0b1001, Linked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:
• The breakpoint is not a context-matching breakpoint.
• EL2 is not implemented.

For context-aware breakpoints, either:
• This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See *Breakpoint instruction address comparisons* on page G2-4482.
  — A successful VMID match defined by this breakpoint.

• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons* on page G2-4500.
  — A successful VMID match defined by this breakpoint, as described in *Breakpoint context comparisons* on page G2-4487.

DBGCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:
• The breakpoint is not a context-matching breakpoint.
• EL2 is not implemented.

For context-matching breakpoints, generation of a Breakpoint exception depends on all of the following:
• DBGCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-4480.
• A successful Context ID match, as described in *Breakpoint context comparisons* on page G2-4487.
The value of `DBGBVR<n>.ContextID` is compared with the current Context ID.

`CONTEXTIDR_EL2` holds the current Context ID when all of:

- The implementation includes `ARMv8.1-VHE`.
- The PE is in Non-secure state.
- EL2 using AArch64 and `HCR_EL2.E2H` is set to 1.
- The PE is executing at EL0 and `HCR_EL2.TGE` is 1, or the PE is executing at EL2.

Otherwise, `CONTEXTIDR` holds the current Context ID.

`Breakpoint context comparisons` on page G2-4487 describes the requirements for a successful Context ID match and a successful VMID match.

`DBGBCR<n>.{LBN, BAS}` for this breakpoint are ignored.

**0b1011, Linked Context ID and VMID Match breakpoint**

BT == 0b1011 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-matching breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on all of the following:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see `Breakpoint instruction address comparisons` on page G2-4482.
  - A successful Context ID match defined by this breakpoint, as described in `Breakpoint context comparisons` on page G2-4487.
  - A successful VMID match defined by this breakpoint.

- Generation of a Watchpoint exception depends on all of the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see `Watchpoint data address comparisons` on page G2-4500.
  - A successful Context ID match defined by this breakpoint, as described in `Breakpoint context comparisons` on page G2-4487.
  - A successful VMID match defined by this breakpoint.

The value of `DBGBVR<n>.ContextID` is compared with the current Context ID.

`CONTEXTIDR_EL2` holds the current Context ID when all of:

- The implementation includes `ARMv8.1-VHE`.
- The PE is in Non-secure state.
- EL2 using AArch64 and `HCR_EL2.E2H` is set to 1.
- The PE is executing at EL0 and `HCR_EL2.TGE` is 1, or the PE is executing at EL2.

Otherwise, `CONTEXTIDR` holds the current Context ID.

`Breakpoint context comparisons` on page G2-4487 describes the requirements for a successful Context ID match and a successful VMID match.

`DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC}` for this breakpoint are ignored.

**0b1100, Unlinked CONTEXTIDR_EL2 Match**

BT == 0b1100 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include `ARMv8.1-VHE`.
For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- \texttt{DBGBCR}^{<n>}.\{SSC, HMC, PMC\}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful \texttt{CONTEXTIDR\_EL2} match, as described in \textit{Breakpoint context comparisons} on page G2-4487.

The Context ID check is made against the value in \texttt{CONTEXTIDR\_EL2}. The value of check against \texttt{CONTEXTIDR\_EL2} means this breakpoint can be generated only if execution is in Non-secure state and EL2 is using AArch64.

\texttt{DBGBCR}^{<n>}.\{LBN, BAS\} for this breakpoint are ignored.

\textbf{0b1101, Linked \texttt{CONTEXTIDR\_EL2} Match}

\texttt{BT == 0b1101} is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.

For context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see \textit{Breakpoint instruction address comparisons} on page G2-4482.
  - A successful \texttt{CONTEXTIDR\_EL2} match, as described in \textit{Breakpoint context comparisons} on page G2-4487.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see \textit{Watchpoint data address comparisons} on page G2-4500.
  - A successful \texttt{CONTEXTIDR\_EL2} match, as described in \textit{Breakpoint context comparisons} on page G2-4487.

The Context ID check is made against the value in \texttt{CONTEXTIDR\_EL2}, regardless of the value of \texttt{HCR\_EL2.E2H}. The check against the \texttt{CONTEXTIDR\_EL2} means this breakpoint or watchpoint can be generated only if execution is in Non-secure state and EL2 is using AArch64.

\texttt{DBGBCR}^{<n>}.\{LBN, SSC, HMC, BAS, PMC\} for this breakpoint are ignored.

\textbf{0b1110, Unlinked Full Context ID Match}

\texttt{BT == 0b1110} is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- \texttt{DBGBCR}^{<n>}.\{SSC, HMC, PMC\}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in \textit{Breakpoint context comparisons} on page G2-4487.

The Context ID check is made by checking the value of \texttt{DBGBVR}^{<n>}.\texttt{ContextID} against the value in \texttt{CONTEXTIDR\_EL1} and the value of \texttt{DBGBXVR}^{<n>}.\texttt{ContextID} against the value in \texttt{CONTEXTIDR\_EL2}. Both comparisons must match for the check to succeed.

- The check against the \texttt{CONTEXTIDR\_EL2} means this breakpoint can be generated only if execution is in Non-secure state and EL2 is using AArch64.

\texttt{DBGBCR}^{<n>}.\{LBN, BAS\} for this breakpoint are ignored.
G2.9 Breakpoint exceptions

0b111, Linked Full Context ID Match

BT == 0b111 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page G2-4482.
  - A successful Context ID match, as described in Breakpoint context comparisons on page G2-4487.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page G2-4500.
  - A successful Context ID match, as described in Breakpoint context comparisons on page G2-4487.

The Context ID check is made by checking the value of DBGBVR<n>.ContextID against the value in CONTEXTIDR_EL1 and the value of DBGBXVR<n>.ContextID against the value in CONTEXTIDR_EL2. Both comparisons must match for the check to succeed.

- The check against the CONTEXTIDR_EL2 means this breakpoint or watchpoint can be generated only if execution is in Non-secure state and EL2 is using AArch64.

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

Note

See Reserved DBGBCR<n>.BT values on page G2-4490 for the behavior of breakpoints programmed with reserved BT values.

G2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at PL0 in Secure state.

DBGBCR<n>.{SSC, HMC, PMC} define the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

Note

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which AArch32 modes the breakpoint generates Breakpoint exceptions in.

Table G2-10 on page G2-4481 shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Privilege levels breakpoints generate Breakpoint exceptions in.
In the table:

- **Y or -** Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row:
  - **Y** Can generate Breakpoint exceptions in AArch32 modes at that Privilege level.
  - **-** Cannot generate Breakpoint exceptions in AArch32 modes at that Privilege level.

- **Res** Means that the combination of HMC, SSC, and PMC is reserved. See Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-4491.

**Table G2-10 Summary of breakpoint HMC, SSC, and PMC encodings**

</table>

<sup>a</sup> Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at PL2 using AArch32.

<sup>b</sup> Only in User, System and Supervisor modes.

<sup>c</sup> This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See Reserved HMC, SSC, and PMC combinations on page G2-4491.
### G2.9.4 Breakpoint instruction address comparisons

Address comparisons are made for each instruction in the program flow. The following subsections describe the criteria for a successful address comparison, for:

- **Address Match breakpoints**.
- **Address Mismatch breakpoints**.

#### Address Match breakpoints

An address match comparison is successful if both:

- Bits [31:2] of the current instruction virtual address are equal to DBGBVR<n>[31:2].
- The word or halfword selected by DBGBCR<n>.BAS matches. That is, either:
  - DBGBCR<n>.BAS is programmed with 0b0011 or 0b1111, and the instruction is at a word-aligned address.
  - DBGBCR<n>.BAS is programmed with 0b1100, and the instruction is not at a word-aligned address.

See [Specifying the halfword-aligned address that an Address breakpoint matches on](#).

---

**Note**

DBGBVR<n>[1:0] are RES0 and are ignored.

---

#### Address Mismatch breakpoints

An address mismatch comparison is successful if either:

- Bits [31:2] of the current instruction virtual address are not equal to DBGBVR<n>[31:2].
- The word or halfword selected by DBGBCR<n>.BAS does not match. That is, either:
  - DBGBCR<n>.BAS is programmed with 0b0011 or 0b1111, and the instruction is not at a word-aligned address.
  - DBGBCR<n>.BAS is programmed with 0b1100, and the instruction is at a word-aligned address.

See [Specifying the halfword-aligned address that an Address breakpoint matches on](#).

---

**Note**

- DBGBVR<n>[1:0] are RES0 and are ignored.
- Address Mismatch breakpoints can be used to single-step through code. See [Using an Address Mismatch breakpoint to single-step an instruction](#) on page G2-4488.

---

#### Specifying the halfword-aligned address that an Address breakpoint matches on

For an Address breakpoint, a debugger can use the *Byte Address Selection* field, DBGBCR<n>.BAS, so that the address comparison is successful on one of:

- The whole word starting at address DBGBVR<n>[31:2]:00.
- The halfword starting at address DBGBVR<n>[31:2]:00.
- The halfword starting at address ((DBGBVR<n>[31:2]:00) + 2).

---

**Note**

The address programmed into the DBGBVR<n> must be word-aligned.
DBGBCR<\text{n}>.BAS can be used in both Address Match breakpoints and Address Mismatch breakpoints, as follows:

- For an Address Match breakpoint, DBGBCR<\text{n}>.BAS selects which halfword-aligned address the breakpoint must generate a Breakpoint exception for. This means that an address comparison is successful only if both of the following match:
  - The instruction address held in bits [31:2] of the DBGBVR<\text{n}>.
  - The halfword defined by the BAS field.

  That is, a successful address comparison = DBGBVR<\text{n}>[31:2] match AND BAS match.

- For an Address Mismatch breakpoint, DBGBCR<\text{n}>.BAS selects which halfword-aligned address the breakpoint must not generate a Breakpoint exception for. This means that an address comparison is successful if either or both of the following do not match:
  - The instruction address held in bits [31:2] of the DBGBVR<\text{n}>.
  - The halfword defined by the BAS field.

  That is, a successful address comparison = NOT (DBGBVR<\text{n}>[31:2] match AND BAS match).

The following subsections show the supported BAS values:

- Using the BAS field in Address Match breakpoints.
- Using the BAS field in Address Mismatch breakpoints on page G2-4485.

For Context breakpoints, DBGBCR<\text{n}>.BAS is RES1 and is ignored.

**Using the BAS field in Address Match breakpoints**

The supported BAS values are:

- **0b0000**: This value is reserved. Behavior is a CONSTRAINED UNPREDICTABLE choice of:
  - The breakpoint is disabled.
  - The breakpoint behaves as if BAS is 0b0011, 0b1100, or 0b1111.

- **0b0011**: The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  - Bits [31:2] of the address equals DBGBVR<\text{n}>[31:2].
  - Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for T32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<\text{n}>[31:2]:00) - 2).

- **0b1100**: The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
  - Bits [31:2] of the address equals DBGBVR<\text{n}>[31:2].
  - Bits [1:0] of the address are 0b10.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for both of the following:

- 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
- 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction starting at a word-aligned address.
The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals DBGBVR<n>[31:2].
- Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for A32 instructions. It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) - 2).

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address ((DBGBVR<n>[31:2]:00) + 2).

All other BAS values are reserved. For these reserved other values, DBGBCR<n>.BAS[3,1] ignore writes and read the same values as DBGBCR<n>[2,0] respectively. This means that the smallest instruction size a debugger can program breakpoints to match on is a halfword.

Figure G2-3 on page G2-4485 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 2 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) + 2).
- Row 6 shows that a breakpoint with a BAS value of either 0b0011 or 0b1111 generates Breakpoint exceptions for A32 instructions. A32 instructions are always at word-aligned addresses.

In the figure:

- **Yes** Means that the breakpoint generates a Breakpoint exception.
- **No** Means that the breakpoint does not generate a Breakpoint exception.
- **UNP** Means that it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page G2-4492.
Using the BAS field in Address Mismatch breakpoints

An Address Mismatch breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed to match.

The supported BAS values are:

0b0000  The breakpoint ignores the address held in the DBGBVR<n> and generates Breakpoint exceptions for all instruction addresses.

0b0011  The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
• Bits [31:2] of the address equals DBGBVR<n>[31:2].
• Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:
• 32-bit T32 instructions at word-aligned addresses.
• 16-bit T32 instructions at word-aligned addresses.
• A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for T32 instructions.

It is CONSTRANIED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) - 2).

0b1100  The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
• Bits [31:2] equals DBGBVR<n>[31:2].
• Bits [1:0] of the address are 0b10.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for either of the following:
• 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
• 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction at a word-aligned address.

0b1111

The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals DBGBVR<n>[31:2].
- Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for A32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) - 2).

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address ((DBGBVR<n>[31:2]:00) + 2).

All other BAS values are reserved. For these reserved other values, DBGBCR<n>.BAS[3,1] ignore writes and read the same values as DBGBCR<n>[2,0] respectively. This means that the smallest instruction size that a breakpoint can never generate a Breakpoint exception for is a halfword.

Figure G2-4 on page G2-4487 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 1 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the word-aligned address held in the DBGBVR<n>.
- Row 5 shows that a breakpoint with a BAS value of 0b0011 generates Breakpoint exceptions for 32-bit T32 instructions starting at the halfword-aligned address immediately after the word aligned address held in the DBGBVR<n>.

In the figure:

- Yes Means that the breakpoint does generate a Breakpoint exception.
- No Means that the breakpoint does not generate a Breakpoint exception.
- UNP Means that it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page G2-4492.

<tr>
<td>0b110x</td>
<td>CONTEXTIDR_EL2 value matches DBGVR&lt;n&gt;.ContextID value</td>
</tr>
<tr>
<td>0b111x</td>
<td>CONTEXTIDR_EL1 value matches DBGVR&lt;n&gt;.ContextID value and CONTEXTIDR_EL2 value matches DBGVR&lt;n&gt;.ContextID value</td>
</tr>
</tbody>
</table>

No context comparison is required for other valid DBGBCR<n>.BT values.

In ARMv8.0 only, context breakpoints do not generate Breakpoint exceptions when execution is at EL2.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of CONTEXTIDR_EL1 and any of:
  - The PE is executing at EL3 using AArch64.

a. 0 means the word-aligned address held in the DBGVRn. The other locations are as follows:
  - -2 means ((DBGVRn[31:2]:00) - 2).
  - -1 means ((DBGVRn[31:2]:00) - 1).
  - ...
  - ...
  - +5 means ((DBGVRn[31:2]:00) + 5).

The solid areas show the location of the instruction.
The PE is executing at EL2.
— The Virtualization Host Extensions are implemented, EL2 is using AArch64, the PE is executing in Non-secure state, and HCR_EL2.\{E2H, TGE\} == \{1, 1\}.

- The comparison uses the value of CONTEXTIDR_EL2 and any of:
  — The Virtualization Host Extensions are not implemented.
  — The PE is in Secure state.
  — EL2 is using AArch32.

- The comparison uses the current VMID value and any of:
  — EL2 is not implemented.
  — The PE is in Secure state.
  — The PE is executing at EL2.
  — The Virtualization Host Extensions are implemented, EL2 is using AArch64, the PE is executing in Non-secure state, and HCR_EL2.\{E2H, TGE\} == \{1, 1\}.

The following Context breakpoint types do not generate Breakpoint exceptions in Secure state:
- VMID Match breakpoints.
- VMID and Context ID Match breakpoints.

---

**Note**

- For all Context breakpoints, DBGBCR\(<n>\.BAS is RES1 and is ignored.
- For Linked Context breakpoints, DBGBCR\(<n>\.\{LBN, SSC, HMC, PMC\} are RES0 and are ignored.

---

### G2.9.6 Using breakpoints

This section contains the following:
- *Using an Address Mismatch breakpoint to single-step an instruction*.
- *ITD control effects on address breakpoints on the first instruction in an IT block on page G2-4489*.
- *Breakpoint usage constraints on page G2-4490*.

**Using an Address Mismatch breakpoint to single-step an instruction**

In execution conditions that an Address Mismatch breakpoint matches, defined by DBGBCR\(<n>\.\{LBN, SSC, PMC\}, the breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed with. Figure G2-5 shows an example of Address Mismatch breakpoint operation, for an Address Mismatch breakpoint programmed with address 0x1014.

**Figure G2-5 Operation of an Address Mismatch breakpoint**

This means that an Address Mismatch breakpoint can be used to single-step an instruction.
In the example shown in Figure G2-5 on page G2-4488:

- If the target of a branch is an instruction other than the instruction at address 0x1014, the breakpoint generates a Breakpoint exception when the instruction is committed for execution.

- If the target of a branch is the instruction at address 0x1014, the PE executes the instruction at 0x1014 and the breakpoint does not generate a Breakpoint exception until the instruction at address 0x1018 is committed for execution. The instruction at address 0x1014 is therefore single-stepped.

However, if the instruction at 0x1014 generates a synchronous exception, or if the PE takes an asynchronous exception while the instruction is being stepped, the breakpoint is evaluated again after taking the exception. This means that behavior is as follows:

- If the exception handler executes in execution conditions that the breakpoint matches, the breakpoint generates a Breakpoint exception for the exception vector, because the exception vector is not address 0x1014. This means that software execution steps into the exception.

- If the exception handler executes in execution conditions that the breakpoint does not match, the breakpoint does not generate any Breakpoint exceptions after the PE has taken the exception, until the exception handler completes and executes an exception return instruction. The effect is to step over the exception. Whether the instruction is stepped again depends on whether the target of the exception return instruction is the instruction at 0x1014 or the instruction at 0x1018.

If the instruction at 0x1014 is single-stepped and branches to itself, it is constrained unpredictable whether the breakpoint generates a Breakpoint exception after the PE has executed the branch.

This means that an instruction is only single-stepped if it is the target of a branch instruction and its address matches the address the breakpoint is programmed for. In the example shown in Figure G2-5 on page G2-4488, this is 0x1014.

Usually this branch instruction is an exception return instruction that changes PE mode, branching from a PE mode in which the breakpoint does not generate a Breakpoint exception. A branch instruction that does not change PE mode would itself generate a Breakpoint exception. However, it might be a branch-to-self instruction as described above.

Because Address Mismatch breakpoints can single-step instructions, the behavior of an address mismatch Breakpoint exception is similar to the behavior of an AArch64 Software Step exception.

Note

- The example shown in Figure G2-5 on page G2-4488 assumes an A32 instruction. The same behavior applies for both 32-bit and 16-bit T32 instructions.

- Software Step exceptions are the highest priority synchronous exception. Breakpoint exceptions are lower priority. See Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827.

ITD control effects on address breakpoints on the first instruction in an IT block

In an implementation that supports the ITD control, if the value of the ITD field that applies to the current Exception level is 1, all of the following are true:

- An IT instruction can only be used to apply to one 16-bit T32 instruction.

- Only certain combinations of an IT instruction and second single 16-bit T32 instruction are permitted.

- For a permitted combination, it is implementation defined whether the implementation treats the combination as:
  - A pair of 16-bit instructions.
  - One 32-bit instruction.

If the implementation treats the combination as one 32-bit instruction, then as described in Other usage constraints for Address breakpoints on page G2-4492, an Address breakpoint might not generate a Breakpoint exception for an address match only on the second halfword of the instruction.
For this reason, if the ITD bit associated with the current Exception level is 1, ARM recommends that a debugger that wants to program a breakpoint to match on the second T32 instruction programs it to match on the IT instruction instead.

However, if returning from an exception whose preferred return address is the address of the second T32 instruction, then because the debugger is aware that the implementation has treated the combination as a pair of 16-bit instructions, the debugger is permitted to program the breakpoint to match on the second T32 instruction.

The ITD control fields are:
- **HSCTLR.ITD** Applies to execution at EL2 when EL2 is using AArch32.
- **SCTLR.ITD** Applies to execution at EL0 or EL1 when EL1 is using AArch32.
- **SCTLR_EL1.ITD** Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0, and therefore the information in this section does not apply to such an implementation.

---

**Note**

Programming the breakpoint to match on the second T32 instruction might be necessary when using an Address Mismatch breakpoint for single stepping.

---

### Breakpoint usage constraints

See the following sections:

- *Reserved DBGBCR<{}>.BT values.*
- *Reserved DBGBCR<{}>.{SSC, HMC, PMC} values* on page G2-4491.
- *Reserved DBGBCR<{}>.BAS values* on page G2-4491.
- *Reserved DBGBCR<{}>.LBN values* on page G2-4492.
- *Other usage constraints for Address breakpoints* on page G2-4492.
- *Other usage constraints for Context breakpoints* on page G2-4493.

#### Reserved DBGBCR<{}>.BT values

Table G2-12 shows when particular DBGBCR<{}>.BT values are reserved.

<table>
<thead>
<tr>
<th>BT value</th>
<th>Breakpoint type</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b001x</td>
<td>Context ID Match</td>
<td>For non context-aware breakpoints</td>
</tr>
<tr>
<td>0b010x</td>
<td>Address Mismatch</td>
<td>If EDSCR.HDE is 1 and halting is allowed</td>
</tr>
<tr>
<td>0b011x</td>
<td>CONTEXTIDR_EL1 Match</td>
<td>When ARMv8.1-VHE is not implemented and breakpoints are not context-aware</td>
</tr>
<tr>
<td>0b100x</td>
<td>VMID Match</td>
<td>For non context-aware breakpoints, or if EL2 is not implemented</td>
</tr>
<tr>
<td>0b101x</td>
<td>Context ID and VMID Match</td>
<td></td>
</tr>
<tr>
<td>0b110x</td>
<td>CONTEXTIDR_EL2 Match</td>
<td>When ARMv8.1-VHE is not implemented and breakpoints are not context-aware</td>
</tr>
<tr>
<td>0b111x</td>
<td>Full Context ID Match</td>
<td></td>
</tr>
</tbody>
</table>

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
— Programmed with a BT value that is not reserved, other than for a direct or external read of DBGBCR<n>.

• For a direct or external read of DBGBCR<n>, if the reserved BT value:
  — Has no function for any execution conditions, the value read back is UNKNOWN.
  — Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGBCR<n>.{SSC, HMC, PMC} values**

Table G2-13 shows when particular combinations of DBGBCR<n>.{SSC, HMC, PMC} are reserved in stage 1 of an AArch32 translation regime.

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10.</td>
<td>When EL3 is not implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b0</td>
<td>When both of EL2 and EL3 are not implemented</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b0</td>
<td>When EL2 is not implemented</td>
</tr>
<tr>
<td>Combinations not included in Table G2-10 on page G2-4481</td>
<td>Always</td>
</tr>
</tbody>
</table>

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

• If the reserved combination has a function for other execution conditions:
  — The breakpoint must behave as if it is disabled.
  — A direct or external read of DBGBCR<n>.{SSC, HMC, PMC} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.

• If the reserved combination does not have a function for other execution conditions:
  — It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  — A direct or external read of DBGBCR<n>.{SSC, HMC, PMC} returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:

• The values of HMC, SSC, and PMC are ignored.
• A direct or external read of DBGBCR<n>.{SSC, HMC, PMC} returns UNKNOWN values

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGBCR<n>.BAS values**

For all Context breakpoints

DBGBCR<n>.BAS is RES1 and is ignored.
For all Address breakpoints

The supported values of the BAS field for the Address Match and Address Mismatch breakpoints are shown in Specifying the halfword-aligned address that an Address breakpoint matches on on page G2-4482.

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BAS value that is not reserved, other than for a direct or external read of DBGBCR<n>.

- A direct or external read of DBGBCR<n>.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved DBGBCR<n>.LBN values

For all Context breakpoints

DBGBCR<n>.LBN reads UNKNOWN and its value is ignored.

For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any DBGBCR<n>.LBN value that is not for a context-aware breakpoint is reserved. If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGBCR<n>.LBN return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint that links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Address breakpoints

DBGBCR<n>.LBN reads UNKNOWN and its value is ignored.

Other usage constraints for Address breakpoints

For all Address breakpoints

- DBGBVR<n>[1:0] are RES0 and are ignored.
- The DBGBXVR<n> is ignored.

For Address Match breakpoints

- For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
- If DBGBCR<n>.BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address ((DBGBVR<n>[31:2]:00) + 2). For T32 instructions, ARM recommends that the debugger programs the BAS field with either 0b0111 or 0b1100.

For Address Mismatch breakpoints

The constraints are the same as those described in For Address Match breakpoints, except that if two Address Mismatch breakpoints are programmed to match in the same Exception level and Security state, it is CONSTRAINED UNPREDICTABLE whether or not the instruction is stepped or a Breakpoint debug even is generated.
Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of DBGBVR<n> and DBGBXVR<n> that are not used to specify Context ID or VMID are RES0 and are ignored.

--- Note ---
This means that for Context ID Match breakpoints, the DBGBXVR<n> is RES0 and is ignored, and for VMID Match breakpoints, the DBGBVR<n> is RES0 and is ignored.

---

For Linked Context breakpoints

If no Linked Address breakpoints or Linked Watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

G2.9.7 Exception syndrome information and preferred return address for a Breakpoint exception

See the following:

- Exception syndrome information for a Breakpoint exception.
- Preferred return address for a Breakpoint exception on page G2-4494.

--- Note ---
Usually, the term exception syndrome is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the IFSR.

---

Exception syndrome information for a Breakpoint exception

The PE takes a Breakpoint exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

Abort mode

The PE sets all of the following:

- DBGDSCRext.MOE to 0b0001, to indicate a Breakpoint exception.
- IFSR.FS to the code for a debug exception, 0b0010.
- The IFAR with an UNKNOWN value.
Hyp mode

The PE does all of the following:

- Records information about the exception in the Hypervisor Syndrome Register, HSR. See Table G2-14.
- Sets DBGDSCRext.MOE to 0b0001, to indicate a Breakpoint exception.
- Sets the HIFAR to an UNKNOWN value.

Table G2-14 Information recorded in the HSR

<table>
<thead>
<tr>
<th>HSR field</th>
<th>Information recorded</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception Class, EC</td>
<td>The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, 0x20.</td>
</tr>
<tr>
<td>Instruction Length, IL</td>
<td>The PE sets this to 1.</td>
</tr>
<tr>
<td>Instruction Specific Syndrome, ISS</td>
<td></td>
</tr>
<tr>
<td>ISS[24:10]</td>
<td>RES0.</td>
</tr>
<tr>
<td>ISS[9]</td>
<td>External Abort type (EA). The PE sets this to 0.</td>
</tr>
<tr>
<td>ISS[8:6]</td>
<td>RES0.</td>
</tr>
<tr>
<td>ISS[5:0]</td>
<td>Instruction Fault Status Code (IFSC). The PE sets this to the code for a debug exception, 0b100010.</td>
</tr>
</tbody>
</table>

Note

For information about how debug exceptions can be routed to PL2, see Routing debug exceptions on page G2-4459.

Preferred return address for a Breakpoint exception

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

G2.9.8 Pseudocode description of Breakpoint exceptions taken from AArch32 state

AArch32.BreakpointValueMatch() returns a pair of results:

- A result for Address Match and Context breakpoints.
- A result for Address Mismatch breakpoints.

AArch32.StateMatch() tests the values in DBGBCR<n>.{SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

AArch32.BreakpointMatch() tests a committed instruction against all breakpoints.

AArch32.CheckBreakpoint() generates a FaultRecord. A Breakpoint exception is taken if all of the following are true:

- DBGDSCRext.MDBGen is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Privilege level and Security state on page G2-4461.
- All of the conditions required for Breakpoint exception generation are met. See About Breakpoint exceptions on page G2-4470.

Note

AArch32.CheckBreakpoint() might halt the PE and cause it to enter Debug state. External debug uses Debug state.
The `AArch32.Abort()` function processes the `FaultRecord` object returned by `AArch32.CheckBreakpoint()`, as described in `Abort exceptions` on page G3-4555. When a Breakpoint exception is taken to AArch32 state, the `AArch32.Abort()` function generates a Prefetch Abort exception.
G2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:

- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

This section contains the following subsections:

- About Watchpoint exceptions.
- Watchpoint types and linking of watchpoints.
- Execution conditions for which a watchpoint generates Watchpoint exceptions.
- Watchpoint data address comparisons.
- Determining the memory location that caused a Watchpoint exception.
- Watchpoint behavior on other instructions.
- Usage constraints.
- Exception syndrome information and preferred return address.
- Pseudocode description of Watchpoint exceptions taken from AArch32 state.

G2.10.1 About Watchpoint exceptions

A watchpoint is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as data breakpoints.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a Watchpoint debug event on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, DBGDIDR.WRPs shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The Watchpoint Control Register, DBGWCR<n>. This holds control information for the watchpoint, for example an enable control.
- The Watchpoint Value Register, DBGWVR<n>. This holds the data virtual address used for watchpoint matching.

The registers are numbered, so that:

- DBGWCR1 and DBGWVR1 are for watchpoint number one.
- DBGWCR2 and DBGWVR2 are for watchpoint number two.
- ...
- ...
- DBGWCRn and DBGWVRn are for watchpoint number n.

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a Linked Context breakpoint, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.
A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the Byte Address Select field, DBGWCR<n>.BAS, to select the bytes. See Programming a watchpoint with eight bytes or fewer on page G2-4501.

- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

A debugger uses the MASK field, DBGWCR<n>.MASK, to program a watchpoint with eight bytes to 2GB. See Programming a watchpoint with eight or more bytes on page G2-4503.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint exceptions is CONSTRAINED UNPREDICTABLE. See Programming dependencies of the BAS and MASK fields on page G2-4506.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, DBGWCR<n>.E, is 1.
- The conditions specified in the DBGWCR<n> are met.
- The comparison with the address held in the DBGWVR<n> is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint are successful. See on page G2-4474 shows this. See also Breakpoint context comparisons on page G2-4487.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.

If halting is allowed and EDSCR.HDE is 1, Watchpoint debug events cause entry to Debug state. Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

--- Note ---

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

--- The debug exception enable controls on page G2-4458 describes the enable controls for Watchpoint debug events. ---
G2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an Unlinked watchpoint.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a Linked watchpoint.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a Linked VMID Match breakpoint.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The Watchpoint Type field for a watchpoint, DBGWCR<\n>WT, controls whether the watchpoint is enabled for linking. If DBGWCR<\n>WT is 1, the watchpoint is enabled for linking.

Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGWCR<\n>LBN, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
  - DBGWCR<\n>WT.\{SSC, HMC, PAC\} for the Linked watchpoint define the execution conditions that the watchpoint generates Watchpoint exceptions for. See Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-4499.
  - DBGBCR<\n>\{SSC, HMC, PMC\} for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See Usage constraints on page G2-4505.
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

--- Note

Multiple Address breakpoints can also link to a single Linked Context breakpoint. Breakpoint exceptions on page G2-4470 describes breakpoints.

Figure G2-2 on page G2-4474 shows an example of permitted watchpoint linking.
G2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL2.

DBGWCR<\text{n}>.\{SSC, HMC, PAC\} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

\textbf{Note}\hspace{1cm}This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Privilege level the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level or Privilege level at which the access was made.

\textbf{Note}\hspace{1cm}This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at PL1, the resulting data access triggers a watchpoint only if both:
- PAC is programmed to a value that generates watchpoints on PL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A32/T32 Load unprivileged and Store unprivileged instructions are LDRT and STRT.

Table G2-15 on page G2-4500 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Privilege levels watchpoints generate Watchpoint exceptions in.

In the table:

\textbf{Y} or -\hspace{1cm}Y or -
-\hspace{1cm}Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:
-\hspace{1cm}Can generate Watchpoint exceptions at that Privilege level.
-\hspace{1cm}Cannot generate Watchpoint exceptions at that Privilege level.

\textbf{Res}\hspace{1cm}Res
-\hspace{1cm}Means that the combination of HMC, SSC, and PAC is reserved. See \textit{Reserved DBGWCR<\text{n}>.\{SSC, HMC, PAC\} values} on page G2-4506.
All combinations of HMC, SSC, and PAC that this table does not show are reserved. See Reserved \textit{DBGWCR\textless{}n\textgreater{}}, \(\text{SSC, HMC, PAC}\) values on page G2-4506.

### G2.10.4 Watchpoint data address comparisons

An address comparison is successful if bits [31:2] of the current data virtual address are equal to \texttt{DBGWVR\textless{}n\textgreater{}}[31:2], taking into account all of the following:

- The size of the access. See Size of the data access on page G2-4501.
- The bytes selected by \texttt{DBGWVR\textless{}n\textgreater{}}.BAS. See Programming a watchpoint with eight bytes or fewer on page G2-4501.
- Any address ranges indicated by \texttt{DBGWVR\textless{}n\textgreater{}}.MASK. See Programming a watchpoint with eight or more bytes on page G2-4503.

\textbf{Note}\quad \texttt{DBGWVR\textless{}n\textgreater{}}[1:0] are RES0 and are ignored.
Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each access must be taken into account. See Example G2-1.

Example G2-1

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address \texttt{0x1009} is accessed.
2. The PE accesses the unaligned doubleword starting at address \texttt{0x1003}.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by \texttt{DCIMVAC} instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that CTR.DminLine defines.
  - 2KB.
- A power-of-two.

The lowest address accessed by a \texttt{DCIMVAC} instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.

The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, \textit{Watchpoint behavior on accesses by DCIMVAC instructions} on page G2-4505.

Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, DBGWCR<n>.BAS, selects which bytes in the doubleword starting at the address contained in the DBGWVR<n> the watchpoint generates Watchpoint exceptions for.

If the address programmed into the DBGWVR<n> is:

- Doubleword-aligned:
  - All eight bits of DBGWCR<n>.BAS are used, and the descriptions given in Table G2-16 apply.
- Word-aligned but not doubleword-aligned:
  - Only DBGWCR<n>.BAS[3:0] are used, and the descriptions given in Table G2-17 on page G2-4502 apply. In this case, DBGWCR<n>.BAS[7:4] are RES0.

Table G2-16 Supported BAS values when the DBGWVRn address alignment is doubleword

<table>
<thead>
<tr>
<th>BAS value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000000</td>
<td>Watchpoint never generates a Watchpoint exception</td>
</tr>
<tr>
<td>BAS[0] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;n&gt;[31:3]:000 is accessed</td>
</tr>
<tr>
<td>BAS[1] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;n&gt;[31:3]:001 is accessed</td>
</tr>
<tr>
<td>BAS[2] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;n&gt;[31:3]:010 is accessed</td>
</tr>
<tr>
<td>BAS[3] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;n&gt;[31:3]:011 is accessed</td>
</tr>
<tr>
<td>BAS[4] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;n&gt;[31:3]:100 is accessed</td>
</tr>
</tbody>
</table>
If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see Other usage constraints on page G2-4507.

When programming the BAS field with anything other than 0b11111111, a debugger must also program DBGWCR<el1>.MASK to be 0b00000. See Programming dependencies of the BAS and MASK fields on page G2-4506.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the DBGWVR<el1>[31:3]. See Example G2-1 on page G2-4501.

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  - DBGWVR<el1> with 0x1000.
  - DBGWCR<el1>.BAS to be 0b00001000.

- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
  - DBGWVR<el1> with 0x2000.
  - DBGWCR<el1>.BAS to be 0b00111000.

- If the address programmed into the DBGWVR<el1> is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program DBGWCR<el1>.BAS to be 0b00001111.
  - To generate a Watchpoint exception when any byte in the word starting at address DBGWVR<el1>[31:3]:100 is accessed, program DBGWCR<el1>.BAS to be 0b11110000.

### Table G2-16 Supported BAS values when the DBGWVRn address alignment is doubleword

<table>
<thead>
<tr>
<th>BAS value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BAS[5] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;el1&gt;[31:3]:101 is accessed</td>
</tr>
<tr>
<td>BAS[6] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;el1&gt;[31:3]:110 is accessed</td>
</tr>
<tr>
<td>BAS[7] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;el1&gt;[31:3]:111 is accessed</td>
</tr>
</tbody>
</table>

### Table G2-17 Supported BAS values when the DBGWVRn address alignment is word

<table>
<thead>
<tr>
<th>BAS value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000000</td>
<td>Watchpoint never generates a Watchpoint exception</td>
</tr>
<tr>

</tr>
</tbody>
</table>

a. DBGWCR<el1>:BAS[7:4] are RES0.
ARM deprecates programming a DBGWVR with an address that is not doubleword-aligned.

--- Note ---

Programming a watchpoint with eight or more bytes

A debugger can use the MASK field, DBGWCR.MASK, to program a single watchpoint with a data address range. The data address range must meet all of the following criteria:

- It is a size that is both:
  - A power-of-two.
  - A minimum of eight bytes.
  - A maximum of 2GB.
- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

<table>
<thead>
<tr>
<th>MASK</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000</td>
<td>No bits are masked.</td>
</tr>
<tr>
<td>0b00001</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0b00010</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0b00011</td>
<td>Three least significant bits are masked.</td>
</tr>
<tr>
<td>0b00100</td>
<td>Four least significant bits are masked.</td>
</tr>
<tr>
<td>0b00101</td>
<td>Five least significant bits are masked.</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>0b11111</td>
<td>31 least significant bits are masked.</td>
</tr>
</tbody>
</table>

If \( n \) least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address DBGWVR[31:31-n]:000...
- Address DBGWVR[31:31-n]:111...
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between DBGWVR[31:4]:0000 and DBGWVR[31:4]:1111, including these addresses.

--- Note ---

The most significant bit cannot be masked. This means that the full address cannot be masked.

- For watchpoint behavior when its MASK field is programmed with a reserved value, see Reserved DBGWCR.MASK values on page G2-4507.

When masking address bits, a debugger must both:

- Program DBGWCR.BAS to be 0b11111111. See Programming dependencies of the BAS and MASK fields on page G2-4506.
- In the DBGWVR, set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see Other usage constraints on page G2-4507.
G2.10.5 Determining the memory location that caused a Watchpoint exception

On a Watchpoint exception, the PE records an address in a Fault Address Register that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- DFAR, if the exception is taken to PL1.
- HDFAR, if the exception is taken to PL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the EDWAR.

--- Note ---

If Debug state was entered from AArch32 state, then EDWAR[63:32] is UNKNOWN and must be ignored by the debugger.

---

For more information, see the subsections that follow. These are:

- Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions.
- Address recorded for Watchpoint exceptions generated by Data Cache instructions on page G2-4505.

Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions

The address recorded must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access that triggered the watchpoint.
  - The highest watchpointed address accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.

- Within a naturally-aligned block of memory that is all of the following:
  - A power-of-two size.
  - No larger than 2KB.
  - No larger than the block size used by the A64 DC ZVA instruction.

--- Note ---

There are no architectural means to discover the A64 DC ZVA instruction block size from AArch32 state.

---

- Contains a watchpointed address accessed by the memory access.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

--- Example G2-2 Address recorded for a watchpoint programmed on 0x8019 ---

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:

- 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
- 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.
Address recorded for Watchpoint exceptions generated by Data Cache instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

G2.10.6 Watchpoint behavior on other instructions

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Preload instructions.
- All data cache maintenance instructions except DCIMVAC.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an IMPLEMENTATION DEFINED subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are IMPLEMENTATION DEFINED.

The access size of the IMPLEMENTATION DEFINED instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

See also:
- Watchpoint behavior on accesses by Store-Exclusive instructions.
- Watchpoint behavior on accesses by DCIMVAC instructions.

Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

Watchpoint behavior on accesses by DCIMVAC instructions

It is IMPLEMENTATION DEFINED whether DCIMVAC operations can generate Watchpoint exceptions. If they can, they are treated as data stores. This means that for a watchpoint to match on an access caused by a DCIMVAC instruction, the debugger must program DBGWCR<n>.LSC to be one of the following:

- Match on data stores only.
- Match on data stores and data loads.

Note

For the size of data accesses performed by DCIMVAC instructions, see Watchpoint data address comparisons on page G2-4500. The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

G2.10.7 Usage constraints

See the following:

- Reserved DBGWCR<n>.[SSC, HMC, PAC] values on page G2-4506.
- Reserved DBGWCR<n>.[LBN] values on page G2-4506.
- Programming dependencies of the BAS and MASK fields on page G2-4506.
- Reserved DBGWCR<n>.[BAS] values on page G2-4507.
- Reserved DBGWCR<n>.[MASK] values on page G2-4507.
- Other usage constraints on page G2-4507.
Reserved DBGWCR<n>.{SSC, HMC, PAC} values

Table G2-18 shows when particular combinations of DBGWCR<n>.{SSC, HMC, PAC} are reserved.

### Table G2-18 Reserved SSC, HMC, and PAC combinations

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10.</td>
<td>When EL3 is not implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>All combinations where HMC or SSC is nonzero, except for the</td>
<td>When both of EL2 and EL3 are not implemented.</td>
</tr>
<tr>
<td>combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00.</td>
<td></td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00.</td>
<td>When EL2 is not implemented.</td>
</tr>
<tr>
<td>Combinations not included in Table G2-15 on page G2-4500.</td>
<td>Always</td>
</tr>
</tbody>
</table>

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct or external read of DBGWCR<n>.
- For a direct or external read of DBGWCR<n>, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGWCR<n>.LBN values

For Linked watchpoints

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGWCR<n>.LBN return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked watchpoints

For Unlinked watchpoints, DBGWCR<n>.LBN reads UNKNOWN and its value is ignored.

Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n> the watchpoint must generate Watchpoint exceptions for.
If the debugger uses the:

- **MASK field**, it must program BAS to be 0b11111111, so that all bytes in the doubleword or word are selected.
- **BAS field**, it must program MASK to be 0b000000, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is non-zero and a BAS field that is not set to 0b11111111, then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

**Reserved DBGWCR<n>.BAS values**

The BAS field must be programmed with a value $\text{Zeros}(8-n-m):\text{Ones}(n):\text{Zeros}(m)$, where:

- $n$ is a non-zero positive integer less-than-or-equal-to 8.
- $m$ is a positive integer less-than 8.
- $n+m$ is less-than-or-equal-to 8.

All other values are reserved.

---

**Note**

If $x$ is zero, then $\text{Zeros}(x)$ is an empty bitstring.

---

If DBGWVR<n>[2] is 1, DBGWCR<n>.BAS[7:4] are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the DBGWVR<n>.
- A direct or external read of DBGWCR<n>.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

**Reserved DBGWCR<n>.MASK values**

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with an UNKNOWN value that is not reserved, that might be 0b000000, other than for a direct or external read of DBGWCR<n>.
- A direct or external read of DBGWCR<n>.MASK returns an UNKNOWN value.

**Other usage constraints**

For all watchpoints:

- DBGWVR<n>[1:0] are RES0 and are ignored.
- If DBGWCR<n>.MASK is nonzero, and any masked bits of DBGWVR<n> are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if DBGWCR<n>.LSC is 0b00.
G2.10.8 Exception syndrome information and preferred return address

See the following:

- Exception syndrome information.
- Preferred return address on page G2-4509.

Exception syndrome information

The PE takes a Watchpoint exception as either:

- A Data Abort exception, if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

Abort mode

The PE sets all of the following:

- DBGDSCRext.MOE to 0b1010, to indicate a Watchpoint exception.
- DFSR.CM to indicate whether a cache maintenance instruction caused the exception.
- DFSR.WnR to indicate whether the exception was generated on a read instruction or a write instruction.
- DFAR to an address that the debugger can use to determine the memory location that triggered the watchpoint. See Determining the memory location that caused a Watchpoint exception on page G2-4504.

In addition, if using the:

- Short-descriptor format, the PE sets DFSR.FS to the code for a debug exception, 0b00010, and DFSR.Domain to an UNKNOWN value.
- Long-descriptor format, the PE sets DFSR.STATUS to the code for a debug exception, 0b100010.

Hyp mode

The PE does all of the following:

- Records information about the exception in the Hypervisor Syndrome Register, HSR. See Table G2-19 on page G2-4509.
- Sets DBGDSCRext.MOE to 0b1001, to indicate a Watchpoint exception.
- Sets the HDFAR to an address that the debugger can use to determine the memory location that triggered the watchpoint. See Determining the memory location that caused a Watchpoint exception on page G2-4504.
For information about how debug exceptions can be routed to PL2, see Routing debug exceptions on page G2-4459.

**Preferred return address**

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

### Table G2-19 Information recorded in the HSR

<table>
<thead>
<tr>
<th>HSR field</th>
<th>Information recorded</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception Class, EC</td>
<td>The PE sets this to the code for a Data Abort exception routed to Hyp mode, 0x24.</td>

</tr>
</tbody>
</table>

**Note**

For information about how debug exceptions can be routed to PL2, see Routing debug exceptions on page G2-4459.

### Pseudocode description of Watchpoint exceptions taken from AArch32 state

`AArch32.WatchpointByteMatch()` tests an individual byte accessed by an operation.

`AArch32.StateMatch()` tests the values in DBGWCR<n>.{HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

`AArch32.WatchpointMatch()` tests the value in DBGWVR<n>.

`AArch32.CheckWatchpoint()` generates a FaultRecord. A Watchpoint exception is taken if all of the following are true:

- `DBGDSCRext.MDBGen` is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Privilege level and Security state on page G2-4461.
- All of the conditions required for Watchpoint exception generation are met. See About Watchpoint exceptions on page G2-4496.

**Note**

`AArch32.CheckWatchpoint()` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The `AArch32.Abort()` function processes the FaultRecord object returned by `AArch32.CheckWatchpoint()`, as described in Abort exceptions on page G3-4555. If a Watchpoint exception is taken to AArch32 state, the `AArch32.Abort()` function generates a Data Abort exception.
G2.11 Vector Catch exceptions

ARM deprecates the use of vector catch.

This section describes Vector Catch exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:
• At EL1 or higher in an Exception level that is using AArch32.
• At EL0 using AArch32 when EL1 is using AArch32.

--- Note ---
Vector Catch exceptions cannot be generated when the PE is using an AArch64 translation regime.

This section contains the following subsections:
• About Vector Catch exceptions.
• Exception vectors that Vector Catch exceptions can be enabled for on page G2-4512.
• Generation of Vector Catch exceptions on page G2-4513.
• Usage constraints on page G2-4515.
• Exception syndrome information and preferred return address for a Vector Catch exception on page G2-4516.
• Pseudocode description of Vector Catch exceptions on page G2-4517.

G2.11.1 About Vector Catch exceptions

Whenever the PE takes an exception, execution is forced to an address that is the exception vector for that exception. Vector catch permits a debugger to trap exceptions based on the exception vector, or based on the exception type associated with the exception vector, as follows:

• If the address-matching form of vector catch is implemented, the debugger can trap exceptions based on the exception vector.
• If the exception-trapping form of vector catch is implemented, the debugger can trap exceptions based on the exception type associated with the exception vector.

The ARMv8-A architecture supports only these two forms of vector catch. Only one form can be implemented, and which is implemented is IMPLEMENTATION DEFINED. The DBGDEVID indicates which form is implemented.

Regardless of the form of vector catch implemented, a debugger enables Vector Catch exceptions for exception vectors or types by programming the DBGVCR. This register contains vector catch enable bits. Each of these bits corresponds to a different vector. When a debugger sets a vector catch enable bit to 1, Vector Catch exceptions are enabled for the corresponding exception vector or type.

--- Note ---
EL2 using AArch64 or EL3 using AArch64 can enable Vector Catch exceptions for vectors by programming the DBGVCR32_EL2. The DBGVCR32_EL2 is architecturally mapped to the DBGVCR.

When Vector Catch exceptions are enabled for an exception vector, this is called an enabled vector catch. The set of exception vectors that Vector Catch exceptions are enabled for is called the enabled vector catch set.

If the form of vector catch implemented is the:

**Address-matching form:**

The PE compares the virtual address of each instruction in the program flow with a subset of the enabled vector catch set.

If an address match occurs, a Vector Catch exception is generated when the instruction that caused the match is committed for execution.
Exception-trapping form

Whenever the PE takes an exception, if the vector the exception is taken to is included in a subset of the enabled vector catch set, a Vector Catch exception is generated.

The Vector Catch exception is generated as part of entry to the exception, and must be taken before the PE either executes any instructions or takes any further exceptions.

The addresses that comprise the subset depend on whether EL3 is implemented and, for the:

- Address-matching form, the current Security state.
- Exception-trapping form, the Security state that the exception is handled in.

See Generation of Vector Catch exceptions on page G2-4513.

Table G2-20 summarizes the differences between the address-matching and exception-trapping forms.

Table G2-20 Differences in behavior of the address-matching and exception-trapping forms of vector catch

<table>
<thead>
<tr>
<th>Address-matching</th>
<th>Exception-trapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>An enabled vector catch generates a Vector Catch exception when an instruction that is fetched from the vector is committed for execution. This means that spurious Vector Catch exceptions might occur, where the Vector Catch exception does not result from an exception entry, but is instead caused by a branch to the vector. A branch to the vector might occur, for example, on a return from a nested exception or when simulating an exception entry.</td>
<td>An enabled vector catch generates a Vector Catch exception immediately after the PE takes the exception that is associated with the vector. This means that Vector Catch exceptions always result from exception entry, and not from branches to exception vectors.</td>
</tr>
<tr>
<td>A Vector Catch exception is generated as a result of an instruction fetch. This means that the Vector Catch exception has a priority relative to the other synchronous exceptions that result from an instruction fetch.</td>
<td>A Vector Catch exception is generated as a result of an exception entry. This means that the Vector Catch exception is part of the exception that caused the Vector Catch exception. Therefore, the Vector Catch exception has no priority associated with it. For this reason, Vector Catch exceptions are outside the scope of the prioritization that Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 describes.</td>
</tr>
<tr>
<td>Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 describes this prioritization.</td>
<td></td>
</tr>
<tr>
<td>A Vector Catch exception can be preempted by another exception. If this happens, the Vector Catch exception is generated again when the exception handler branches back to the vector.</td>
<td>Vector Catch exceptions must be taken before other exceptions.</td>
</tr>
<tr>
<td>A Vector Catch exception can be generated as a result of an instruction fetch executed in any AArch32 mode except Hyp mode, including User mode.</td>
<td>Because a Vector Catch exception is generated as the result of an exception entry, the Vector Catch exception is only generated when the PE is in the AArch32 exception handling mode.</td>
</tr>
<tr>
<td>If HCR.TGE is 1, Vector Catch exceptions can be generated for User mode instruction fetches from Non-secure PL1 vectors.</td>
<td>If HCR.TGE is 1, Vector Catch exceptions are never generated in Non-secure state, because:</td>
</tr>
<tr>
<td></td>
<td>• Exceptions are routed away from Non-secure PL1 vectors, to PL2.</td>
</tr>
<tr>
<td></td>
<td>• The architecture does not provide vector catch enable bits for the Hyp exception vectors.</td>
</tr>
</tbody>
</table>

Depending on the implementation, some vector catch enable bits in the DBGVCR might be RES0. For example, if EL3 is not implemented or is implemented but is using AArch64, Monitor mode is not implemented, and so the enable bits for exception vectors for exceptions taken to Monitor mode are RES0. See Exception vectors that Vector Catch exceptions can be enabled for on page G2-4512 for the vector catch enable bits that exist for different implementations.

The debug exception enable controls on page G2-4458 describes the enable controls for Vector Catch exceptions.
G2.11.2 Exception vectors that Vector Catch exceptions can be enabled for

When the PE takes an exception, the exception vector is contained in a vector table at the Privilege level the exception is taken to.

Depending on the Security state and AArch32 mode the exception is taken to, when the exception is taken, the vector table used is the table that contains one of:

- Local exception vectors.
- Non-secure Local exception vectors.
- Secure Local exception vectors.
- Hyp exception vectors.
- Monitor exception vectors.

Table G2-21 shows which vector tables are implemented for different implementations. In the table:

- A dash, -, means that the Exception level is not implemented.
- 64 means that the Exception level is using AArch64.
- 32 means that the Exception level is using AArch32.

Table G2-21 Vector tables implemented for different implementations

</tbody>
</table>

For example, in an AArch32-only implementation that includes EL0, EL1, and EL3, when the PE takes an exception to Monitor mode, it uses the vector table containing Monitor exception vectors.
The tables that follow show the vectors that Vector Catch exceptions can be enabled for, and their corresponding vector catch enable bits in the DBGVCR:

- **Table G2-22** shows the Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for.
- **Table G2-23** shows the Monitor exception vectors that Vector Catch exceptions can be enabled for.

The ARMv8-A architecture does not provide vector catch enable bits for the Hyp exception vectors.

</tr>
</tbody>
</table>

**Note**

There is no vector catch enable bit for Monitor trap exceptions.

### G2.11.3 Generation of Vector Catch exceptions

How Vector Catch exceptions are generated depends on which form is implemented:

- **Address-matching form** on page G2-4514.
- **Exception-trapping form** on page G2-4514.
Address-matching form

The PE compares the virtual address of each instruction in the program flow with some or all of the addresses in the enabled vector catch set, as follows:

- If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE compares the virtual address of each instruction in the program flow, including those executed at EL0, with all addresses in the enabled vector catch set.

- If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
  — Monitor exception vectors, if EL3 is using AArch32.
  — Secure Local exception vectors.
  — Non-secure Local exception vectors.

In this case, Table G2-24 shows which addresses, in the enabled vector catch set, the virtual address of each instruction in the program flow is compared with.

For example, for exceptions taken to a Secure PL1 mode when EL3 is using AArch64, the virtual address of each instruction in the program flow is compared with each Secure Local exception vector in the enabled vector catch set.

For each instruction in the program flow, the PE tests for any possible Vector Catch exceptions before executing the instruction. If a match occurs, a Vector Catch exception is generated when the instruction is committed for execution, regardless of all of the following:

- Whether the instruction passes its Condition code check.
- Whether the instruction is executed as part of exception entry.
- If EL2 is implemented, what HCR.\{IMO, FMO, AMO\} are set to.
- If EL3 is implemented, what SCR.\{IRQ, FIQ, EA\} are set to.

Exception-trapping form

When the PE takes an exception, it tests whether the exception is by branching to an exception vector in a subset of the enabled vector catch set, as follows:

- If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE tests whether the exception is by branching to any address in the enabled vector catch set.

- If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
  — Monitor exception vectors, if EL3 is using AArch32.
  — Secure Local exception vectors.
  — Non-secure Local exception vectors.

Table G2-24 Comparisons made if the implementation includes EL3

<table>
<thead>
<tr>
<th>EL3 is using</th>
<th>For exceptions taken to:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64</td>
<td>Secure PL1 modes</td>
<td>Non-secure PL1 modes</td>
</tr>
<tr>
<td></td>
<td>Secure Local exception vectors</td>
<td>Non-secure Local exception vectors</td>
</tr>
<tr>
<td>AArch32</td>
<td>Secure Local exception vectors and Monitor exception vectors</td>
<td></td>
</tr>
</tbody>
</table>
In this case, the PE tests whether the exception is by branching to a vector in one of the subsets that Table G2-25 shows. In the table, n/a means not applicable.

**Table G2-25 Subsets that the PE tests within if EL3 is implemented**

<table>
<thead>
<tr>
<th>EL3 is using</th>
<th>Monitor mode</th>
<th>Other Secure PL1 modes</th>
<th>Non-secure PL1 modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64</td>
<td>n/a</td>
<td>Secure Local exception vectors</td>
<td>Non-secure Local exception vectors</td>
</tr>
<tr>
<td>AArch32</td>
<td>Monitor exception vectors</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For example, for an exception taken to a Secure PL1 mode when EL3 is using AArch64, the PE tests whether the exception is by branching to any of the Secure Local exception vectors in the enabled vector address set.

If the exception is by branching to a vector in the subset, a Vector Catch exception is generated as part of exception entry. That is, a Vector Catch exception is generated instead of the exception handler executing its first instruction.

**G2.11.4 Usage constraints**

See the following subsections:

- Usage constraints that apply to both forms of vector catch.
- Usage constraints that apply only to the address-matching form.

**Usage constraints that apply to both forms of vector catch**

For Vector Catch exceptions enabled for either the Prefetch Abort exception vector or the Data Abort exception vector, if one of these exception types is taken to the Exception level that debug exceptions are targeting, behavior is CONSTRAINED UNPREDICTABLE. Either:

- Vector catch is ignored, therefore a Vector Catch exception is not generated.
- Vector catch generates a Prefetch Abort debug exception. For Vector Catch exceptions enabled for the Prefetch Abort exception vector, the PE might enter a recursive loop of Prefetch Abort exceptions causing Vector Catch exceptions and Vector Catch exceptions causing Prefetch Abort exceptions.

**Note**

The Exception level that debug exceptions are targeting is called the debug target Exception level, EL_D. *Routing debug exceptions* on page G2-4459 describes how EL_D is derived.

**Usage constraints that apply only to the address-matching form**

Exception vectors are at word-aligned addresses, and:

- It is CONSTRAINED UNPREDICTABLE whether an enabled vector catch generates a Vector Catch exception for a 32-bit T32 instruction starting at the halfword-aligned address immediately prior to the vector address.
- T32 instructions that start at the halfword-aligned address immediately after the exception vector do not generate Vector Catch exceptions.

For the address-matching form, Vector Catch exceptions have the same priority as Breakpoint exceptions. If a single instruction causes both a Vector Catch exception and a Breakpoint exception, it is CONSTRAINED UNPREDICTABLE which of these debug exceptions the PE takes.
G2.11.5 Exception syndrome information and preferred return address for a Vector Catch exception

See the following:

- Exception syndrome information for a Vector Catch exception.
- Preferred return address for a Vector Catch exception on page G2-4517.

Note

Usually, the term exception syndrome is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the IFSR.

Exception syndrome information for a Vector Catch exception

The PE takes a Vector Catch exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

PL1 Abort mode

The PE sets all of the following:

- IFSR.FS to the code for a debug exception, 0b00010.
- DBGDSCRext.MOE to 0b0101, to indicate a Vector Catch exception.
- The IFAR with an UNKNOWN value.

PL2 Hyp mode

The PE does all of the following:

- Records information about the exception in the Hypervisor Syndrome Register, HSR. See Table G2-26.
- Sets DBGDSCRext.MOE to 0b0101, to indicate a Vector Catch exception.
- Sets the HIFAR to an unknown value.

Table G2-26 Information recorded in the HSR

<table>
<thead>
<tr>
<th>HSR field</th>

</tr>
<tr>
<td>ISS[8:6]</td>
<td>RES0.</td>
</tr>
<tr>
<td>ISS[5:0]</td>
<td>Instruction Fault Status Code (IFSC). The PE sets this to the code for a debug exception, 0b100010.</td>
</tr>
</tbody>
</table>

Note

For information about how debug exceptions can be routed to PL2, see Routing debug exceptions on page G2-4459.
Preferred return address for a Vector Catch exception

The preferred return address of a Vector Catch exceptions is the address of the instruction that was not executed because the PE took the Vector Catch exception instead.

