE state is defined. If the PE resets to AArch32 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- If reset is into EL3 using AArch32 then all fields of the SCR reset to zero.
  
  Note
  This means SCR.NS correctly indicates that the PE is in Secure state.

- If reset is into EL2 using AArch32 then reset is into Hyp mode and CPSR.M resets to 0b1010, otherwise reset is into Supervisor mode and CPSR.M resets to 0b0011.
  
  CPSR.IL resets to 0.

- The CPACR.{cp11, cp10} fields reset to zero, and if CPACR.ASEDIS is implemented as an RW field it resets to zero.
  
  Note
  When CPACR.TRCDIS is a RW field, its reset value is architecturally unknown.

- PSTATE is reset to the values defined by the AArch32.TakeReset() pseudocode function, see Pseudocode descriptions of reset on page G1-4402.

- The FPEXC.EN field resets to 0.

- In the SCTLR:
  - The {AFE, TRE, UWXN, WXN, I, SED, ITD, C, A, M} fields reset to 0.
  - The {nTWE, nTWI, CP15BEN} fields reset to 1.
  - The {TE, EE, V} fields reset to implementation defined values, see the register description for more information.

  When the reset is to EL3 using AArch32 then these reset values apply only to the Secure instance of the SCTLR, and the reset value of the Non-secure SCTLR is architecturally unknown.

- All field of the TTBCR reset to 0.

  When the reset is to EL3 using AArch32 then:
  - All fields of the Secure TTBCR reset to 0.
  - In the Non-secure TTBCR, the EAE field resets to 0, and the reset values of all other fields are architecturally unknown.

- The VBAR resets to an implementation defined value.

  When the reset is to EL3 using AArch32 then this reset value applies only to the Secure instance of the register, and the reset value of the Non-secure VBAR is architecturally unknown.

- All fields of the DBGDCCINT reset to 0.

- The DBGDSCRext. { MDBGen, UDCCdis} fields reset to 0.

- The DBGOSDLR.DLK field resets to 0.
In addition:

**If the reset is into EL1 using AArch32**
- In the **RMR** register, the RR field resets to 0 on any warm or cold reset, and the AA64 field resets to 0 on a cold reset.

**If the reset is into EL2 using AArch32**
- In the **HRMR**, the RR field resets to 0 on any warm or cold reset, and the AA64 field resets to 0 on a cold reset.
- The **HSCTLR.**{I, C, M} fields all reset to 0, and the **HSCTLR.**EE field resets to an IMPLEMENTATION DEFINED value.

**If the reset is into EL2 using AArch32 or into EL3 using AArch32**

For a reset into EL3 using AArch32 these reset values apply only if the implementation includes EL2, see the register descriptions for more information.
- All fields of the **HCPTR** reset to zero.
- All fields of the **HCR** reset to zero.
- The **HCR.**{ID, CD} fields reset to zero.
- All fields of the **HSTR** reset to zero.
- The **VMPIDR** resets to the value of the **MPIDR**, see the register description for more information.
- The **VPIDR** resets to the value of the **MIDR**, see the register description for more information.
- The **VTTBR.**VMID field resets to zero.
- In the **HDCR**:
  - The HPMN field resets to the IMPLEMENTATION DEFINED value of **PMCR.**N.
  - The reset value of the HPME field is architecturally UNKNOWN.
  - All other fields reset to 0.

**If the reset is into EL3 using AArch32**
- The **MVBAR** resets to an IMPLEMENTATION DEFINED value, see the register description for more information.
- If the **NSACR.**{NSTRCDIS, NSASEDIS} fields are RW fields then they reset to 0.
- In the **RMR** register, the RR field resets to 0 on any warm or cold reset, and the AA64 field resets to 0 on a cold reset.
- All fields of the **SCR** reset to zero.
- All fields of the **SDER** reset to 0.
- All fields of the **SDCR** reset to zero.

For either a warm or a cold reset
- The **EDPRSR.**SR field resets to 1.
- The **EDESR.**{SS, RC, OSUC} fields reset to 0.

For a cold reset only
- The **EDSCR.**{RXO, TXU, INTdis, TDA, MA, HDE, ERR, RXfull, TXfull} fields reset to 0.
- The **EDECCR.**{NSE, SE} fields reset to 0.
- The **EDPRSR.**{SPMAD, SDAD} fields reset to 0, and the **EDPRSR.**SPD field resets to 1.
- The **DBGOSLRS.**OSLK field resets to 1.
- The **DBGPRCR.**CORENPDRQ field resets to the value of **EDPRCR.**COREPURQ.
G1.16.2 Pseudocode descriptions of reset

The `AArch32.TakeReset()` pseudocode procedure describes how the PE behaves when reset is deasserted.

The `AArch32.ResetGeneralRegisters()` pseudocode function resets the general-purpose registers.

The `AArch32.ResetSIMDFPRegisters()` pseudocode function resets the SIMD and floating-point registers.

The `AArch32.ResetSpecialRegisters()` pseudocode function resets the Special-purpose registers, and the debug System registers DLR and DSPSR, that are used for handling Debug exceptions.

The `AArch32.ResetSystemRegisters()` pseudocode function resets all System registers in the (coproc==0b111x) encoding space to their reset state as defined in the register descriptions in Chapter G6 AArch32 System Register Descriptions.

--- Note ---
The `ResetSystemRegisters()` function only resets the System registers. It has no effect on memory-mapped registers.

---

The `ResetExternalDebugRegisters()` pseudocode function resets all external debug registers to their reset state as defined in the register descriptions in Chapter H9 External Debug Register Descriptions.

---

An External Debug reset sets `EDPRCR.COREPURQ` to 0, see External debug register resets on page H8-5572. If an External Debug reset and a cold reset coincide, both `DBGPRCR.CORENPRDRQ` and `EDPRCR.COREPURQ` are reset to 0.

- The debug CLAIM bits are reset to 0.

---

Note

These are the bits that are set to 1 by writing to `DBGCLAIMSET.CLAIM`, and reset to 0 by writing to `DBGCLAIMCLR.CLAIM`.

---
G1.17 Mechanisms for entering a low-power state

The following sections describe the architectural mechanisms that a PE can use to request entry to a low-power state:

- Wait For Event and Send Event.
- Wait For Interrupt on page G1-4406.

G1.17.1 Wait For Event and Send Event

The Wait For Event (WFE) mechanism permits a PE to request entry to a low-power state, and, if the request succeeds, to remain in that state until an event is generated by a Send Event operation, or another WFE wake-up event occurs. Example G1-2 describes how a spinlock implementation might use this mechanism to save energy.

Example G1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device it might need to add data received from the device to a queue. If another PE is removing data from the queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the lock has been released. It cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in Synchronization and semaphores on page E2-2795.
- If the PE obtains the lock it performs its memory operation and releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. At this point it again attempts to obtain the lock.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multithreaded implementation the execution of spin-locks by waiting threads can significantly degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock. In this situation, a PE that fails to obtain a lock can execute a Wait For Event instruction, `WFE`, to request entry to a low-power state. When a PE releases a lock, it must execute a Send Event instruction, `SEV`, causing any waiting PEs to wake up. Then, these PEs can attempt to gain the lock again.

The execution of a `WFE` instruction can cause suspension of execution only if all of the following are true:

- The instruction does not cause any other exception.
- When the instruction is executed:
  - The Event Register is not set.
  - There is not a pending WFE wakeup event.

For more information about the trap to EL2 see Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437.

The architecture does not define the exact nature of the low power state entered as a result of executing a `WFE` instruction, but the execution of a `WFE` instruction must not cause a loss of memory coherency.
Note

Although a complex operating system can contain thousands of distinct locks, the event sent by this mechanism does not indicate which lock has been released. If the event relates to a different lock, or if another PE acquires the lock more quickly, the PE fails to acquire the lock and can reenter the low-power state waiting for the next event.

The Wait For Event system relies on hardware and software working together to achieve energy saving:

- The hardware provides the mechanism to enter the Wait For Event low-power state.
- The operating system software is responsible for issuing:
  - A Wait For Event instruction, to request entry to the low-power state, used in the example when waiting for a spin-lock.
  - A Send Event instruction, required in the example when releasing a spin-lock.

The mechanism depends on the interaction of:

- WFE wake-up events, see WFE wake-up events on page G1-4405.
- The Event Register, see The Event Register.
- The Send Event instructions, see The Send Event instructions on page G1-4405.
- The Wait For Event instruction, see The Wait For Event instruction.

The Event Register

The Event Register is a single bit register for each PE. When set, an event register indicates that an event has occurred, since the register was last cleared, that might require some action by the PE. Therefore, the PE must not suspend operation on issuing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- The execution of an SEVL instruction by the PE.
- An exception return.
- An event from a Generic Timer event stream, see Event streams on page G5-4757.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

As shown in this list, the Event Register might be set by IMPLEMENTATION DEFINED mechanisms.

The Event Register is cleared only by a Wait For Event instruction.

Software cannot read or write the value of the Event Register directly.

The Wait For Event instruction

The action of the Wait For Event instruction depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately. Normally, if this happens the software makes another attempt to claim the lock.
- If the Event Register is clear the PE can suspend execution, and hardware might enter a low-power state. The PE can remain suspended until a WFE wake-up event or a reset occurs. When a WFE wake-up event occurs, or earlier if the implementation chooses, the WFE instruction completes.

The execution in AArch32 state of a WFE instruction that would otherwise cause suspension of execution might be trapped, see:

- Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-4421.
- Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437.
- Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-4447.
The Wait For Event instruction, \texttt{WFE}, is available at all privilege levels, see \texttt{WFE} on page F5-3668.

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake ups.

**WFE wake-up events**

The following events are \texttt{WFE} wake-up events:

- The execution of an \texttt{SEV} instruction on any PE in the system.
- The execution of an \texttt{SEVL} instruction on the PE.
- A physical IRQ interrupt, unless masked by the \texttt{PSTATE.I} bit.
- A physical FIQ interrupt, unless masked by the \texttt{PSTATE.F} bit.
- A physical SError interrupt, unless masked by the \texttt{PSTATE.A} bit.
- In Non-secure state in any mode other than Hyp mode:
  - When \texttt{HCR.IMO} is set to 1, a virtual IRQ interrupt, unless masked by the \texttt{PSTATE.I} bit.
  - When \texttt{HCR.FMO} is set to 1, a virtual FIQ interrupt, unless masked by the \texttt{PSTATE.F} bit.
  - When \texttt{HCR.AMO} is set to 1, a virtual SError interrupt, unless masked by the \texttt{PSTATE.A} bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of \textit{halting is allowed} see \textit{Halting allowed and halting prohibited} on page H2-5435.
  
  See also \textit{External Debug Request debug event} on page H3-5490.
- An event sent by the timer event stream, see \textit{Event streams} on page D6-2186.
- An event sent by some IMPLEMENTATION DEFINED mechanism.
- An event caused by the clearing of the global monitor associated with the PE.

In addition to the possible masking of WFE wake-up events shown in this list, when invasive debug is enabled and \texttt{EDSCR.HDE} is set to 1, \texttt{EDSCR.INTdis} can mask interrupts, including masking them acting as WFE wake-up events. For more information, see \textit{EDSCR, External Debug Status and Control Register} on page H9-5662.

As shown in the list of wake-up events, an implementation can include IMPLEMENTATION DEFINED hardware mechanisms to generate wake-up events.

\textbf{—— Note ———}

For more information about \texttt{PSTATE} masking see \textit{Asynchronous exception masking controls} on page G1-4368. If the configuration of the masking controls provided by EL2 and EL3 mean that a \texttt{PSTATE} mask bit cannot mask the corresponding exception, then the physical exception is a WFE wake-up event, regardless of the value of the \texttt{PSTATE} mask bit.

\textbf{——— Note ————}

A \texttt{DSB} instruction ensures that no instruction, including any \texttt{SEV} instruction, that appears in program order after the \texttt{DSB} instruction, can execute until the \texttt{DSB} instruction has completed. For more information, see \textit{Data Synchronization Barrier (DSB)} on page E2-2769.
The `SEVL` instruction appears to execute in program order relative to any subsequent `WFE` instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

Execution of the Send Event instruction sets the Event Register.

The Send Event instructions are available at all privilege levels.

**Pseudocode description of the Wait For Event mechanism**

This section defines pseudocode functions that describe the operation of the Wait For Event mechanism.

The `ClearEventRegister()` pseudocode procedure clears the Event Register of the current PE.

The `IsEventRegisterSet()` pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear.

The `WaitForEvent()` pseudocode procedure optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a `ClearEventRegister()` to occur.

The `SendEvent()` pseudocode procedure sets the Event Register of every PE in the system.

---

### G1.17.2 Wait For Interrupt

AArch32 state supports Wait For Interrupt through an instruction, `WFI`, that is provided in the A32 and T32 instruction sets. For more information, see `WFI` on page F5-3670.

When a PE issues a `WFI` instruction, its execution can be suspended, and a low-power state can be entered.

The execution in AArch32 state of a `WFI` instruction that would otherwise cause suspension of execution might be trapped, see:

- **Traps to Undefined mode of EL0 execution of WFE and WFI instructions** on page G1-4421.
- **Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions** on page G1-4437.
- **Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode** on page G1-4447.

The execution of a `WFI` instruction can cause suspension of execution only if both:

- The instruction does not cause any other exception.
- When the instruction is executed, there is not a pending WFI wakeup event.

#### WFI wake-up events

The PE can remain suspended in its WFI state until it is reset, or one of the following **WFI wake-up events** occurs:

- A physical IRQ interrupt, regardless of the value of the `PSTATE.I` bit.
- A physical FIQ interrupt, regardless of the value of the `PSTATE.F` bit.
- A physical SError interrupt, regardless of the value of the `PSTATE.A` bit.
- In Non-secure state in any mode other than Hyp mode:
  - When `HCR.IMO` is set to 1, a virtual IRQ interrupt, regardless of the value of the `PSTATE.I` bit.
  - When `HCR.FMO` is set to 1, a virtual FIQ interrupt, regardless of the value of the `PSTATE.F` bit.
  - When `HCR.AMO` is set to 1, a virtual SError interrupt, regardless of the value of the `PSTATE.A` bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed see **Halting allowed and halting prohibited** on page H2-5435.
  
  See also **External Debug Request debug event** on page H3-5490.

An implementation can include other IMPLEMENTATION DEFINED hardware mechanisms to generate WFI wake-up events.

When a WFI wake-up event is detected, or earlier if the implementation chooses, the `WFI` instruction completes.

WFI wake-up events cannot be masked by the mask bits in the `PSTATE`. 

The architecture does not define the exact nature of the low power state, but the execution of a WFI instruction must not cause a loss of memory coherency.

--- Note ---

- Because debug events are WFI wake-up events, ARM strongly recommends that is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures the intervention of debug while waiting does not significantly change the function of the program being debugged.

- In some previous implementations of Wait For Interrupt, the idle loop is followed by exit functions that must be executed before taking the interrupt. The operation of Wait For Interrupt remains consistent with this model, and therefore differs from the operation of Wait For Event.

- Some implementations of Wait For Interrupt drain down any pending memory activity before suspending execution. The ARM architecture does not require this operation, and software must not rely on Wait For Interrupt operating in this way.

### Using WFI to indicate an idle state on bus interfaces

A common implementation practice is to complete any entry into powerdown routines with a WFI instruction. Typically, the WFI instruction:

1. Forces the completion of execution of any instructions that are in progress, and of all associated bus activity.
2. Suspends the execution of instructions by the PE.

The control logic required to do this tracks the activity of the bus interfaces used by the PE. This means it can signal to an external power controller when there is no ongoing bus activity.

However, memory-mapped and external debug interface accesses to debug registers must continue to be processed while the PE is in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the value of DBGOSDLR.DLK, the OS Double Lock status bit, is set to 1, this idle state must not be signaled to the PE unless the system can guarantee, also, that the debug interface is idle.

--- Note ---

When separate core and debug power domains are implemented, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see Power domains and debug on page H6-5535.

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

### Pseudocode description of Wait For Interrupt

The WaitForInterrupt() pseudocode function optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.
G1.18 The AArch32 System register interface

In ARMv8, most system registers are accessed using the instructions described in System register access instructions on page F1-2828. The System register interface provides access to those instructions, and:

- These registers are encoded using the parameters \{coproc, opc1, CRn, CRm, opc2\}, with permitted coproc values of 0b1110 and 0b1111.
- Some of these encodings provide the AArch32 System instructions summarized in:
  - Cache maintenance instructions, functional group on page G4-4734.
  - TLB maintenance instructions, functional group on page G4-4735.
  - Address translation instructions, functional group on page G4-4737.
- To maintain compatibility with previous versions of the ARM architecture, the access controls for the AArch32 System registers include the access controls for AArch32 Advanced SIMD and floating-point functionality.

Note

See Background to the System register interface on page G1-4410 for more information.

The following sections give more information about the AArch32 System register interface:

- System registers in the coproc == 0b111x encoding space.
- Access to System registers.
- Access controls for Advanced SIMD and floating-point functionality on page G1-4409.
- Pseudocode description of checking accesses to the System registers on page G1-4409.
- Background to the System register interface on page G1-4410.

G1.18.1 System registers in the coproc == 0b111x encoding space

In AArch32 state:

- The coproc == 0b1110 encoding space is reserved for the configuration and control of:
  - Debug features, see Debug registers on page G6-5239.
  - Trace features, see the Embedded Trace Macrocell Architecture Specification.
  - Identification registers for the Trivial Jazelle implementation, see Trivial implementation of the Jazelle extension on page G1-4338.
- The coproc == 0b1111 encoding space is reserved for the control and configuration of the PE, including architecture and feature identification. This means these encodings provide access to the System registers that control and return status information for PE operation.

For more information see Chapter G6 AArch32 System Register Descriptions.

G1.18.2 Access to System registers

Most System registers are accessible only from EL1 or higher. For possible accesses from EL0:

- The register descriptions in Chapter G6 AArch32 System Register Descriptions indicate whether a register is accessible from EL0.
- PL0 views of the System registers in the (coproc==0b1111) encoding space on page G4-4723 summarizes the permitted accesses to System registers in the coproc == 0b1111 encoding space from EL0.
G1.18.3 Access controls for Advanced SIMD and floating-point functionality

In ARMv8, the CPACR controls access to Advanced SIMD and floating-point functionality from software executing at PL1 or EL0 in AArch32 state:

- The \{cp10, cp11\} fields control access to all Advanced SIMD and floating-point functionality, and can:
  - Disable EL0 and PL1 access to this functionality.
  - Enable access to this functionality at PL1 only.
  - Enable access to this functionality at EL0 and PL1.

- The ASEDIS field controls access to Advanced SIMD instructions that are not also floating-point instructions.

Initially on powerup or reset into AArch32 state, all access to all Advanced SIMD and floating-point functionality from PL1 and EL0 is disabled.

--- Note ---

The CPACR has no effect on accesses from Hyp mode.

---

If an implementation includes EL3, the NSACR determines whether Advanced SIMD and floating-point functionality can be accessed from Non-secure state:

- The \{cp10, cp11\} fields control Non-secure access to all Advanced SIMD and floating-point functionality.
- The NSASEDIS field controls Non-secure access to Advanced SIMD instructions that are not also floating-point instructions.

If an implementation includes EL2, the HCPTR provides additional controls on Non-secure accesses to Advanced SIMD and floating-point functionality. For accesses that are otherwise permitted by the CPACR and NSACR settings, setting HCPTR bits to 1:

- Traps otherwise-permitted accesses from EL1 or EL0 to EL2. When EL2 is using AArch32, these accesses are trapped to Hyp mode.
- Makes accesses from EL2 mode UNDEFINED. When EL2 is using AArch32, this makes accesses from Hyp mode UNDEFINED.

In the HCPTR:

- The \{TCP10, TCP11\} fields control access to all Advanced SIMD and floating-point functionality.
- The TASE field controls access to Advanced SIMD instructions that are not also floating-point instructions.
- The TCPAC field traps Non-secure EL1 accesses to the CPACR to Hyp mode.

For more information, see General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-4437.

--- Note ---

Whenever a pair of fields control the access to the Advanced SIMD and floating-point functionality, the values of each field of the pair must be identical. In ARMv8, if these settings are not identical the behavior of the Advanced SIMD and floating-point functionality is CONSTRAINED UNPREDICTABLE, see Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-6102.

---

For more information about Advanced SIMD and floating-point support see Advanced SIMD and floating-point support on page G1-4412.

G1.18.4 Pseudocode description of checking accesses to the System registers

The AArch32.CheckSystemAccess() function determines whether a System register access instruction that targets a System register in the (coproc == #0111x) encoding space is accepted.
G1.18.5  Background to the System register interface

--- Note ---
This section is not part of the ARMv8 Architecture specification. It is included only to present the rationale of some aspects of the System register interface.

The interface to the System registers was originally defined as part of a generic coprocessor interface, that gave access to fifteen coprocessors, CP0 - CP15. Of these, CP8 - CP15 were reserved for use by ARM, while CP0 - CP7 were available for implementation-defined coprocessors.

The coprocessors were accessed using coprocessor instructions. These instructions remain part of the T32 and A32 instruction sets, see System register access instructions on page F1-2828.

In the ARM coprocessor model, a coprocessor included both:

- Primary and secondary coprocessor registers, that form part of the coprocessor interface.
- A number of internal registers.

When accessing a 32-bit internal coprocessor register, using an MCR or MRC instruction, the instruction specified:

- The target coprocessor, specified by the coproc parameter and taking a value between p0 for CP0 and p15 for CP15.
- The primary coprocessor register, specified by the CRn parameter and taking a value between c0 and c15.
- The secondary coprocessor register, specified by the CRm parameter and taking a value between c0 and c15.
- Up to two additional parameters, opc1 and opc2, taking values between 0 and 7.

Other instructions in the group described in System register access instructions on page F1-2828 take a subset of these parameters:

- In the ARMv7 definitions, LDC and STC instructions take parameters \{coproc, CRd\}, where CRd is the primary coprocessor register.
- MCRR and MRRC instructions take parameters \{coproc, opc1, CRm\}, where CRm is the primary coprocessor register.

To maintain backwards compatibility, the arguments to an MCR or MRC instruction remain \{coproc, opc1, CRn, CRm, opc2\}. Correspondingly, the encoding of the AArch64 System registers is described using the parameters \{op0, op1, CRn, CRm, op2\}. However:
- The naming of these parameters no longer has any particular significance.
- While the coproc field is a 4-bit field, op0 is a 2-bit field.

Of the coprocessors reserved for use by ARM, in ARMv7 and earlier versions of the architecture:

- CP15 provided access to the System registers relating to non-debug operation, and was originally called the System control coprocessor. In ARMv8 these registers are described as being in the coproc == 0b1111 encoding space.
- CP14 provided access to additional System registers, including those relating to debug and trace. In ARMv8 these registers are described as being in the coproc == 0b1110 encoding space.
- CP10 and CP11 were used for Advanced SIMD and floating-point control, and many coprocessor instruction encodings targeting CP10 and CP11 were used as floating-point instruction encodings:
  - Generally ARMv8 does not relate these instructions to the coprocessor encoding space, but the naming of registers and register fields for Advanced SIMD and floating-point control reflects the historic coprocessor model.
  - Because the Advanced SIMD and floating-point functionality used both CP10 and CP11, some System register controls of this functionality have a pair of fields, for example NSACR.\{cp10, cp11\}. In these cases, both fields must be set to the same value. For more information see Access controls for Advanced SIMD and floating-point functionality on page G1-4409.
In ARMv8:

- The AArch32 System registers include registers that were described as Special registers in ARMv7 and earlier versions of the architecture. This means that the ARMv8 System registers include registers that are outside the earlier coprocessor model.

- The ARMv7 AArch32 instruction encodings for LDC, STC, MCR, MRC, MCRR, and MRRC instructions with coproc field values other than \{1010, 1011, 1110, 1111\} are available for reuse. ARMv8.2 re-uses some encodings in this way.
G1.19 Advanced SIMD and floating-point support

Advanced SIMD and floating-point instructions on page E1-2740 introduces:

- The scalar floating-point instructions in the A32 and T32 instruction sets.
- The Advanced SIMD integer and floating-point vector instructions in the A32 and T32 instruction sets.
- The SIMD and floating-point register file, that can be viewed as:
  - Singleword registers S0 - S31.
  - Doubleword registers D0 - D31.
  - Quadword registers Q0 - Q15.
- The Floating-Point Status and Control Register (FPSCR).

For more information about the System registers for the Advanced SIMD and floating-point operation see Advanced SIMD and floating-point System registers on page G1-4415. Software can interrogate these registers to discover the implemented Advanced SIMD and floating-point support.

AArch32 implications of not including support for Advanced SIMD and floating-point summarizes the effects of not supporting these instructions, and the following subsections give more information about the Advanced SIMD and Floating-point support:

- Enabling Advanced SIMD and floating-point support on page G1-4413.
- Advanced SIMD and floating-point System registers on page G1-4415.
- Context switching when using Advanced SIMD and floating-point functionality on page G1-4415.
- Floating-point exception traps on page G1-4416.

G1.19.1 AArch32 implications of not including support for Advanced SIMD and floating-point

As stated in Implementations not including Advanced SIMD and floating-point instructions on page D1-1901, although ARMv8-A generally requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets, for implementations targeting specialized markets, ARM might produce or license ARMv8-A implementations that do not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- The CPACR.{ASEDIS, cp11, cp10} fields are RES0.
- The NSACR.{NSASEDIS, cp11, cp10} fields are RES0.
- The HCPTR.{TASE, TCP11, TCP10} fields are RES1.
- The FPEXC, FPSCR, FPSSID, MVFR0, MVFR1, and MVFR2 registers are not implemented and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
  - All Advanced SIMD and floating-point instructions are UNDEFINED.
  - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.
G1.19.2  **Enabling Advanced SIMD and floating-point support**

Software must ensure that the required access to the Advanced SIMD and floating-point features is enabled. Most of those controls are described in *Configurable instruction enables and disables, and trap controls on page G1-4418*, and this section:

- Summarizes those controls.
- Provides additional information in the following subsections:
  - *FPEXC control of access to Advanced SIMD and floating-point functionality on page G1-4414.*
  - *EL0 access to Advanced SIMD and floating-point functionality on page G1-4414.*

**Note**

This section shows the controls when the controlling Exception levels are using AArch32. Similar controls are provided when the Exception levels are using AArch64, and then apply to lower Exception levels that are using AArch32.

The controls of access to Advanced SIMD and floating-point functionality are:

**General {cp10, cp11} or {TCP10, TCP11} controls**

This relates to the CPACR.{cp10, cp11}, NSACR.{cp10, cp11}, and HCPTR.{TCP10, TCP11} controls.

**Note**

*Background to the System register interface on page G1-4410* explains the naming of these controls.

The {cp10, cp11} controls provide general control of the use of Advanced SIMD and floating-point functionality, as follows:

- CPACR.{cp10, cp11} control access from PE modes other than Hyp mode.
  These fields have no effect on accesses to Advanced SIMD and floating-point functionality from Hyp mode.
- In an implementation that includes EL3, NSACR.{cp10, cp11} control access from Non-secure state.
- In an implementation that includes EL2, if NSACR.{cp10, cp11} permit Non-secure accesses, or if EL3 is not implemented, HCPTR.{TCP10, TCP11} provide an additional control on those accesses.

In each case, the {cp10, cp11} controls must be programmed to the same value, otherwise operation is CONSTRAINED UNPREDICTABLE. The ARMv8 CONSTRAINED UNPREDICTABLE behavior is that, for all purposes other than reading the value of the register field, behavior is as if the cp11 field has the same value as the cp10 field. For more information see *Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-6102*.

For more information about these controls, see:

- *Enabling PL0 and PL1 accesses to the SIMD and floating-point registers on page G1-4423.*
- *General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-4437.*
- *Enabling Non-secure access to SIMD and floating-point functionality on page G1-4449.*

**Control of accesses to the CPACR from Non-secure PL1 modes**

As stated in *General {cp10, cp11} or {TCP10, TCP11} controls*, the CPACR controls access to Advanced SIMD and floating-point functionality from PE modes other than Hyp mode. Accesses to the CPACR from Non-secure PL1 modes can be trapped to EL2, see *Traps to Hyp mode of Non-secure EL1 accesses to the CPACR on page G1-4439*.

**Additional controls of Advanced SIMD functionality**

- If implemented as an RW field, CPACR.ASEDIS can make all Advanced SIMD instructions UNDEFINED in all modes other than Hyp mode.
In an implementation that includes EL3, when CPACR.ASEDIS permits use of the Advanced SIMD instructions or if the CPACR.ASEDIS control is not implemented, NSACR.NSASEDIS can make all Advanced SIMD instructions UNDEFINED in Non-secure state.

In an implementation that includes EL2, when the CPACR and NSACR settings permit Non-secure use of the Advanced SIMD instructions, if HCPTR.TASE is implemented as an RW field it can make these instructions UNDEFINED in Hyp mode, and trap to Hyp mode any use of these instructions in a Non-secure PL0 or PL1 mode.

For more information about these controls, see:

- Disabling PL0 and PL1 execution of Advanced SIMD instructions on page G1-4424.
- Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality on page G1-4438.
- Disabling Non-secure access to Advanced SIMD functionality on page G1-4450.