This means that the preferred return address is the exception vector. This is true regardless of whether the address-matching form or the exception trapping form is implemented.

G2.11.6 Pseudocode description of Vector Catch exceptions

The AArch32.VCRMatch() pseudocode function checks whether the instruction at address generates a Vector Catch exception. It therefore shows the address-matching form of vector catch.

The AArch32.CheckVectorCatch() pseudocode function uses AArch32.VCRMatch() to test whether the instruction generates a Vector Catch exception, and if AArch32.VCRMatch() returns TRUE it generates that event.

The AArch32.Abort() function processes the Faultrecord object returned by AArch32.CheckVectorCatch(), as described in Abort exceptions on page G3-4555. If there is a Vector Catch exception, the AArch32.Abort() function generates a Prefetch Abort exception.
G2.12 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

• The state of the external debug authentication interface.
• Indirect reads of:
  — External debug registers.
  — System registers, including system debug registers.
  — Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a Context synchronization event has occurred.

For any instructions executed between the time when the change is made and the time when the next Context synchronization event occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

Example G2-3

1. Software changes DBGDSCRext.MDBGen from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A Context synchronization event occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

Example G2-4

1. Software unlocks the OS lock.
2. The PE executes some instructions.
3. A Context synchronization event occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

——— Note ————

Some register updates are self-synchronizing. Others require an explicit Context synchronization event. For more information, see:

• Synchronization of changes to AArch32 System registers on page G6-4768.
• Accessing PSTATE fields on page G1-4333.
• Synchronization of changes to the external debug registers on page H8-5554.
G2.12.1 State and mode changes without explicit context synchronization events

Most changes to the Exception level, and most changes to the Security state if EL3 is implemented, happen as a result of operations that are an explicit Context synchronization event. This is because taking an exception and returning from an exception are both explicit Context synchronization events, and the Privilege level and Security state can only change as a result of taking or returning from an exception.

However, some Security state and AArch32 mode changes can happen because of operations that are not an explicit Context synchronization event. These are:

- AArch32 mode changes caused by MSR and CPS instructions. A mode change might be to a mode at a lower Privilege level.
- If EL3 is using AArch32, a Security state change caused by a direct write to the SCR in a privileged mode other than Monitor mode, to set SCR.NS to 1.
Chapter G3
The AArch32 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

• About the memory system architecture on page G3-4522.
• Address space on page G3-4523.
• Mixed-endian support on page G3-4524.
• AArch32 cache and branch predictor support on page G3-4525.
• System register support for IMPLEMENTATION DEFINED memory features on page G3-4549.
• External aborts on page G3-4550.
• Memory barrier instructions on page G3-4552.
• Pseudocode description of general memory system instructions on page G3-4553.
G3.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see Memory hierarchy on page E2-2772.

G3.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a Virtual Memory System Architecture (VMSA). Chapter G4 The AArch32 Virtual Memory System Architecture describes the AArch32 view of the VMSA.

G3.1.2 Memory attributes

Memory types and attributes on page E2-2782 describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table G3-1 shows the memory attributes that are visible at the system level.

Table G3-1 Memory attribute summary

<table>
<thead>
<tr>
<th>Memory type</th>
<th>Shareability</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device*</td>

<td>Non-cacheable.</td>
</tr>
<tr>
<td>Normal</td>
<td>One of:</td>
<td>One of*:</td>
</tr>
<tr>
<td></td>
<td>• Non-shareable.</td>
<td>• Non-cacheable.</td>
</tr>
<tr>
<td></td>
<td>• Inner Shareable.</td>
<td>• Write-Through Cacheable.</td>
</tr>
<tr>
<td></td>
<td>• Outer Shareable.</td>
<td>• Write-Back Cacheable.</td>
</tr>
</tbody>
</table>

a. Takes additional attributes, see Device memory on page E2-2786.
b. See also Cacheability, cache allocation hints, and cache transient hints on page G3-4528.

For more information on Cacheability and Shareability see The Cacheability and Shareability memory attributes on page E2-2773, Non-shareable Normal memory on page E2-2784, and Caches and memory hierarchy on page E2-2772.
G3.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of physical address (PA) sizes, and provides associated control and identification mechanisms. For more information, see About VMSAv8-32 on page G4-4558.

G3.2.1 Address space overflow or underflow

This subsection describes address space overflow or underflow:

Instruction address space overflow

When a PE performs a normal, sequential execution of instructions, it calculates:

(address of current instruction) + (size of executed instruction)

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an A32 or T32 instruction overflows 0xFFFF FFFF, the program counter becomes UNKNOWN.

If the PE executes an instruction for which the instruction address, size, and alignment mean that it contains the bytes 0xFFFFFFFF and 0x00000000, the bytes that apparently from 0x00000000 onwards come from an UNKNOWN address.

Data address space overflow and underflow

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean that it accesses bytes 0xFFFFFFFF and 0x00000000, then the bytes that apparently come from 0x00000000 onwards come from UNKNOWN addresses.
G3.3 Mixed-endian support

Table G3-2 shows the endianness of explicit data accesses and translation table walks.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>Explicit data accesses</th>
<th>Stage 1 translation table walks</th>
<th>Stage 2 translation table walks</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>PSTATE.E</td>
<td>SCTLR(S/NS).EE</td>
<td>HSCTRL.EE</td>
</tr>
<tr>
<td>EL1</td>
<td>PSTATE.E</td>
<td>SCTLR(S/NS).EE</td>
<td>HSCTRL.EE</td>
</tr>
<tr>
<td>EL2</td>
<td>PSTATE.E</td>
<td>HSCTRL.EE</td>
<td>N/A</td>
</tr>
<tr>
<td>EL3</td>
<td>PSTATE.E</td>
<td>SCTLR(S).EE</td>
<td>N/A</td>
</tr>
</tbody>
</table>

AArch32 state provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - SCTLR(S/NS).EE, HSCTRL.EE, and PSTATE.E are RW.

- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - SCTLR(S/NS).EE and HSCTRL.EE are RES0. PSTATE.E is RW when in EL0 and RES0 when in EL1, EL2, or EL3. SPSR.E is also RES0 when not returning to EL0.

- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - SCTLR(S/NS).EE and HSCTRL.EE are RES1. PSTATE.E is RW when in EL0 and RES1 when in EL1, EL2, or EL3. SPSR.E is also RES1 when not returning to EL0.

- All Exception levels support only little-endianness:
  - Each of SCTLR(S/NS).EE, HSCTRL.EE, PSTATE.E, and SPSR.E is RES0.

- All Exception levels support only big-endianness:
  - Each of SCTLR(S/NS).EE, HSCTRL.EE, PSTATE.E, and SPSR.E is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by PSTATE.E. For exception returns to AArch32 state, PSTATE.E is copied from SPSR_ELx.E. If the target Exception level supports only little-endian accesses, SPSR_ELx.E is RES0. If the target Exception level supports only big-endian accesses, SPSR_ELx.E is RES1.

---

**Note**

- When using AArch32, ARM deprecates PSTATE.E having a different value from the equivalent System register EE bit when in EL1, EL2 or EL3. The use of the SETE00 instruction is also deprecated.

- If the higher Exception levels are using AArch64, the corresponding registers are:
  - SCTLR_EL1 for SCTLR(NS).
  - SCTLR_EL2 for HSCTRL.
  - SCTLR_EL3 for SCTLR(S).

The BigEndian() function determines whether the current Exception level and Execution state is using big-endian data.

For more information about endianness in the ARM architecture see Endian support on page E2-2779.
G3.4 AArch32 cache and branch predictor support

The following sections describe the support for caches and branch predictors in AArch32 state:

- General behavior of the caches.
- Cache identification on page G3-4527.
- Cacheability, cache allocation hints, and cache transient hints on page G3-4528.
- Enabling and disabling the caching of memory accesses in AArch32 state on page G3-4529.
- Behavior of caches at reset on page G3-4531.
- AArch32 cache and branch predictor maintenance instructions on page G3-4535.
- About cache maintenance in AArch32 state on page G3-4531.
- AArch32 cache and branch predictor maintenance instructions on page G3-4535.
- Cache lockdown on page G3-4546.
- System level caches on page G3-4547.

See also Chapter G4 The AArch32 Virtual Memory System Architecture, and in particular Caches in VMSAv8-32 on page G4-4646.

--- Note ---

- Branch predictors typically use a form of cache to hold branch target data. Therefore, they are included in this section.
- In the instruction mnemonics, MVA is a synonym for VA.

G3.4.1 General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  — A particular implementation.
  — Some memory attributes.

- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
• A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

—— Note ————
For more information, see The interaction of cache lockdown with cache maintenance instructions on page G3-4546.

• Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.

• It is guaranteed that no memory location that does not have a Normal Cacheable attribute is allocated into the cache.

• It is guaranteed that no memory location is allocated to the cache if it has a Normal Non-cacheable attribute or any type of Device memory attribute in both:
  — The translation regime at the current Exception level.
  — The translation regime at any higher Exception level.

• For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all masters in its Shareability domain.

• Any memory location is not guaranteed to remain incoherent with the rest of memory.

• The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the Shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the Cache Write-back Granule. In some implementations the CTR identifies the Cache Write-back Granule, see CTR, Cache Type Register on page G6-4843.

• The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

—— Note ————
The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR. {I, C} controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.
G3.4.2 Cache identification

The ARMv8 cache identification consists of a set of registers that describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes cache maintenance instructions that:

- Affect the entire cache, for example ICIALLUIS.
- Operate by VA, for example ICIMVAU.
- Operate by set/way, for example DCISW.

The cache identification registers are:

- A single Cache Type Register, CTR, that defines:
  - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
  - The cache indexing and tagging policy of the Level 1 instruction cache.

  **Note**

  It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see System level caches on page G3-4547.

- A single Cache Level ID Register, CLIDR, that defines:
  - The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
  - The Level of Unification Inner Shareable (LoUIS), Level of Coherence (LoC) and the Level of Unification (LoU) for the caches. See Terms used in describing the cache maintenance instructions on page G3-4532 for a definition of these terms.
  - An optional ICB field to indicate the boundary between the caches use for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.

- A single Cache Size Selection Register, CSSELR, that selects the cache level and cache type of the current Cache Size Identification Register.

- For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, CCSIDR, that defines:
  - Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
  - The number of sets, associativity and line length of the cache. See Terms used in describing the cache maintenance instructions on page G3-4532 for a definition of these terms.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.

2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.
3. For each cache identified at stage 2:
   • Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
     — An instruction cache.
     — A data or unified cache.
   • Read the Cache Size ID Register to find details of the cache.

G3.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and is defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in Memory types and attributes on page E2-2782, the memory attributes include a cacheability attribute that is one of:
   • Non-cacheable.
   • Write-Through cacheable.
   • Write-Back cacheable.

In ARMv8, Cacheability attributes other than Non-cacheable can be complemented by a cache allocation hint. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a cache transient hint is supported, see Transient cacheability hint.

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hit is supported the following cache allocation hints can be used:

For read accesses: Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

For write accesses: Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

Note

• A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.

• Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.

• For VMSAv8-32 translation table walks using the Long-descriptor translation table format, the appropriate TCR.[IRGnR, ORGnR] fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

Transient cacheability hint

In ARMv8, it is IMPLEMENTATION DEFINED whether a transient hint is supported for the VMSAv8-32 translation scheme when using the Long-descriptor translation table format. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

Note

The architecture does not specify what is meant by a relatively short period.
When using the Short-descriptor translation table format, VMSAv8-32 cannot support the Transient hint.

The description of the MAIR0, MAIR1, HMAIR0, and HMAIR1 registers includes the assignment of the Transient attribute in an implementation that supports this option. In this assignment:
- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
- A single Transient hint applies to both read and write accesses to a memory region.

### G3.4.4 Enabling and disabling the caching of memory accesses in AArch32 state

In ARMv8, Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:
- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

--- Note ---

These Cacheability controls replace the cache enable controls provided in previous versions of the ARM architecture.

In AArch32 state, the Cacheability control fields and their effects are as follows:

#### For the Non-secure PL1&0 translation regime

The Non-secure instance of SCTLR holds the EL1 controls that affect cachability:
- When the value of SCTLR.C is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the PL1&0 stage 1 translation tables are Non-cacheable.
- When the value of SCTLR.I is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR2.CD is 1:
  - All stage 2 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the PL1&0 stage 2 translation tables are Non-cacheable.
- When the value of HCR2.ID is 1:
  - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR.DC is 1, all Non-secure stage 1 translations and all accesses to the Non-secure ELI&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of SCTLR.C. This applies to translations for both data and instruction accesses.

In addition, when the value of SCTLR.M is 0, indicating that the stage 1 translations are disabled for the translation regime, then if EL2 is using AArch32 and the value of HCR.DC is 0 or if EL2 is using AArch64 and the value of HCR_EL2.DC is 0, then:
- If the value of SCTLR.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of SCTLR.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.
--- Note ---

- In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in *Combining the Cacheability attribute on page G4-4626.*
- The Non-secure SCTLR.\{C, I\} and HCR.DC fields have no effect on the Secure PL1&0 and EL2 translation regimes.
- The HCR2.\{ID, CD\} fields affect only stage 2 of the Non-secure PL1&0 translation regime.
- In Non-secure state, the PL1&0 translation regime can be described as the Non-secure EL1&0 translation regime. This is consistent with the equivalent AArch64 descriptions.

---

**For the Secure PL1&0 translation regime**

The Secure instance of SCTLR holds the controls that determine cacheability:

- When the value of SCTLR.C is 0:
  - All data accesses to Normal memory using the Secure PL1&0 translation regime are Non-cacheable.
  - All accesses to the Secure PL1&0 translation tables are Non-cacheable.
- When the value of SCTLR.I is 0:
  - All instruction accesses to Normal memory using the Secure PL1&0 translation regime are Non-cacheable.

In addition, when the value of SCTLR.M is 0, indicating that stage 1 translations are disabled, then:

- If the value of SCTLR.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of SCTLR.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

--- Note ---

The Secure SCTLR.\{I, C, M\} fields have no effect on the Non-secure PL1&0 and EL2 translation regimes.

---

**For the EL2 translation regime**

- When the value of HSCTLR.C is 0:
  - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
  - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of HSCTLR.I is 0:
  - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

In addition, when the value of HSCTLR.M is 0, indicating that stage 1 translations are disabled, then:

- If the value of HSCTLR.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of HSCTLR.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

--- Note ---

The HSCTLR.\{I, C, M\} fields have no effect on the PL1&0 and EL3 translation regimes.

---

The effect of the SCTLR.C or HSCTLR.C and HCR2.CD bits is reflected in the result of the address translation instructions in the PAR.
G3 The AArch32 System Level Memory Model
G3.4 AArch32 cache and branch predictor support

--- Note ---
- The requirements in this section mean the architecturally required effects of SCTLR.I and HSCTLR.I are limited to their effects on caching instruction accesses in unified caches.
- This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in Mismatched memory attributes on page E2-2792 must be followed to manage the corresponding loss of coherency.

G3.4.5 Behavior of caches at reset

In ARMv8:
- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.
- The Cacheability control fields described in Enabling and disabling the caching of memory accesses in AArch32 state on page G3-4529 reset to values that force all memory locations to be treated as Non-cacheable.

--- Note ---
This applies only to the controls that apply to the Translation regime that is used by the Exception level, PE mode, and Security state entered on reset.

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.

- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
  — Provide a mechanism to ensure the correct initialization of the caches.
  — Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

Similar rules apply to:
- Branch predictor behavior, see Behavior of the branch predictors at reset on page G3-4539.
- TLB behavior, see TLB behavior at reset on page G4-4629.

G3.4.6 About cache maintenance in AArch32 state

The following sections give general information about cache maintenance in ARMv8:
- Terms used in describing the cache maintenance instructions on page G3-4532.
- The ARMv8 abstraction of the cache hierarchy on page G3-4534.

The following sections describe the AArch32 state cache maintenance instructions:
- AArch32 instruction cache maintenance instructions (IC*) on page G3-4536.
- AArch32 data cache maintenance instructions (DC*) on page G3-4537.

--- Note ---
Some descriptions of the cache maintenance instructions refer to the Cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR.\{I, C\} controls.
Terms used in describing the cache maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:
- By the virtual address of the memory location to be maintained, referred to as operating by VA.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating by set/way.

In addition, for instruction caches and branch predictors, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:
- Terminology for cache maintenance instructions operating by set/way.
- Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

Note
There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4567.

Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

Level
The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the CLIDR.

In the ARM architecture, the lower numbered cache levels are those closest to the PE. See Memory hierarchy on page E2-2772.

Set
Each level of a cache is split up into a number of sets. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.

In the ARM architecture, sets are numbered from 0.

Way
The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The way number specifies one of these locations.

In the ARM architecture, ways are numbered from 0.

Note
Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.

2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or stale, copy of the memory location that has been updated.
The *Clean and Invalidate* instructions address these two issues. The definitions of these instructions are:

**Clean**

A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the Shareability domain of that memory location.

**Invalidate**

A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

--- Note ---

Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

---

**Clean and Invalidate**

A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- **For instructions operating by set/way,** the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
- **For instructions operating by VA,** two conceptual points are defined:
  - **Point of Coherency (PoC)**
    
    The point at which all agents that can access memory are guaranteed to see the same copy of a memory location for accesses of any memory type or cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

  --- Note ---

  The presence of system caches can affect the determination of the point of coherency as described in *System level caches* on page G3-4547.

  ---

  **Point of Unification (PoU)**

  The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

  The PoU for an Inner Shareable Shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable Shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:
  1. Clean data cache entry by address.
  2. Invalidate instruction cache entry by address.
The following fields in the CLIDR relate to these conceptual points:

**LoC, Level of Coherence**
This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is 0x0, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

**LoUU, Level of Unification, uniprocessor**
This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is 0x0, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

**LoUIS, Level of Unification, Inner Shareable**
In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is 0x0, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see [CLIDR, Cache Level ID Register on page G6-4823](#).

### The ARMv8 abstraction of the cache hierarchy

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- *Cache maintenance instructions that operate by VA*.  
- *Cache maintenance instructions that operate by set/way on page G3-4535*.

#### Cache maintenance instructions that operate by VA

The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.

See [Terms used in describing the cache maintenance instructions on page G3-4532](#) for definitions of Point of Coherency and Point of Unification, and more information about possible meanings of VA.

*AArch32 cache and branch predictor maintenance instructions on page G3-4535* lists the VA-based maintenance instructions.

The CTR holds minimum line length values for:

- The instruction caches.
- The data and unified caches.
These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

**Cache maintenance instructions that operate by set/way**

_AArch32 cache and branch predictor maintenance instructions_ lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

### G3.4.7 AArch32 cache and branch predictor maintenance instructions

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. _Table G3-3_ shows the AArch32 system instructions. Instructions that take an argument include Rt in the instruction description.

AArch32 state also provides branch predictor maintenance instructions.

**Note**

- In _Table G3-3_ the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.
- In AArch32 state, all of the maintenance instructions are available from EL1 or higher.
- In AArch64 state, branch predictors are always invisible to software, and therefore AArch64 state does not provide any branch predictor maintenance instructions.

### Table G3-3 AArch32 System instructions for cache maintenance

<table>
<thead>

</tbody>
</table>
A DSB or DMB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.

In an implementation where the branch predictors are architecturally invisible, the BPIMVA, BPIALLIS, and BPIALL instructions can execute as NOPs.

The following subsections give more information about these instructions:

- **AArch32 instruction cache maintenance instructions (IC*)**
- **AArch32 data cache maintenance instructions (DC*)** on page G3-4537.
- **Branch predictors** on page G3-4538.
- **General requirements for the scope of cache and branch predictor maintenance instructions** on page G3-4539.
- **Effects of instructions that operate by VA to the Point of Coherency** on page G3-4540.
- **Effects of instructions that operate by VA but not to the Point of Coherency** on page G3-4540.
- **Effects of All and set/way maintenance instructions** on page G3-4541.
- **Effects of virtualization and security on the AArch32 cache maintenance instructions** on page G3-4541.
- **Boundary conditions for cache maintenance instructions** on page G3-4543.
- **Ordering of cache and branch predictor maintenance instructions** on page G3-4543.
- **Performing cache maintenance instructions** on page G3-4545.

### AArch32 instruction cache maintenance instructions (IC*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system Address Space IDentifier, ASID.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
- For an instruction executed from a Non-secure EL1 state, the Virtual Machine IDentifier, VMID.

For an instruction cache maintenance instruction that operates by VA:

- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
- The operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault case described in **Stage 2 fault on a stage 1 translation table walk** on page G4-4656.

For more information about these possible faults on an instruction that operates by VA see **MMU faults in AArch32 state** on page G4-4657.
An instruction cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction.

See also Ordering of cache and branch predictor maintenance instructions on page G3-4543.

AArch32 data cache maintenance instructions (DC*)

Data cache maintenance instructions that take a set/way/level argument take a 32-bit register.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-6107 or the instruction description.

DCISW instructions executed at EL1 perform a clean and invalidate, meaning they execute as a DCCISW instruction, if all of the following apply:

- EL2 is implemented.
- Either:
  - EL2 is using AArch32 and the value of HCR.SWIO is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.SWIO is 1.
- EL3 is not implemented, or either:
  - EL3 is using AArch32 and the value of SCR.NS is 1.
  - EL3 is using AArch64 and the value of SCR_EL3.NS is 1.

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system Address Space Identifier, ASID.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
- For an instruction executed from a Non-secure EL1 state, the Virtual Machine Identifier, VMID.

A data or unified cache maintenance instruction that operates by VA cannot generate a Data Abort exception for a Domain fault, and cannot generate a Data Abort exception for a Permission fault, except for the Permission fault described in Stage 2 fault on a stage 1 translation table walk on page G4-4656.

For more information about the possible faults on an instruction that operates by VA see MMU faults in AArch32 state on page G4-4657.

DCIMVAC and DCISW instructions executed at EL1 perform a clean and invalidate, meaning they execute as a DCCIMVAC or DCCISW instruction, if all of the following apply:

- EL2 is implemented.
- PL1&0 stage two address translation is enabled, meaning either:
  - EL2 is using AArch32 and the value of HCR.VM is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.VM is 1.
- EL3 is not implemented, or either:
  - EL3 is using AArch32 and the value of SCR.NS is 1.
  - EL3 is using AArch64 and the value of SCR_EL3.NS is 1.

If a memory fault that sets FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

See also Ordering of cache and branch predictor maintenance instructions on page G3-4543.
Branch predictors

In AArch32 state it is IMPLEMENTATION DEFINED whether branch prediction is architecturally visible. This means that under some circumstances software must perform branch predictor maintenance to avoid incorrect execution caused by out-of-date entries in the branch predictor. For example, to ensure correct operation it might be necessary to invalidate branch predictor entries on a change to instruction memory, or a change of instruction address mapping. For more information, see Specific requirements for branch predictor maintenance instructions.

In an implementation where the branch predictors are architecturally invisible, the branch predictor maintenance instructions can execute as NOPs.

An invalidate all operation on the branch predictor ensures that any location held in the branch predictor has no functional effect on execution. An invalidate branch predictor by VA instruction operates on the address of the branch instruction, but can affect other branch predictor entries.

—— Note ———
The architecture does not make visible the range of addresses in a branch predictor to which the invalidate operation applies. This means the address used in the invalidate by VA operation must be the address of the branch to be invalidated.

If branch prediction is architecturally visible, an instruction cache invalidate all operation also invalidates all branch predictors.

See also Ordering of cache and branch predictor maintenance instructions on page G3-4543.

Specific requirements for branch predictor maintenance instructions

If, for a given translation regime and a given ASID and VMID as appropriate, the instructions at any virtual address change, then branch predictor maintenance instructions must be performed to invalidate entries in the branch predictor, to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

• For any translation regime other than the Non-secure PL1&0 translation regime, enabling or disabling stage 1 translations.

• For the Non-secure PL1&0 translation regime:
  — When stage 2 translations are enabled, enabling or disabling stage 1 translations unless accompanied by a change of VMID.
  — When stage 2 translations are disabled, enabling or disabling stage 1 translations.
  — Enabling or disabling stage 2 translations.

• Writing new mappings to the translation tables.

• Any change to the TTBR0, TTBR1, or TTBCR registers, unless:
  — For a change to the Secure PL1&0 translation regime, the change is accompanied by a change to the ASID.
  — For a change to the stage 1 translations of the Non-secure PL1&0 translation regime, the change is accompanied by a change to the ASID or a change to the VMID.

• Any change to the VTTBR or VTCR registers, unless accompanied by a change to the VMID.
--- Note ---

Invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged throughout the sequence of changes to the translations. Examples of translation changes to which this applies:

- Changing a valid translation to a translation that generates an MMU fault.
- Changing a translation that generates an MMU fault to a valid translation.

Failure to invalidate entries might give CONSTRANDED UNPREDICTABLE results, caused by the execution of old branches. For more information, see Ordering of cache and branch predictor maintenance instructions on page G3-4543.

--- Note ---

- In ARMv8, there is no requirement to use the branch predictor maintenance operations to invalidate the branch predictor after:
  - Changing the ContextID or VMID.
  - A cache maintenance instruction that is identified as also flushing the branch predictors, see AArch32 cache and branch predictor maintenance instructions on page G3-4535.

Cache maintenance instructions, functional group on page G4-4734 shows the branch predictor maintenance operations in a VMSA implementation.

**Behavior of the branch predictors at reset**

In AArch32 state:

- If branch predictors are not architecturally invisible:
  - The branch predictors reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
  - The branch predictors are disabled at reset.

- An implementation can require the use of a specific branch predictor initialization routine to invalidate the branch predictor storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, but the routine must be documented clearly as part of the documentation of the device.

- ARM recommends that whenever an invalidation routine is required, it is based on the AArch32 branch predictor maintenance operations.

Similar rules apply:

- To cache behavior, see Behavior of caches at reset on page G3-4531.
- To TLB behavior, see TLB behavior at reset on page G4-4629.

**General requirements for the scope of cache and branch predictor maintenance instructions**

The ARMv8 specification of the cache maintenance and branch predictor instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in General behavior of the caches on page G3-4525, Behavior of caches at reset on page G3-4531, and Preloading caches on page E2-2775.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

As a side-effect of a branch predictor maintenance instruction, any entry in the branch predictor might be invalidated.
ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

**Effects of instructions that operate by VA to the Point of Coherency**

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the Shareability domain described by the Shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable Shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable Shareability domain as the PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable Shareability domain as the PE performing the operation</td>
<td>The Point of Coherency of the entire system</td>
</tr>
</tbody>
</table>

**Effects of instructions that operate by VA but not to the Point of Coherency**

The following instruction operate by VA but not to the Point of Coherency:

- Clean data or unified cache line by MVA to the Point of Unification, **DCCMVNU**.
- Invalidate instruction cache line by MVA to Point of Unification, **ICIMVNU**.
- Invalidate by MVA from branch predictors, **BPIMVA**.

For these instructions, Table G3-5 shows how, for a VA in a Normal or Device memory location, the Shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable Shareability domain as the PE executing the instruction</td>
<td>The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain as the PE executing the instruction</td>
</tr>
</tbody>
</table>

**Note**

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable Shareability domain containing the PE executing the instruction.
Effects of All and set/way maintenance instructions

The ICIALLU, BPIALL and DC* set/way instructions apply only to the caches and branch predictors of the PE that performs the instruction. If the branch predictors are architecturally-visible, ICIALLU also performs a BPIALL operation.

The ICIALLUIS and BPIALLIS instructions can affect the caches and branch predictors of all PEs in the same Inner Shareable Shareability domain as the PE that performs the instruction. If the branch predictors are architecturally-visible, ICIALLUIS also performs a BPIALLIS operation. These instructions have an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain.

Note

The possible presence of system caches, as described in System level caches on page G3-4547, means architecture does not guarantee that all levels of cache can be maintained using set/way instructions.

Effects of virtualization and security on the AArch32 cache maintenance instructions

Each Security state has its own physical address space, and therefore cache entries are associated with physical address space. In addition, cache maintenance and branch predictor instructions performed in Non-secure state have to take account of:

- Whether the instruction was performed at EL1 or at EL2.
- For instructions that operate by VA, the current VMID.

Table G3-6 shows the effects of virtualization and security on these maintenance instructions.

Table G3-6 Effects of virtualization and security on the AArch32 cache maintenance instructions

</tr>
</tbody>
</table>
For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in *The interaction of cache lockdown with cache maintenance instructions on page G3-4546* applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way instructions can, instead, perform a clean and invalidate by set/way.
• The AArch32 Data cache invalidate instructions DCIMVAC and DCISW, perform a cache clean as well as a cache invalidate, meaning DCIMVAC performs the same invalidation as a DCCIMVAC instruction, and DCISW performs the same invalidation as a DCCISW instruction, if both of the following apply:
  — The value of HCR.VM is 1.
  — The instruction is executed in Non-secure state, or EL3 is not implemented.

• The AArch32 Data cache invalidate by set/way instruction DCISW performs a cache clean as well as a cache invalidate, meaning it performs the same invalidation as a DCCISW instruction, if both of the following apply:
  — The value of HCR.SWIO is 1.
  — The instruction is executed in Non-secure state, or EL3 is not implemented.

• When the value of HCR.FB is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch32, this applies to the TLBIMVA, TLBIMVAA, TLBIMVAL, TLBIMVAAL, and ICIALLU instructions. This means the instruction performs the invalidation that would be performed by the corresponding Inner Shareable instruction, for example ICIALLU performs the invalidation that would be performed by ICIALLUIS, and BPIALL performs the invalidation that would be performed by BPIALLIS.

For more information about the cache maintenance instructions, see About cache maintenance in AArch32 state on page G3-4531, AArch32 cache and branch predictor maintenance instructions on page G3-4535, and Chapter G4 The AArch32 Virtual Memory System Architecture.

Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

• Whether the address accessed:
  — Is Normal memory or Device memory.
  — Has the Cacheable attribute or the Non-cacheable attribute.

• Any applicable domain control of the address accessed.

• The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering of cache and branch predictor maintenance instructions

The following rules describe the effect of the memory order model on the cache and branch predictor maintenance instructions:

• All cache and branch predictor maintenance instructions that do not specify an address execute, relative to each other, in program order.

All cache and branch predictor instructions that specify an address:

• Execute in program order relative to all cache and branch predictor operations that do not specify an address.

• Execute in program order relative to all cache and branch predictor operations that specify the same address.

• Can execute in any order relative to cache and branch predictor operations that specify a different address.

• Where a cache maintenance or branch predictor instruction appears in program order before a change to the translation tables, the architecture guarantees that the cache or branch predictor maintenance instruction uses the translations that were visible before the change to the translation tables.
• Where a change of the translation tables appears in program order before a cache maintenance or branch predictor instruction, software must execute the sequence outlined in Ordering and completion of TLB maintenance instructions on page G4-4635 before performing the cache or branch predictor maintenance instruction, to ensure that the maintenance operation uses the new translations.

• A DMB instruction causes the effect of all data or unified cache maintenance instructions appearing in program order before the DMB to be visible to all explicit load and store operations appearing in program order after the DMB.

Also, a DMB instruction ensures that the effects of any data or unified cache maintenance instruction appearing in program order before the DMB are observable by any observer in the same required Shareability domain before any data or unified cache maintenance or explicit memory operations appearing in program order after the DMB are observed by the same observer. Completion of the DMB does not guarantee the visibility of all data to other observers. For example, all data might not be visible to a translation table walk, or to instruction fetches.

• A DSB is required to guarantee the completion of all cache maintenance instruction that appear in program order before the DSB instruction.

• A Context synchronization event is required to guarantee the effects of any branch predictor maintenance operation. This means a Context synchronization event causes the effect of all completed branch predictor maintenance operations appearing in program order before the Context synchronization event to be visible to all instructions after the Context synchronization event.

This means that, if a branch instruction appears after an invalidate branch predictor operation and before any Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the branch instruction is affected by the invalidate. Software must avoid this ordering of instructions, because it might cause CONSTRAINED UNPREDICTABLE behavior.

• Any data or unified cache maintenance instruction by VA must be executed in program order relative to any explicit load or store on the same PE to an address covered by the VA of the cache instruction if that load or store is to Normal Cacheable memory. The order of memory accesses that result from the cache maintenance instruction, relative to any other memory accesses to Normal Cacheable memory, are subject to the memory ordering rules. For more information, see Definition of the ARMv8 memory model on page E2-2762.

Any data or unified cache maintenance instruction by VA can be executed in any order relative to any explicit load or store on the same PE to an address covered by the VA of the cache maintenance instruction if that load or store is not to Normal Cacheable memory.

• There is no restriction on the ordering of data or unified cache maintenance instruction by VA relative to any explicit load or store on the same PE where the address of the explicit load or store is not covered by the VA of the cache instruction. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.

• There is no restriction on the ordering of a data or unified cache maintenance instruction by set/way relative to any explicit load or store on the same PE. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.

• Software must execute a Context synchronization event after the completion of an instruction cache maintenance instruction, to guarantee that the effect of the maintenance instruction is visible to any instruction fetch.

A DSB or DMB instruction intended to ensure the completion of cache maintenance instructions or branch predictor instructions must have an access type of both loads and stores.

The scope of instruction cache maintenance depends on the type of the instruction cache. For more information see Instruction caches on page G4-4647.

Example G3-1 Cache cleaning operations for self-modifying code

The sequence of cache cleaning operations for a line of self-modifying code on a uniprocessor system is:

; Coherency example for data and instruction accesses within the same Inner Shareable domain.
Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the CTR.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the CTR.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can be used to clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Note

Because the set/way instructions operate only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Because any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the cache line is not affected by set/way based cache maintenance. Therefore, ARM strongly discourages the use of set/way instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and ARM advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

System level caches on page G3-4547 refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency.

```assembly
MRC p15, 1, R0, c0, c0, 1 ; Read CLIDR into R0
ANDS R3, R0, #0x07000000
MOV R3, R3, LSR #23 ; Cache level value (naturally aligned)
BEQ Finished
MOV R10, #0
Loop1
```
ADD R2, R10, R10, LSR #1    ; Work out 3 x cache level
MOV R1, R0, LSR R2          ; bottom 3 bits are the cache type for this level
AND R1, R1, #7              ; get those 3 bits alone
CMP R1, #2                 ; no cache or only instruction cache at this level
BLT Skip
MCR p15, 2, R10, c0, c0, 0  ; write CSSELR from R10
ISB                       ; ISB to sync the change to the CCSIDR
MRC p15, 1, R1, c0, c0, 0  ; read current CCSIDR to R1
AND R2, R1, #7             ; extract the line length field
ADD R2, R2, #4             ; add 4 for the line length offset (log2 16 bytes)
MOV R4, #0x3FF
ANDS R4, R4, R1, LSR #3    ; R4 is the max number on the way size (right aligned)
CLZ R5, R4                 ; R5 is the bit position of the way size increment
MOV R9, R4                 ; R9 working copy of the max way size (right aligned)
Loop2
MOV R7, #0x00007FFF
ANDS R7, R7, R1, LSR #13    ; R7 is the max number of the index size (right aligned)
Loop3
ORR R11, R10, R9, LSL R5   ; factor in the way number and cache number into R11
ORR R11, R11, R7, LSL R2   ; factor in the index number
MCR p15, 0, R11, c7, c10, 2 ; DCISW, clean by set/way
SUBS R7, R7, #1            ; decrement the index
BCE Loop3
SUBS R9, R9, #1            ; decrement the way number
BCE Loop2
Skip
ADD R10, R10, #2           ; increment the cache number
CMP R3, R10                ; ensure completion of previous cache maintenance instruction
DSB
BGT Loop1
Finished

Similar approaches can be used for all cache maintenance instructions.

G3.4.8 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

• An implementation.
• Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

• The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  — Cache clean by set/way, DCCSW.
  — Cache invalidate by set/way, DCISW.
  — Cache clean and invalidate by set/way, DCISW.
  — Instruction cache invalidate all, ICIALLU and ICIALLUIS.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the Fault status code defined for this purpose. See Data Abort exception on page G1-4387. This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, DCCMVAC and DCCMVAU.
- Cache invalidate by virtual address, DCIMVAC.
- Cache clean and invalidate by virtual address, DCCIMVAC.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.

2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.

3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the Fault status code defined for this purpose. See DFSR or HSR.

In an implementation that includes EL2, if HCR.TIDCP is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.

**Note**

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.

- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

**Additional cache functions for the implementation of lockdown**

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED space. See IMPLEMENTATION DEFINED registers, functional group on page G4-4744.

### G3.4.9 System level caches

The ARM Architecture defines a system cache as a cache that is not described in the PE Cache Identification registers, CCSIDR and CLIDR, and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the ARM architecture is explicitly prohibited.
2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entire system cache must be performed, as is the case for power management, it must be performed using non-architectural mechanisms.

3. System caches which lie beyond the point of coherency and so are invisible to software. The management of such caches is outside the scope of architecture.
G3.5 System register support for IMPLEMENTATION DEFINED memory features

The VMSAv8-32 defines the following registers for describing IMPLEMENTATION DEFINED features of the memory system:

- The TCM Type Register, TCMTR, must be implemented. The following conditions apply to this register:
  - If no TCMs are implemented, the TCMTR indicates zero-size TCMs.
  - If bits[31:29] are 0b100, the format of the rest of the register is IMPLEMENTATION DEFINED. This value indicates that the implementation includes TCMs that do not follow the legacy usage model. Other fields in the register might give more information about the TCMs.

- The System register encoding space with \{coproc==0b1111, CRn==c9, CRm==\{c0-c2, c5-c7\}\} is IMPLEMENTATION DEFINED for all values of opc2 and opc1. This space is reserved for branch predictor, cache and TCM functionality, for example maintenance, override behaviors and lockdown.

- In a VMSAv8-32 implementation, part of the System register encoding space with \{coproc==0b1111, CRn==c10\} is IMPLEMENTATION DEFINED and reserved for TLB functionality, see TLB lockdown on page G4-4630.

- The System register encoding space with \{coproc==0b1111, CRn==c11, CRm==\{c0-c8, c15\}\} is IMPLEMENTATION DEFINED for all values of opc2 and opc1. This space is reserved for DMA operations to and from the TCMs.

In addition, the System register encoding space with \{coproc==0b1111, CRn==c15\} is reserved for IMPLEMENTATION DEFINED registers, and can provide additional registers for the memory system. For more information, see Reserved encodings in the VMSAv8-32 System register (coproc==0b1111) space on page G4-4709.
G3.6 External aborts

The ARM architecture defines external aborts as errors that occur in the memory system, other than those that are detected by the MMU or Debug hardware. External aborts include parity or ECC errors detected by the caches or other parts of the memory system. For example, an uncorrectable parity or ECC failure on a Level 2 memory structure might generate an external abort.

An external abort is one of:
- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see Exception terminology on page G1-4310.

The ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous external aborts.

VMSA v8-32 permits external aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous. The reported fault code identifies whether the external abort is synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which external aborts, if any, are supported. Asynchronous external aborts are taken as SError interrupt exceptions.

In AArch32 state:
- SError interrupts are taken as asynchronous Data Abort exceptions.
- Synchronous external aborts:
  - On data accesses are taken as synchronous Data Abort exceptions.
  - On instruction fetches, or prefetches, are taken as synchronous Prefetch Abort exceptions.

See also:
- External abort on a translation table walk on page G4-4659.
- Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340.

Normally, external aborts are rare. An imprecise asynchronous external abort is likely to be fatal to the process that is running. ARM recommends that implementations make external aborts precise wherever possible.

The following subsections give more information about possible external aborts:
- External abort on instruction fetch.
- External abort on data read or write.
- Provision for classification of external aborts on page G3-4551.
- Parity or ECC error reporting on page G3-4551.

The section Exception reporting in a VMSA v8-32 implementation on page G4-4663 describes the reporting of external aborts.

G3.6.1 External abort on instruction fetch

An external abort on an instruction fetch can be either synchronous or asynchronous. A synchronous external abort on an instruction fetch is taken precisely.

An implementation can report the external abort asynchronously from the instruction that it applies to. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when PSTATE.A is set to 1, otherwise they are reported using the Data Abort exception.

G3.6.2 External abort on data read or write

Externally-generated errors during a data read or write can be either synchronous or asynchronous.
An implementation can report the external abort asynchronously from the instruction that generated the access. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when PSTATE.A is set to 1, otherwise they are reported using the Data Abort exception.

G3.6.3 Provision for classification of external aborts

For a synchronous external abort taken to a privileged mode other than Hyp mode, an implementation can use the DFSR.ExT and IFSR.ExT bits to provide more information about synchronous external aborts:

- DFSR.ExT provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on data accesses.
- IFSR.ExT provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on instruction accesses.

For a synchronous external abort taken to Hyp mode, the HSR.EA, ISS[9] bit, provides an IMPLEMENTATION DEFINED classification of external aborts.

For all aborts other than synchronous external aborts these bits return a value of 0.

G3.6.4 Parity or ECC error reporting

The ARM architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache systems. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see Exception reporting in a VMSAv8-32 implementation on page G4-4663. However when parity or ECC error reporting is implemented it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code, or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as external aborts.
G3.7 Memory barrier instructions

Memory barriers on page E2-2768 describes the memory barrier instructions. This section describes the system level controls of those instructions.

G3.7.1 EL2 control of the Shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 and supports Shareability limitations on the data barrier instructions, the HCR.BSU field can modify the required Shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. Table G3-7 shows the encoding of this field:

Table G3-7 EL2 control of Shareability of barrier instructions executed at EL0 or EL1

<table>
<thead>
<tr>
<th>HCR.BSU</th>
<th>Minimum Shareability of barrier instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect, Shareability is as specified by the instruction</td>

G3.8 Pseudocode description of general memory system instructions

This section lists the pseudocode describing general memory operations:

- Memory data type definitions.
- Basic memory access.
- Aligned memory access on page G3-4554.
- Unaligned memory access on page G3-4554.
- Exclusives monitors operations on page G3-4554.
- Access permission checking on page G3-4555.
- Abort exceptions on page G3-4555.
- Memory barriers on page G3-4555.

G3.8.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the AddressDescriptor type.
- Full address, defined by the FullAddress type.
- Memory attributes, defined by the MemoryAttributes type.
- Memory type, defined by the MemType enumeration.
- Device memory type, defined by the DeviceType enumeration.
- Normal memory attributes, defined by the MemAttrHints type.
- Cacheability attributes, defined by the MemAttr_NC, MemAttr_WT, and MemAttr_WB constants.
- Allocation hints, defined by the MemHint_No, MemHint_WA, Memhint_RA, and MemHint_RWA constants.
- Access permissions, defined by the Permissions type.

G3.8.2 Basic memory access

The two forms of the \_Mem[] accessor, non-assignment (memory read) \_Mem[] and assignment (memory write) \_Mem[], are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The functions address the array using desc.paddress, that supplies:

- The physical address.
- An NS bit that selects between the Secure and Non-secure parts of the array.

The attributes in desc.memattrs are used by the memory system to determine caching and ordering behaviors as described in Memory types and attributes on page E2-2782, Definition of the ARMv8 memory model on page E2-2762, and Atomicity in the ARM architecture on page E2-2758.

An additional parameter to the \_Mem[] accessor defines the access type, for example normal, exclusive, or ordered, and whether the access is made as part of a translation table walk.

The actual implemented array of memory might be smaller than the maximum address size that can be accessed from AArch32 state. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to external aborts or a System Error.

PAMax() returns the IMPLEMENTATION DEFINED size of the physical address.

Note

A stage of address translation using VMSAv8-32 cannot generate an output address of more than 40 bits.
G3.8.3  Aligned memory access

The AArch32.MemSingle[] functions make atomic, little-endian accesses of size bytes.

G3.8.4  Unaligned memory access

See Unaligned data access on page E2-2777 for details of the SCTLR.A and HSCTLR.A controls on the generation of alignment faults. The HSCTLR control applies to Normal memory accesses from Hyp mode, and the SCTLR control applies to Normal memory accesses from all other modes.

The Mem_with_type[] functions make an access of the required type. If that access is naturally aligned, each form of the function performs an atomic access by making a single call to AArch32.MemSingle[]. If that access is not aligned but passes the AArch32.CheckAlignment() checks, each form of the function synthesizes the required access from multiple calls to AArch32.MemSingle[]. It also reverses the byte order if the access is big-endian.

G3.8.5  Exclusives monitors operations

The AArch32.SetExclusiveMonitors() function sets the Exclusives monitors for a Load-Exclusive instruction, for a block of bytes. The size of the blocks is determined by size, at the VA address. The ExclusiveMonitorsPass() function checks whether a Store-Exclusive instruction still has possession of the Exclusives monitors and therefore completes successfully.

The AArch32.ExclusiveMonitorsPass() function checks whether a Store-Exclusive instruction still has possession of the Exclusives monitors, by checking whether the Exclusives monitors are set to include the location of the memory block specified by size, at the virtual address defined by address. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to AArch32.SetExclusiveMonitors().

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The MarkExclusiveGlobal() procedure takes as arguments a FullAddress.paddress, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The MarkExclusiveLocal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records in a local record that PE processorid has requested exclusive access to an address covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a MarkExclusiveGlobal() using the same parameters.

The IsExclusiveGlobal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked in a global record an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, IsExclusiveGlobal() returns FALSE.

The IsExclusiveLocal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked an address range as exclusive access requested that covers at least the size bytes from address paddress. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of size bytes from address paddress. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of IsExclusiveGlobal() with the same parameters.
The `ClearExclusiveByAddress()` procedure takes as arguments a FullAddress `paddress`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of size bytes starting from `paddress` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of size bytes starting from `paddress` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

**G3.8.6 Access permission checking**

The function `AArch32.CheckPermission()` is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors.

The interpretation of access permission is shown in Memory access control on page G4-4605.

**G3.8.7 Abort exceptions**

The function `AArch32.Abort()` generates a Data Abort exception or a Prefetch Abort exception by calling the `AArch32.TakeDataAbortException()` or `AArch32.TakePrefetchAbortException()` function.

The `FaultRecord` type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. Pseudocode description of VMSAv8-32 memory system operations on page G4-4748 provides a number of wrappers to generate a FaultRecord.

The function `AArch32.NoFault()` returns a null record that indicates no fault. The `IsFault()` function tests whether a FaultRecord contains a fault.

**G3.8.8 Memory barriers**

The definition for the memory barrier functions is given by the enumerations `MBReqDomain` and `MBReqTypes`.

These enumerations define the required Shareability domains and required access types used as arguments for `DMB` and `DSB` instructions.

The procedures `DataMemoryBarrier()`, `DataSynchronizationBarrier()`, and `InstructionSynchronizationBarrier()` perform the memory barriers.
G3 The AArch32 System Level Memory Model
G3.8 Pseudocode description of general memory system instructions
Chapter G4
The AArch32 Virtual Memory System Architecture

This chapter describes the ARMv8-A AArch32 Virtual Memory System Architecture (VMSA), that is backwards-compatible with VMSAv7. It includes the following sections:

- About VMSAv8-32 on page G4-4558.
- The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4567.
- Translation tables on page G4-4571.
- The VMSAv8-32 Short-descriptor translation table format on page G4-4576.
- The VMSAv8-32 Long-descriptor translation table format on page G4-4585.
- Memory access control on page G4-4605.
- Memory region attributes on page G4-4616.
- Translation Lookaside Buffers (TLBs) on page G4-4628.
- TLB maintenance requirements on page G4-4632.
- Caches in VMSAv8-32 on page G4-4646.
- VMSAv8-32 memory aborts on page G4-4649.
- Exception reporting in a VMSAv8-32 implementation on page G4-4663.
- Address translation instructions on page G4-4682.
- About the System registers for VMSAv8-32 on page G4-4689.
- VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space on page G4-4704.
- VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G4-4707.
- Functional grouping of VMSAv8-32 System registers on page G4-4726.
- Pseudocode description of VMSAv8-32 memory system operations on page G4-4748.

Note
This chapter must be read with Chapter G3 The AArch32 System Level Memory Model.
G4.1 About VMSAv8-32

Note

This chapter describes the ARMv8 VMSA for AArch32 state, VMSAv8-32. This is generally equivalent to VMSAv7 for an implementation that includes all of the Security Extensions, the Multiprocessing Extensions, the Large Physical Address Extension, and the Virtualization Extensions.

This chapter describes the control of the VMSA by Exception levels that are using AArch32. Security state, Exception levels, and AArch32 execution privilege on page G1-4318 summarizes how the AArch32 PE modes map onto the Exception levels.

Chapter D4 The AArch64 Virtual Memory System Architecture describes the control of the VMSA by Exception levels that are using AArch64.

For details of the VMSA differences in previous versions of the ARM architecture see the ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.

The main function of the VMSA is to perform address translation, and access permissions and memory attribute determination and checking, for memory accesses made by the PE. Address translation, and permissions and attribute determination and checking, is performed by a stage of address translation.

In VMSAv8-32, the Memory Management Unit (MMU) provides a number of stages of address translation. This chapter describes only the stages that are visible from Exception levels that are using AArch32, which are as follows:

For operation in Secure state

A single stage of address translation, for use when executing at PL1 or PL0. This is the Secure PL1&0 stage 1 address translation stage.

For operation in Non-secure state

- A single stage of address translation for use when executing at PL2. This is the Non-secure PL2 stage 1 address translation stage.
- Two stages of address translation for use when executing at PL1 or PL0. These are:
  - The Non-secure PL1&0 stage 1 address translation stage.
  - The Non-secure PL1&0 stage 2 address translation stage.

The System registers provide independent control of each supported stage of address translation, including a control to disable that stage of translation.

However, if the PE is executing at EL0 using AArch32 when EL1 is using AArch64 then it is using the VMSAv8-64 EL1&0 translation regime, described in Chapter D4 The AArch64 Virtual Memory System Architecture.

These features mean the VMSAv8-32 can support a hierarchy of software supervision, for example an Operating System and a hypervisor.

Each stage of address translation uses address translations and associated memory properties held in memory mapped tables called translation tables.

For information about how the MMU features differ if an implementation does not include all of the Exception levels, see About address translation for VMSAv8-32 on page G4-4562.

The translation tables define the following properties:

Access to the Secure or Non-secure address map

The translation table entries determine whether an access from Secure state accesses the Secure or the Non-secure address map. Any access from Non-secure state accesses the Non-secure address map.
Memory access permission control

This controls whether a program is permitted to access a memory region. For instruction and data access, the possible settings are:

- No access.
- Read-only.
- Write-only. This is possible only in a translation regime with two stages of translation.
- Read/write.

For instruction accesses, additional controls determine whether instructions can be fetched and executed from the memory region.

If a PE attempts an access that is not permitted, a memory fault is signaled to the PE.

Memory region attributes

These describe the properties of a memory region. The top-level attribute, the Memory type, is one of Normal, or a type of Device memory, as follows:

- Both translation table formats support the following Device memory types:
  - Device-nGnRnE
  - Device-nGnRE
- The Long-descriptor translation table format supports, in addition, the following Device memory types:
  - Device-nGRE
  - Device-GRE

Note

ARMv8 added the Device-nGRE and Device-GRE memory types. Also, in versions of the ARM architecture before ARMv8:

- Device-nGnRnE memory is described as Strongly-ordered memory.
- Device-nGnRE memory is described as Device memory.

Normal memory regions can have additional attributes.

For more information, see Memory types and attributes on page E2-2782.

Address translation mappings

An address translation maps an input address to an output address.

A stage 1 translation takes the address of an explicit data access or instruction fetch, a virtual address (VA), as the input address, and translates it to a different output address:

- If only one stage of translation is provided, this output address is the physical address (PA).
- If two stages of address translation are provided, the output address of the stage 1 translation is an intermediate physical address (IPA).

Note

In the ARMv8-32 architecture, a software agent, such as an Operating System, that uses or defines stage 1 memory translations, might be unaware of the distinction between IPA and PA.

A stage 2 translation translates the IPA to a PA.

The possible Security states and privilege levels of memory accesses define a set of translation regimes, where a translation regime maps an input VA to the corresponding PA, using one or two stages of translation. See The VMSAv8-32 translation regimes on page G4-4560.

System registers control VMSAv8-32, including defining the location of the translation tables, and enabling and configuring the MMU, including enabling and disabling the different address translation stages. Also, they report any faults that occur on a memory access. For more information, see Functional grouping of VMSAv8-32 System registers on page G4-4726.
The following sections give an overview of VMSAv8-32, and of the implementation options for VMSAv8-32:

- **The VMSAv8-32 translation regimes.**
- **Address types used in a VMSAv8-32 description** on page G4-4561.
- **Address spaces in VMSAv8-32** on page G4-4561.
- **About address translation for VMSAv8-32** on page G4-4562.

The remainder of the chapter fully describes the VMSA, including the different implementation options, as summarized in **Organization of the remainder of this chapter** on page G4-4565.

### G4.1.1 The VMSAv8-32 translation regimes

As introduced in **Address translation mappings** on page G4-4559, a translation regime maps an input VA to the corresponding PA, using one or two stages of translation. **Figure G4-1** shows the VMSAv8-32 translation regimes, and their associated translation stages and the Exception levels from which they are controlled.

![Figure G4-1 VMSAv8-32 translation regimes, and associated control](image)

Conceptually, a translation regime that has only a stage 1 address translation is equivalent to a regime with a fixed, flat stage 2 mapping from IPA to PA.

**Limited use of Privilege level in ARMv8 AArch32 state** on page G1-4319 describes the mapping between the PE modes and the Privilege levels (PLs).

### Alternative descriptions of the PL1&0 translation regime

The PL1&0 is described in terms of Privilege level because of the way the AArch32 PE modes map onto the Exception levels, as described in **Limited use of Privilege level in ARMv8 AArch32 state** on page G1-4319. The description of this translation regime in terms of the Exception levels using depends on the current state of the PE, as follows:

- **In Non-secure state**, PL1 always maps to EL1, and therefore the Non-secure PL1&0 translation regime could be described as the Non-secure EL1&0 translation regime.

- **In Secure state:**
  - When EL3 is using AArch32, PL1 maps to EL3, and therefore under these conditions the Secure PL1&0 translation regime could be described as the Secure EL3&0 translation regime,
  - When EL3 is using AArch64, Secure PL1 maps to Secure EL1, and therefore under these conditions the Secure PL1&0 translation regime could be described as the Secure EL1&0 translation regime,

However, these descriptions all refer to the same translation regime, with the same System registers that are associated with its stage 1 translations. Therefore, the regime is generally referred to as the PL1&0 translation regime.

**Note**

As **Figure G4-1** shows, Stage 2 translation is supported only in Non-secure state.
G4.1.2 Address types used in a VMSA\textsuperscript{8-32} description

A description of VMSA\textsuperscript{8-32} refers to the following address types.

--- Note ---

These descriptions relate to a VMSA\textsuperscript{8-32} description and therefore sometimes differ from the generic definitions given in the Glossary.

**Virtual address (VA)**

An address that is used in an instruction, as a data or instruction address, is a virtual address (VA).

An address that is held in the PC, LR, or SP, is a VA.

The VA map runs from zero to the size of the VA space. For AArch32 state, the maximum VA space is 4GB, giving a maximum VA range of \(0x00000000-0xFFFFFFFF\).

**Intermediate physical address (IPA)**

In a translation regime that provides two stages of address translation, the IPA is the address after the stage 1 translation, and is the input address for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA.

A VMSA\textsuperscript{8-32} implementation provides only one stage of address translation:

- If the implementation does not include EL2.
- When executing in Secure state.
- When executing in Hyp mode.

**Physical address (PA)**

The address of a location in the Secure or Non-secure memory map. That is, an output address from the PE to the memory system.

G4.1.3 Address spaces in VMSA\textsuperscript{8-32}

For execution in AArch32 state, the ARMv8 architecture supports:

- A VA space of up to 32 bits. The actual width is IMPLEMENTATION DEFINED.
- An IPA space of up to 40 bits. The translation tables and associated System registers define the width of the implemented address space.

--- Note ---

AArch32 defines two translation table formats. The \textit{Long-descriptor} format gives access to the full 40-bit IPA or PA space at a granularity of 4KB. The \textit{Short-descriptor} format:

- Gives access to a 32-bit PA space at 4KB granularity.
- Gives access to a 40-bit PA space, but only at 16MB granularity, by the use of Supersections.

If an implementation includes EL3, the address maps are defined independently for Secure and Non-secure operation, providing two independent 40-bit address spaces, where:

- A VA accessed from Non-secure state can only be translated to the Non-secure address map.
- A VA accessed from Secure state can be translated to either the Secure or the Non-secure address map.
G4.1.4 About address translation for VMSAv8-32

Address translation is the process of mapping one address type to another, for example, mapping VAs to IPAs, or mapping VAs to PAs. A translation table defines the mapping from one address type to another, and a *translation table base register* (TTBR) indicates the start of a translation table. Each implemented stage of address translation shown in Figure G4-1 on page G4-4560 requires its own translation tables.

For PL1&0 stage 1 translations, the mapping can be split between two tables, one controlling the lower part of the VA space, and the other controlling the upper part of the VA space. This can be used, for example, so that:

- One table defines the mapping for operating system and I/O addresses, that do not change on a context switch.
- A second table defines the mapping for application-specific addresses, and therefore might require updating on a context switch.

The VMSAv8-32 implementation options determine the supported address translation stages. The following descriptions apply when all implemented Exception levels are using AArch32:

**VMSAv8-32 without EL2 or EL3**

Supports only a single PL1&0 stage 1 address translation. Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by TTBR0 and TTBR1, and controlled by TTBCR.

**VMSAv8-32 with EL3 but without EL2**

Supports only the Secure PL1&0 stage 1 address translation and the Non-secure PL1&0 stage 1 address translation. In each Security state, this stage of translation can be split between two sets of translation tables, with base addresses defined by the Secure and Non-secure copies of TTBR0 and TTBR1, and controlled by the Secure and Non-secure copies of TTBCR.

**VMSAv8-32 with EL2 but without EL3**

The implementation supports the following stages of address translation:

**Non-secure PL2 stage 1 address translation**

The HTTBR defines the base address of the translation table for this stage of address translation, controlled by HTCR.