Pseudocode description of enabling SIMD and floating-point functionality on page G1-4451 provides links to the pseudocode descriptions of all of these controls.

FPEXC control of access to Advanced SIMD and floating-point functionality

In addition, FPEXC.EN is an enable bit for most Advanced SIMD and floating-point operations. When FPEXC.EN is 0, all Advanced SIMD and floating-point instructions are treated as UNDEFINED except for:

- A VMSR to the FPEXC or FPSID register.
- A VMRS from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2 register.

These instructions can be executed only at EL1 or higher.

Note

- When the FPSID is accessible, any write access to the FPSID is ignored.
- When FPEXC.EN is 0, these operations are treated as UNDEFINED:
  - A VMSR to the FPSCR.
  - A VMRS from the FPSCR.

Note

See Enabling access to the SIMD and floating-point registers on page G1-4424 for more information about the scope of the FPEXC.EN control.

When executing at EL0, the PE behaves as if the value of FPEXC.EN is 1 if either:

- EL1 is using AArch64.
- Execution is in Non-secure state, EL2 is using AArch64. and the value of HCR_EL2.TGE is 1.

Note

In this state, if the value of HCR_EL2.RW is 0 then it is permitted for the value of FPEX32_EL2.EN to control whether Advanced SIMD and floating-point functionality is enabled. However, ARM deprecates using the value of FPEX32_EL2.EN to determine behavior.

EL0 access to Advanced SIMD and floating-point functionality

When the access controls summarized in this section permit EL0 access to the Advanced SIMD and floating-point functionality, this applies only to the subset of functionality that is available at EL0. In particular:

- Only Advanced SIMD and Floating-point System register that is accessible is the FPSCR.
- The Advanced SIMD and floating-point instructions are available.

Execution at EL0 corresponds to the application level view of the Advanced SIMD and floating-point functionality, as described in Advanced SIMD and floating-point System registers on page E1-2742.
G1.19.3 Advanced SIMD and floating-point System registers

AArch32 state provides a common set of System registers for the Advanced SIMD and floating-point functionality. This section gives general information about this set of registers, and indicates where each register is described in detail. It contains the following subsections:

• Register map of the Advanced SIMD and floating-point System registers.
• Accessing the Advanced SIMD and floating-point System registers.

Register map of the Advanced SIMD and floating-point System registers

Table G4-66 on page G4-4745 shows the register map of the Advanced SIMD and Floating-point registers. Each register is 32 bits wide. In an implementation that includes EL3, the Advanced SIMD and Floating-point registers are common registers, see Common System registers on page G4-4698.

Accessing the Advanced SIMD and floating-point System registers

Software accesses the Advanced SIMD and floating-point System registers using the VMRS and VMSR instructions, see:

• VMRS on page F6-4017.
• VMSR on page F6-4020.

For example:

VMRS <Rt>, FPSID ; Read Floating-Point System ID Register
VMRS <Rt>, MVFR1 ; Read Media and VFP Feature Register 1
VMSR FPSCR, <Rt> ; Write Floating-Point System Control Register

Software can access the Advanced SIMD and floating-point System registers only if the access controls permit the access, see Enabling Advanced SIMD and floating-point support on page G1-4413.

——— Note ————

All hardware ID information can be accessed only from EL1 or higher. This means:

The FPSID is accessible only from EL1 or higher.

This is a change introduced from VFPv3. Previously, the FPSID register can be accessed in all modes.

The MVFR registers are accessible only from EL1 or higher.

Unprivileged software must issue a system call to determine what features are supported.

G1.19.4 Context switching when using Advanced SIMD and floating-point functionality

When the Advanced SIMD and floating-point functionality is used by only a subset of processes, the operating system might implement lazy context switching of the Advanced SIMD and floating-point register file and System registers.

In the simplest lazy context switch implementation, the primary context switch software uses the CPACR.{cp10, cp11} controls to disable access to the Advanced SIMD and floating-point functionality, see Enabling Advanced SIMD and floating-point support on page G1-4413. Subsequently, when a process or thread attempts to use an Advanced SIMD or floating-point instruction, it triggers an Undefined Instruction exception. The operating system responds by saving and restoring the Advanced SIMD and floating-point register file and System registers. Typically, it then re-executes the Advanced SIMD or floating-point instruction that generated the Undefined Instruction exception.
G1.19.5 Floating-point exception traps

Execution of a floating-point instruction can generate an exceptional condition, called a floating-point exception.

The ARMv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

--- Note ---
Do not confuse floating-point exceptions with the AArch32 architectural exceptions summarized in AArch32 state exception descriptions on page G1-4376.

Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED:

- For an implementation that does provide this capability, FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} are the control bits that enable synchronous exception generation for each of the floating-point exceptions.
- For an implementation that does provide this capability, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} are RAZ/WI.

--- Note ---
The ARMv8-A architecture does not support asynchronous reporting of floating-point exceptions.

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that an exception can never be taken to a lower Exception level. This means that trapped floating-point exceptions taken:

- From EL0 are taken to EL1, except for the following cases when they are taken from Non-secure EL0 to EL2:
  - EL2 is using AArch32 and the value of HCR.TGE is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.TGE is 1
- From EL1 are taken to EL1.
- From EL2 are taken to EL2.
- From EL3 are taken to EL3.

If the exception is taken to an Exception level that is using AArch64 then it is reported in the ELR_ELx for the Exception level to which it is taken, as described in Exception entry on page D1-1799.

If the exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception, see Undefined Instruction exception on page G1-4376. The FPEXC identifies the floating-point exceptions that occurred since the corresponding status bits in that register were last set to 0.

See also Floating-point exceptions and exception traps on page E1-2743.
In an implementation that provides synchronous exception generation for floating-point exceptions:

- Synchronous exception generation applies to floating-point exceptions generated by scalar SIMD and floating-point instructions executed in AArch32 state.

- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception flags in the event of such an exception.

ARMv8 does not support the trapping of floating-point exceptions from Advanced SIMD instructions executed in AArch32 state.

The `AArch32.FPTrappedException()` and `FPProcessEvent()` pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch32 state.

The `AArch32.FPTrappedException()` and `FPProcessEvent()` functions are described in Chapter J1 *ARMv8 Pseudocode*. 
G1.20 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch32 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an instruction enable, an instruction disable, or a trap control.

Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Privilege level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

The exception generated by attempting to execute an UNDEFINED instruction is:

- Taken to EL1 if the UNDEFINED instruction was executed at EL0, unless the instruction was executed at Non-secure EL0 and is routed to EL2 by the control described in Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.
  
  When the exception is taken to EL1 it is taken to Undefined mode.

- Otherwise, taken to the Exception level at which the UNDEFINED instruction was executed:
  - If the instruction was executed in Hyp mode the exception is taken to Hyp mode.
  - Otherwise, the exception is taken to Undefined mode.

Trap controls

Control whether one or more instructions, when executed at a particular Privilege level, are trapped.

--- Note ---

AArch32 trap controls are described in terms of Privilege levels, rather than Exception levels, because the PL1 traps apply at and are controlled from:

- **EL1**: In Non-secure state, and in Secure state when EL3 is using AArch64.
- **EL3**: In Secure state when EL3 is using AArch32.

For more information see Security state, Exception levels, and AArch32 execution privilege on page G1-4318.

---

Trap controls are grouped as:

**PL1, excluding Monitor mode**

Trapped instructions generate Undefined Instruction exceptions that are taken to Undefined mode, unless the instruction was executed at Non-secure EL0 and is routed to EL2 by the control described in Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.

For more information about these traps see PL1 configurable controls on page G1-4419.

**Hyp mode (PL2)**

These traps apply only to execution in Non-secure state. This section only describes the traps that apply when EL2 is using AArch32.

Trapped instructions generate:

- Hyp Trap exceptions, taken to Hyp mode, if trapped from a mode other than Hyp mode.
- Undefined Instruction exceptions taken to Hyp mode, if trapped from Hyp mode.

For more information about these traps see EL2 configurable controls on page G1-4427.

See also Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.

**Monitor mode (Secure PL1)**

This section only describes the traps that apply when EL3 is using AArch32.

Trapped instructions generate Monitor Trap exceptions, that are taken to Monitor mode.

For more information about these traps see EL3 configurable controls on page G1-4446.

An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if the instruction does not also generate a higher priority exception. Exception prioritization for exceptions taken to AArch32 state on page G1-4344 defines the prioritization of different exceptions on the same instruction.
Exceptions generated as a result of these controls are synchronous exceptions.

For exceptions taken to an Exception level that is using AArch32, only exceptions that are taken to Hyp mode are reported in a syndrome register, the HSR.

Note

• A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, CPACR.TRCDIS is a trap control even though TRCDIS is a mnemonic for Trace Disable.

• An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

• Configurable instruction enables and disables, and trap controls on page D1-1842 describes controls provided by AArch64 state for enabling, disabling, and trapping instructions. Generally, where an AArch64 control applies to execution at lower Exception levels, it traps the equivalent functionality when that lower Exception level is using AArch32. See the AArch64 trap controls for more information.

This section is organized as follows:

• Register access instructions.
• PL1 configurable controls.
• EL2 configurable controls on page G1-4427.
• EL3 configurable controls on page G1-4446.
• Pseudocode description of configurable instruction enables, disables, and traps on page G1-4451.

G1.20.1 Register access instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:

• No access is made before the exception is taken.
• Side-effects that are normally associated with the access do not occur before the exception is taken.

G1.20.2 PL1 configurable controls

In AArch32 state, each control is associated with a particular System register field that is accessible:

• When EL3 is using AArch64, or when an implementation does not include EL3, from EL1.
• When EL3 is using AArch32:
   — In Non-secure state, from EL1.
   — In Secure state, from EL3.

This means that the controls are described as PL1 controls, because PL1 is defined as being the Privilege level of software that is executing:

• At EL3, if the PE is executing in EL3 and EL3 is using AArch32.
• At EL1 under all other conditions.

Where there is an AArch64 control that is equivalent to an AArch32 PL1 control, the AArch64 control is an EL1 control.

Any exception that is generated because of an AArch32 PL1 control is taken to a PL1 mode.

Note

Any exception generated because of an AArch32 PL1 control is taken to AArch32 state.
Table G1-25 shows the AArch32 System registers that contain these controls.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.
Instructions that fail their Condition code check

See Conditional execution of undefined instructions on page G1-4378.

Trapping to PL1 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates an Undefined Instruction exception.

Traps to Undefined mode of EL0 execution of WFE and WFI instructions

SCTLR.{nTWE, nTWI} trap EL0 execution of WFE and WFI instructions to Undefined mode:

- **SCTLR.nTWE**
  - 1: This control has no effect on the EL0 execution of WFE instructions.
  - 0: Any attempt to execute a WFE instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

- **SCTLR.nTWI**
  - 1: This control has no effect on the EL0 execution of WFI instructions.
  - 0: Any attempt to execute a WFI instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- Wait For Event and Send Event on page G1-4403.
- Wait For Interrupt on page G1-4406.

Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality

Table G1-28 on page G1-4422 shows the deprecated AArch32 functionality that might have disable controls in the SCTLR:

- The SED control is always implemented.

- Whether each of the ITD or CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.

When an instruction is disabled by one of these controls, it is UNDEFINED at PL0 and PL1. This means an attempt to execute the instruction at PL0 or PL1 generates an Undefined Instruction exception that is taken to Undefined mode, unless both of the following apply, in which case the attempted execution generates an exception that is taken to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-4356:

- The instruction is executed at Non-secure EL0 using AArch32.
- Either:
  - EL2 is using AArch32 and the value of HCR.TGE is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.
Note
The uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB barrier instructions, are deprecated for performance reasons.

Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers

If implemented, the CPACR.TRCDIS control traps PL0 and PL1 System register accesses to the trace registers to Undefined mode, as follows:

1. PL0 and PL1 accesses to the System register interface to the trace macrocell are trapped to Undefined mode.
2. This control has no effect on PL0 and PL1 accesses to the System register interface to the trace macrocell.

If the CPACR.TRCDIS control is not implemented, then the CPACR.TRCDIS field is RAZ/WI. This means the CPACR does not provide a trap to Undefined mode of PL1 and PL0 System register accesses to trace registers. See the register description for more information.

Note

- System register accesses to the trace macrocell use the (coproc==0b1110) encoding space.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace System registers are UNDEFINED.
- The ARMv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace System registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Register access instructions on page G1-4419.

If EL3 is implemented and is using AArch32, and NSACR.NSTRCDIS is 1, CPACR.TRCDIS behaves as RAO/WI in Non-secure state. This behavior also applies if the CPACR.TRCDIS control is not implemented.

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.
Enabling use of Advanced SIMD and floating-point functionality

Table G1-29 summarizes the controls of Advanced SIMD and floating-point functionality.

### Table G1-29 Controls of use of Advanced SIMD and floating-point functionality

<table>
<thead>
<tr>
<th>Control</th>
<th>Type</th>
<th>Description, see</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPACR.{cp11, cp10}</td>
<td>E</td>
<td>Enabling PL0 and PL1 accesses to the SIMD and floating-point registers</td>
</tr>
<tr>
<td>FPEXC.EN</td>
<td>E</td>
<td>Enabling access to the SIMD and floating-point registers on page G1-4424</td>
</tr>
<tr>
<td>CPACR.ASEDIS</td>
<td>D</td>
<td>Disabling PL0 and PL1 execution of Advanced SIMD instructions on page G1-4424</td>
</tr>
</tbody>
</table>

If any of CPACR.{cp11, cp10}, FPEXC.EN, or for Advanced SIMD instructions, CPACR.ASEDIS, disable a floating-point or an Advanced SIMD instruction, the instruction is UNDEFINED. Support for the CPACR.ASEDIS control is optional, and if the control is not implemented behavior is as if the control permits the execution of Advanced SIMD instructions at PL1 and PL0.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-4356.

**Enabling PL0 and PL1 accesses to the SIMD and floating-point registers**

CPACR.{cp11, cp10} enable PL0 and PL1 accesses to the SIMD and floating-point registers.

When CPACR.cp10 is:

- **00**: PL0 and PL1 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
- **01**: PL0 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
- **10**: Reserved. The effect of programming this field to this value is CONSTRAINED UNPREDICTABLE.
- **11**: This control permits full access to the Advanced SIMD and floating-point functionality from PL0 and PL1.

The value of CPACR.cp11 is ignored. If CPACR.cp11 is programmed with a different value to CPACR.cp10 then CPACR.cp11 is UNKNOWN on a direct read of the CPACR.

---

**Note**

- Software must set CPACR.cp11 and CPACR.cp10 to the same value.

Table G1-30 shows the registers for which accesses are enabled.