**Non-secure PL1&0 stage 1 address translation**

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of TTBR0 and TTBR1 and controlled by the Non-secure instance of TTBCR.

**Non-secure PL1&0 stage 2 address translation**

The VTTBR defines the base address of the translation table for this stage of address translation, controlled by VTCR.

**VMSAv8-32 with EL2 and EL3**

The implementation supports all the stages of address translation, as follows:

**Secure PL1&0 stage 1 address translation**

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Secure copies of TTBR0 and TTBR1, and controlled by the Secure instance of TTBCR.

**Non-secure PL2 stage 1 address translation**

The HTTBR defines the base address of the translation table for this stage of address translation, controlled by HTCR.

**Non-secure PL1&0 stage 1 address translation**

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of TTBR0 and TTBR1 and controlled by the Non-secure instance of TTBCR.
Non-secure PL1&0 stage 2 address translation

The VTTBR defines the base address of the translation table for this stage of address translation, controlled by VTCR.

Figure G4-2 shows the translation regimes and stages in a VMSAv8-32 implementation that includes all the Exception levels, and indicates the PE mode that, typically, defines each set of translation tables, if that stage of address translation is controlled by a Privilege level that is using AArch32:

![Figure G4-2 VMSAv8-32 address translation summary](image)

Note

The term *Typically configured* is used in Figure G4-2 to indicate the expected software usage. However, stages of address translation used in AArch32 state can also be configured:

- From an Exception level higher than the Exception level of the configuring PE mode shown in Figure G4-2, regardless of whether that Exception level is using AArch32 or is using AArch64, except that a Non-secure Exception level can never configure a stage of address translation that is used in Secure state.

- From an Exception level that is using AArch64 and is higher than the level at which the translation stage is being used. For example, if Non-secure EL0 is the only Non-secure Exception level that is using AArch32, then the Non-secure PL1&0 stage of address translation is configured from Non-secure EL1, that is using AArch64.

In general:

- The translation from VA to PA can require multiple stages of address translation, as Figure G4-2 shows.
- A single stage of address translation takes an *input address* and translates it to an *output address*.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single input address to output address translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:

- The required output address.
- The *attributes* and *access permissions* of the addressed memory.

*Translation Lookaside Buffers* (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and VMSAv8-32 provides TLB maintenance instructions for the management of TLB contents.

Note

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.
To reduce the software overhead of TLB maintenance, for the PL1&0 translation regimes VMSAv8-32 distinguishes between *Global pages* and *Process-specific pages*. The *Address Space Identifier* (ASID) identifies pages that are associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

If an implementation includes EL2, the *virtual machine identifier* (VMID) identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs. For stage 2 translations, all translations are associated with the current VMID. There is no mechanism to associate a particular stage 2 translation with multiple virtual machines.

**Atomicity of register changes on changing virtual machine**

From the viewpoint of software executing at Non-secure PL1 or PL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This rule applies to the registers for the Non-secure PL1&0 translation regime. This means that all of the following registers must change atomically:

- The registers that are associated with the stage 1 translations:
  - MAIR0, MAIR1, AMAIR0, and AMAIR1.
  - TTBR0, TTBR1, TTBCR, TTBCR2, and CONTEXTIDR.
  - SCTLR.
- The registers that are associated with the stage 2 translations:
  - VTTBR and VTCR.
  - HSCTLR.

**Note**

Only some fields of SCTLR affect the stage 1 translation, and only some fields of HSCTLR affect the stage 2 translation. However, in each case, changing these fields requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution using the Non-secure PL1&0 translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are out of context when they are updated, and no synchronization precautions are required.

**Use of out-of-context translation regimes**

The architecture requires that:

- When executing at EL3 or EL2, the PE must not use the registers that are associated with the Non-secure PL1&0 translation regime for speculative memory accesses.
- When executing at EL3 the PE must not use the registers that are associated with the EL2 translation regime for speculative memory accesses.
- When executing at EL3, EL2, or Non-secure EL1, the PE must not use the registers that are associated with the Secure PL1&0 translation regime for speculative memory accesses.

When entering an Exception level on completion of a DSB instruction, no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered, will be observed by any observers to the extent that those accesses are required to be observed, as determined by the Shareability and Cacheability of those translation table entries.

**Note**

- This does not require that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.
This requirement does not imply that, on taking an exception to a higher Exception level, any translation table
walks started before the exception was taken will be completed by the time the higher Exception level is
entered, and therefore memory accesses required for such a translation table walk might, in effect, be
performed speculatively. However, the execution of a 
DSB on entry to the higher Exception level ensures that
these accesses are complete.

G4.1.5 Organization of the remainder of this chapter

The remainder of this chapter is organized as follows.

The next part of the chapter describes address translation and the associated memory properties held in the
translation table entries, in the following sections:

- The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4567.
- Translation tables on page G4-4571.
- Secure and Non-secure address spaces on page G4-4574.
- The VMSAv8-32 Short-descriptor translation table format on page G4-4576.
- The VMSAv8-32 Long-descriptor translation table format on page G4-4585.
- Memory access control on page G4-4605.
- Memory region attributes on page G4-4616.
- Translation Lookaside Buffers (TLBs) on page G4-4628.
- TLB maintenance requirements on page G4-4632.

Caches in VMSAv8-32 on page G4-4646 describes VMSAv8-32-specific cache requirements.

The following sections then describe aborts on VMSAv8-32 memory accesses, and how these and other faults are
reported:

- VMSAv8-32 memory aborts on page G4-4649.
- Exception reporting in a VMSAv8-32 implementation on page G4-4663.

Address translation instructions on page G4-4682 then describes these operations, and how they relate to address
translation.

A number of sections then describe the System registers for VMSAv8-32. The following sections give general
information about the System registers, and the organization of the registers in the primary encoding spaces,
(coproc==0b1110) and (coproc==0b1111) for these registers:

- About the System registers for VMSAv8-32 on page G4-4689.
- VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space on page G4-4704.
- VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G4-4707.
- Functional grouping of VMSAv8-32 System registers on page G4-4726.

The following sections then describe each of the functional groups of the System registers in the (coproc==0b1111)
encoding space, including a full description of each register in the group:

- Identification registers, functional group on page G4-4727.
- Virtual memory control registers, functional group on page G4-4729.
- Exception and fault handling registers, functional group on page G4-4733.
- General system control registers, functional group on page G4-4728.
- Lockdown, DMA, and TCM features, functional group on page G4-4738.
- Cache maintenance instructions, functional group on page G4-4734.
- TLB maintenance instructions, functional group on page G4-4735.
- Address translation instructions, functional group on page G4-4737.
- Legacy feature registers, functional group on page G4-4744.
- Performance Monitors Extension registers, functional group on page G4-4738.
- Security registers, functional group on page G4-4732.
- Virtualization registers, functional group on page G4-4730.
- IMPLEMENTATION DEFINED registers, functional group on page G4-4744.
Note

The System registers in the (coproc==0b1110) encoding space provide the following functionality:

- Self-hosted debug. These registers are described in Debug registers on page G6-5239.
- The System register interface to a trace macrocell. These registers are not described in this manual.
- Jazelle registers. These registers are summarized in Legacy feature registers, functional group on page G4-4744.

Therefore, there is no summary of these registers by functional groups.

Pseudocode description of VMSAv8-32 memory system operations on page G4-4748 then summarizes the pseudocode functions that describe many features of VMSAv8-32 operation.
G4.2 The effects of disabling address translation stages on VMSAv8-32 behavior

About VMSAv8-32 on page G4-4558 defines the translation regimes and the associated stages of address translation, each of which has its own System registers for control and configuration. VMSAv8-32 includes an enable bit for each stage of address translation, as follows:

- SCTLR.M, in the Secure instance of the register, controls Secure PL1&0 stage 1 address translation.
- SCTLR.M, in the Non-secure instance of the register, controls Non-secure PL1&0 stage 1 address translation.
- HCR.VM controls Non-secure PL1&0 stage 2 address translation.
- HSCTLR.M controls Non-secure PL2 stage 1 address translation.

Note

- The descriptions throughout this chapter describe address translation as seen by Exception levels that are using AArch32. However, for the Non-secure PL1&0 translation regime, the stage 2 translation:
  - Is controlled by the HCR if EL2 is using AArch32.
  - Is controlled by the HCR_EL2 if EL2 is using AArch64.

For this reason, links to the HCR link to a table that disambiguates between the AArch32 HCR and the AArch64 HCR_EL2.

- If EL2 is using AArch64, then the equivalent of the Non-secure PL2 translation regime is described in Chapter D4 The AArch64 Virtual Memory System Architecture, not in this chapter.

The following sections describe the effect on VMSAv8-32 behavior of disabling each stage of translation:

- VMSAv8-32 behavior when stage 1 address translation is disabled.
- VMSAv8-32 behavior when stage 2 address translation is disabled on page G4-4569.
- Behavior of instruction fetches when all associated address translations are disabled on page G4-4569.

Enabling stages of address translation on page G4-4569 gives more information about each stage of address translation, in particular after a reset on an implementation that includes EL3.

G4.2.1 VMSAv8-32 behavior when stage 1 address translation is disabled

When stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of address translation are treated as follows:

Non-secure PL1 and PL0 accesses when EL2 is implemented and HCR.DC is set to 1

In an implementation that includes EL2, for an access from a Non-secure PL1 or PL0 mode when HCR.DC is set to 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate memory attributes.

See also Effect of the HCR.DC field on page G4-4568.

All other accesses

For all other accesses, when a stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

Instruction access

The stage 1 translation assigns Normal memory attribute, with the Cacheability and Shareability attributes determined by the value of:

- The Secure instance of SCTLR.I for the Secure PL1&0 translation regime.
- The Non-secure instance of SCTLR.I for the Non-secure PL1&0 translation regime.
- HSCTLR.I for the Non-secure PL2 translation regime.
In these cases, the meaning of the I field is as follows:

**When I is set to 0**
- The stage 1 translation assigns the attributes Outer Shareable, Non-cacheable.

**When I is set to 1**
- The stage 1 translation assigns the attributes Inner Write-Through Read-Allocate No Write-Allocate, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

--- **Note** ---

On some implementations, if the SCTLR.TRE field is set to 0 then this behavior can be changed by the remap settings in the memory remap registers. The details of TEX remap when SCTLR.TRE is set to 0 are IMPLEMENTATION DEFINED, see SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers on page G4-4621.

For this stage of translation, no memory access permission checks are performed, and therefore no MMU faults relating to this stage of translation can be generated.

--- **Note** ---

Alignment checking is performed, and therefore Alignment faults can occur.

---

For every access, when stage 1 translation is disabled, the output address of the stage 1 translation is equal to the input address. This is called a flat address mapping. If the implementation supports output addresses of more than 32 bits then the output address bits above bit[31] are zero. For example, for a VA to PA translation on an implementation that supports 40-bit PAs, PA[39:32] is 0x00.

For a Non-secure PL1 or PL0 access, if the PL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

See also *Behavior of instruction fetches when all associated address translations are disabled* on page G4-4569.

---

**Effect of the HCR.DC field**

The HCR.DC field determines the default memory attributes assigned for the first stage of the Non-secure PL1&0 translation regime when that stage of translation is disabled.

When executing in a Non-secure PL1 or PL0 mode with HCR.DC set to 1:

- For all purposes other than reading the value of the SCTLR, the PE behaves as if the value of the SCTLR.M field is 0. This means Non-secure PL1&0 stage 1 address translation is disabled.
- For all purposes other than reading the value of the HCR, the PE behaves as if the value of the HCR.VM field is 1. This means Non-secure PL1&0 stage 2 address translation is enabled.

The effect of HCR.DC might be held in TLB entries associated with a particular VMID. Therefore, if software executing at EL2 changes the HCR.DC value without also changing the current VMID, it must also invalidate all TLB entries associated with the current VMID. Otherwise, the behavior of Non-secure software executing at EL1 or EL0 is CONSTRAINED UNPREDICTABLE, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-6101.

---

**Effect of disabling translation on maintenance and address translation instructions**

Cache maintenance instructions act on the target cache whether address translation is enabled or not, and regardless of the values of the memory attributes. However, if a stage of translation is disabled, they use the flat address mapping for that stage, and all mappings are considered global.

TLB invalidate operations act on the target TLB whether address translation is enabled or not.

When the Non-secure PL1&0 stage 1 address translation is disabled, any ATS1C** or ATS12NSO** address translation instruction that accesses the Non-secure state translation reflects the effect of the HCR.DC field.
G4.2.2 VMSAv8-32 behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:
- The IPA output from the stage 1 translation maps flat to the PA.
- The memory attributes and permissions from the stage 1 translation apply to the PA.

If the stage 1 address translation and the stage 2 address translation are both disabled, see *Behavior of instruction fetches when all associated address translations are disabled*.

G4.2.3 Behavior of instruction fetches when all associated address translations are disabled

The information in this section applies to memory accesses:
- From Secure PL1 and PL0 modes, when the Secure PL1&0 stage 1 address translation is disabled.
- From Hyp mode, when the Non-secure PL2 stage 1 address translation is disabled.
- From Non-secure PL1 and PL0 modes, when all of the following apply:
  - The Non-secure PL1&0 stage 1 address translation is disabled.
  - The Non-secure PL1&0 stage 2 address translation is disabled.
  - HCR.DC is set to 0.

In these cases, when execution is in AArch32 state a memory location might be accessed as a result of an instruction fetch if either:
- The memory location is in the same 4KB block of memory, aligned to 4KB, as an instruction which a simple sequential execution of the program either requires to be fetched now or has required to be fetched since the last reset, or is in the 4KB block immediately following such a block.
- The memory location is the target of a direct branch that a simple sequential execution of the program would have taken since the most recent of:
  - The last reset.
  - If the branch predictor is architecturally invisible, the last synchronization of instruction cache maintenance targeting the address of the branch instruction.
  - If the branch predictor is not architecturally invisible, the last synchronization of branch predictor maintenance targeting the address of the branch instruction.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

Note

To ensure architectural compliance, software must ensure that both of the following apply:
- Instructions that will be executed when address translation is disabled are located in 4KB blocks of the address space that contain only memory that is tolerant to speculative accesses.
- Each 4KB block of the address space that immediately follows a 4KB block that holds instructions that will be executed when address translation is disabled also contains only memory that is tolerant to speculative accesses.

G4.2.4 Enabling stages of address translation

On powerup or reset, only the SCTLR.M field for the Exception level and Security state entered on reset is reset to 0, disabling address translation for the initial state of the PE. All other SCTLR.M and HSCTLR.M fields that are implemented are UNKNOWN after the reset.
This means, on powerup or reset:

- On an implementation that includes EL3, where EL3 is using AArch32:
  - The PL1&0 stage 1 address translation enable bit, SCTLR.M, is Banked, meaning there are separate enables for operation in Secure and Non-secure state.
  - If EL3 is using AArch32, only the Secure instance of the SCTLR.M field resets to 0, disabling the Secure state PL1&0 stage 1 address translation. The reset value of the Non-secure instance of SCTLR.M is UNKNOWN.

- On an implementation that includes EL2, where EL2 is using AArch32, the HSCTLR.M field, that controls the Non-secure PL2 stage 1 address translation:
  - If the implementation does not include EL3, resets to 0.
  - Otherwise, is UNKNOWN.

- On an implementation that does not include either EL2 or EL3, there is a single stage of translation. This is controlled by SCTLR.M, that resets to 0.

**Note**

If, for the software that enables or disables a stage of address translation, the input address of a stage 1 translation differs from the output address of that stage 1 translation, and the software is running in translation regime that is affected by that stage of translation, then the requirement to synchronize changes to the System registers means it is uncertain where in the instruction stream the change of the translation takes place. For this reason, ARM strongly recommends that the input address and the output address are identical in this situation.
G4.3 Translation tables

VMSAv8-32 defines two alternative translation table formats:

**Short-descriptor format**

It uses 32-bit descriptor entries in the translation tables, and provides:

- Up to two levels of address lookup.
- 32-bit input addresses.
- Output addresses of up to 40 bits.
- Support for PAs of more than 32 bits by use of supersections, with 16MB granularity.
- Support for No access, Client, and Manager domains.

**Long-descriptor format**

It uses 64-bit descriptor entries in the translation tables, and provides:

- Up to three levels of address lookup.
- Input addresses of up to 40 bits, when used for stage 2 translations.
- Output addresses of up to 40 bits.
- 4KB assignment granularity across the entire PA range.
- No support for domains, all memory regions are treated as in a Client domain.
- Fixed 4KB table size, unless truncated by the size of the input address space.

--- Note ---

- Translation with a 40-bit input address range requires two concatenated 4KB top-level tables, aligned to 8KB.
- The VMSAv8-64 Long-descriptor translation table format is generally similar to this format, but supports input and output addresses of up to 48 bits, and has an assignment granularity and table size defined by its translation granule. This can be 4KB, 16KB, or 64KB. See *The VMSAv8-64 translation table format* on page D4-2042.

In all implementations, of the possible address translations shown in Figure G4-2 on page G4-4563, for stages of address translation that are using AArch32:

- In a particular Security state, the translation tables for the PL1&0 stage 1 translations can use either translation table format, and the TTBCR.EAE field indicates the current translation table format.
- The translation tables for the Non-secure PL2 stage 1 translations, and for the Non-secure PL1&0 stage 2 translations, must use the Long-descriptor translation table format.

Many aspects of performing a translation table walk depend on the current translation table format. Therefore, the following sections describe the two formats, including how the MMU performs a translation table walk for each format:

- *The VMSAv8-32 Short-descriptor translation table format* on page G4-4576.
- *The VMSAv8-32 Long-descriptor translation table format* on page G4-4585.

The following subsections describe aspects of the translation tables and translation table walks, for memory accesses from AArch32 state, that are independent of the translation table format:

- *Translation table walks for memory accesses using VMSAv8-32 translation regimes* on page G4-4572.
- *Information returned by a translation table lookup* on page G4-4572.
- *Determining the translation table base address in the VMSAv8-32 translation regimes* on page G4-4573.
- *Control of translation table walks on a TLB miss* on page G4-4574.
- *Access to the Secure or Non-secure physical address map* on page G4-4574.

See also *TLB maintenance requirements* on page G4-4632.
Translation table walks for memory accesses using VMSAv8-32 translation regimes

A translation table walk occurs as the result of a TLB miss, and starts with a read of the appropriate starting-level translation table. The result of that read determines whether additional translation table reads are required, for this stage of translation, as described in either:

- Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G4-4582.
- Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G4-4600.

--- Note ---
When using the Short-descriptor translation table format, the starting level for a translation table walk is always a level 1 lookup. However, with the Long-descriptor translation table format, the starting-level can be either a level 1 or a level 2 lookup.

---

For the PL1&0 stage 1 translations, SCTLR.EE determines the endianness of the translation table lookups. SCTLR is Banked, and therefore the endianness is determined independently for each Security state.

HSCTLR.EE defines the endianness for the Non-secure PL2 stage 1 and Non-secure PL1&0 stage 2 translations.

--- Note ---
Dynamically changing translation table endianness

Because any change to SCTLR.EE or HSCTLR.EE requires synchronization before it is visible to subsequent operations, ARM strongly recommends that:

- SCTLR.EE is changed only when either:
  - Executing in a mode that does not use the translation tables affected by SCTLR.EE.
  - Executing with SCTLR.M set to 0.
- HSCTLR.EE is changed only when either:
  - Executing in a mode that does not use the translation tables affected by HSCTLR.EE.
  - Executing with HSCTLR.M set to 0.

---

The physical address of the base of the starting-level translation table is determined from the appropriate TTBR, see Determining the translation table base address in the VMSAv8-32 translation regimes on page G4-4573.

For more information, see Ordering and completion of TLB maintenance instructions on page G4-4635.

Translation table walks must access data or unified caches, or data and unified caches, of other agents participating in the coherency protocol, according to the Shareability attributes described in the TTBR. These Shareability attributes must be consistent with the Shareability attributes for the translation tables themselves.

Information returned by a translation table lookup

When an associated stage of address translation is enabled, a memory access requires one or more translation table lookups. If the required translation table descriptor is not held in a TLB, a translation table walk is performed to obtain the descriptor. A lookup, whether from the TLB or as the result of a translation table walk, returns both:

- An output address that corresponds to the input address for the lookup.
- A set of properties that correspond to that output address.

The returned properties are classified as providing address map control, access controls, or region attributes. This classification determines how the descriptions of the properties are grouped. The classification is based on the following model:

**Address map control**

Memory accesses from Secure state can access either the Secure or the Non-secure address map, as summarized in Access to the Secure or Non-secure physical address map on page G4-4574.

Memory accesses from Non-secure state can only access the Non-secure address map.
G4.3 Translation tables

Access controls
Determine whether the PE, in its current state, can access the output address that corresponds to the given input address. If not, an MMU fault is generated and there is no memory access.

*Memory access control on page G4-4605* describes the properties in this group.

Attributes
Are valid only for an output address that the PE, in its current state, can access. The attributes define aspects of the required behavior of accesses to the target memory region.

*Memory region attributes on page G4-4616* describes the properties in this group.

G4.3.3 Determining the translation table base address in the VMSAv8-32 translation regimes

On a TLB miss, the VMSA must perform a translation table walk, and therefore must find the base address of the translation table to use for its lookup. A TTBR holds this address. As Figure G4-2 on page G4-4563 shows:

- For a Non-secure PL2 stage 1 translation, the HTTBR holds the required base address. The HTCR is the control register for these translations.
- For a Non-secure PL1&0 stage 2 translation, the VTTBR holds the required base address. The VTCR is the control register for these translations.
- For a PL1&0 stage 1 translation, either TTBR0 or TTBR1 holds the required base address. The TTBCR is the control register for these translations.

The Non-secure copies of TTBR0, TTBR1, and TTBCR, relate to the Non-secure PL1&0 stage 1 translation. The Secure copies of TTBR0, TTBR1, and TTBCR, relate to the Secure PL1&0 stage 1 translation.

For the PL1&0 translation table walks:

- TTBR0 can be configured to describe the translation of VAs in the entire address map, or to describe only the translation of VAs in the lower part of the address map.
- If TTBR0 is configured to describe the translation of VAs in the lower part of the address map, TTBR1 is configured to describe the translation of VAs in the upper part of the address map.

The contents of the appropriate instance of the TTBCR determine whether the address map is separated into two parts, and where the separation occurs. The details of the separation depend on the current translation table format, see:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G4-4581.*
- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4594.*

Example G4-1 shows a typical use of the two sets of translation tables:

Example G4-1 Example use of TTBR0 and TTBR1

An example of using the two TTBRs for PL1&0 stage 1 address translations is:

**TTBR0**
Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- TTBR0 is updated to point to the level 1 translation table for the new context.
- TTBCR is updated if this change changes the size of the translation table.
- The CONTEXTIDR is updated.

TTBCR can be programmed so that all translations use TTBR0 in a manner compatible with architecture versions before ARMv6.

**TTBR1**
Used for operating system and I/O addresses, that do not change on a context switch.
G4.3.4 Control of translation table walks on a TLB miss

Two fields in the TCR for the translation stage required by a memory access control whether a translation table walk is performed on a TLB miss. These two fields are the:

- PD0 and PD1 fields, on a PE using the Short-descriptor translation table format.
- EPD0 and EPD1 fields, on a PE using the Long-descriptor translation table format.

**Note**

For the VMSAv8-32 translation regimes, the different field names are because the fields are in different positions in TTBCR, depending on the translation table format.

The effect of these fields is:

{E}PDx == 0  If a TLB miss occurs based on TTBRx, a translation table walk is performed. The current Security state determines whether the memory access is Secure or Non-secure.

{E}PDx == 1  If a TLB miss occurs based on TTBRx, a level 1 Translation fault is returned, and no translation table walk is performed.

G4.3.5 Access to the Secure or Non-secure physical address map

As stated in Address spaces in VMSAv8-32 on page G4-4561, a PE can access independent Secure and Non-secure address maps. When the PL1 Exception level is using AArch32, these are defined by the translation tables identified by the Secure TTBR0 and TTBR1. In both translation table formats in the Secure translation tables, the NS field in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map:

NS == 0  Access the Secure physical address space.

NS == 1  Access the Non-secure physical address space.

**Note**

In the Non-secure translation tables, the corresponding field is SBZ. Non-secure accesses always access the Non-secure physical address space, regardless of the value of this field.

The Long-descriptor translation table format extends this control, adding an NSTable field to the Secure translation tables, as described in Hierarchical control of Secure or Non-secure memory accesses. Long-descriptor format on page G4-4593. In the Non-secure translation tables, the corresponding field is SBZ, and Non-secure accesses ignore the value of this field.

The following sections describe the address map controls in the two implementations:

- *Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G4-4581.*
- *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4593.*

The following subsection gives more information.

**Secure and Non-secure address spaces**

EL3 provides two physical address spaces, a Secure physical address space and a Non-secure physical address space.

As described in Access to the Secure or Non-secure physical address map, for the PL1&0 stage 1 translations when controlled from an Exception level using AArch32, the registers that control the stage of translation, TTBR0, TTBR1, TTBCR, and TTBCR2 are Banked to provide independent Secure and Non-secure instances of the registers, and the Security state of the PE when it performs a memory access whether the Secure or Non-secure instances are used. This means that for stage 1 of the PL1&0 translation regime there are independent Secure and Non-secure translation tables, and translation table walks are made to the physical address space corresponding to the Security state of the translation tables used.
For a translation table walk caused by a memory access from Non-secure state, all memory accesses are to the Non-secure address space.

For a translation table walk caused by a memory access from Secure state:

- When address translation is using the Long-descriptor translation table format:
  - The initial lookup performed must access the Secure address space.
  - If a table descriptor read from the Secure address space has the NSTable field set to 0, then the next level of lookup is from the Secure address space.
  - If a table descriptor read from the Secure address space has the NSTable field set to 1, then the next level of lookup, and any subsequent level of lookup, is from the Non-secure address space.

For more information, see Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4593.

- Otherwise, all memory accesses are to the Secure address space.

--- Note ---

- When executing in Non-secure state, additional translations are supported. For memory accesses from AArch32 state these are:
  - Non-secure PL2 stage 1 translation.
  - Non-secure PL1&0 stage 2 translation.

These translations can access only the Non-secure address space.

- A system implementation can alias parts of the Secure physical address space to the Non-secure physical address space in an implementation-specific way. As with any other aliasing of physical memory, the use of aliases in this way can require the use of cache maintenance instructions to ensure that changes to memory made using one alias of the physical memory are visible to accesses to the other alias of the physical memory.
G4.4 The VMSAv8-32 Short-descriptor translation table format

The Short-descriptor translation table format supports a memory map based on memory sections or pages:

**Supersections** Consist of 16MB blocks of memory. Support for Supersections is optional, except that an implementation that supports more than 32 bits of physical address must also support Supersections to provide access to the entire physical address space.

**Sections** Consist of 1MB blocks of memory.

**Large pages** Consist of 64KB blocks of memory.

**Small pages** Consist of 4KB blocks of memory.

Supersections, Sections and Large pages map large regions of memory using only a single TLB entry.

**Note**

Whether a VMSAv8-32 implementation of the Short-descriptor format translation tables supports supersections is IMPLEMENTATION DEFINED.

When using the Short-descriptor translation table format, two levels of translation tables are held in memory:

**Level 1 table**

Holds *level 1 descriptors* that contain the base address and

- Translation properties for a Section and Supersection.
- Translation properties and pointers to a level 2 table for a Large page or a Small page.

**Level 2 tables**

Hold *level 2 descriptors* that contain the base address and translation properties for a Small page or a Large page. With the Short-descriptor format, level 2 tables can be referred to as *Page tables*.

A level 2 table requires 1KB of memory.

In the translation tables, in general, a descriptor is one of:

- An invalid or fault entry.
- A Page table entry, that points to a next-level translation table.
- A page or section entry, that defines the memory properties for the access.
- A reserved format.

Bits[1:0] of the descriptor give the primary indication of the descriptor type.

**Figure G4-3 on page G4-4577** gives a general view of address translation when using the Short-descriptor translation table format.
G4 The AArch32 Virtual Memory System Architecture

G4.4 The VMSAv8-32 Short-descriptor translation table format

Additional requirements for Short-descriptor format translation tables on page G4-4580 describes why, when using the Short-descriptor format, Supersection and Large page entries must be repeated 16 times, as shown in Figure G4-3.

VMSAv8-32 Short-descriptor translation table format descriptors, Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4580, and Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G4-4581 describe the format of the descriptors in the Short-descriptor format translation tables.

The following sections then describe the use of this translation table format:

• Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G4-4581.
• Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G4-4582.

G4.4.1 VMSAv8-32 Short-descriptor translation table format descriptors

The following sections describe the formats of the entries in the Short-descriptor translation tables:

• Short-descriptor translation table level 1 descriptor formats on page G4-4578.
• Short-descriptor translation table level 2 descriptor formats on page G4-4579.

For more information about level 2 translation tables see Additional requirements for Short-descriptor format translation tables on page G4-4580.

Note

Information returned by a translation table lookup on page G4-4572 describes the classification of the non-address fields in the descriptors as address map control, access control, or attribute fields.
Short-descriptor translation table level 1 descriptor formats

Each entry in the level 1 table describes the mapping of the associated 1MB VA range.

Figure G4-4 shows the possible level 1 descriptor formats.

<table>
<thead>
<tr>
<th>Descriptor bits[1:0]</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00, Invalid entry</td>
<td>Invalid entry</td>
<td>The associated VA is unmapped, and any attempt to access it generates a Translation fault. Bits[31:2] of the descriptor are IGNORED, see IGNORED on page Glossary-6341. This means software can use these bits for its own purposes.</td>
</tr>
<tr>
<td>0b01, Page table</td>
<td>Page table</td>
<td>The descriptor gives the address of a level 2 translation table, that specifies the mapping of the associated 1MByte VA range.</td>

<td>0b10, Section or Supersection</td>
<td>Section or Supersection</td>
<td>The descriptor gives the base address of the Section or Supersection. Bit[18] determines whether the entry describes a Section or a Supersection. This encoding also defines the PXN field as 0.</td>
</tr>
<tr>
<td>0b11, Section or Supersection, if the implementation supports the PXN attribute</td>
<td>Section or Supersection, if the implementation supports the PXN attribute</td>
<td>This encoding is identical to 0b10, except that it defines the PXN field as 1.</td>
</tr>
</tbody>
</table>
Note

A VMSA8-32 implementation can use the Short-descriptor translation table format for the PL1&0 stage 1 translations, by setting TTBCR.EAE to 0.

The address information in the level 1 descriptors is:

**Page table** Bits[31:10] of the descriptor are bits[31:10] of the address of a Page table.

**Section** Bits[31:20] of the descriptor are bits[31:20] of the address of the Section.

**Supersection** Bits[31:24] of the descriptor are bits[31:24] of the address of the Supersection.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see Memory attributes in the VMSA8-32 Short-descriptor translation table format descriptors on page G4-4580.

**Short-descriptor translation table level 2 descriptor formats**

Figure G4-5 shows the possible formats of a level 2 descriptor.

</tr>
</tbody>
</table>

**Large page**

- Bits[31:16] of the descriptor are bits[31:16] of the address of the Large page.
- The associated VA is unmapped, and attempting to access it generates a Translation fault.

**Small page**

- Bits[31:12] of the descriptor are bits[31:12] of the address of the Small page.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

---
For descriptions of the other fields in the descriptors, see *Memory attributes in the VMSA v8-32 Short-descriptor translation table format descriptors*.

### Additional requirements for Short-descriptor format translation tables

When using Supersection or Large page descriptors in the Short-descriptor translation table format, the input address field that defines the Supersection or Large page descriptor address overlaps the table address field. In each case, the size of the overlap is 4 bits. The following diagrams show these overlaps:

- Figure K6-14 on page K6-6194 for the level 1 translation table entry for a Supersection.
- Figure K6-16 on page K6-6196 for the level 2 translation table entry for a Large page.

Considering the case of using Large page descriptors in a level 2 translation table, this overlap means that for any specific Large page, the bottom four bits of the level 2 translation table entry might take any value from 0b0000 to 0b1111. Therefore, each of these sixteen index values must point to a separate copy of the same descriptor.

This means that each Large page or Supersection descriptor must:

- Occur first on a sixteen-word boundary.
- Be repeated in 16 consecutive memory locations.

### G4.4.2 Memory attributes in the VMSA v8-32 Short-descriptor translation table format descriptors

This section describes the descriptor fields other than the descriptor type field and the address field:

**TEX[2:0], C, B**

Memory region attribute fields, see *Memory region attributes on page G4-4616*. These fields are not present in a descriptor for a Page table.

**XN bit**

The Execute-never bit. Determines whether the PE can execute software from the addressed region, see *Access permissions for instruction execution on page G4-4609*. This bit is not present in a descriptor for a Page table.

**PXN bit**

The Privileged execute-never bit. Determines whether the PE can execute software from the region when executing at PL1, see *Access permissions for instruction execution on page G4-4609*.

--- **Note**

Memory accesses by software executing at EL2 always use the Long-descriptor translation table format.

---

When this bit is set to 1 in the descriptor for a Page table, it indicates that all memory pages described in the corresponding Page table are Privileged execute-never.

**NS bit**

Non-secure bit. Specifies whether the translated PA is in the Secure or Non-secure address map, see *Control of Secure or Non-secure memory access, VMSA v8-32 Short-descriptor format on page G4-4581*. This bit is not present in level 2 descriptors. The value of the NS bit in a level 1 descriptor for a Page table applies to all entries in the corresponding level 2 translation table.

**Domain**

Domain field, see *Domains, Short-descriptor format only on page G4-4612*. This field is not present in a Supersection entry. Memory described by Supersections is in domain 0. This bit is not present in level 2 descriptors. The value of the Domain field in the level 1 descriptor for a Page table applies to all entries in the corresponding level 2 translation table.

**An IMPLEMENTATION DEFINED bit**

This bit is not present in level 2 descriptors.
AP[2], AP[1:0]
Access Permissions bits, see Memory access control on page G4-4605.
AP[0] can be configured as the Access flag, see The Access flag on page G4-4613.
These bits are not present in a descriptor for a Page table.

S bit
Shareable bit. Used in determining the Shareability of the addressed region, see Memory region attributes on page G4-4616.

Note
The naming of this bit as the Shareable bit is carried forward from early versions of the ARM architecture. This name is no longer an adequate description of the interpretation of the bit.

This bit is not present in a descriptor for a Page table.

nG bit
The not global bit. If a lookup using this descriptor is cached in a TLB, determines whether the TLB entry applies to all ASID values, or only to the current ASID value. See Global and process-specific translation table entries on page G4-4628.

This bit is not present in a descriptor for a Page table.

Bit[18], when bits[1:0] indicate a Section or Supersection descriptor
0  Descriptor is for a Section.
1  Descriptor is for a Supersection.

G4.4.3  Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format

Access to the Secure or Non-secure physical address map on page G4-4574 describes how the NS bit in the translation table entries:
• For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
• Is ignored by accesses from Non-secure state.

In the Short-descriptor translation table format, the NS bit is defined only in the level 1 translation tables. This means that, in a level 1 descriptor for a Page table, the NS bit defines the physical address map, Secure or Non-secure, for all of the Large pages and Small pages of memory described by that table.

The NS bit of a level 1 descriptor for a Page table has no effect on the physical address map in which that translation table is held. As stated in Secure and Non-secure address spaces on page G4-4574, the physical address of that translation table is in:
• The Secure address map if the translation table walk is in Secure state.
• The Non-secure address map if the translation table walk is in Non-secure state.

This means the granularity of the Secure and Non-secure memory maps is 1MB. However, in these memory maps, table entries can define physical memory regions with a granularity of 4KB.

G4.4.4  Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format

As described in Determining the translation table base address in the VMSAv8-32 translation regimes on page G4-4573, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and TTBR0 and TTBR1 hold the base addresses for the two sets of tables. When using the Short-descriptor translation table format, the value of TTBCR.N indicates the number of most significant bits of the input VA that determine whether TTBR0 or TTBR1 holds the required translation table base address, as follows:
• If N == 0 then use TTBR0. Setting TTBCR.N to zero disables use of a second set of translation tables.
• If N > 0 then:
  — If bits[31:32-N] of the input VA are all zero then use TTBR0.
  — Otherwise use TTBR1.
Table G4-1 shows how the value of N determines the lowest address translated using TTBR1, and the size of the level 1 translation table addressed by TTBR0.

<table>
<thead>
<tr>
<th>TTBCR.N</th>
<th>First address translated with TTBR1</th>
<th>TTBR0 table</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b000</td>
<td>TTBR1 not used</td>
<td>16KB VA[31:20]</td>
</tr>
<tr>
<td>0b001</td>
<td>0x80000000</td>
<td>8KB VA[30:20]</td>
</tr>
<tr>
<td>0b010</td>
<td>0x40000000</td>
<td>4KB VA[29:20]</td>
</tr>
<tr>
<td>0b011</td>
<td>0x20000000</td>
<td>2KB VA[28:20]</td>
</tr>
<tr>
<td>0b100</td>
<td>0x10000000</td>
<td>1KB VA[27:20]</td>
</tr>
<tr>
<td>0b101</td>
<td>0x80000000</td>
<td>512 bytes VA[26:20]</td>
</tr>
<tr>
<td>0b110</td>
<td>0x40000000</td>
<td>256 bytes VA[25:20]</td>
</tr>
<tr>
<td>0b111</td>
<td>0x20000000</td>
<td>128 bytes VA[24:20]</td>
</tr>
</tbody>
</table>

Whenever TTBCR.N is nonzero, the size of the translation table addressed by TTBR1 is 16KB.

Figure G4-6 shows how the value of TTBCR.N controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

Figure G4-6 How TTBCR.N controls the boundary between the TTBRs, Short-descriptor format

In the selected TTBR, bits RGN, S and IRGN[1:0] define the memory region attributes for the translation table walk.

Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format describes the translation.

G4.4.5 Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format

When using the Short-descriptor translation table format, and a memory access requires a translation table walk:

- A section-mapped access only requires a read of the level 1 translation table.
- A page-mapped access also requires a read of the level 2 translation table.
Reading a level 1 translation table describes how either TTBR1 or TTBR0 is used, with the accessed VA, to determine the address of the level 1 descriptor.

Reading a level 1 translation table shows the output address as A[39:0]:

- For a Non-secure PL1&0 stage 1 translation, this is the IPA of the required descriptor. A Non-secure PL1&0 stage 2 translation of this address is performed to obtain the PA of the descriptor.
- Otherwise, this address is the PA of the required descriptor.

The full translation flow for Sections, Supersections, Small pages and Large pages on page G4-4584 then shows the complete translation flow for each valid memory access.

Reading a level 1 translation table

When performing a fetch based on TTBR0:

- The address bits taken from TTBR0 vary between bits[31:14] and bits[31:7].
- The address bits taken from the VA, that is the input address for the translation, vary between bits[31:20] and bits[24:20].

The width of the TTBR0 and VA fields depend on the value of TTBCR.N, as Figure G4-7 shows.

When performing a fetch based on TTBR1, Bits TTBR1[31:14] are concatenated with bits[31:20] of the VA. This makes the fetch equivalent to that shown in Figure G4-7, with N==0.

--- Note ---

See The address and Properties fields shown in the translation flows on page K6-6198 for more information about the Properties label used in this and other figures.

--- Diagram ---

Figure G4-7 Accessing level 1 translation table based on TTBR0, Short-descriptor format

Regardless of which register is used as the base for the fetch, the resulting output address selects a four-byte translation table entry that is one of:

- A level 1 descriptor for a Section or Supersection.
- A descriptor for a Page table, that points to a level 2 translation table. In this case:
  - A second fetch is performed to retrieve a level 2 descriptor.
  - The descriptor also contains some attributes for the access, see Figure G4-4 on page G4-4578.
- A faulting entry.
The full translation flow for Sections, Supersections, Small pages and Large pages

In a translation table walk, only the initial lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

Address translation examples using the VMSAv8-32 Short descriptor translation table format on page K6-6193 shows the full translation flow for each of the memory section and page options. As described in VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4577, these options are:

**Supersection**  A 16MB memory region, see Translation flow for a Supersection on page K6-6194.

**Section**  A 1MB memory region, see Translation flow for a Section on page K6-6195.

**Large page**  A 64KB memory region, described by the combination of:
- A level 1 translation table entry that indicates the address of a level 2 Page table.
- A level 2 descriptor that indicates a Large page.

See Translation flow for a Large page on page K6-6196.

**Small page**  A 4KB memory region, described by the combination of:
- A level 1 translation table entry that indicates the address of a level 2 Page table.
- A level 2 descriptor that indicates a Small page.

See Translation flow for a Small page on page K6-6197.
G4.5 The VMSAv8-32 Long-descriptor translation table format

The VMSAv8-32 Long-descriptor translation table format supports the assignment of memory attributes to memory Pages, at a granularity of 4KB, across the complete input address range. It also supports the assignment of memory attributes to blocks of memory, where a block can be 2MB or 1GB.

--- Note ---

- Although the VMSAv8-32 Long-descriptor format is limited to three levels of address lookup, its design and naming conventions support extension to additional levels, to support a larger input address range.
- Similarly, while the VMSAv8-32 implementation limits the output address range to 40 bits, its design supports extension to a larger output address range.

Figure G4-2 on page G4-4563 shows the different address translation stages. The Long-descriptor translation table format:

- Is used for:
  - The Non-secure PL2 stage 1 translation.
  - The Non-secure PL1&0 stage 2 translation.
- Can be used for the Secure and Non-secure PL1&0 translations.

When used for a stage 1 translation, the translation tables support an input address of up to 32 bits, corresponding to the VA address range of the PE.

When used for a stage 2 translation, the translation tables support an input address range of up to 40 bits, to support the translation from IPA to PA. If the input address for the stage 2 translation is a 32-bit address then this address is zero-extended to 40 bits.

--- Note ---

When the Short-descriptor translation table format is used for the Non-secure stage 1 translations, this generates 32-bit IPAs. These are zero-extended to 40 bits to provide the input address for the stage 2 translation.

Overview of VMSAv8-32 address translation using Long-descriptor translation tables on page G4-4586 summarizes address translation from AArch32 state when using the Long-descriptor format translation tables.

The following sections then describe the format of the descriptors in the Long-descriptor format translation tables:

- VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4586.
- Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4589.
- Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4593.

The following sections then describe this translation table format:

- Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4594.
- VMSAv8-32 Long-descriptor translation table format address lookup levels on page G4-4597.
- Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G4-4600.
- The algorithm for finding the translation table entries, VMSAv8-32 Long-descriptor format on page G4-4603.
G4.5.1 Overview of VMA64-32 address translation using Long-descriptor translation tables

Figure G4-8 gives a general view of VMA64-32 stage 1 address translation when using the Long-descriptor translation table format.

Figure G4-8 General view of VMA64-32 stage 1 address translation using Long-descriptor format

Use of concatenated translation tables for the initial stage 2 lookup on page G4-4597 describes how using concatenated level 2 tables means lookup can start at level 2, as referred to in Figure G4-9.

Figure G4-9 General view of VMA64-32 stage 2 address translation, Long-descriptor translation table format

G4.5.2 VMA64-32 Long-descriptor translation table format descriptors

As described in VMA64-32 Long-descriptor translation table format address lookup levels on page G4-4597, the Long-descriptor translation table format provides up to three levels of address lookup. A translation table walk starts either at level 1 or level 2 of the address lookup.

In general, a descriptor is one of:
- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.
The following sections describe the Long-descriptor translation table descriptor formats:

- **VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats.**
- **VMSAv8-32 Long-descriptor translation table level 3 descriptor formats** on page G4-4588.

*Information returned by a translation table lookup* on page G4-4572 describes the classification of the non-address fields in the descriptors between *address map control*, *access controls*, and *region attributes*.

### VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats

In the Long-descriptor translation tables, the formats of the level 1 and level 2 descriptors differ only in the size of the block of memory addressed by the block descriptor. A block entry:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

Figure G4-10 shows the Long-descriptor level 1 and level 2 descriptor formats:

#### Descriptor encodings, Long-descriptor level 1 and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- **0, Block**  The descriptor gives the base address of a block of memory, and the attributes for that memory region.
- **1, Table**  The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

‡ See the descriptions of the address fields for more information about bits[47:40] of the Block and Table descriptors.
The other fields in the valid descriptors are:

**Block descriptor**

Gives the base address and attributes of a block of memory:
- For a level 1 Block descriptor, bits[39:30] are bits[39:30] of the output address that specifies a 1GB block of memory.

In both cases, if bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see Address size fault on page G4-4658.

Bits[63:52, 11:2] provide attributes for the target memory block, see Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4589. The position and contents of these bits is identical in the level 2 block descriptor and in the level 3 page descriptor.

**Table descriptor**

Bits[39:m] are bits[39:m] of the address of the required next-level table. Bits[m-1:0] of the table address are zero:
- For a level 1 Table descriptor, this is the address of a level 2 table.
- For a level 2 Table descriptor, this is the address of a level 3 table.

In both cases, if bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see Address size fault on page G4-4658.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4589.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

**VMSAv8-32 Long-descriptor translation table level 3 descriptor formats**

Each entry in a level 3 table describes the mapping of the associated 4KB input address range.

Figure G4-11 shows the Long-descriptor level 3 descriptor formats.

![Figure G4-11 VMSAv8-32 Long-descriptor level 3 descriptor formats](image-url)

---

† See the description of the address field for more information about bits[47:40] of the Page descriptor.

Figure G4-11 VMSAv8-32 Long-descriptor level 3 descriptor formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.
Descriptor bit[1] identifies the descriptor type, and is encoded as:

**0, Reserved, invalid**

Behaves identically to encodings with bit[0] set to 0.
This encoding must not be used in level 3 translation tables.

**1, Page**
Gives the address and attributes of a 4KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

**Page descriptor**

If bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see *Address size fault on page G4-4658*.

Bits[63:52, 11:2] provide attributes for the target memory page, see *Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors*. The position and contents of these bits are identical in the level 1 block descriptor and in the level 2 block descriptor.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

### G4.5.3 Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors

The memory attributes in the VMSAv8-32 Long-descriptor translation tables are based on those in the Short-descriptor translation table format, with some extensions. *Memory region attributes on page G4-4616* describes these attributes. In the Long-descriptor translation table format:

- Table entries for stage 1 translations define attributes for the next level of lookup, see *Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors*. The hierarchical attributes in the translation tables, APTable, XNTable, and PXNTable, permit subtrees of the translation tables to be used by different agents. Not all operating systems use this functionality, and so ARMv8.2-AA32HPD adds a facility to disable these bits. This ability to disable hierarchical attribute bits has no effect on the NSTable bit.

- Block and Page entries define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:
  - *Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors on page G4-4590*.
  - *Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors on page G4-4592*.

#### Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the following attributes for the next-level translation table access:

**NSTable, bit[63]**
For memory accesses from Secure state, specifies the Security state for subsequent levels of lookup, see *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G4-4593*. For memory accesses from Non-secure state, this bit is ignored.

**APTable, bits[62:61]**
Access permissions limit for subsequent levels of lookup, see *Hierarchical control of access permissions, Long-descriptor format on page G4-4607*. APTable[0] is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables. From ARMv8.2, when ARMv8.2-AA32HPD is implemented, this field can be disabled.
When the value of TTBCR2.HPD0 or TTBCR2.HPD1 is 1, and the value of TTBCR.T2E is also 1:

- The value of the corresponding APTable field is ignored by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding APTable field is 0, that is to say, the APTable field has an effective value of 0.

**XNTable, bit[60]**  
XN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching, Long-descriptor format* on page G4-4611.  
From ARMv8.2, when ARMv8.2-AA32HPD is implemented, this field can be disabled.  
When the value of TTBCR2.HPD0 or TTBCR2.HPD1 is 1, and the value of TTBCR.T2E is also 1:

- The value of the corresponding XNTable field is ignored by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding XNTable field is 0, that is to say, the XNTable field has an effective value of 0.

**PXNTable, bit[59]**  
PXN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching, Long-descriptor format* on page G4-4611.  
This bit is RES0 in the Non-secure PL2 stage 1 translation tables.  
From ARMv8.2, when ARMv8.2-AA32HPD is implemented, this field can be disabled.  
When the value of TTBCR2.HPD0 or TTBCR2.HPD1 is 1 and the value of TTBCR.T2E is also 1:

- The value of the corresponding PXNTable field is ignored by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding PXNTable field is 0, that is to say, the PXNTable field has an effective value of 0.

### Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block as shown for a stage 1 translation:

```
<table>
<thead>
<tr>
<th>Upper attributes</th>
<th>Lower attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>11</td>
</tr>
<tr>
<td>59 58</td>
<td>10</td>
</tr>
<tr>
<td>55 54 53 52</td>
<td>9 8</td>
</tr>
<tr>
<td>PBHA</td>
<td>7 6 5</td>
</tr>
<tr>
<td>IGNORED</td>
<td>4</td>
</tr>
<tr>
<td>Reserved for software use</td>
<td>2</td>
</tr>
<tr>
<td>XN</td>
<td></td>
</tr>
<tr>
<td>PXN</td>
<td></td>
</tr>
<tr>
<td>Contiguous</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

For a stage 1 descriptor, the attributes are:

**PBHA, bits[62:59]**

Page based hardware attributes bits.

These bits are ignored in descriptors at any level above level 3, and are ignored in level 3 descriptors in an implementation that does not include ARMv8.2-TTPBHA.

In an implementation that includes ARMv8.2-TTPBHA, the HTCR and the TTBCR2 registers both contain a control bit for each PBHA bit in the translation tables that they control. When the value of that control bit is 1, and the value of the corresponding Hierarchical permission disables bit is 1, hardware can use that PBHA bit for implementation defined purposes.
The control bits for this feature are:

**For a Non-secure PL2 translation regime:**

**HTCR.HWUnn**
Controls whether level 3 descriptor bit[nn] can be used by hardware.
These controls apply only when the value of HTCR.HPD is 1.

**For a PL1&0 translation regime:**

**TTBCR2.HWU1nn**
For the translation tables indicated by TTBR1, controls whether level 3 descriptor bit[nn] can be used by hardware.
These controls apply only when the value of TTBCR2.HPD1 is 1 and the value of TTBCR.T2E is 1.

**TTBCR2.HWU0nn**
For the translation tables indicated by TTBR0, controls whether level 3 descriptor bit[nn] can be used by hardware.
These controls apply only when the value of TTBCR2.HPD0 is 1 and the value of TTBCR.T2E is 1.

Implementation of ARMv8.2-TTPBHA requires the implementation of ARMv8.2-AA32HPD, which provides the Hierarchical permission disables bits. If ARMv8.2-AA32HPD is implemented but ARMv8.2-TTPBHA is not implemented, then the control bits are RAZ/WI but other aspects of ARMv8.2-AA32HPD functionality are implemented. If neither feature is implemented, then:

- The control bits are RAZ/WI.
- The ARMv8.2-AA32HPD identification registers indicate that the functionality is not supported, see ARMv8.2-AA32HPD on page A1-61.
- The TTBCR2 register encoding is treated as unallocated.

**XN, bit[54]**
The Execute-never bit. Determines whether the region is executable, see Access permissions for instruction execution on page G4-4609.

**PXN, bit[53]**
The Privileged execute-never bit. Determines whether the region is executable at EL1, see Access permissions for instruction execution on page G4-4609.
This bit is RES0 in the Non-secure PL2 stage 1 translation tables.

**Contiguous, bit[52]**
Indicates that 16 adjacent translation table entries point to contiguous memory regions, see Contiguous bit on page G4-4623.

**nG, bit[11]**
The not global bit. Determines how the translation is marked in the TLB, see Global and process-specific translation table entries on page G4-4628.
This bit is RES0 in the Non-secure PL2 stage 1 translation tables.

**AF, bit[10]**
The Access flag, see The Access flag on page G4-4613.

**SH, bits[9:8]**
Shareability field, see Memory region attributes on page G4-4616.

**AP[2:1], bits[7:6]**
Access Permissions bits, see Memory access control on page G4-4605.

--- Note ---

For consistency with the Short-descriptor translation table formats, the Long-descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

**AP[1]** is RES1 in the Non-secure PL2 stage 1 translation tables.

**NS, bit[5]**
Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in Secure or Non-secure memory, see Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4593.
For memory accesses from Non-secure state, this bit is res0 and is ignored by the PE.

AttrIndx[2:0], bits[4:2]

Stage 1 memory attributes index field, for the indicated Memory Attribute Indirection Register, see VMSAv8-32 Long-descriptor format memory region attributes on page G4-4622.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see IGNORED on page Glossary-6341. For more information about these fields see Other fields in the Long-descriptor translation table format descriptors on page G4-4623.

Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block as shown for a stage 2 translation:

For a stage 2 descriptor, the attributes are:

**PBHA, bits[62:59]**

Page based hardware attributes bits.

These bits are IGNORED in descriptors at any level above level 3, and are IGNORED in level 3 descriptors in an implementation that does not include ARMv8.2-TTPBHA.

In an implementation that includes ARMv8.2-TTPBHA, the VTCR register contains a control bit for each PBHA bit in the translation tables that it controls. When the value of that control bit, VTCR.HWUnn, is 1, hardware can use the corresponding level 3 descriptor bit[nn] for IMPLEMENTATION DEFINED purposes.

Implementation of ARMv8.2-TTPBHA requires the implementation of ARMv8.2-AA32HPD. If neither feature is implemented, or if ARMv8.2-AA32HPD is implemented but ARMv8.2-TTPBHA is not implemented, then the VTCR control bits are RAZ/WI.

**XN[1:0], bits[54:53]**

The Execute-never field. Determines whether the region is executable.

For more information, see Access permissions for instruction execution on page G4-4609.

In an implementation that does not support ARMv8.2-TTS2UXN, bit[53] is res0.

**Contiguous, bit[52]**

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see Contiguous bit on page G4-4623.

**AF, bit[10]**

The Access flag, see The Access flag on page G4-4613.

**SH, bits[9:8]**

Shareability field, see EL2 control of Non-secure memory region attributes on page G4-4624.

**S2AP, bits[7:6]**

Stage 2 Access Permissions bits, see Hyp mode control of Non-secure access permissions on page G4-4614.
In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

MemAttr, bits[5:2]
Stage 2 memory attributes, see EL2 control of Non-secure memory region attributes on page G4-4624.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see IGNORED on page Glossary-6341. For more information about these fields see Other fields in the Long-descriptor translation table format descriptors on page G4-4623.

G4.5.4 Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format

Access to the Secure or Non-secure physical address map on page G4-4574 describes how the NS bit in the translation table entries:
• For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
• Is ignored by accesses from Non-secure state.

In the Long-descriptor format:
• The NS bit relates only to the memory block or page at the output address defined by the descriptor.
• The descriptors also include an NSTable bit, see Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format.

The NS and NSTable bits are valid only for memory accesses from Secure state. Memory accesses from Non-secure state ignore the values of these bits.

Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format

For Long-descriptor format table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

NSTable == 0 The defined table address is in the Secure physical address map. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.

NSTable == 1 The defined table address is in the Non-secure physical address map. Because this table is fetched from the Non-secure address map, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:
• The value of the NS bit in any block or page descriptor is ignored. The block or page address refers to Non-secure memory.
• The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if it is read from Non-secure memory. That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see Global and process-specific translation table entries on page G4-4628.

The effect of NSTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to NSTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.
Note

- When using the Long-descriptor format, table descriptors are defined only for the level 1 and level 2 of lookup.
- Stage 2 translations are performed only for operations in Non-secure state, that can access only the Non-secure address map. Therefore, the stage 2 descriptors do not include NS or NSTable bits.

G4.5.5 Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format

As described in Determining the translation table base address in the VMSAv8-32 translation regimes on page G4-4573, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and TTBR0 and TTBR1 hold the base addresses for the two sets of tables. The Long-descriptor translation table format provides more flexibility in defining the boundary between using TTBR0 and using TTBR1. When a PL1&0 stage 1 address translation is enabled, TTBR0 is always used. If TTBR1 is also used then:
- TTBR1 is used for the top part of the input address range.
- TTBR0 is used for the bottom part of the input address range.

The TTBCR.T0SZ and TTBCR.T1SZ size fields control the use of TTBR0 and TTBR1, as Table G4-2 shows.

<table>
<thead>
<tr>
<th>TTBCR</th>
<th>Input address range using:</th>
</tr>
</thead>
<tbody>
<tr>
<td>T0SZ</td>
<td>T1SZ</td>
</tr>
<tr>
<td>0b000</td>
<td>0b000</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>0b000</td>
<td>0b000</td>
</tr>
<tr>
<td></td>
<td>0b000</td>
</tr>
<tr>
<td>0b000</td>
<td>0b000</td>
</tr>
</tbody>
</table>

For stage 1 translations, the input address is always a VA, and the maximum possible VA is $(2^{32}-1)$.

When address translation is using the Long-descriptor translation table format:
- Figure G4-12 shows how, when TTBCR.T1SZ is zero, the value of TTBCR.T0SZ controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.
Figure G4-13 shows how, when TTBCR.T1SZ is nonzero, the values of TTBCR.T0SZ and TTBCR.T1SZ control the boundaries between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

When T0SZ and T1SZ are both nonzero:

- If both fields are set to \(0b001\), the boundary between the two regions is \(0x80000000\). This is identical to having T0SZ set to \(0b000\) and T1SZ set to \(0b001\).
- Otherwise, the TTBR0 and TTBR1 regions are non-contiguous. In this case, any attempt to access an address that is in that gap between the TTBR0 and TTBR1 regions generates a Translation fault.

**Note**

The handling of the Contiguous bit can mean that the boundary between the translation regions defined by the TCR_EL1.TnSZ values and the region for which an access generates a Translation fault is wider than shown in Figure G4-13. That is, if the descriptor for an access to the region shown as generating a fault has the Contiguous bit set to 1, the access might not generate a fault. Possible errors in programming the translation table registers describes this possibility.

When using the Long-descriptor translation table format:

- The TTBCR contains fields that define memory region attributes for the translation table walk, for each TTBR. These are the SH0, ORGN0, IRGN0, SH1, ORGN1, and IRGN1 bits.
- TTBR0 and TTBR1 each contain an ASID field, and the TTBCR.A1 field selects which ASID to use.

For this translation table format, VMSAv8-32 Long-descriptor translation table format address lookup levels on page G4-4597 summarizes the lookup levels, and Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G4-4600 describes the possible translations.

**Possible errors in programming the translation table registers**

In all the descriptions in this subsection, the size of the input address supported for a PL1&0 stage 1 translation refers to the size specified by a TTBCR.TxSZ field.

**Note**

For a PL1&0 stage 1 translation, the input address range can be split so that the lower addresses are translated by TTBR0 and the higher addresses are translated by TTBR1. In this case, each of input address sizes specified by TTBCR.\{T0SZ, T1SZ\} is smaller than the total address size supported by the stage of translation.
The following are possible errors in the programming of TTBR0, TTBR1, and TTBCR. For the translation of a particular address at a particular stage of translation, either:

- The block size being used to translate the address is larger than the size of the input address supported at a stage of translation used in performing the required translation. This can occur only for the PL1&0 stage 1 translations, and only when either TTBCR.T0SZ or TTBCR.T1SZ is zero, meaning there is no gap between the address range translated by TTBR0 and the range translated by TTBR1. In this case, this programming error occurs if a block translated from the region that has TxSZ set to zero straddles the boundary between the two address ranges. Example G4-2 shows an example of this mis-programming.

- The address range translated by a set of blocks marked as contiguous, by use of the contiguous bit, is larger than the size of the input address supported at a stage of translation used in performing the required translation.

**Example G4-2 Error in programming the translation table registers**

If TTBCR.T0SZ is programmed to 0 and TTBCR.T1SZ is programmed to 7, this means:

- TTBR0 translates addresses in the range 0x00000000-0xFDFFFFFF.
- TTBR1 translates addresses in the range 0xFE000000-0xFFFFFFFF.

The translation table indicated by TTBR0 might be programmed with a block entry for a 1GB region starting at 0xC0000000. This covers the address range 0xC0000000-0xFFFFFFFF, that overlaps the TTBR1 address range. This means this block size is larger than the input address size supported for translations using TTBR0, and therefore this is a programming error.

To understand why this must be a programming error, consider a memory access to address 0xFFFF0000. According to the TTBCR.{T0SZ, T1SZ} values, this must be translated using TTBR1. However, the access matches a TLB entry for the translation, using TTBR0, of the block at 0xC0000000. Hardware is not required to detect that the access to 0xFFFF0000 is being translated incorrectly.

In these cases, an implementation might use one of the following approaches:

- Treat such a block as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation. The block might be a block within a contiguous set of blocks.

- Treat such a block as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

  The block might be a block within a contiguous set of blocks.

Additional constraints apply to programming the VTCR, see *Determining the required initial lookup level for stage 2 translations on page G4-4602.*
### G4.5.6 VMSAv8-32 Long-descriptor translation table format address lookup levels

As stated at the start of this section, because the Long-descriptor translation table format is used for the Non-secure PL1&0 stage 2 translations, the format must support input addresses of up to 40 bits.

Table G4-3 summarizes the properties of the different levels of address lookup when using this format.

<table>
<thead>
<tr>
<th>Level</th>
<th>Input address</th>
<th>Output address&lt;sup&gt;a&lt;/sup&gt;</th>
<th>Number of entries</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Size</td>
<td>Address range&lt;sup&gt;b&lt;/sup&gt;</td>
<td>Size</td>
</tr>
<tr>
<td>First</td>
<td>Up to 512GB</td>
<td>Up to Address[38:0]</td>
<td>1GB</td>
</tr>
<tr>
<td>Second</td>
<td>Up to 1GB</td>
<td>Up to Address[29:0]</td>
<td>2MB</td>
</tr>
<tr>
<td>Third</td>
<td>2MB</td>
<td>Address[20:0]</td>
<td>4KB</td>
</tr>
</tbody>
</table>

a. Output address when an entry addresses a block of memory or a memory page. If an entry addresses the next level of address lookup it specifies Address[39:12] for the next-level translation table.

b. Input address range for the translation table. See Use of concatenated level 1 translation tables on page G4-4598 for details of support for additional bits of address at a given level, including possible support of a 40-bit input address range for stage 2 translations at level 1. For stage 1 translations at level 1 the input address range is limited to the VA size of [31:0].

For level 1 and level 2 tables, reducing the input address range reduces the number of addresses in the table and therefore reduces the table size. The appropriate Translation Table Control Register specifies the input address range.

Stage 1 translations require an input address range of up to 32 bits, corresponding to VA[31:0]. For these translations:

- For a memory access from a mode other than Hyp mode, the Secure or Non-secure TTBR0 or TTBR1 holds the translation table base address, and the Secure or Non-secure TTBCR is the control register.

- For a memory access from Hyp mode, HTTBR holds the translation table base address, and HTCR is the control register.

**Note**

For translations controlled by TTBR0 and TTBR1, if neither TTBR has an input address range larger than 1GB, then translation starts at level 2. Together, TTBR0 and TTBR1 can still cover the 32-bit VA input address range.

Stage 2 translations require an input address range of up to 40 bits, corresponding to IPA[39:0], and the supported input address size is configurable in the range 25-40 bits. Table G4-3 indicates a requirement for the translation mechanism to support a 39-bit input address range, Address[38:0]. Use of concatenated translation tables for the initial stage 2 lookup describes how a 40-bit IPA address range is supported. For stage 2 translations:

- VTTBR holds the translation table base address, and VTCR is the control register.

- If a supplied input address is larger than the configured input address size, a Translation fault is generated.

**Use of concatenated translation tables for the initial stage 2 lookup**

If a stage 2 translation would require 16 entries or fewer in its top-level translation table, that stage of translation can, instead, be configured so that:

- It requires the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.

- The stage 2 translation starts at that next translation level.
Stage 2 translations always use the Long-descriptor translation table format.

This use of concatenated translation tables is:

- Required when the stage 2 translation supports a 40-bit input address range, see Use of concatenated level 1 translation tables.
- Supported for a stage 2 translation with an input address range of 31-34 bits, see Use of concatenated level 2 translation tables.

The use of concatenated translation tables requires the software that is defining the translation to:

- Define the concatenated translation tables with the required overall alignment.
- Program VTTBR to hold the address of the first of the concatenated translation tables.
- Program VTCR to indicate the required input address range and initial lookup level.

Use of concatenated level 1 translation tables

The Long-descriptor format translation tables provide 9 bits of address resolution at each level of lookup. However, a 40-bit input address range with a translation granularity of 4KB requires a total of 28 bits of address resolution. Therefore, a stage 2 translation that supports a 40-bit input address range requires two concatenated level 1 translation tables, together aligned to 8KB, where:

- The table at the address with PA[12:0]==0b0_0000_0000_0000 defines the translations for input addresses with bit[39]==0.
- The table at the address with PA[12:0]==0b1_0000_0000_0000 defines the translations for input addresses with bit[39]==1.
- The 8KB alignment requirement means that both tables have the same value for PA[39:13].

Use of concatenated level 2 translation tables

A stage 2 translation with an input address range of 31-34 bits can start the translation either:

- With a level 1 lookup, accessing a level 1 translation table with 2-16 entries.
- With a level 2 lookup, accessing a set of concatenated level 2 translation tables.

Table G4-4 on page G4-4599 shows these options, for each of the input address ranges that can use this scheme.

Because these are stage 2 translations, the input address range is an IPA range.
### Table G4-4 Possible uses of concatenated translation tables for level 2 lookup

See also *Determining the required initial lookup level for stage 2 translations* on page G4-4602.
G4.5.7 Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format

Figure G4-2 on page G4-4563 shows the possible address translations. If a stage of translation is controlled from an Exception level that is using AArch32, the input and output address constraints and the registers that control the translation are as follows:

Stage 1 translations

For all stage 1 translations:

- The input address range is up to 32 bits, as determined by either:
  - TTBCR.T0SZ or TTBCR.T1SZ, for a PL1&0 stage 1 translation.
  - HTCR.T0SZ, for a PL2 stage 1 translation.
- The output address range is 40 bits.

The stage 1 translations are:

Non-secure PL1&0 stage 1 translation

The stage 1 translation for memory accesses from Non-secure modes other than Hyp mode. This translates a VA to an IPA. For this translation, when Non-secure EL1 is using AArch32:

- Non-secure TTBR0 or TTBR1 holds the translation table base address.
- Non-secure TTBCR determines which TTBR is used.

Non-secure PL2 stage 1 translation

The stage 1 translation for memory accesses from Hyp mode, translates a VA to a PA. For this translation, when EL2 is using AArch32, HTTBR holds the translation table base address.

Secure PL1&0 stage 1 translation

The stage 1 translation for memory accesses from Secure modes, translates a VA to a PA. For this translation, when the Secure PL1 modes are using AArch32:

- Secure TTBR0 or TTBR1 holds the translation table base address.
- Secure TTBCR determines which TTBR is used.

Stage 2 translation

Non-secure PL1&0 stage 2 translation

The stage 2 translation for memory accesses from Non-secure modes other than Hyp mode, and translates an IPA to a PA. For this translation, when EL2 is using AArch32:

- The input address range is 40 bits, and VTCR.T0SZ determines the input address size.
- The output address range depends on the implemented memory system, and is up to 40 bits.
- VTTBR holds the translation table base address.
- VTCR specifies the required input address range, and whether the initial lookup is at level 1 or at level 2.

The descriptions of the VMSAv8-32 translation stages state that the maximum output address size is 40 bits. However, the register and Long-descriptor format descriptor fields that hold these addresses are 48 bits wide. If bits[47:40] of an output address are not all zero then the address generates an Address size fault.

The Long-descriptor translation table format provides up to three levels of address lookup, as described in VMSAv8-32 Long-descriptor translation table format address lookup levels on page G4-4597, and the initial lookup, in which the MMU reads the translation table base address, is at either level 1 or level 2. The following determines the level of the initial lookup:

- For a stage 1 translation, the required input address range. For more information see Determining the required initial lookup level for stage 1 translations on page G4-4602.

- For a stage 2 translation, the level specified by the VTCR.SL0 field. For more information see Determining the required initial lookup level for stage 2 translations on page G4-4602.
**Note**

For a stage 2 translation, the size of the required input address range constrains the VTCR.SL0 value.

Figure G4-14 shows how the descriptor address for the initial lookup for a translation using the Long-descriptor translation table format is determined from the input address and the TTBR value. This figure shows the lookup for a translation that starts with a level 1 lookup, that translates bits[39:30] of the input address, zero extended if necessary.

For a translation that starts with a level 1 lookup, as shown in Figure G4-14:

**For a stage 1 translation**

\( n \) is in the range 4-5 and:

- For a memory access from Hyp mode:
  - HTTBR is the TTBR.
  - \( n=5-(HTCR.T0SZ) \).
- For other accesses:
  - The Secure or Non-secure instance of TTBR0 or TTBR1 is the TTBR.
  - \( n=(5-TTBCR.TxSZ) \), where \( x \) is 0 when using TTBR0, and 1 when using TTBR1.

**For a stage 2 translation**

\( n \) is in the range 4-13 and:

- VTTBR is the TTBR.
- \( n=5-(VTCR.T0SZ) \).
For a translation that starts with a level 2 lookup, the descriptor address is obtained in the same way, except that bits\([(n+17):21]\) of the input address provide bits\([(n-1):3]\) of the descriptor address, where:

**For a stage 1 translation**

\( n \) is in the range 7-12. As *Determining the required initial lookup level for stage 1 translations* shows, for a stage 1 translation to start with a level 2 lookup, the corresponding T0SZ or T1SZ field must be 2 or more. This means:

- For a memory access from Hyp mode, \( n=14-\text{HTCR.T0SZ} \).
- For other memory accesses, \( n=14-(\text{TTBCR.T}x\text{SZ}) \), where \( x \) is 0 when using TTBR0, and 1 when using TTBR1.

**For a stage 2 translation**

\( n \) is in the range 7-16. For a stage 2 translation to start with a level 2 lookup, VTCR.SL0 is \( \text{\text{0b00}} \), and \( n=14-(\text{VTCR.T0SZ}) \).

The following sections describe how the level of the initial lookup is determined:

- *Determining the required initial lookup level for stage 1 translations*.
- *Determining the required initial lookup level for stage 2 translations*.

*Address translation examples using the VMSAv8-32 Long descriptor translation table format* on page K6-6198 shows examples of full translation flows, to an entry for a 4KB memory page, for lookups starting at level 1 and lookups starting at level 2.

**Determining the required initial lookup level for stage 1 translations**

For a stage 1 translation, the required input address range, indicated by a T0SZ or T1SZ field in a translation table control register, determines the initial lookup level. The size of this input address region is \( 2^{(32-TxSZ)} \) bytes, and if this size is:

- Less than or equal to \( 2^{30} \) bytes, the required start is at level 2, and translation requires two levels of table to map to 4KB pages. This corresponds to a TxSZ value of 2 or more.
- More than \( 2^{30} \) bytes, the required start is at level 1, and translation requires three levels of table to map to 4KB pages. This corresponds to a TxSZ value that is less than 2.

For the PL1&0 stage 1 translations, the TTBCR:

- Splits the 32-bit VA input address range between TTBR0 and TTBR1, see *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format* on page G4-4594.
- Holds the input address range sizes for TTBR0 and TTBR1, in the TTBCR.T0SZ and TTBCR.T1SZ fields.

For the PL2 stage 1 translations, HTCR.T0SZ indicates the size of the required input address range. For example, if this field is \( \text{\text{0b000}} \), it indicates a 32-bit VA input address range, and translation lookup must start at level 1.

**Determining the required initial lookup level for stage 2 translations**

For a PL1&0 stage 2 translation, the output address range from the PL1&0 stage 1 translations determines the required input address range for the stage 2 translation.

VTCR.SL0 indicates the starting level for the lookup. The permitted SL0 values are:

- \( \text{\text{0b00}} \) Stage 2 translation lookup must start at level 2.
- \( \text{\text{0b01}} \) Stage 2 translation lookup must start at level 1.

In addition, VTCR.T0SZ must indicate the required input address range. The size of the input address region is \( 2^{(32-T0SZ)} \) bytes.
Note

VTCR.T0SZ holds a four-bit signed integer value, meaning it supports values from -8 to 7. This is different from the other translation control registers, where TnSZ holds a three-bit unsigned integer, supporting values from 0 to 7.

The programming of VTCR must follow the constraints shown in Table G4-5, otherwise any attempt to perform a translation table walk that uses the stage 2 address translation generates a stage 2 level 1 Translation Fault. The table also shows how the VTCR.SLO and VTCR.T0SZ values determine the VTTBR.BADDR field width.

Note

If VTCR.SLO is programmed to a reserved value then the constraints shown in Table G4-5 are not met, and a translation table walk that uses stage 2 translation generates a stage 2 level 1 Translation fault.

Table G4-5 Input address range constraints on programming VTCR

<table>
<thead>
<tr>
<th>VTCR.SL0</th>
<th>VTCR.T0SZ</th>

a. The first range corresponds to the first T0SZ value, the second range to the second T0SZ value.

In addition, VTCR.S must be programmed to the value of T0SZ[3], otherwise behavior is CONSTRAINED UNPREDICTABLE with the resulting behavior being that VTCR.T0SZ is treated as an UNKNOWN value.

Note

VTCR.T0SZ being treated as an UNKNOWN value results in a stage 2 level 1 Translation Fault if that UNKNOWN value is not consistent with the programmed value of VTCR.SLO.

CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR on page K1-6114 describes these CONSTRAINED UNPREDICTABLE behaviors.

Where necessary, the initial lookup level provides multiple concatenated translation tables, as described in Use of concatenated level 2 translation tables on page G4-4598. This section also gives more information about the alternatives, shown in Table G4-5, when R is in the range 2^{31}-2^{34}.

G4.5.8 The algorithm for finding the translation table entries, VMSAv8-32 Long-descriptor format

This section gives the algorithm for finding the translation table entry that corresponds to a given IA, for each required level of lookup. The algorithm encodes the descriptions of address translation given earlier in this section. The VMSAv8-32 Long-descriptor format uses a 4KB translation granule.

The description uses the following terms:

BaseAddr The base address for the level of lookup, as defined by:
- For the initial lookup level, the TTBR.BADDR base address field in the appropriate TTBR, see the description of TnSZ on page G4-4604.
- Otherwise, the translation table address returned by the previous level of lookup.

IA The supplied IA for this stage of translation.
### TnSZ

The translation table size for this stage of translation:

- **For PL1&0 stage 1**
  - Either: [\(\text{TTBCR.T0SZ}\) if the translation is using TTBR0.]
  - [\(\text{TTBCR.T1SZ}\) if the translation is using TTBR1.]

- **For PL1&0 stage 2**
  - [\(\text{VTCR.T0SZ}\). The translation uses VTTBR.]

- **For PL2 stage 1**
  - [\(\text{HTCR.T0SZ}\). The translation uses HTTBR.]

### SL0

- \(\text{VTCR.SL0}\). Applies to the Non-secure PL1&0 stage 2 translation only.

Table G4-6 shows the translation table descriptor address, for each level of lookup. The table shows only architecturally-valid programming of the TCR. See also *Possible errors in programming the translation table registers* on page G4-4595.

#### Table G4-6 Translation table entry addresses, VMSAv8-32 using Long-descriptor format

<table>

</tr>
</tbody>
</table>

- a. This line indicates the range of permitted values for TnSZ, for a lookup that starts at this level, see *Use of concatenated translation tables for the initial stage 2 lookup* on page G4-4597.
- b. \(\text{SL0} == 0\) if the initial lookup is level 2, \(\text{SL0} == 1\) if the initial lookup is level 1.
- c. This is the case where this level of lookup is not the initial level of lookup.
G4.6 Memory access control

In addition to an output address, a translation table entry that refers to page or region of memory includes fields that define properties of the target memory region. Information returned by a translation table lookup describes the classification of those fields as address map control, access control, and memory attribute fields. The access control fields, described in this section, determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- About access permissions.
- About the PAN bit on page G4-4608.
- Access permissions for instruction execution on page G4-4609.
- Domains, Short-descriptor format only on page G4-4612.
- The Access flag on page G4-4613.
- Hyp mode control of Non-secure access permissions on page G4-4614.

G4.6.1 About access permissions

The translation table descriptors include fields that define access permissions for data accesses and for instruction fetches. This section introduces those fields. In addition:

- System register controls can prevent execution from writeable locations, see Preventing execution from writeable locations on page G4-4612.
- In ARMv8.1, the PSTATE.PAN can affect the access permissions for privileged data accesses, see About the PAN bit on page G4-4608.

Note

This section gives a general description of memory access permissions. Software executing at PL1 in Non-secure state can see only the access permissions defined by the Non-secure PL1&0 stage 1 translations. However, software executing at PL2 can modify these permissions, as described in Hyp mode control of Non-secure access permissions on page G4-4614. This modification is invisible to Non-secure software executing at EL1 or EL0.

Access permission bits in a translation table descriptor control access to the corresponding memory region. The details of this control depend on the translation table format, as follows:

Short-descriptor format

This format supports two options for defining the access permissions:

- Three bits, AP[2:0], define the access permissions.
- Two bits, AP[2:1], define the access permissions, and AP[0] can be used as an Access flag.

SCTLR.AFE selects the access permissions option. Setting this bit to 1, to enable the Access flag, also selects use of AP[2:1] to define access permissions.

ARM deprecates any use of the AP[2:0] scheme for defining access permissions.

Long-descriptor format

AP[2:1] to control the access permissions, and the descriptors provide an AF bit for use as an Access flag. This means VMSAv8-32 behaves as if the value of SCTLR.AFE is 1, regardless of the value that software has written to this bit.

Note

When use of the Long-descriptor format is enabled, SCTLR.AFE is UNK/SBOP.

The Access flag on page G4-4613 describes the Access flag, for both translation table formats.

The XN and PXN bits provide additional access controls for instruction fetches, see Access permissions for instruction execution on page G4-4609.
An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation. However, when using the Short-descriptor translation table format, it generates the fault only if the access is to memory in the Client domain, see Domains, Short-descriptor format only on page G4-4612.

--- Note ---

For the Non-secure PL1&0 translation regime, memory accesses are subject to two stages of translation. Each stage of translation has its own, independent, fault checking. Fault handling is different for the two stages, see Exception reporting in a VMSAv8-32 implementation on page G4-4663.

The following sections describe the two access permissions models:

- **AP[2:1] access permissions model.**
- **AP[2:0] access permissions control, Short-descriptor format only on page G4-4607.** This section includes some information on access permission control in earlier versions of the ARM VMSA.

**AP[2:1] access permissions model**

--- Note ---

ARM recommends that this model is always used, even where the AP[2:0] model is permitted. Some documentation describes the AP[2:1] model as the simplified access permissions model.

This access permissions model is used if the translation is either:

- Using the Long-descriptor translation table format.
- Using Short-descriptor translation table format, and the SCTL.R.AFE bit is set to 1.

In this model:

- One bit, AP[2], selects between read-only and read/write access.
- A second bit, AP[1], selects between Application level (PL0) and System level (PL1) control. For the Non-secure PL2 stage 1 translations, AP[1] is SBO.

This provides four access combinations:

- Read-only at all privilege levels.
- Read/write at all privilege levels.
- Read-only at PL1, no access by software executing at PL0.
- Read/write at PL1, no access by software executing at PL0.

Table G4-7 shows this access control model.

<table>
<thead>
<tr>
<th>AP[2], disable write access</th>
<th>AP[1], enable unprivileged access</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0a</td>
<td>Read/write, only at PL1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Read/write, at any privilege level</td>
</tr>
<tr>
<td>1</td>
<td>0a</td>
<td>Read-only, only at PL1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Read-only, at any privilege level</td>
</tr>
</tbody>
</table>

a. Not valid for Non-secure PL2 stage 1 translation tables. AP[1] is SBO in these tables.
Hierarchical control of access permissions, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that entries at one level of translation table lookup can use to set limits on the permitted entries at subsequent levels of lookup. This rule applies to the access permissions, and also to the restrictions on instruction fetching described in Hierarchical control of instruction fetching, Long-descriptor format on page G4-4611.

The restrictions apply only to subsequent levels of lookup at the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table G4-8 shows.

However, in an implementation that includes ARMv8.2-AA32HPD, when hierarchical control of data access permissions is disabled for a translation regime, the information in this subsection does not apply. See Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4589.

As stated in the table footnote, for the Non-secure PL2 stage 1 translation tables, APTable[0] is reserved, SBZ.

Table G4-8 Effect of APTable[1:0] on subsequent levels of lookup

<table>
<thead>
<tr>
<th>APTable[1:0]</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect on permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>01</td>
<td>Access at PL0 not permitted, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>10</td>
<td>Write access not permitted, at any Exception level, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>11</td>
<td>Regardless of permissions in subsequent levels of lookup:</td>
</tr>
<tr>
<td></td>
<td>• Write access not permitted, at any Exception level.</td>
</tr>
<tr>
<td></td>
<td>• Read access not permitted at PL0.</td>
</tr>
</tbody>
</table>

a. Not valid for the Non-secure PL2 stage 1 translation tables. In those tables, APTable[0] is SBZ.

Note

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The Long-descriptor format provides APTable[1:0] control only for the stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

AP[2:0] access permissions control, Short-descriptor format only

This access permissions model applies when using the Short-descriptor translation tables format, and the SCTLR.AFE bit is set to 0. ARM deprecates any use of this access permissions model.

When SCTLR.AFE is set to 0, ensuring that the AP[0] bit is always set to 1 effectively changes the access model to the simpler model described in AP[2:1] access permissions model on page G4-4606.
Table G4-9 shows the full AP[2:0] access permissions model:

<table>
<thead>
<tr>
<th>AP[2]</th>
<th>AP[1:0]</th>
<th>PL1 access</th>
<th>Unprivileged access</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>00</td>
<td>No access</td>
<td>No access</td>
<td>All accesses generate Permission faults</td>
</tr>
<tr>
<td></td>
<td>01</td>
<td>Read/write</td>
<td>No access</td>
<td>Access only at PL1</td>
</tr>
<tr>
<td></td>
<td>10</td>
<td>Read/write</td>
<td>Read-only</td>
<td>Writes at PL0 generate Permission faults</td>
</tr>
<tr>
<td></td>
<td>11</td>
<td>Read/write</td>
<td>Read/write</td>
<td>Full access</td>
</tr>
<tr>
<td>1</td>
<td>00</td>
<td>-</td>
<td>-</td>
<td>Reserved</td>
</tr>
<tr>
<td></td>
<td>01</td>
<td>Read-only</td>
<td>No access</td>
<td>Read-only, only at PL1</td>
</tr>
<tr>
<td></td>
<td>10</td>
<td>Read-only</td>
<td>Read-only</td>
<td>Read-only at any Exception level, deprecated&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td></td>
<td>11</td>
<td>Read-only</td>
<td>Read-only</td>
<td>Read-only at any Exception level&lt;sup&gt;b&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

<sup>a</sup> From VMSAv7, ARM strongly recommends use of the 0b11 encoding for Read-only at any Exception level.

<sup>b</sup> This mapping was introduced in VMSAv7, and is reserved in earlier versions of the VMSA.

---

**Note**

- VMSAv8-32 supports the full set of access permissions shown in Table G4-9 only when SCTLR.AFE is set to 0. When SCTLR.AFE is set to 1, the only supported access permissions are those described in AP[2:1] access permissions model on page G4-4606.