### Table G1-30 Register accesses enabled at PL0 and PL1 by CPACR.{cp11, cp10}

<table>
<thead>
<tr>
<th>Enabled at</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL0 and PL1, or PL0 only&lt;sup&gt;a&lt;/sup&gt;</td>
<td>FPSCR, FPEXC, FPSID, MVFR0, MVFR1, MVFR2, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers&lt;sup&gt;b&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

---

<sup>a</sup> Depending on the value of CPACR.{cp11, cp10}. See the register description for details.

<sup>b</sup> Permitted VMSR accesses to the FPSID are ignored, but for the purposes of the {cp10}, controls the architecture defines a VMSR accesses to the FPSID from EL1 or higher is an access to a SIMD and floating-point register.

If EL3 is implemented and is using AArch32, and NSACR.{cp11, cp10} are both set to 0, the functionality described in this section is disabled in Non-secure state, and CPACR.{cp11, cp10} are RAZ/WI in Non-secure state. See *Enabling Non-secure access to SIMD and floating-point functionality* on page G1-4449.
For more information about SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-4412.

**Enabling access to the SIMD and floating-point registers**

FPEXC.EN enables accesses to the SIMD and floating-point registers at all Exception levels, but does not control the following:

- \( \text{VMRS} \) accesses to the FPEXC or FPSID.
- \( \text{VMSR} \) accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

When FPEXC.EN is:

- 1 Accesses to the registers shown in Table G1-31 are enabled at all Exception levels.
- 0 All accesses to the registers shown in Table G1-31 are UNDEFINED.

Table G1-31 shows the registers for which accesses are enabled, and for an exception taken to Hyp mode, how the exception is reported in HSR.

<table>
<thead>
<tr>
<th>Enabled at</th>
<th>Registers</th>
<th>Syndrome reporting in HSR(^a)</th>

<tr>
<td></td>
<td>registers Q0-Q15, including their views as</td>
<td></td>
</tr>
<tr>
<td></td>
<td>D0-D31 registers or S0-S31 registers.</td>
<td></td>
</tr>
</tbody>
</table>

\(^{a}\) Only for exceptions that are taken to Hyp mode.

For more information, see Advanced SIMD and floating-point support on page G1-4412.

**Disabling PL0 and PL1 execution of Advanced SIMD instructions**

If implemented as an RW field, CPACR.ASEDIS can disable PL0 and PL1 execution of Advanced SIMD instructions, as follows:

- 1 Advanced SIMD instructions are UNDEFINED at PL0 and PL1.
- 0 Advanced SIMD instruction execution is enabled at PL0 and PL1.

The instructions that CPACR.ASEDIS disables are those described in Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2746.

When the control is not implemented, meaning the CPACR.ASEDIS field is RAZ/WI, behavior is as if the control permits execution of Advanced SIMD instructions at PL0 and PL1.

If EL3 is implemented and is using AArch32, and NSACR.NSASEDIS is 1, CPACR.ASEDIS is RAO/WI in Non-secure state. This also applies when the CPACR.ASEDIS control is not implemented.

**Traps to Undefined mode of EL0 accesses to the Debug Communications Channel (DCC) registers**

DBGDSCRext.UDCCdis traps EL0 accesses to the DCC registers to Undefined mode:

- 1 EL0 accesses to the DCC registers are trapped to Undefined mode
- 0 This control has no effect on EL0 accesses to the DCC registers.

Traps of EL0 accesses to the DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

Table G1-32 shows the registers for which accesses are trapped.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>DBGDSCRint, DBGDTRRXint, DBGDTRTXint, DBGDIDR,</td>
</tr>
<tr>
<td></td>
<td>DBGDSAR, DBGDRAR</td>
</tr>
</tbody>
</table>
Note

All accesses to these registers are trapped, including LDC and STC accesses to DBGDTRXint and DBGDTRRXint, and MRRC accesses to DBGDSAR and DBGDRAR.

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.

Traps to Undefined mode of EL0 accesses to the Generic Timer registers

CNTKCTL.{PL0PTEN, PL0VTEN, PL0PCTEN, PL0VCTEN} trap EL0 accesses to the Generic Timer registers to Undefined mode, as follows:

• CNTKCTL.PL0PTEN traps EL0 accesses to the physical timer registers.
• CNTKCTL.PL0VTEN traps EL0 accesses to the virtual timer registers.
• CNTKCTL.PL0PCTEN traps EL0 accesses to the frequency register and physical counter register.
• CNTKCTL.PL0VCTEN traps EL0 accesses to the frequency register and virtual counter register.

For all of these controls:

1 This control has no effect on EL0 accesses to the corresponding registers.
0 EL0 accesses to the corresponding registers are trapped to Undefined mode.

Accesses to the frequency register, CNTFRQ, are only trapped if CNTKCTL.PL0PCTEN and CNTKCTL.PL0VCTEN are both 0.

Table G1-33 shows the registers for which accesses are trapped.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>PL0PTEN</td>
<td>CNTP_CTL, CNTP_CVAL, CNTP_TVAL</td>
</tr>
<tr>
<td></td>
<td>PL0VTEN</td>
<td>CNTV_CTL, CNTV_CVAL, CNTV_TVAL</td>
</tr>
<tr>
<td></td>
<td>PL0PCTEN</td>
<td>CNTFRQ, CNTPCT</td>
</tr>
<tr>
<td></td>
<td>PL0VCTEN</td>
<td>CNTFRQ, CNTVCT</td>
</tr>
</tbody>
</table>

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.

Traps to Undefined mode of EL0 accesses to Performance Monitors registers

PMUSERENR.{ER, CR, SW, EN} trap EL0 accesses to the Performance Monitors registers to Undefined mode. For each of these controls:

1 This control has no effect on EL0 accesses to the corresponding registers.
0 EL0 accesses to the corresponding registers are trapped to Undefined mode.

For those Performance Monitors registers that more than one PMUSERENR.{ER, CR, SW, EN} control applies to, accesses are only trapped if all controls that apply are set to 0.

The accesses that these trap controls trap might be reads, writes, or both.

Note

• The architecture does not provide traps on Performance Monitors register accesses through the memory-mapped external debug interface.
• If the Performance Monitors Extension is not implemented, the Performance Monitors registers, including PMUSERENR, are reserved.
Table G1-34 shows the registers for which EL0 accesses are trapped. For each register, the table shows the type of access trapped.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Registers</th>
<th>Access type</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>ER</td>
<td>PMXEVcnTR, PMEVCNTR&lt;n&gt;</td>

</tr>
<tr>
<td></td>
<td>EN</td>
<td>PMCNTENSET, PMCNTENCLR, PMCR, PMOVSr, PMSWINC, PMSELr, PMCEID0, PMCE1, PMCCNTR, PMXEVTYPE, PMXEVcnTR&lt;n&gt;, PMOVSSET, PMEVCnTR&lt;n&gt;, PMEVTYPEn&lt;n&gt;, PMCCFILTR</td>
<td>RW</td>
</tr>
</tbody>
</table>

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-4356.
### G1.20.3 EL2 configurable controls

These controls are ignored in Secure state.

Table G1-35 shows the System registers that contain these controls.

<table>
<thead>
<tr>
<th>Register name</th>
<th>Register description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPEXC</td>
<td>Floating-point Exception Control Register</td>

</table>

Also see the following:

- Register access instructions on page G1-4419.
- Instructions that fail their Condition code check on page G1-4429.
- Trapping to EL2 of instructions that are UNPREDICTABLE on page G1-4429.
Instructions that fail their Condition code check

For UNDEFINED instructions that fail their Condition code check, see Conditional execution of undefined instructions on page G1-4378.

For an instruction that has a Hyp trap set, that fails its Condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
  - Generates a Hyp Trap exception.
  - Executes as a NOP.

Any implementation must be consistent in its handling of instructions that fail their Condition code check. This means that:

- Whenever a Hyp trap is set on an instruction it must either:
  - Always generate a Hyp Trap exception.
  - Always treat the instruction as a NOP.

- The IMPLEMENTATION DEFINED part of the requirements of Conditional execution of undefined instructions on page G1-4378 must be consistent with the handling of Hyp traps on instructions that fail their Condition code check. Table G1-38 shows this:

<table>
<thead>
<tr>
<th>Behavior of conditional UNDEFINED instruction</th>
<th>Hyp trap on instruction that fails its Condition code check</th>
</tr>
</thead>
<tbody>
<tr>
<td>Executes as a NOP</td>
<td>Executes as a NOP</td>
</tr>
<tr>
<td>Generates an Undefined Instruction exception</td>
<td>Generates a Hyp Trap exception</td>
</tr>
</tbody>
</table>

a. As defined in Conditional execution of undefined instructions on page G1-4378. In Non-secure EL0 and EL1 modes, this applies only if no Hyp trap is set for the instruction, otherwise see the behavior in the other column of the table.
b. For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

Note

Hyp traps on WFE and WFI instructions generate Hyp Trap exceptions only if the instruction passes its Condition code check. See Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437.

Trapping to EL2 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates a Hyp Trap exception.

Note

UNPREDICTABLE and CONSTRAINED UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. This means that disabling or trapping an instruction changes the set of instructions that might be executed in Non-secure state at EL1 or EL0. This indirectly affects the permitted behavior of UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions.

If no instructions are trapped, the attempted execution of an UNPREDICTABLE instruction in a Non-secure EL1 or EL0 mode must not generate a Hyp Trap exception.
Disabling or enabling EL2 use of AArch32 deprecated functionality

Table G1-39 shows the deprecated AArch32 functionality that might have disable controls in the HSCTLR:

- The SED control is always implemented.
- Whether each of the ITD, CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.

These HSCTLR controls apply only to execution at EL2 using AArch32. When an instruction is disabled by one of these controls, it is UNDEFINED at EL2, meaning it is undefined in Hyp mode.

### Table G1-39 EL2 controls for disabling and enabling EL2 use of AArch32 deprecated functionality

<table>
<thead>
<tr>
<th>Deprecated AArch32 functionality</th>
<th>Instruction enable or disable in the HSCTLR</th>
<th>Disabled instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETEND instructions</td>
<td>SED(^a)</td>
<td>SETEND instructions</td>
</tr>
<tr>
<td>Some uses of IT instructions</td>
<td>ITD(^b)</td>
<td>See the HSCTLR.IT description</td>
</tr>
<tr>
<td>Accesses to the System register (coproc==0b1111) DMB, DSB, and ISB barrier operations</td>
<td>CP15BEN(^c)</td>
<td>MCR accesses to the CP15DMB, CP15DSB, and CP15ISB</td>
</tr>
</tbody>
</table>

\(^a\) SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.

\(^b\) IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.

\(^c\) System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

---

**Note**

- These controls have no effect on instructions executed in any mode other than Hyp mode. The SCTLR provides similar controls that apply to execution in other modes.

- The uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB barrier instructions, are deprecated for performance reasons.

---

Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers

HCR.[TRVM, TVM] trap Non-secure EL1 accesses to the virtual memory control registers to Hyp mode:

**HCR.TRVM**, for read accesses:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Non-secure EL1 reads of the virtual memory control registers are trapped to Hyp mode.</td>
</tr>
<tr>
<td>0</td>
<td>This control has no effect on Non-secure EL1 reads of the virtual memory control registers.</td>
</tr>
</tbody>
</table>

**HCR.TVM**, for write access:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Non-secure EL1 writes to the virtual memory control registers are trapped to Hyp mode.</td>
</tr>
<tr>
<td>0</td>
<td>This control has no effect on Non-secure EL1 writes to the virtual memory control registers.</td>
</tr>
</tbody>
</table>

Table G1-40 on page G1-4431 shows the registers for which:

- Reads are trapped to Hyp mode when HCR.TRVM is 1.
- Writes are trapped to Hyp mode when HCR.TVM is 1.
The table also shows how the exceptions are reported in **HSR**.

### Table G1-40 Register read and write accesses trapped when **HCR.(TRVM, TVM)** are 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in <strong>HSR</strong></th>
</tr>
</thead>
</table>
| Non-secure EL1   | **SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR** | Trapped **MCR or MRC access** (coproc==0b1111), using EC value 0x03  
|                  |               | Trapped **MCR or MRC access** (coproc==0b1111), using EC value 0x04 |

**Note**

These registers are not accessible at EL0.

### Disabling Non-secure state execution of **HVC** instructions

**HCR.HCD** disables Non-secure state execution of **HVC** instructions:

1. **HVC** instructions are **UNDEFINED** at EL2 and Non-secure EL1. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.

0. **HVC** instruction execution is enabled at EL2 and Non-secure EL1.

**Note**

**HVC** instructions are always **UNDEFINED** at EL0.

**HCR.HCD** is only implemented if EL3 is not implemented. Otherwise, it is **RES0**. See the **HCR** register description.

Table G1-41 shows how the exceptions are reported in **HSR**.

### Table G1-41 Instruction that causes exceptions when **HCR.HCD** is 1

<table>
<thead>
<tr>
<th>Attempted execution in</th>
<th>Disabled instruction</th>
<th>Syndrome reporting in <strong>HSR</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Hyp mode</td>
<td><strong>HVC</strong></td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td>Mode other than Hyp mode</td>
<td><strong>HVC</strong></td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

### Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions

In the ARMv8-A architecture, the system instruction encoding space includes TLB maintenance instructions.

**HCR.TTLB** traps Non-secure EL1 execution of TLB maintenance instructions to Hyp mode:

1. Any attempt to execute a **TLBI** instruction at Non-secure EL1 is trapped to Hyp mode.

0. This control has no effect on the Non-secure EL1 execution of **TLBI** instructions.

Table G1-42 shows the instructions that are trapped, and how the exceptions are reported in **HSR**.

### Table G1-42 Instructions trapped to Hyp mode when **HCR.TTLB** is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in <strong>HSR</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td><strong>TLBIALLIS, TLBIMVAIS, TLBIALISIDIS, TLBIMVAAIL, TLBIMVALIS, TLBIMVAAILIS, ITLBIALL, ITLBMVA, ITLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, TLBIALL, TLBIMVA, TLBIALISD, TLBIMVAAIL, TLBIMVAL, TLBIMVAAIL.</strong></td>
<td>Trapped <strong>MCR or MRC access</strong> (coproc==0b1111), using EC value 0x00</td>
</tr>
</tbody>
</table>

**Note**

These registers are not accessible at EL0.
Note

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see *The scope of TLB maintenance instructions* on page G4-4641.

Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions

HCR.{TSW, TPC, TPU} trap cache maintenance instructions to Hyp mode:

0  The control has no effect on the execution of cache maintenance instructions.

1  Any attempt to execute one of the cache maintenance instructions shown in Table G1-44 at Non-secure EL1 is trapped to Hyp mode.

Table G1-43 Controls for trapping cache maintenance instructions to Hyp mode

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Trapped instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR.TSW</td>
<td>Data or unified cache maintenance by set/way</td>

</tr>
</tbody>
</table>

Table G1-44 shows the instructions that are trapped to Hyp mode, and how the exceptions are reported in HSR.

Table G1-44 Instructions trapped to Hyp mode when HCR.{TSW, TPC, TPU} are 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>TSW</td>
<td>DCISW, DCCSW, DCCISW</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x3</td>
</tr>
<tr>
<td></td>
<td>TPC</td>
<td>DCIMVAC, DCCIMVAC, DCCMVAC</td>
<td></td>
</tr>
<tr>
<td></td>
<td>TPU</td>
<td>ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAU</td>
<td></td>
</tr>
</tbody>
</table>

Note

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see *Cache maintenance instructions, functional group* on page G4-4734.

Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register

HCR.TAC traps Non-secure EL1 accesses to the Auxiliary Control Registers to Hyp mode:

1  Non-secure EL1 accesses to the Auxiliary Control Registers are trapped to Hyp mode.

0  This control has no effect on Non-secure EL1 accesses to the Auxiliary Control Registers.

Table G1-45 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR:

Table G1-45 Register accesses trapped to Hyp mode when HCR.TAC is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>ACTLR and, if implemented, ACTLR2.</td>
<td>Trapped MCR or MRC access (coproc==0b1111) access, using EC value 0x3</td>
</tr>
</tbody>
</table>
Note

The ACTLR and ACTLR2 are not accessible at EL0.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARMv8-A architecture are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of System registers for control of these features.

HCR.TIDCP traps the execution of System register access instructions that access these registers, as follows:

1. At Non-secure EL1, any attempt to execute an MCR or MRC instruction with a reserved register encoding shown in Table G1-46 is trapped to Hyp mode.

   At Non-secure EL0, it is IMPLEMENTATION DEFINED whether attempts to execute MCR or MRC instructions with reserved register encodings are:
   • Trapped to Hyp mode.
   • UNDEFINED, and the PE takes the Undefined Instruction exception to Non-secure Undefined mode.

   Any lockdown fault in the memory system caused by the use of these operations in Non-secure state generates a Data Abort exception that is taken to Hyp mode.

0. This control has no effect on Non-secure EL0 and EL1 System register access instructions with reserved register encodings shown in Table G1-46.

Note

This means that a Hyp Trap exception taken from Non-secure EL1 to Hyp mode, generated because of a configuration setting in HCR.TIDCP is a higher priority exception than an Undefined Instruction exception generated because either the System register encoding is unallocated or because the register is never accessible at EL1. As Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to EL2.

Table G1-46 shows the register encodings for which accesses are trapped to Hyp mode, and how the exceptions are reported in HSR.

Table G1-46 Encodings trapped to Hyp mode when HCR.TIDCP is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Register encodings</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>An access to any of the following encodings:</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
<tr>
<td></td>
<td>• CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}.</td>
<td></td>
</tr>
</tbody>
</table>

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

Note

ARM expects the trapping of Non-secure User mode accesses to these functions to Hyp mode to be unusual, and used only when the hypervisor is virtualizing User mode operation. ARM strongly recommends that unless the hypervisor must virtualize User mode operation, a Non-secure User mode access to any of these functions generates an Undefined Instruction exception, as it would if the implementation did not include EL2. The PE then takes this exception to Non-secure Undefined mode.
Traps to Hyp mode of Non-secure EL1 execution of SMC instructions

HCR.TSC traps Non-secure EL1 execution of SMC instructions to Hyp mode:

1 Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of SCR.SCD.

0 This control has no effect on Non-secure EL1 execution of SMC instructions.

Table G1-47 shows how the exceptions are reported in HSR:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instruction</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>SMC on page F5-3429</td>
<td>Trapped SMC instruction execution in AArch32 state, using EC value 0x13</td>
</tr>
</tbody>
</table>

The ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their Condition code check, in the same way as with traps on other conditional instructions.

Note

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are always UNDEFINED at EL0.
- HCR.TSC traps execution of the SMC instruction. It is not a routing control for the SMC exception. Hyp Trap and SMC exceptions have different preferred return addresses.

For more information about SMC instructions, see SMC on page F5-3429.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers

Other than the MIDR, MPIDR, and PMCR.N, the ID registers are divided into groups, with a trap control in the HCR for each group.

Table G1-48 ID register groups

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Register group</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR.TID0</td>
<td>ID group 0, Primary device identification registers on page G1-4435</td>
</tr>
<tr>
<td>HCR.TID1</td>
<td>ID group 1, Implementation identification registers on page G1-4436</td>
</tr>
<tr>
<td>HCR.TID2</td>
<td>ID group 2, Cache identification registers on page G1-4436</td>
</tr>
<tr>
<td>HCR.TID3</td>
<td>ID group 3, Detailed feature identification registers on page G1-4436</td>
</tr>
</tbody>
</table>

These controls trap register accesses from Non-secure EL0 or EL1 to Hyp mode, as follows:

<table>
<thead>
<tr>
<th>HCR.TID0</th>
<th>0</th>
<th>This control has no effect on Non-secure EL1 reads of the ID group 0 registers.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1</td>
<td>Any attempt at Non-secure EL0 or EL1 to read any register in ID group 0 is trapped to Hyp mode</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>HCR.TID1</th>
<th>0</th>
<th>This control has no effect on Non-secure EL1 reads of the ID group 1 registers.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1</td>
<td>Any attempt at Non-secure EL1 to read any register in ID group 1 is trapped to Hyp mode.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>HCR.TID2</th>
<th>0</th>
<th>This control has no effect on Non-secure EL1 and EL0 accesses to the ID group 2 registers.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1</td>
<td>Any attempt at Non-secure EL0 or EL1 to read any register in ID group 2, and any attempt at Non-secure EL0 or EL1 to write to the CSSELR, is trapped to Hyp mode.</td>
</tr>
</tbody>
</table>

Table G1-47 SMC Instruction trapped to Hyp mode when HCR.TSC is 1
**HCR.TID3**

- **0** This control has no effect on Non-secure EL1 reads of the ID group 3 registers.
- **1** Any attempt at Non-secure EL1 to read any register in ID group 3 is trapped to Hyp mode.

For the MIDR and MPIDR, and for PMCR.N, the architecture provides read/write aliases. The original register becomes accessible only from Hyp mode and Secure state, and a Non-secure EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

### Table G1-49 ID register substitution

<table>
<thead>
<tr>
<th>Register</th>
<th>Original</th>
<th>Alias, EL2 using AArch32</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main ID</td>
<td>MIDR</td>
<td>VPIDR</td>
</tr>
<tr>
<td>Multiprocessor Affinity</td>
<td>MPIDR</td>
<td>VMPIDR</td>
</tr>
<tr>
<td>Performance Monitors Control Register</td>
<td>PMCR.N</td>
<td>HDCR.HPMN</td>
</tr>
</tbody>
</table>

Reads of the MIDR, MPIDR, or PMCR.N from Hyp mode or Secure state are unchanged by the implementation of EL2, and access the physical registers.

**Note**

- If the optional Performance Monitors Extension is not implemented, HDCR.HPMN is RES0 and PMCR is reserved.
- HDCR.HPMN also affects whether a Performance Monitors counter can be accessed from Non-secure EL1 or EL0. See the register description of HDCR for more information.
- PMCR contains other fields that identify the implementation. For more information about trapping accesses to the PMCR, see *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers* on page G1-4444.

A reset into AArch32 state sets VPIDR to the MIDR value, VMPIDR to the MPIDR value, and HDCR.HPMN to the PMCR.N value.

**ID group 0, Primary device identification registers**

These registers identify some top-level implementation choices.

Table G1-50 shows the registers that are in ID group 0 for traps to Hyp mode, and how the exceptions are reported in HSR.

### Table G1-50 ID group 0 registers

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 0 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>FPSID</td>
<td>Trapped VMRS access, for ID group traps, using EC value 0x08</td>
</tr>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>JIDR</td>
<td>Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05</td>
</tr>
</tbody>
</table>

**Note**

The FPSID is not accessible at EL0.

If HCPTR.{TCP11, TCP10} traps accesses to SIMD and floating-point functionality, then for a read of FPSID, that trap has priority over this trap.

When the FPSID is accessible, a VMSR FPSID, <Rt> instruction is permitted but is ignored. The execution of this VMSR instruction is not trapped by the ID group 0 trap.
**ID group 1, Implementation identification registers**

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table G1-51 shows the registers that are in ID group 1 for traps to Hyp mode, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 1 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>TCMTR, TLBTR, REVIDR, AIDR</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**ID group 2, Cache identification registers**

These registers describe and control the cache implementation.

Table G1-52 shows the registers that are in ID group 2 for traps to Hyp mode, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 2 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>CTR, CCSIDR, CLIDR, CSSELR</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**ID group 3, Detailed feature identification registers**

These registers provide detailed information about the features of the implementation.

---

*Note*

These registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See *The CPUID identification scheme on page G4-4728*.

Table G1-53 shows the registers that are in ID group 3 for traps to Hyp mode, and how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 3 registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>MVFR0, MVFR1, MVFR2</td>
<td>Trapped VMRS access for ID group traps, using EC value 0x08</td>
</tr>
</tbody>
</table>

ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4, except that if ID_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether reads of the register are trapped.

ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5.

Any MRC access to any of the following encodings when coproc==0b1111:

- \( \text{opc1} = 0, \text{CRn} = c0, \text{CRm} = \{c3-c7\}, \text{opc2} = \{0, 1\} \).
- \( \text{opc1} = 0, \text{CRn} = c0, \text{CRm} = c3, \text{opc2} = 2 \).
- \( \text{opc1} = 0, \text{CRn} = c0, \text{CRm} = c5, \text{opc2} = \{4, 5\} \).

It is IMPLEMENTATION DEFINED whether HCR.TID3 traps MRC accesses with coproc==0b1111 to encodings in the following range that are not already mentioned in this table:

- \( \text{CRn} = c0, \text{opc1} = 0, \text{CRm} = \{c2-c7\}, \text{opc2} = \{0-7\} \).
If HCPTR traps accesses to SIMD and floating-point functionality, then for reads of MVFR0, MVFR1, and MVFR2, that trap has priority over this trap.

**Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions**

HCR.{TWE, TWI} trap Non-secure EL0 and EL1 execution of WFE and WFI instructions to Hyp mode:

**HCR.TWE:**

1. Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.
2. This control has no effect on Non-secure EL0 or EL1 execution of WFE instructions.

**HCR.TWI:**

1. Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.
2. This control has no effect on Non-secure EL0 or EL1 execution of WFI instructions.

Table G1-54 shows how the exceptions are reported in HSR.

<table>
<thead>
<tr>
<th>Traps from Non-secure EL0 and EL1</th>
<th>WFE</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>WFI</td>
<td></td>
<td>Trapped WFI or WFE instruction, using EC value 0x01</td>
</tr>
</tbody>
</table>

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

--- **Note** ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- Wait For Event and Send Event on page G1-4403.
- Wait For Interrupt on page G1-4406.

**General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers**

HCPTR.{TCP11, TCP10} trap Non-secure accesses to the SIMD and floating-point registers to Hyp mode:

0b11

All Non-secure accesses to the SIMD and floating-point registers are trapped to Hyp mode. Trapped instructions generate:

- Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
- Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.

0b00

This control has no effect on Non-secure accesses to the SIMD and floating-point registers.

--- **Note** ---

Software must set HCPTR.TCP11 and HCPTR.TCP10 to the same value.
Table G1-55 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

Table G1-55 Register accesses trapped to Hyp mode when HCPTR.(TCP11, TCP10) are both 0b11

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure state</td>
<td>FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point System registers on page G1-4415.</td>
<td>Trapped access to SIMD and floating-point register, resulting from HCPTR, using EC value 0x07a.</td>
</tr>
</tbody>
</table>

a. VMSR accesses to the FPSID are ignored, but for the purposes of this trap the architecture defines a VMSR access to the FPSID from EL1 or higher as an access to a SIMD and floating-point register.

If EL3 is implemented and is using AArch32, and NSACR.{cp11, cp10} are both set to 0, then HCPTR.{TCP11, TCP10} behave as RAO/WI, regardless of their actual value.

For more information about SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-4412.

Enabling access to the SIMD and floating-point registers

FPEXC.EN is an instruction enable that enables access to the SIMD and floating-point registers from all Exception levels, but does not control the following:

• VMSR accesses to the FPEXC or FPSID.
• VMSR accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

FPEXC.EN is a PL1 control that also applies at EL2. See Enabling access to the SIMD and floating-point registers on page G1-4424.

Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality

If implemented as an RW field, HCPTR.TASE can trap Non-secure execution of Advanced SIMD instructions to Hyp mode, as follows. This trap applies only when HCPTR.{TCP11, TCP10} are both 0:

1 Any attempt to execute an Advanced SIMD instruction in Non-secure state is trapped to Hyp mode. Trapped instructions generate:
   • Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
   • Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.

0 This control has no effect on Non-secure execution of Advanced SIMD instructions.

When the control is not implemented, meaning the HCPTR.TASE field is RAZ/WI, the HCPTR does not provide a trap to Hyp mode of the Non-secure execution of Advanced SIMD instructions, other than the HCPTR.{TCP11, TCP10} trap that applies to Non-secure execution of both Advanced SIMD and floating-point instructions.

Table G1-30 on page G1-4423 shows the instructions that are trapped, and how the exceptions are reported in HSR.

Table G1-56 Instructions trapped to Hyp mode when HCPTR.TASE is set to 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Instructions</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure state</td>
<td>All Advanced SIMD instructions that are not also floating-point instructions. For more information see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2746.</td>
<td>Trapped access to SIMD and floating-point register, resulting from HCPTR, using EC value 0x07</td>
</tr>
</tbody>
</table>

Traps from | Instructions | Syndrome reporting in HSR |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure state</td>
<td>All Advanced SIMD instructions that are not also floating-point instructions. For more information see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2746.</td>
<td>Trapped access to SIMD and floating-point register, resulting from HCPTR, using EC value 0x07</td>
</tr>
</tbody>
</table>
If EL3 is implemented and is using AArch32, and NSACR.NSASEDIS is 1, then HCPTR.TASE behaves as RAO/WI, regardless of its actual value. This behavior also applies when the HCPTR.TASE control is not implemented.

**Traps to Hyp mode of Non-secure EL1 accesses to the CPACR**

HCPTR.TCPAC traps Non-secure EL1 accesses to the CPACR to Hyp mode:

1. Non-secure EL1 accesses to the CPACR are trapped to Hyp mode.
2. This control has no effect on Non-secure EL1 accesses to the CPACR.

Table G1-57 shows how the exceptions are reported in HSR:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Register</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>CPACR</td>
<td>Trapped MCR or MRC access to System register with coproc==0b1111, using EC value 0x03</td>
</tr>
</tbody>
</table>

--- Note ---

- The CPACR is not accessible at EL0.
- In ARMv7 and earlier versions of the ARM architecture, one use of the CPACR is to identify what coprocessor, or conceptual coprocessor, functionality is implemented. Legacy software might use this identification mechanism. A hypervisor can use this trap to emulate this mechanism. See *Background to the System register interface* on page G1-4410 for more information about this functionality.

---

**Traps to Hyp mode of Non-secure System register accesses to trace registers**

If implemented, the HCPTR.TTA control traps System register accesses to the trace registers from Non-secure state to Hyp mode, as follows:

1. Non-secure System register accesses to the trace registers are trapped to Hyp mode. Trapped instructions generate:
   - Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
   - Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.

0. This control has no effect on Non-secure System register accesses to the trace registers.

If the HCPTR.TTA control is not implemented, then HCPTR.TTA is RAO/WI. See the register description for more information.

--- Note ---

- System register accesses to the trace registers use the System register (coproc==0b1110) encoding space.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED. A resulting Undefined Instruction exception is higher priority than an HCPTR.TTA Hyp Trap exception.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see *Register access instructions* on page G1-4419.
Table G1-58 shows the registers for which accesses are trapped to Hyp mode when HCPTR.TTA is 1, and how the exceptions are reported in HSR.

### Table G1-58 Register accesses trapped to Hyp mode when HCPTR.TTA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure state</td>
<td>System register accesses to all implemented trace registers</td>
<td>For accesses using:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x05.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x0C.</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch32, and NSACR.NSTRCDIS is 1, then HCPTR.TTA behaves as RAO/WI, regardless of its actual value. This behavior applies, also, when the HCPTR.TTA control is not implemented.

### General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space

HSTR. {T0-T3, T5-T13, T15} trap Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, or MRRC instructions, to the System registers in the (coproc==0b1111) encoding space, by:

- The value of the CRn argument to the instruction, for MCR and MRC instructions.
- The value of the CRm argument to the instruction, for MCRR and MRRC instructions.

This applies for the set of CRn, or CRm, values \{c0-c3, c5-c13, c15\}.

When an HSTR.Tn trap control is:

1. Non-secure EL1 accesses to the corresponding System registers in the (coproc==0b1111) encoding space are trapped to Hyp mode.
   - EL0 accesses to the corresponding System registers are trapped to Hyp mode if they would not be UNDEFINED if the bit was zero.

0. This control has no effect on Non-secure EL0 or EL1 accesses to System registers.

#### Note

This means that a Hyp Trap exception taken from EL1 to EL2, generated because of a configuration setting in HSTR.Tn, is a higher priority exception than an Undefined Instruction exception generated because either the System register encoding is unallocated or because a register is never accessible at Non-secure EL1. As Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to EL2. This prioritization includes any access from Non-secure EL1 to a register that is only accessible in Secure state. So, for example, an access to the SCR from Non-secure EL1:

- When the value of HSTR.T1 is 0, generates an Undefined Instruction exception.
- When the value of HSTR.T1 is 1, generates a Hyp Trap exception.

Table G1-59 shows the accesses that are trapped, and how the exceptions are reported in HSR.

### Table G1-59 Accesses trapped to Hyp mode when an HSTR.Tn trap is enabled

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1 (^a)</td>
<td>Tn</td>
<td>MCR and MRC instructions, with coproc set to 0b1111 and CRn set to n</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MCRR and MRRC instructions, with coproc set to 0b1111 and CRm set to n</td>
<td>Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04</td>
</tr>
</tbody>
</table>
a. As described in this section, traps from EL1 apply whenever the value of HSTR.Tn is 1. Traps from EL0 apply only if the value of HSTR.Tn is 1 and the access would not be UNDEFINED if the value of HSTR.Tn was 0.

For example, when HSTR.T7 is 1, considering only accesses from Non-secure EL1:

- Any 32-bit access from a Non-secure PL1 mode using an MRC or MCR instruction with coproc set to 0b1111 and CRn set to c7, is trapped to Hyp mode.
- Any 64-bit access from a Non-secure PL1 mode using an MRRC or MCRR instructions with coproc set to 0b1111 and CRm set to c7, is trapped to Hyp mode.

--- Note ---

- Bits[4,14] of the HSTR are reserved, RES0. Although the Generic Timer control registers are implemented in the coproc == 0b1111 encoding space with CRn == c14 for an MRC or MCR access, EL2 does not provide a trap on accesses to the Generic Timer System registers.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide finer-grained control of control of trapping of IMPLEMENTATION DEFINED features.

--- System registers in the (coproc==0b1111) encoding space with IMPLEMENTATION DEFINED access permission from EL0 ---

For a System register in the (coproc==0b1111) encoding space, that is accessed using a CRn or CRm value that can be trapped by a HSTR.Tn control, if an access to the register from User mode is UNDEFINED when the value of the corresponding HSTR.Tn trap control is 0, then when that HSTR.Tn trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure User mode generates:

- A Hyp Trap exception.
- An Undefined Instruction exception taken to Non-secure Undefined mode.

--- Note ---

ARM expects that trapping to Hyp mode of Non-secure User mode accesses to System register in the (coproc==0b1111) encoding space will be unusual, and used only when the hypervisor must virtualize User mode operation. ARM recommends that, whenever possible, Non-secure User mode accesses to System register in the (coproc==0b1111) encoding space behave as they would if the processor did not implement EL2, generating an Undefined Instruction exception taken to Non-secure Undefined mode if the architecture does not support the User mode access.

--- Traps to Hyp mode of Non-secure System register accesses to debug registers ---

HDCR.\{TDRA, TDOSA, TDA\} trap Non-secure System register accesses to debug registers to Hyp mode, as follows:

- HDCR.\{TDRA, TDA\} trap Non-secure EL0 and EL1 accesses.
- HDCR.TDOSA traps Non-secure EL1 accesses.

--- Note ---

EL2 does not provide traps of debug register accesses through the optional memory-mapped external debug interface.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to Hyp mode, no side-effects occur before the exception is taken to Hyp mode. See Register access instructions on page G1-4419.
Table G1-60 shows the subsections that list the accesses trapped. The subsections describe how the traps are reported in HSR.

Table G1-60 Traps of Non-secure EL0 and EL1 accesses to debug registers

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Subsection</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDCR.TDRA</td>
<td>Trapping Non-secure System register accesses to Debug ROM registers</td>
</tr>
<tr>
<td>HDCR.TDOSA</td>
<td>Trapping Non-secure System register accesses to powerdown debug registers</td>
</tr>
<tr>
<td>HDCR.TDA</td>
<td>Trapping general Non-secure System register accesses to debug registers on page G1-4443</td>
</tr>
</tbody>
</table>

--- Note ---

System register accesses to debug registers use the (coproc==0b1110) encoding space.

**Trapping Non-secure System register accesses to Debug ROM registers**

HDCR.TDRA traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to Hyp mode:

1  Non-secure EL0 or EL1 System register accesses to the Debug ROM registers are trapped to Hyp mode.

0  This control has no effect on Non-secure EL0 and EL1 System register accesses to the Debug ROM registers.

Table G1-61 shows the register accesses that are trapped, and how the exceptions are reported in HSR:

Table G1-61 Register accesses trapped to Hyp mode when HDCR.TDRA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL0 and EL1</td>
<td>DBGDRAR, DBGDSAR</td>
<td>For accesses using:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MRRR instructions, trapped MRRR access (coproc==0b1110), using EC value 0x0C.</td>
</tr>
</tbody>
</table>

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDRA is 1 other than for the purpose of a direct read.

**Trapping Non-secure System register accesses to powerdown debug registers**

HDCR.TDOSA traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode:

1  Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.

0  This control has no effect on Non-secure EL1 System register accesses to the powerdown debug registers.

Table G1-62 shows the register accesses that are trapped, and how the exceptions are reported in HSR:

Table G1-62 Register accesses trapped to Hyp mode when HDCR.TDOSA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in HSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure EL1</td>
<td>DBGOSLSR, DBGOSLAR, DBGOSDLR, DBGPRCR</td>
<td>Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05</td>
</tr>
</tbody>
</table>
Note

These registers are not accessible at EL0.

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDOSA is 1 other than for the purpose of a direct read.

Trapping general Non-secure System register accesses to debug registers

HDCR.TDA traps Non-secure EL0 and EL1 System register accesses to the debug registers that are not mentioned in either of the following:

• Traps to Hyp mode of Non-secure System register accesses to debug registers on page G1-4441.
• Trapping Non-secure System register accesses to powerdown debug registers on page G1-4442.

This means that HDCR.TDA traps to Hyp mode Non-secure EL0 and EL1 System register accesses to all debug registers except the following:

• Non-secure System register accesses to DBGDRAR or DBGDSAR. The HDCR.TDRA trap traps these accesses.
• Non-secure System register access to DBGOSLSR, DBGOSLAR, DBGOSDLR, or DBGPRCR. The HDCR.TDOSA trap traps these accesses.

HDCR.TDA does not trap accesses to DBGDTRRXint or DBGDTRRXint when the PE is in Debug state.

When HDCR.TDA is:

1

Non-secure EL0 or EL1 System register accesses to any of the registers shown in Table G1-63 are trapped to Hyp mode.

0

This control has no effect on Non-secure EL0 or EL1 System register accesses.

Table G1-63 shows how the exceptions are reported in HSR.

### Table G1-63 Accesses trapped to Hyp mode when HDCR.TDA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped accesses</th>

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDA is 1 other than for the purpose of a direct read.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the Generic Timer registers

CNTHTCTL.{PL1PCEN, PL1PCTEN} trap Non-secure EL0 and EL1 accesses to the Generic Timer registers to Hyp mode, as follows:

• CNTHTCTL.PL1PCEN traps Non-secure EL0 and EL1 accesses to the physical timer registers.
• CNTHTCTL.PL1PCTEN traps Non-secure EL0 and EL1 accesses to the physical counter register.

For each of these controls:

1

This control has no effect on Non-secure EL0 and EL1 accesses to the registers shown in Table G1-64 on page G1-4444.
Non-secure EL0 and EL1 accesses are trapped to Hyp mode.

Table G1-64 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

### Table G1-64 Register accesses trapped to Hyp mode by CNTHCTL trap controls

### Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers

If the Performance Monitors Extension is implemented, HDCR.\{TPM, TPMCR\} trap Non-secure EL0 and EL1 accesses to the Performance Monitors registers to Hyp mode:

**HDCR.TPM:**

- **1** Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.
- **0** This control has no effect on Non-secure EL0 and EL1 accesses to the Performance Monitors registers.

**HDCR.TPMCR:**

- **1** Non-secure EL0 and EL1 accesses to the Performance Monitors Control Register are trapped to Hyp mode.

    —— **Note** ——

    The conditions for this trap are identical to those for the trap controlled by HDCR.TPM

- **0** This control has no effect on Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers.

    —— **Note** ——

    • EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

    • If the Performance Monitors Extension is not implemented, HDCR.\{TPM, TPMCR\} are RES0.
Table G1-65 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

**Table G1-65 Register accesses trapped to Hyp mode when HDCR.(TPM, TPMCR) are 1**

Also see the following:

- Register access instructions on page G1-4419.
- Instructions that fail their Condition code check.
- Trapping to EL3 of instructions that are UNPREDICTABLE on page G1-4447.

Instructions that fail their Condition code check

For UNDEFINED instructions that fail their Condition code check, see Conditional execution of undefined instructions on page G1-4378.

For an instruction that has a Monitor trap set, that fails its Condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
  - Generates a Monitor Trap exception.
  - Executes as a NOP.
Any implementation must be consistent in its handling of instructions that fail their Condition code check. This means that:

- Whenever a Monitor trap is set on such an instruction it must either:
  - Always generate a Monitor trap exception.
  - Always treat the instruction as a NOP.
- The IMPLEMENTATION DEFINED part of the requirements of *Conditional execution of undefined instructions on page G1-4378* must be consistent with the handling of Monitor traps on instructions that fail their Condition code check. Table G1-69 shows this:

<table>
<thead>
<tr>
<th>Behavior of conditional UNDEFINED instruction(^a)</th>
<th>Monitor trap on instruction that fails its Condition code check(^b)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Executes as a NOP</td>
<td>Executes as a NOP</td>
</tr>
<tr>
<td>Generates an Undefined Instruction exception</td>
<td>Generates a Monitor trap exception</td>
</tr>
</tbody>
</table>

\(^a\) As defined in *Conditional execution of undefined instructions on page G1-4378*. In Non-secure EL0 and EL1 modes, this applies only if no Monitor trap is set for the instruction, otherwise see the behavior in the other column of the table.

\(^b\) For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

---

**Note**

When SCR{TWE, TWI} is set so that conditional WFE and WFI instructions are trapped to Monitor mode, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check. See *Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode*.

---

**Trapping to EL3 of instructions that are UNPREDICTABLE**

For an instruction that is UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates a Monitor Trap exception.

---

**Note**

UNPREDICTABLE and CONSTRAINED UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. This means that disabling or trapping an instruction changes the set of instructions that might be executed in modes other than Monitor mode. This affects, indirectly, the permitted behavior of UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions.

---

If no instructions are trapped, the attempted execution of an UNPREDICTABLE instruction in a mode other than Monitor mode must not generate a Monitor Trap exception.

**Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode**

SCR{TWE, TWI} trap WFE and WFI instructions to Monitor mode:

- **SCR.TWE**
  - 1: Any attempt to execute a WFE instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state.
  - 0: This control has no effect on the execution of WFE instructions.
SCR.TWI 1 Any attempt to execute a WFI instruction in any mode other than Monitor mode is
trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter
a low-power state.

0 This control has no effect on the execution of WFI instructions.

For PL0 and PL1, these traps apply to WFE and WFI instruction execution in both Security states.
The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition
code check.

——— Note ————
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed
to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the
instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:
• Wait For Event and Send Event on page G1-4403.
• Wait For Interrupt on page G1-4406.

Enabling EL2 and Non-secure EL1 execution of HVC instructions
SCR.HCE enables EL2 and Non-secure EL1 execution of HVC instructions:

1 HVC instruction execution is enabled at EL2 and Non-secure EL1.

0 HVC instructions are:
• UNDEFINED at Non-secure EL1. The Undefined Instruction exception is taken to Undefined
  mode.
• CONSTRAINED UNPREDICTABLE at EL2. The behavior must be one of the following:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.

——— Note ————
• If EL2 is not implemented, SCR.HCE is RES0 and HVC is UNDEFINED.
• HVC instructions are always UNDEFINED at EL0 and in Secure state.

Disabling SMC instructions
SCR.SCD disables SMC instructions:

1 In Non-secure state
SMC instructions are UNDEFINED. The Undefined Instruction exception is taken from the
current Exception level to the current Exception level.

In Secure state
Behavior is one of the following:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.

0 SMC instructions are enabled.

——— Note ————
• SMC instructions are always UNDEFINED at EL0.
• When the value of HCR.TSC is 1, any attempted execution of an SMC instruction at Non-secure EL1 is trapped to EL2, regardless of the value of SCR.SCD, see Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-4434. As Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to a higher Exception level.

Disabling Non-secure System register access to the trace registers

NSACR.NSTRCDIS disables Non-secure System register accesses to the trace registers, from all Privilege levels:

1  Non-secure state accesses are disabled. Secure state accesses are enabled. If the PE is in Non-secure state:
   • CPACR.TRCDIS behaves as RAO/WI, regardless of its actual value. See Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers on page G1-4422.
     This behavior applies even if the CPACR.TRCDIS control is not implemented. See the referenced section for more information.
   • HCPTR.TTA behaves as RAO/WI, regardless of its actual value. See Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-4439.

0  There is no effect on accesses to CPACR.TRCDIS and HCPTR.TTA.

   Note

• System register accesses to the trace registers use the (coproc==0b1111) encoding space.

• NSACR.NSTRCDIS might be implemented as RAZ/WI. See the NSACR register description for more information.

• The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.

• EL3 does not provide Non-secure access controls on trace register accesses through the optional memory-mapped external debug interface.

Enabling Non-secure access to SIMD and floating-point functionality

NSACR.{cp11, cp10} enable Non-secure access to the SIMD and floating-point registers, from all Privilege levels:

0b11  All accesses, from both Security states, are enabled.

0b00  Non-secure state accesses are disabled. Secure state accesses are enabled. If the PE is in Non-secure state:
   • CPACR.{cp11, cp10} behave as RAZ/WI. See Enabling PL0 and PL1 accesses to the SIMD and floating-point registers on page G1-4423.
   • HCPTR.{TCP11, TCP10} behave as RAO/WI. See General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-4437.

   Note

Software must set NSACR.cp11 and NSACR.cp10 to the same value.

For more information about SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-4412.
Disabling Non-secure access to Advanced SIMD functionality

NSACR.NSASEDIS disables Non-secure accesses to the Advanced SIMD functionality, from all Privilege levels:

1 Non-secure state accesses are disabled. Secure accesses are enabled. If the PE is in Non-secure state:
   • CPACR.ASEDIS behaves as RAO/WI. See Disabling PL0 and PL1 execution of Advanced SIMD instructions on page G1-4424.
   • HCPTR.TASE behaves as RAO/WI. See Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality on page G1-4438.

These behaviors apply even if one or both of the CPACR.ASEDIS and HCPTR.TASE controls is not implemented. See the referenced sections for more information.

0 There is no effect on CPACR.ASEDIS and HCPTR.TASE.
G1.20.5  **Pseudocode description of configurable instruction enables, disables, and traps**

The pseudocode function `AArch32.CheckITEnabled()` checks whether the T32 IT instruction is enabled.

The pseudocode function `AArch32.CheckSETENDEnabled()` checks whether the SETEND instruction is disabled.

The pseudocode function for `AArch32.CheckForSMCTrap()` checks for traps on an SMC instruction.

The `AArch32.CheckForWFxTrap()` pseudocode function checks for traps on WFE and WFI instructions:

**Pseudocode description of enabling SIMD and floating-point functionality**

The `AArch32.CheckAdvSIMDOrFPEnabled()` and `AArch32.CheckFPAdvSIMDTrap()` pseudocode functions take appropriate action if an SIMD or floating-point instruction is used when the SIMD and floating-point functionality is not enabled or is trapped.

The `CheckAdvSIMDOrVFPEnabled()`, `CheckAdvSIMDEnabled()`, and `CheckVFPEnabled()` wrapper functions support the `AArch32.CheckAdvSIMDOrFPEnabled()` and `AArch32.CheckFPAdvSIMDTrap()` functions.

The `AArch32.CheckAdvSIMDOrFPEnabled()`, `AArch32.CheckFPAdvSIMDTrap()`, `CheckAdvSIMDOrVFPEnabled()`, `CheckAdvSIMDEnabled()`, and `CheckVFPEnabled()` functions are described in Chapter J1 *ARMv8 Pseudocode*. 
G1 The AArch32 System Level Programmers' Model
G1.20 Configurable instruction enables and disables, and trap controls
Chapter G2
AArch32 Self-hosted Debug

When the PE is using self-hosted debug, it generates debug exceptions. This chapter describes the AArch32 self-hosted debug exception model. It is organized as follows:

Introductory information

- About self-hosted debug on page G2-4454.
- The debug exception enable controls on page G2-4458.

The debug Exception model

- Routing debug exceptions on page G2-4459.
- Enabling debug exceptions from the current Privilege level and Security state on page G2-4461.
- The effect of powerdown on debug exceptions on page G2-4463.
- Summary of permitted routing and enabling of debug exceptions on page G2-4464.
- Pseudocode description of debug exceptions on page G2-4466.

The debug exceptions

- Breakpoint Instruction exceptions on page G2-4467.
- Breakpoint exceptions on page G2-4470.
- Watchpoint exceptions on page G2-4496.
- Vector Catch exceptions on page G2-4510.

Synchronization requirements

The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a Context synchronization event guarantees the effects of the changes:

- Synchronization and debug exceptions on page G2-4518.
G2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of debug exceptions, that are taken using the exception model described in:

- Chapter D1 The AArch64 System Level Programmers’ Model, if the exception is taken to AArch64 state.
- Chapter G1 The AArch32 System Level Programmers’ Model, if the exception is taken to AArch32 state.

This section introduces some terms used in describing self-hosted debug, and then introduces the debug exceptions. See:

- Definition of a debugger in the context of self-hosted debug.
- Context ID and Process ID.

G2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, debugger means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

G2.1.2 Context ID and Process ID

In AArch32 state, the CONTEXTIDR identifies the current Context ID, that is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

When using the Long-descriptor translation table format, the CONTEXTIDR has a single field, PROCID, that is defined as the Process Identifier (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical when using this translation table format.

When using the Short-descriptor translation table format:

- CONTEXTIDR[31:0] defines the Context ID, that is used for breakpoint and watchpoint matching.
- CONTEXTIDR[31:8] defines the Process ID.
- CONTEXTIDR[7:0] define the ASID. See Global and process-specific translation table entries on page G4-4628. This means that, when using the Short-descriptor translation table format, the ASID is always bits[7:0] of the Context ID.

G2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions. The debug exceptions that can be generated in an AArch32 stage 1 translation regime are:

- Breakpoint Instruction exceptions on page G2-4455.
- Breakpoint exceptions on page G2-4455, generated by hardware breakpoints.
- Watchpoint exceptions on page G2-4456, generated by hardware watchpoints.
- Vector Catch exceptions on page G2-4456.

Note

In addition, Software Step exceptions can be generated in stage 1 of an AArch32 translation regime. However, these are always taken to AArch64 state. Software Step exceptions on page D2-1908 describes this.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.
2. A debugger has enabled that particular debug exception.

All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the DBGDSCRext. See The debug exception enable controls on page G2-4458.

--- Note ---

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

For the definition of halting is allowed, see Halting allowed and halting prohibited on page H2-5435.

When a debug exception is taken to an Exception level that is using AArch32:

- If the debug exception is a Watchpoint exception, it is taken as a Data Abort exception.
- Otherwise, it is taken as a Prefetch Abort exception.

The following list summarizes each of the debug exceptions:

**Breakpoint Instruction exceptions**

*Breakpoint instructions* generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A32 and T32 instruction sets is `BKPT #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

**PE behavior**

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Privilege level and AArch32 mode.
- The current Security state.

For more information, see Breakpoint Instruction exceptions on page G2-4467.

**Breakpoint exceptions**

The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address 0x1000 is committed for execution.

The ARMv8-A architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch32 translation regime:

- **Address:**
  - Address Match.
  - Address Mismatch.
  Comparisons are made with the virtual address of each instruction in the program flow.

- **Context:**
  - Context ID Match. Matches with the Context ID value held in the CONTEXTIDR.
  - VMID Match. Matches with the VMID value held in the VTTBR.
  - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match or mismatch occurs.

See Enabling debug exceptions from the current Privilege level and Security state on page G2-4461. Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see *Breakpoint exceptions on page G2-4470.*

**Watchpoint exceptions**

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range 0x1000 - 0x101F.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a Linked Context type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see *Watchpoint exceptions on page G2-4496.*

**Vector Catch exceptions**

These are used to trap exceptions. The ARMv8-A architecture provides two forms of vector catch, address-matching and exception-trapping. Only one form can be implemented.

Whichever form is implemented, a debugger must enable Vector Catch exceptions for one or more exception vectors by programming the DBGVCR. Generation of Vector Catch exceptions is then as follows:

- For the address-matching form, a Vector Catch exception is generated whenever the virtual address of an instruction matches a vector that Vector Catch exceptions are enabled for.
- For the Exception-trapping form, a Vector Catch exception is generated as part of exception entry for exception types that correspond to vectors that Vector Catch exceptions are enabled for.

**PE behavior**

If debug exceptions are:

- Enabled, Vector Catch exceptions can be generated.
- Disabled, vector catch is ignored.

For more information, see *Vector Catch exceptions on page G2-4510.*

Table G2-1 on page G2-4457 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.
## Table G2-1 PE behavior and pseudocode for each of the debug exceptions

<table>
<thead>
<tr>
<th>Debug exception</th>
<th>PE behavior if debug exceptions are:</th>
<th>Pseudocode</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td>Breakpoint Instruction exception</td>
<td>Takes Prefetch Abort exception</td>
<td>Takes Prefetch Abort exception</td>
</tr>
<tr>
<td>Breakpoint exception</td>
<td>Takes Prefetch Abort exception&lt;sup&gt;a&lt;/sup&gt;</td>
<td>Ignored</td>
</tr>
<tr>
<td>Watchpoint exception</td>
<td>Takes Data Abort exception&lt;sup&gt;a&lt;/sup&gt;</td>
<td>Ignored</td>
</tr>
<tr>
<td>Vector Catch exception</td>
<td>Takes Prefetch Abort exception</td>
<td>Ignored</td>
</tr>
</tbody>
</table>

<sup>a</sup> If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Chapter H2 Debug State.
G2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

**Breakpoint Instruction exceptions**

None. Breakpoint Instruction exceptions are always enabled.

**Breakpoint exceptions**

DBGDSCRext.MDBGen, plus an enable control for each breakpoint, DBGBCR<n>.E.

**Watchpoint exceptions**

DBGDSCRext.MDBGen, plus an enable control for each watchpoint, DBGWCR<n>.E.

**Vector Catch exceptions**

DBGDSCRext.MDBGen.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See Enabling debug exceptions from the current Privilege level and Security state on page G2-4461.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
## G2.3 Routing debug exceptions

Debug exceptions are usually routed to Abort mode. However, if EL2 is implemented, the routing of debug exceptions taken from Non-secure state depends on the Effective values of HDCR.TDE and HCR.TGE:

**If the Effective value of \{HDCR.TDE, HCR.TGE\} is not \{0, 0\}**

Debug exceptions taken from Non-secure state are routed to Hyp mode.

**Otherwise**

In Non-secure state debug exceptions behave as follows:

- Debug exceptions taken from Non-secure EL1 and Non-secure EL0 are routed to Non-secure Abort mode.
- Breakpoint Instruction exceptions taken from Hyp mode are routed to Hyp mode.
- All other debug exceptions are disabled from Hyp mode.

**Note**

If EL2 is not implemented, the Effective value of HCR.TGE is 0 and the Effective value of HDCR.TDE is 0.

Table G2-2, Table G2-3, and Table G2-4 show the routing of debug exceptions taken from an Exception level that is using AArch32 to an Exception level that is using AArch32. In these tables:

- **TDE** Means the logical OR of HDCR.TDE and HCR.TGE.
- **(Hyp mode)** Means:
  - All debug exceptions other than Breakpoint Instruction exceptions are disabled from this Privilege level.
  - Breakpoint Instruction exceptions taken from this Privilege level are taken to Hyp mode.

### Table G2-2 Routing when both EL3 and EL2 are implemented

G2.3.1  Pseudocode description of routing debug exceptions

`DebugTarget()` returns the current debug target Exception level. `DebugTargetFrom()` returns the debug target Exception level for the specified Security state.
**G2.4 Enabling debug exceptions from the current Privilege level and Security state**

A debug exception can only be taken if all of the following are true:

- The OS lock is unlocked.
- `DoubleLockStatus()` == FALSE.
- The debug exception is enabled from the current Privilege level.
- The debug exception is enabled from the current Security state.

Table G2-5 shows when debug exceptions are enabled from the current Privilege level.

<table>
<thead>
<tr>
<th>Current Privilege level</th>
<th>Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL2</td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td>PL1</td>

</tr>
<tr>
<td></td>
<td></td>
<td>See Disabling debug exceptions from Secure state.</td>
</tr>
</tbody>
</table>

**G2.4.1 Disabling debug exceptions from Secure state**

If EL3 is implemented, software executing at EL3 can enable or disable all debug exceptions taken from Secure PL1 other than Breakpoint Instruction exceptions, by using one of:

- The Secure Privileged Debug field, `SDCR.SPD`, if EL3 is using AArch32.
- The AArch32 Secure Privileged Debug field, `MDCR_EL3.SPD32`, if EL3 is using AArch64.

If debug exceptions are disabled from Secure PL1, software executing at Secure PL1 can set the Secure User Invasive Debug Enable bit, `SDER.SUIDEN`, to 1 to enable all debug exceptions taken from Secure PL0 other than Breakpoint Instruction exceptions.

--- **Note** ---

Breakpoint Instruction exceptions are always enabled.

--- **Note** ---

The ARMv8-A architecture does not support disabling debug in Non-secure state.

--- **Note** ---

If the boot software that is executed when reset is deasserted programs SUIDEN and SPD so that all debug exceptions are disabled from Secure state, software operating at EL3 never has to switch any of the debug registers between the Security states.
G2.4.2 Pseudocode description of enabling debug exceptions

`AArch64.GenerateDebugExceptions()` determines whether debug exceptions are enabled from the current Exception level and Security state. `AArch64.GenerateDebugExceptionsFrom()` determines whether debug exceptions are enabled from the specified Exception level and Security state.
G2.5 The effect of powerdown on debug exceptions

*Debug OS Save and Restore sequences on page H6-5541* describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and `doubleLockStatus() == FALSE`.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.
### G2.6 Summary of permitted routing and enabling of debug exceptions

Behavior is as follows:

**Breakpoint Instruction exceptions**

These are always enabled, regardless of the current Privilege level and Security state. Table G2-7 shows the routing of these. In the table, n/a means not applicable.

<table>
<thead>
<tr>
<th>Current Security state</th>
<th>HDCR.TDE(^a)</th>
<th>Target when enabled from:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>PL0</td>
</tr>
<tr>
<td>Secure</td>
<td>X</td>
<td>Secure Abort mode(^b)</td>
</tr>
<tr>
<td>Non-secure</td>
<td>0</td>
<td>Non-secure Abort mode</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>Hyp mode</td>
</tr>
</tbody>
</table>

\(^a\) If EL2 is not implemented, behavior is as if the value of this bit is 0. Otherwise, if the value of HCR.TGE is 1, HDCR.TDE is treated as being 1 other than for a direct read of HDCR.

\(^b\) If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1.

**All other debug exceptions**

The enabling and permitted routing is controlled by all of the following:

- SDCR.SPD.
- SDER.SUIDEN.
- HDCR.TDE.
- The IMPLEMENTATION DEFINED authentication interface.

Table G2-8 shows the valid combinations of the values of SDCR.SPD, SDER.SUIDEN, HDCR.TDE, and, in the Auth column, the input from the IMPLEMENTATION DEFINED authentication interface described by the pseudocode function AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled(). For each combination, the table shows where debug exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

---

<sup>a.</sup> The value of (O<sub>LSR_EL1.OSLK</sub> == 1 || DoubleLockStatus()).

<sup>b.</sup> If EL3 is not implemented, behavior is as if this is 0b11.

<sup>c.</sup> See the text that introduces this table for an explanation of the Auth on page G2-4464 column. An entry of TRUE indicates that the authentication mechanism permits the debug exceptions to be taken to their default target PE mode.

<sup>d.</sup> If HCR.TGE is 1, this bit is treated as being 1 other than for a direct read of HDCR. If EL2 is not implemented, behavior is as if TDE is 0.

<sup>e.</sup> If EL3 is implemented and is using AArch 32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1.
G2.7 Pseudocode description of debug exceptions

AArch32.DebugFault() returns a FaultRecord() that indicates that a memory access has generated a debug exception.

The AArch32.Abort() function processes FaultRecord(), as described in *Abort exceptions* on page G3-4555, and generates:

- Data Abort exceptions for watchpoints.
- Prefetch Abort exceptions for all other debug exceptions.
G2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch32 translation regime.

--- Note ---
When the PE is executing in EL0 using AArch32 and EL1 is using AArch64, it is using the AArch64 EL1&0 translation regime. A T32 or A32 BKPT instruction executed at EL0 can generate a Breakpoint Instruction exception that is taken to an Exception level that is using AArch64. For more information about the handling of these exceptions, see Breakpoint Instruction exceptions on page D2-1919.

It contains the following subsections:
- About Breakpoint Instruction exceptions.
- Breakpoint instruction in the A32 and T32 instruction sets.
- BKPT instructions as the first instruction in an IT block on page G2-4468.
- Exception syndrome information and preferred return address for a BKPT instruction on page G2-4468.
- Pseudocode description of Breakpoint Instruction exceptions on page G2-4469.

G2.8.1 About Breakpoint Instruction exceptions

A breakpoint is an event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
- The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint Instruction exceptions, that this section describes, are software breakpoints. Breakpoint exceptions on page G2-4470 describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:
- The current Exception level.
- The current Security state.
- Whether the debug target Exception level, EL_D, is using AArch64 or AArch32.

--- Note ---
- EL_D is the Exception level that debug exceptions are targeting. See Enabling debug exceptions from the current Privilege level and Security state on page G2-4461.
- Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See Concurrent modification and execution of instructions on page B2-84.

G2.8.2 Breakpoint instruction in the A32 and T32 instruction sets

The breakpoint instruction, in both instruction sets, is:
- `BKPT #<immediate>`

For details of the instruction encoding, see BKPT on page F5-3065.

About whether the BKPT instruction is conditional

In the T32 instruction set, BKPT instructions are always unconditional.

In the A32 instruction set:
- If the Condition code field is AL, the BKPT instruction is unconditional.
• If the Condition code field is anything other than AL, behavior is CONSTRAINED UNPREDICTABLE, and is one of the following:
  — The instruction is UNDEFINED.
  — The instruction is treated as a NOP instruction.
  — The instruction is executed unconditionally.
  — The instruction is executed conditionally.

G2.8.3 BKPT instructions as the first instruction in an IT block

If the first instruction in an IT block is a T32 BKPT instruction, then in an implementation that supports the ITD control, if ITD field that applies to the current Exception level is:

- 0 The BKPT instruction generates a Breakpoint Instruction exception.
- 1 The combination of IT instruction and BKPT instruction is UNDEFINED. Either the IT instruction or the BKPT instruction generates an Undefined Instruction exception.

In such an implementation, to ensure consistent behavior when making the first instruction in one or more IT blocks a BKPT instruction, the debugger must replace the IT instruction.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

The ITD control fields are:

**HSCTLR.ITD** Applies to execution at EL2 when EL2 is using AArch32.

**SCTLR.ITD** Applies to execution at EL0 or EL1 when EL1 is using AArch32.

**SCTLR_EL1.ITD** Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

Note

T32 BKPT instructions are always unconditional, even when they are inside an IT block. See:

- *Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality* on page G1-4421.
- *Disabling or enabling EL2 use of AArch32 deprecated functionality* on page G1-4430.

G2.8.4 Exception syndrome information and preferred return address for a BKPT instruction

See the following:

- *Exception syndrome information for a Breakpoint Instruction exception.*
- *Preferred return address for a Breakpoint Instruction exception* on page G2-4469.

Note

Usually, the term exception syndrome is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the IFSR.

**Exception syndrome information for a Breakpoint Instruction exception**

The PE takes a Breakpoint Instruction exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp Trap exception, if it is taken to PL2 because either HCR.TGE or HDCCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

**PL1 Abort mode**

The PE sets all of the following:

- `DBGDSCRext.MOE` to 0b0011, to indicate a Breakpoint Instruction exception.
• IFSR.FS to the code for a debug, 0b00010.
• The IFAR with an UNKNOWN value.

PL2 Hyp mode

The PE does all of the following:
• Records information about the exception in the Hypervisor Syndrome Register, HSR. See Table G2-9.
• Sets DBGDSRMOE to 0b0011, to indicate a Breakpoint Instruction exception.
• Sets the HIFAR to an UNKNOWN value.

### Note
For information about how debug exceptions can be routed to PL2, see Routing debug exceptions on page G2-4459.

### Preferred return address for a Breakpoint Instruction exception

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

### G2.8.5 Pseudocode description of Breakpoint Instruction exceptions

AArch32.SoftwareBreakpoint() generates a Prefetch Abort exception that is taken from AArch32 state.

### Table G2-9 Information recorded in the HSR

<table>
<thead>
<tr>
<th>HSR field</th>
<th>Information recorded</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
G2.9  Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:

- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

This section contains the following subsections:

- About Breakpoint exceptions.
- Breakpoint types and linking of breakpoints on page G2-4471.
- Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480.
- Breakpoint instruction address comparisons on page G2-4482.
- Breakpoint context comparisons on page G2-4487.
- Using breakpoints on page G2-4488.
- Exception syndrome information and preferred return address for a Breakpoint exception on page G2-4493.
- Pseudocode description of Breakpoint exceptions taken from AArch32 state on page G2-4494.

G2.9.1  About Breakpoint exceptions

A **breakpoint** is an event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a **hardware breakpoint**.
- The instruction itself. That is, the instruction is a **breakpoint instruction**. These can be included in the program that the PE executes. This type of breakpoint is called a **software breakpoint**.

**Breakpoint exceptions** are generated by **Breakpoint debug events**. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in **Breakpoint Instruction exceptions** on page G2-4467.

An implementation can include between 2-16 hardware breakpoints. DBGIDR.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The **Breakpoint Control Register**, DBGBCR<n>. This contains controls for the breakpoint, for example an enable control.
- The **Breakpoint Value Register**, DBGBVR<n>. This holds a value used for breakpoint matching, that is one of:
  - An instruction virtual address.
  - A Context ID.
- If EL2 is implemented, the **Breakpoint Extended Value Register**, DBGBXVR<n>, that holds a VMID value used for breakpoint matching.

These registers are numbered, so that:

- DBGBCR1, DBGBVR1, and DBGBXVR1 are for breakpoint number one.
- DBGBCR2, DBGBVR2, and DBGBXVR2 are for breakpoint number two.
- ...
- DBGBCR<n>, DBGBVR<n>, and DBGBXVR<n> are for breakpoint number <n>.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.
For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, DBGBCR<n>.E, is 1.
- The conditions specified in the DBGBCR<n> are met.
- The comparisons with the values held in one or both of the DBGBVR<n> and DBGBXVR<n>, as applicable, are successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its Condition code check.
- The instruction type.

If halting is allowed and EDSR.HDE is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are

- Enabled, Breakpoint debug events generate Breakpoint exceptions
- Disabled, Breakpoint debug events are ignored.

Note

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.

However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls on page G2-4458 describes the enable controls for Breakpoint debug events.

G2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A context-aware breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match.
  - An instruction address mismatch.
  - A Context ID match, with the value held in the CONTEXTIDR.
  - A VMID match, with the value held in the VTTBR.
  - Both a Context ID match and a VMID match.

- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match or an instruction address mismatch.

DBGDIDR.CTX_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match or mismatch is categorized as an Address breakpoint. Breakpoints that are programmed to match on anything else are categorized as Context breakpoints.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an Unlinked breakpoint.
- Enabled for linking to another breakpoint. In this case, the breakpoint is called a Linked breakpoint.
By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match or mismatch occurs. For example, a debugger might:

1. Program breakpoint number one to be a **Linked Address Match** breakpoint.
2. Program breakpoint number five to be a **Linked Context ID Match** breakpoint.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The **Breakpoint Type** field for a breakpoint, $\text{DBGBCR}<n>.BT$, controls the breakpoint type and whether the breakpoint is enabled for linking. If BT[0] is 1, the breakpoint is enabled for linking.

Figure G2-1 shows all of the possible breakpoint types that stage 1 of an AArch32 translation regime supports, and their associated BT field values.

Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See [*Specifying the halfword-aligned address that an Address breakpoint matches on*](#) on page G2-4482.
Rules for linking breakpoints

The rules for breakpoint linking are as follows:

• Only Linked breakpoint types can be linked.

• Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGBCR<\text{n}>.LBN, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  — DBGBCR<\text{n}>.{SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480.
  — DBGBCR<\text{n}>.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.

• Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.

• Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.

• If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See Other usage constraints for Address breakpoints on page G2-4492.

• If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.

• Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

  \textbf{Note}

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. Watchpoint exceptions on page G2-4496 describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

• Multiple Linked Address Match breakpoints.
• Multiple Linked Address Mismatch breakpoints.
• Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

Figure G2-2 on page G2-4474 shows an example of permitted breakpoint and watchpoint linking.
In Figure G2-2, each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

**Breakpoint types defined by DBGBCRn.BT**

The following list provides more detail about each breakpoint type:

0b0000, **Unlinked Address Match breakpoint**

Generation of a Breakpoint exception depends on both:

- **DBGBCR<n>.{SSC, HMC, PMC}.** These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-4480.

- A successful address match, as described in *Breakpoint instruction address comparisons* on page G2-4482.

**DBGBCR<n>.LBN** for this breakpoint is ignored.
0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- \texttt{DBGBCR}<n>.\{SSC, HMC, PMC\} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See \textit{Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480}.
- A successful address match defined by this breakpoint, as described in \textit{Breakpoint instruction address comparisons on page G2-4482}.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

\texttt{DBGBCR}<n>.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, Unlinked Context ID Match breakpoint

\texttt{BT} == 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- \texttt{DBGBCR}<n>.\{SSC, HMC, PMC\}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See \textit{Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480}.
- A successful Context ID match, as described in \textit{Breakpoint context comparisons on page G2-4487}.

The value of \texttt{DBGBVR}<n>[31:0] is compared with the current Context ID. \texttt{CONTEXTIDR_EL2} holds the current Context ID when all of:

- The implementation includes the Virtualization Host Extensions.
- The PE is in Non-secure state.
- \texttt{HCR_EL2.E2H} is set to 1.
- The PE is executing at EL0 and \texttt{HCR_EL2.TGE} is 1, or PE is executing at EL2.

Otherwise, \texttt{CONTEXTIDR} holds the current Context ID.

\texttt{DBGBCR}<n>.\{LBN, BAS\} for this breakpoint are ignored

0b0011, Linked Context ID Match breakpoint

\texttt{BT} == 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see \textit{Breakpoint instruction address comparisons on page G2-4482}.
  - A successful Context ID match defined by this breakpoint, as described in \textit{Breakpoint context comparisons on page G2-4487}.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see \textit{Watchpoint data address comparisons on page G2-4500}.
  - A successful Context ID match defined by this breakpoint, as described in \textit{Breakpoint context comparisons on page G2-4487}.

The value of \texttt{DBGBVR}<n>[31:0] is compared with the current Context ID. \texttt{CONTEXTIDR_EL2} holds the current Context ID when all of:

- The implementation includes the Virtualization Host Extensions.
- The PE is in Non-secure state.
- \texttt{HCR_EL2.E2H} is set to 1.
- The PE is executing at EL0 and \texttt{HCR_EL2.TGE} is 1, or PE is executing at EL2.
Otherwise, CONTEXTIDR holds the current Context ID.

DBGBCR<\n>.{LBN, SSC, HMC, BAS PMC} for this breakpoint are ignored.

0b0100, Unlinked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on both:

• DBGBCR<\n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480.

• A successful address mismatch, as described in Breakpoint instruction address comparisons on page G2-4482.

DBGBCR<\n>.LBN for this breakpoint is ignored.

0b0101, Linked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on all of the following:

• DBGBCR<\n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480.

• A successful address mismatch defined by this breakpoint, as described in Breakpoint instruction address comparisons on page G2-4482.

• A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

DBGBCR<\n>.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0110, Unlinked CONTEXTIDR_EL1 Match

BT == 0b0110 is a reserved value if either:

• The breakpoint is not a context-aware breakpoint.

• The implementation does not include ARMv8.1-VHE.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

• DBGBCR<\n>.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.

• A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-4487.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGBVR<\n>.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1. DBGBCR<\n>.{LBN, BAS} for this breakpoint are ignored.

0b0111, Linked CONTEXTIDR_EL1 Match

BT == 0b0111 is a reserved value if either:

• The breakpoint is not a context-aware breakpoint.

• The implementation does not include ARMv8.1-VHE.

For context-aware breakpoints, one of the following applies:

• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.

• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page G2-4482.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page G2-4487.
• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons* on page G2-4500.
  — A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons* on page G2-4487.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGVR<n>.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1. DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:
• DBGCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-4480.
• A successful VMID match, as described in *Breakpoint context comparisons* on page G2-4487.

DBGCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.