### G4.6.2 About the PAN bit

When the value of PSTATE.PAN is 1, any privileged data access from PL1 or EL2 to a virtual memory address that is accessible at EL0 generates a Permission fault.

When the value of PSTATE.PAN is 0, the translation system is the same as in ARMv8.0.

A corresponding PAN bit is added to CPSR and SPSR for exception returns, and DSPSR for entry to and exit from Debug state.

A new SPAN bit is added to SCTLR that controls whether the PAN state bit is set on taking an exception to EL1 from either Secure or Non-secure state, or to EL3 from Secure state when EL3 is using AArch32.

CPSR.PAN bit can be written using an MSR instruction at PL1 or higher. Data writes to CPSR.PAN using an MSR instruction at EL0 are ignored. The value that is returned for an MSR instruction of CPSR from EL0 is UNKNOWN. In keeping with all other writes to the CPSR, other than for instruction fetches, the effect of the PAN state bit does not need to be explicitly synchronized.

The PAN state bit has no effect on:
- Data Cache instructions.
- Address translation instructions, other than ATS1CPRP and ATS1CPWP when ARMv8.2-ATS1E1 is implemented.
- Unprivileged instructions, LDRBT, LDRHT, LDRT, LDRSBT, LDRSHT, STRBT, STRHT, STRT, STRSBT, and STRSHT, unless HCR_EL2.{E2H, TGE} == {1, 0}.
- Instruction accesses.
- Manager domains.

If access is disabled, then the access will give rise to a stage 1 Permission fault.
On an exception taken from AArch32:
- CPSR.PAN is copied to SPSR_ELx.PAN, when the target Exception level is AArch64.
- CPSR.PAN is copied to SPSR.PAN, when the target Exception level is AArch32.

On an exception return from AArch32 to AArch32, SPSR.PAN is copied to CPSR.PAN.

On entry to Debug state, CPSR.PAN is copied to DSPSR.PAN.

On exit from Debug state, DSPSR.PAN is copied to CPSR.PAN.

The CPSR.PAN bit is not an Execution state bit.

--- Note
A debugger can use the DRPS instruction to modify the PAN state bit.

### G4.6.3 Access permissions for instruction execution

Execute-never controls provide an additional level of control on memory accesses permitted by the access permissions settings. These controls are:

**XN, Execute-never**

Descriptor bit[54], defined as XN for:
- Stage 1 of any translation regime.
- Stage 2 of the Non-secure PL1&0 translation regime when ARMv8.2-TTS2UXN is not implemented.

--- Note
XN[1:0], Execute-never, for stage 2 control describes the stage 2 control when ARMv8.2-TTS2UXN is implemented.

A value of 0 indicates that this control permits execution.

**PXN, Privileged execute-never**

Descriptor bit[53], used only for stage 1 of any translation regime that applies to EL0 and a higher Exception level:
- For stage 1 of a translation regime that applies to only a single Exception level the descriptors define a PXN field that is RES0, meaning it is ignored by hardware.

--- Note
For stage 2 of the Non-secure PL1&0 translation regime when ARMv8.2-TTS2UXN is not implemented, descriptor bit[53] is RES0, meaning it is ignored by hardware.

A value of 0 indicates that this control permits execution.

**XN[1:0], Execute-never, for stage 2 control**

Descriptor bits[54:53], defined as XN[1:0] for:
- Stage 2 of the PL1&0 translation regime in an implementation where ARMv8.2-TTS2UXN is supported.

Table G4-10 on page G4-4610 shows the operation of this control.

--- Note
Because the stage 2 controls apply only in Non-secure state, PL1 always corresponds to EL1 and the controls are described in terms of instruction execution at EL1 and EL0.
Executing an instruction at PLx generates a Permission fault unless all of the follow are true for the instruction address:

- The stage 1 execute-never control that applies to execution at PLx permits execution.
- For PL0 or PL1, the stage 2 execute-never control that applies to execution at PLx permits execution.
- Read access is permitted.

However, when using the Short-descriptor translation table format, the Permission fault is generated only if the access is to memory in the Client domain, see Domains, Short-descriptor format only on page G4-4612. See also Hyp mode control of Non-secure access permissions on page G4-4614.

In addition, System register controls can enforce execute-never restrictions, regardless of the settings in the translation table XN and PXN fields, see:

- Restriction on Secure instruction fetch on page G4-4612.
- Preventing execution from writeable locations on page G4-4612.

The execute-never controls apply also to speculative instruction fetching. This means a speculative instruction fetch from a memory region that is execute-never at the current level of privilege is prohibited.

The execute-never controls means that, when the stage of address translation is enabled, the PE can fetch, or speculatively fetch, an instruction from a memory location only if all of the following apply:

- If using the Short-descriptor translation table format, the translation table descriptor for the location does not indicate that it is in a No access domain.
- If using the Long-descriptor translation table format, or using the Short descriptor format and the descriptor indicates that the location is in a Client domain, in the descriptor for the location the following apply:
  - The stage 1 execute-never control for the Exception level at which the instruction is executed permits execution.
  - For a translation regime with two stages of address translation, the stage 2 execute-never control that applies to the Exception level at which the instruction is executed permits execution.
  - The access permissions permit a read access from the current PE mode.
- No other Prefetch Abort condition exists.

**Note**

- The PXN control applies to the PE privilege when it attempts to execute the instruction. In an implementation that fetches instructions speculatively, this might not be the privilege when the instruction was prefetched. Therefore, the architecture does not require the PXN control to prevent instruction fetching.
- Although the XN control applies to speculative fetching, on a speculative instruction fetch from an XN location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an XN location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.

---

**Table G4-10 XN[1:0] stage 2 access permissions model**

</tr>
</tbody>
</table>
• The software that defines a translation table must mark any region of memory that is read-sensitive as XN, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as XN. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.

• When using the Short-descriptor translation table format, the XN attribute is not checked for domains marked as Manager. Therefore, the system must not include read-sensitive memory in domains marked as Manager, because the XN field does not prevent speculative fetches from a Manager domain.

When no stage of address translation for the translation regime is enabled, memory regions cannot have XN or PXN attributes assigned. Behavior of instruction fetches when all associated address translations are disabled on page G4-4569 describes how disabling all MMUs affects instruction fetching.

Hierarchical control of instruction fetching, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that means entries at one level of translation tables lookup can set limits on the permitted entries at subsequent levels of lookup. This rule applies to the restrictions on instruction fetching, and also to the access permissions described in Hierarchical control of access permissions, Long-descriptor format on page G4-4607.

Note

Similar hierarchical controls apply to data accesses, see Hierarchical control of access permissions, Long-descriptor format on page G4-4607.

However, in an implementation that includes ARMv8.2-HPD, when hierarchical control of instruction fetching is disabled for a translation regime, the information in this subsection does not apply. See Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4589.

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

• **XNTable** restricts the XN control:
  — When XNTable is set to 1, the XN field is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the field.
  — When XNTable is set to 0 it has no effect.

• **PXNTable** restricts the PXN control:
  — When PXNTable is set to 1, the PXN field is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the field.
  — When PXNTable is set to 0 it has no effect.

Note

The XNTable and PXNTable settings are combined with the XN and PXN fields in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The XNTable and PXNTable controls are provided only in the Long-descriptor translation table format, and only for stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

The effect of XNTable or PXNTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to XNTable or PXNTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.
Preventing execution from writeable locations

ARMv8 provides control bits that, when the corresponding stage 1 address translation is enabled, force writeable memory to be treated as XN or PXN, regardless of the value of the XN or PXN field. When the translation stages are controlled by an Exception level that is using AArch32:

- For PL1&0 stage 1 translations, when SCTLR.WXN is set to 1, all regions that are writeable at stage 1 of the address translation are treated as XN.
- For PL1&0 stage 1 translations, when SCTLR.UWXN is set to 1, an instruction fetch is treated as accessing a PXN region if it accesses a region that software executing at PL0 can write to.
- For Non-secure PL2 stage 1 translations, when HSCTLR.WXN is set to 1, all regions that are writeable at stage 1 of the address translation are treated as XN.

**Note**

- The SCTLR.WXN controls are intended to be used in systems with very high security requirements.
- Setting a WXN or UWXN bit to 1 changes the interpretation of the translation table entry, overriding a zero value of an XN or PXN field. It does not cause any change to the translation table entry.

For any given virtual machine, ARM expects WXN and UWXN to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular VMID reflect the effect of the values of these fields. A generic sequence to ensure synchronization of a change to these fields, when that change is made without a corresponding change of VMID, is:

1. Change the WXN or UWXN bit
2. ISB; This ensures synchronization of the change
3. Invalidate entire TLB of associated entries
4. DSB; This completes the TLB Invalidation
5. ISB; This ensures instruction synchronization

As with all Permission fault checking, if the stage 1 translation is using the Short-descriptor translation table format, the permission checks are performed only for Client domains. For more information, see About access permissions on page G4-4605.

For more information about address translation, see About address translation for VMSAv8-32 on page G4-4562.

Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, SCR.SIF. When this bit is set to 1, any attempt in Secure state to execute an instruction fetched from Non-secure physical memory causes a Permission fault. As with all Permission fault checking, when using the Short-descriptor format translation tables the check applies only to Client domains, see About access permissions on page G4-4605.

ARM expects SCR.SIF to be static during normal operation. In particular, whether the TLB holds the effect of the SIF bit is IMPLEMENTATION DEFINED. The generic sequence to ensure visibility of a change to the SIF bit is:

1. Change the SCR.SIF bit
2. ISB; This ensures synchronization of the change
3. Invalidate entire TLB
4. DSB; This completes the TLB Invalidation
5. ISB; This ensures instruction synchronization

G4.6.4 Domains, Short-descriptor format only

A domain is a collection of memory regions. The Short-descriptor translation table format supports 16 domains, and requires the software that defines a translation table to assign each VMSAv8-32 memory region to a domain. When using the Short-descriptor format:

- Level 1 translation table entries for Page tables and Sections include a domain field.
Translation table entries for Supersections do not include a domain field. The Short-descriptor format defines Supersections as being in domain 0.

Level 2 translation table entries inherit a domain setting from the parent level 1 Page table descriptor.

Each TLB entry includes a domain field.

The domain field specifies which of the 16 domains the entry is in, and a two-bit field in the DACR defines the permitted access for each domain. The possible settings for each domain are:

- **No access**: Any access using the translation table descriptor generates a Domain fault.
- **Clients**: On an access using the translation table descriptor, the access permission attributes are checked. Therefore, the access might generate a Permission fault.
- **Managers**: On an access using the translation table descriptor, the access permission attributes are not checked. Therefore, the access cannot generate a Permission fault.

See [The MMU fault-checking sequence](#) on page G4-4652 for more information about how, when using the Short-descriptor translation table format, the Domain attribute affects the checking of the other attributes in the translation table descriptor.

--- **Note** ---

A single program might:
- Be a Client of some domains.
- Be a Manager of some other domains.
- Have no access to the remaining domains.

---

The Long-descriptor translation table format does not support domains. When a stage of translation is using this format, all memory is treated as being in a Client domain, and the settings in the DACR are ignored.

### G4.6.5 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0:

- If address translation is using the Short-descriptor translation table format, it must set SCTL.R.AFE to 1 to enable use of the Access flag. Setting this bit to 1 redefines the AP[0] bit in the translation table descriptors as an Access flag, and limits the access permissions information in the translation table descriptors to AP[2:1], as described in [AP[2:1] access permissions model](#) on page G4-4606.

- The Long-descriptor format always supports an Access flag bit in the translation table descriptors, and address translation using this format behaves as if SCTL.R.AFE is set to 1, regardless of the value of that bit.

In ARMv8.0, the Access flag is managed by software as described in [Software management of the Access flag](#).

--- **Note** ---

Previous version of the ARM architecture optionally supported hardware management of the Access flag. ARMv8.0 obsoletes this option.

--- **Software management of the Access flag** ---

ARMv8.0 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a translation table descriptor entry for which the value of the Access flag is 0.
Note

When using the Short-descriptor translation table format, Access flag faults are generated only if SCTLR.AFE is set to 1, to enable use of a translation table descriptor bit as an Access flag.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

Note

If a system incorporates components that can autonomously update translation table entries that are shared with the ARM PE, then the software must be aware of the possibility that such components can update the access flag autonomously.

In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.

G4.6.6 Hyp mode control of Non-secure access permissions

When EL2 is using AArch32, Non-secure software executing in Hyp mode controls two sets of translation tables, both of which use the Long-descriptor translation table format:

- The translation tables that control the Non-secure PL2 stage 1 translations. These map VAs to PAs, for memory accesses made when executing in Non-secure state in Hyp mode, and are indicated and controlled by the HTTBR and HTCR.

  These translations have similar access controls to other Non-secure stage 1 translations using the Long-descriptor translation table format, as described in:
  - Access permissions for instruction execution on page G4-4609.

  The differences from the Non-secure stage 1 translations are that:
  - The APTable[0], PXNTable, and PXN bits are reserved, SBZ.
  - AP[1] is reserved, SBO.

- The translation tables that control the Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, for memory accesses made when executing in Non-secure state at PL1 or PL0, and are indicated and controlled by the VTTBR and VTCR.

  The descriptors in the virtualization translation tables define stage 2 access permissions, that are combined with the permissions defined in the stage 1 translation. This section describes this combining of access permissions.

Note

The level 2 access permissions mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The stage 2 access controls defined from Hyp mode:

- Affect only the Non-secure stage 1 access permissions settings.
- Take no account of whether the accesses are from a Non-secure PL1 mode or a Non-secure PL0 mode.
- Permit software executing in Hyp mode to assign a write-only attribute to a memory region.
The S2AP field in the stage 2 descriptors define the stage 2 access permissions, as Table G4-11 shows:

<table>
<thead>
<tr>
<th>S2AP</th>
<th>Access permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No access permitted</td>
</tr>
<tr>
<td>01</td>
<td>Read-only. Writes to the region are not permitted, regardless of the stage 1 permissions.</td>
</tr>
<tr>
<td>10</td>
<td>Write-only. Reads from the region are not permitted, regardless of the stage 1 permissions.</td>
</tr>
<tr>
<td>11</td>
<td>Read/write. The stage 1 permissions determine the access permissions for the region.</td>
</tr>
</tbody>
</table>

For more information about the S2AP field see Attribute fields in VMSA v8-32 Long-descriptor stage 2 Block and Page descriptors on page G4-4592.

If the stage 2 permissions cause a Permission fault, this is a stage 2 MMU fault. Stage 2 MMU faults are taken to Hyp mode, and reported in the HSR using an EC code of 0x20 or 0x24. For more information, see Use of the HSR on page G4-4677.

Note

In the HSR, the combination of the EC code and the DFSC or IFSC value in the ISS indicate that the fault is a stage 2 MMU fault.

The stage 2 permissions include an XN attribute. If this is set to 1, execution from the region is not permitted, regardless of the value of the XN attribute in the stage 1 translation. If a Permission fault is generated because the stage 2 XN bit is set to 1, this is reported as a stage 2 MMU fault.

AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660 describes the abort prioritization if both stages of a translation generate a fault.
G4.7 Memory region attributes

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of that target memory region. Information returned by a translation table lookup on page G4-4572 describes the classification of those fields as address map control, access control, and memory attribute fields. The memory region attribute fields control the memory type, Cacheability, and Shareability of the region.

The following sections describe the assignment of memory region attributes for stage 1 translations:

- Overview of memory region attributes for stage 1 translations.
- Short-descriptor format memory region attributes, without TEX remap on page G4-4617.
- Short-descriptor format memory region attributes, with TEX remap on page G4-4619.
- VMS\&8-32 Long-descriptor format memory region attributes on page G4-4622.

For an implementation that is operating in Secure state, or in Hyp mode, these assignments define the memory attributes of the accessed region.

For an implementation that is operating in a Non-secure PL1 or PL0 mode, the Non-secure PL1&0 stage 2 translation can modify the memory attributes assigned by the stage 1 translation. EL2 control of Non-secure memory region attributes on page G4-4624 describes these stage 2 assignments.

G4.7.1 Overview of memory region attributes for stage 1 translations

The description of the memory region attributes in a translation descriptor divides into:

Memory type and attributes

These are described either:

- Directly, by bits in the translation table descriptor.
- Indirectly, by registers referenced by bits in the table descriptor. This is described as remapping the memory type and attribute description.

The Short-descriptor translation table format can use either of these approaches, selected by the SCTLR.TRE bit:

**TRE == 0** Remap disabled. The TEX[2:0], C, and B bits in the translation table descriptor define the memory region attributes. Short-descriptor format memory region attributes, without TEX remap on page G4-4617 describes this encoding.

--- Note ---

With the Short-descriptor format, remapping is called TEX remap, and the SCTLR.TRE bit is the TEX remap enabled bit.

The description of the TRE == 0 encoding includes information about the encoding in previous versions of the architecture.

**TRE == 1** Remap enabled. The TEX[0], C, and B bits in the translation table descriptor are index bits to the remap registers, that define the memory region attributes:

- The Primary Region Remap Register, PRRR.
- The Normal Memory Remap Register, NMRR.

Short-descriptor format memory region attributes, with TEX remap on page G4-4619 describes this encoding scheme.

This scheme reassigns translation table descriptor bits TEX[2:1] for use as bits managed by the operating system.

The Long-descriptor translation table format always uses remapping. This means that when the value of TTBCR.EAE is 1, enabling use of the Long-descriptor translation table format, SCTLR.TRE is RES1.

VMS\&8-32 Long-descriptor format memory region attributes on page G4-4622 describes this encoding.
In the Short-descriptor translation table format, the S bit in the translation table descriptor is used in determining the Shareability of the region. How the S bit is interpreted depends on whether TEX remap is enabled, see:

- Shareability and the S bit, without TEX remap on page G4-4618.
- Determining the Shareability, with TEX remap on page G4-4620.

In the Long-descriptor translation table format, the SH[1:0] field in the translation table descriptor encodes the Shareability of the region, see Shareability, Long-descriptor format on page G4-4622.

Note
Shareability is one of Non-shareable, Inner Shareable, and Outer Shareable. However, when using the Short-descriptor translation table format without TEX remap, VMSAv8-32 does not support any distinction between Inner Shareable and Outer Shareable memory, and a memory region is either Non-shareable or Outer Shareable.

G4.7.2 Short-descriptor format memory region attributes, without TEX remap

When using the Short-descriptor translation table formats, TEX remap is disabled when the value of SCTLR.TRE is 0.

Note
- The Short-descriptor format scheme without TEX remap is the scheme used in VMSAv6.
- The B (Bufferable), C (Cacheable), and TEX (Type extension) bit names are inherited from earlier versions of the architecture. These names no longer adequately describe the function of the B, C, and TEX bits.

Table G4-12 shows the C, B, and TEX[2:0] encodings when TEX remap is disabled. In the Page Shareability column, an entry of S bit indicates that the S bit in the translation table descriptor determines the Shareability, see Shareability and the S bit, without TEX remap on page G4-4618.

Cacheability attributes, without TEX remap

When the value of TEX[2] is 0, the same Cacheability attribute applies to Inner Cacheable and Outer Cacheable memory regions, and the \{TEX[1:0], C, B\} values identify this attribute, as Table G4-12 on page G4-4617 shows.

When the value of TEX[2] is 1, the memory described by the translation table entry is cacheable, and the rest of the encoding defines the Inner Cacheability and Outer Cacheability attributes:

- TEX[1:0]: Define the Outer Cacheability attribute.
- C, B: Define the Inner Cacheability attribute.

The translation table entries use the same encoding for the Outer and Inner Cacheability attributes, as Table G4-13 shows.

\^c In ARMv8, all Device memory types are Outer Shareable. For the Device-nGnRE memory type this is a change from previous versions of the architecture. This is why Device-nGnRE memory has two entries in this table. For compatibility with ARMv7 software should use the \{TEX, C, B\} values \{000, 0, 1\}.

\^ In ARMv8, Normal Inner Non-cacheable, Outer Non-cacheable memory is always Outer Shareable. This is a change from previous versions of the architecture, where the S bit determined the Shareability. For compatibility with ARMv7 software should set S to 1.

\^ For more information, see Cacheability attributes, without TEX remap.

See Memory types and attributes on page E2-2782 for an explanation of Normal memory, and the types of Device memory, and of the Shareability attribute.

Shareability and the S bit, without TEX remap

The Short-descriptor format translation table entries include an S bit. This bit:

- is ignored if the entry refers to any type of Device memory, or to Normal memory that is Inner Non-cacheable, Outer Non-cacheable.
- For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, determines whether the memory region is Outer Shareable or Non-shareable:
  - S == 0: Normal memory region is Non-shareable.
  - S == 1: Normal memory region is Outer Shareable.

Without TEX remapping there is no distinction between Inner Shareable and Outer Shareable memory, meaning the S bit determines whether the region is Non-shareable or Outer Shareable.
G4.7.3   Short-descriptor format memory region attributes, with TEX remap

When using the Short-descriptor translation table formats, TEX remap is enabled when the value of SCTLR.TRE is 1. In this configuration:

- The software that defines the translation tables must program the PRRR and NMRR to define seven possible memory region attributes.
- The TEX[0], C, and B bits of the translation table descriptors define the memory region attributes, by indexing PRRR and NMRR.
- Hardware makes no use of TEX[2:1], see The OS managed translation table bits on page G4-4621.

When TEX remap is enabled:

- For seven of the eight possible combinations of the TEX[0], C and B bits, fields in the PRRR and NMRR define the region attributes, as described in this section.
- The meaning of the eighth combination for the TEX[0], C and B bits is IMPLEMENTATION DEFINED.
- If the TEX[0], C and B bits determine that the region is a Device memory type, or is Normal Inner Non-cacheable, Outer Non-cacheable, then the region is Outer Shareable. Otherwise, the Shareability is determined by the combination of:
  - The S bit from the translation table descriptor.
  - The value of the PRRR.NS0 or PRRR.NS1 bit.
  - The value of the appropriate PRRR.NOSn bit, as shown in Table G4-14.

For more information, see Determining the Shareability, with TEX remap on page G4-4620.

For each of the possible encodings of the TEX[0], C, and B bits in a translation table entry, Table G4-14 shows which fields of the PRRR and NMRR registers describe the memory region attributes.

</tr>
</tbody>
</table>

a. For details of the Memory type and Outer Shareable encodings see the description of the PRRR. For details of the Cache attributes encodings the description of the NMRR.
b. Applies only if the memory type for the region is mapped as Normal memory.
c. Applies only if both of the following apply:
  - The memory type for the region is mapped as Normal memory that is not Inner Non-cacheable and Outer Non-cacheable.
  - The region is not Non-shareable.

See Determining the Shareability, with TEX remap on page G4-4620.
As Table G4-14 on page G4-4619 shows, when TEX remap is enabled, for a given set of \{TEX[0], C, B\} bits from
a translation table descriptor:

1. The primary mapping, to memory type, is given by the PRRR.TRn field as shown in the Memory type
   column.
2. For any region that the PRRR.TRn maps as Normal memory, NMRR.IRn determines the Inner cacheability
   attribute, and NMRR.ORn determines the Outer cacheability attribute.
3. For a region that PRRR.TRn maps as Normal memory, if NMRR.\{IRn, ORn\} do not map the region as Inner
   Non-cacheable, Outer Non-cacheable, PRRR.\{NS0, NS1\} and PRRR.NOSn are used to determine the
   Shareability of the region, see Determining the Shareability, with TEX remap.

The TEX remap registers and the SCTLR.TRE bit are Banked between the Secure and Non-secure Security states.
For more information, see The effect of EL3 on TEX remap on page G4-4622.

The TEX remap registers must be static during normal operation. In particular, when the remap registers are
changed:

- It is IMPLEMENTATION DEFINED when the changes take effect.
- It is CONSTRAINED UNPREDICTABLE whether the TLB caches the effect of the TEX remap on translation
  tables, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on
  page K1-6101.

The software sequence to ensure the synchronization of changes to the TEX remap registers is:

1. Execute a DSB instruction. This ensures any memory accesses using the old mapping have completed.
2. Write the TEX remap registers or SCTLR.TRE bit.
3. Execute an ISB instruction. This ensures synchronization of the register updates.
4. Invalidate the entire TLB.
5. Execute a DSB instruction. This ensures completion of the entire TLB operation.
6. Clean and invalidate all caches. This removes any cached information associated with the old mapping.
7. Execute a DSB instruction. This ensures completion of the cache maintenance.
8. Execute an ISB instruction. This ensures instruction synchronization.

This extends the standard rules for the synchronization of changes to System registers described in Synchronization
of changes to AArch32 System registers on page G6-4768, and provides implementation freedom as to whether or
not the effect of the TEX remap is cached.

**Determining the Shareability, with TEX remap**

The memory type of a region, as indicated in the Memory type column of Table G4-14 on page G4-4619, provides
the first level of control of the Shareability of the region:

- If the memory is any type of Device memory, then the region is Outer Shareable, and any Shareability
  attributes in the translation table descriptor and PRRR for that region are ignored.
  This rule applies also to a Normal memory region that the NMRR attributes identify as Inner Non-cacheable
  and Outer Non-cacheable,
- If using the Short descriptor translation table format then the Shareability of the region is determined using
  the value of the S bit in the translation table descriptor to index one of the PRRR.\{NS1, NS0\} bits, as
  described in this section.

Table G4-15 shows how the translation table S bit indexes into the PRRR:

<table>
<thead>
<tr>
<th>Memory type</th>
<th>Remapping when $S = 0$</th>
<th>Remapping when $S = 1$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device or Normal Inner Non-cacheable, Outer Non-cacheable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Normal, not Inner Non-cacheable, Outer Non-cacheable</td>
<td>PRRR.NS0</td>
<td>PRRR.NS1</td>
</tr>
</tbody>
</table>
For a Normal memory region that is not Inner Non-cacheable, Outer Non-cacheable, the appropriate bit of the PRRR indicates whether the region is Non-shareable, as follows:

\[ \text{PRRR.NS} = 0 \] Non-shareable.
\[ \text{PRRR.NS} = 1 \] The appropriate PRRR.NOS\textsubscript{m} field, as shown in Table G4-14 on page G4-4619, indicates whether the region is Inner Shareable or Outer Shareable:
\[ \text{PRRR.NOS} = 0 \] Region is Outer Shareable.
\[ \text{PRRR.NOS} = 1 \] Region is Inner Shareable.

--- Note ---

This means that TEX remapping can map a translation table entry with \( S = 0 \) as shareable memory.

**SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers**

When TEX remap is disabled, because the value of the SCTLR.TRE bit is 0:

- The effect of the PRRR and NMRR registers can be IMPLEMENTATION DEFINED.
- The interpretation of the fields of the PRRR and NMRR registers can differ from the description given earlier in this section. One implication of this is that the implementation can provide an IMPLEMENTATION DEFINED mechanism to interpret the PRRR.\{NOS7: NOS0\} fields.

VMSAv8-32 requires that the effect of these registers is limited to remapping the attributes of memory locations. These registers must not change whether any cache hardware or stages of address translation are enabled. The mechanism by which the TEX remap registers have an effect when the value of the SCTLR.TRE bit is 0 is IMPLEMENTATION DEFINED. The AArch32 architecture requires that from reset, if the IMPLEMENTATION DEFINED mechanism has not been invoked:

- If the PL1&0 stage 1 address translation is enabled and is using the Short-descriptor format translation tables, the architecturally-defined behavior of the TEX[2:0], C, and B bits must apply, without reference to the TEX remap functionality. In other words, memory attribute assignment must comply with the scheme described in *Short-descriptor format memory region attributes, without TEX remap* on page G4-4617.
- If the PL1&0 stage 1 address translation is disabled, then the architecturally-defined behavior of VMSAv8-32 with address translation disabled must apply, without reference to the TEX remap functionality. See *The effects of disabling address translation stages on VMSAv8-32 behavior* on page G4-4567.

Possible mechanisms for enabling the IMPLEMENTATION DEFINED effect of the TEX remap registers when the value of SCTLR.TRE is 0 include:

- A control bit in the ACTLR, or in an IMPLEMENTATION DEFINED System register.
- Changing the behavior when the PRRR and NMRR registers are changed from their IMPLEMENTATION DEFINED reset values.

In addition, if the stage of address translation is disabled and the value of the SCTLR.TRE bit is 1, the architecturally-defined behavior of the VMSAv8-32 with the stage of address translation disabled must apply without reference to the TEX remap functionality.

In an implementation that includes EL3, the IMPLEMENTATION DEFINED effect of these registers must only take effect in the Security state of the registers. See also *The effect of EL3 on TEX remap* on page G4-4622.

**The OS managed translation table bits**

When TEX remap is enabled, the TEX[2:1] bits in the translation table descriptors are available as two bits that can be managed by the operating system. In VMSAv8-32, as long as the SCTLR.TRE bit is set to 1, the values of the TEX[2:1] bits are IGNORED by the PE. Software can write any value to these bits in the translation tables.
The effect of EL3 on TEX remap

In an implementation that includes EL3, when EL3 is using AArch32, the TEX remap registers are Banked between the Secure and Non-secure Security states. When EL3 is using AArch32, write accesses to the Secure register for the current Security state apply to all PL1&0 stage 1 translation table lookups in that state. The SCTLR.TRE bit is Banked in the Secure and Non-secure copies of the register, and the appropriate version of this bit determines whether TEX remap is applied to translation table lookups in the current Security state.

Write accesses to the Secure copies of the TEX remap registers are disabled when the CP15SDISABLE input is asserted HIGH, meaning the MCR operations to access these registers are UNDEFINED. For more information, see The CP15SDISABLE input signal on page G4-4699.

G4.7.4 VMSAv8-32 Long-descriptor format memory region attributes

When a PE is using the VMSAv8-32 Long-descriptor translation table format, the AttrIndx[2:0] field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field, in the appropriate MAIR register, that specifies the attributes for the corresponding memory region, as follows:

- AttrIndx[2] indicates the MAIR register to be used:
  - AttrIndx[2] == 0: Use MAIR0.
- AttrIndx[2:0] indicates the required Attr field, Attr, where \( n = \text{AttrIndx}[2:0] \).

Each AttrIndx field defines, for the corresponding memory region:

- The memory type, Normal or a type of Device memory.
- For Normal memory:
  - The Inner cacheability and Outer cacheability attributes, each of which is one of Non-cacheable, Write-Through Cacheable, or Write-Back Cacheable.
  - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is Allocate or No allocate.

For more information about the AttrIndx[2:0] descriptor field, see Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors on page G4-4590.

Shareability, Long-descriptor format

When a PE is using the Long-descriptor translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region, if the MAIR entry for that region identifies it as Normal memory that is not both Inner Non-cacheable and Outer Non-cacheable. Table G4-16 shows the encoding of this field.

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>Reserved, CONSTRAINED UNPREDICTABLE, see Reserved values in System and memory-mapped registers and translation table entries on page K1-6117 for the permitted behavior.</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

See Combining the Shareability attribute on page G4-4627 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.
For any type of Device memory, and for Normal Inner Non-cacheable, Outer Non-cacheable memory, the value of the SH[1:0] field of the translation table descriptor is ignored.

Other fields in the Long-descriptor translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors when a PE is using the Long-descriptor translation table format:

- Contiguous bit
- IGNORED fields
- Field reserved for software use

Contiguous bit

The Long-descriptor translation table format descriptors contain a Contiguous bit. Setting this bit to 1 indicates that 16 adjacent translation table entries point to a contiguous output address range. These 16 entries must be aligned in the translation table so that the top five bits of their input addresses, that index their position in the translation table, are the same. For example, to use this bit for a block of 16 entries in the level 3 translation table, bits[20:16] of the input addresses for the 16 entries must be the same.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

Use of this bit means that the TLB can cache a single entry to cover the 16 translation table entries.

This bit acts as a hint. The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of this bit.

--- Note ---

The use of the contiguous bit is similar to the approach used, in the Short-descriptor translation table format, for optimized caching of Large Pages and Supersections in the TLB. However, an important difference in the contiguous bit capability is that TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues. That is, any use of the contiguous bit has no effect on the minimum size of entry that must be invalidated from the TLB.

---

IGNORED fields

For stage 1 and stage 2 Block and Page descriptors, the architecture defines bits[63:59] and bits[58:55] as IGNORED fields, meaning the architecture guarantees that a PE makes no use of these fields. In addition:

- Bits[58:55] are reserved for software use, see Field reserved for software use.
- In the stage 2 Block and Page descriptors, bits[63:60] are reserved for use by a System MMU.

--- Note ---

The definition of IGNORED means there is no need to invalidate the TLB if these bits are changed.

---

Field reserved for software use

The architecture reserves a 4-bit field in the Block and Page table descriptors, bits[58:55], for software use. In considering migration from using the Short-descriptor format to the Long-descriptor format, this field is an extension of the Short-descriptor field described in The OS managed translation table bits on page G4-4621.

--- Note ---

The definition of IGNORED means there is no need to invalidate the TLB if these bits are changed.
**G4.7.5 EL2 control of Non-secure memory region attributes**

Software executing at EL2 controls two sets of translation tables, both of which use the Long-descriptor translation table format. These are:

- The translation tables that control Non-secure PL2 stage 1 translations. These map VAs to PAs, and when EL2 is using AArch32 they are indicated and controlled by the HTTBR and HTCR.
  
  These translations have exactly the same memory region attribute controls as any other stage 1 translations, as described in *VMSAv8-32 Long-descriptor format memory region attributes* on page G4-4622.

- The translation tables that control Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, and are indicated and when EL2 is using AArch32 they are controlled by the VTTBR and VTCR.

  The descriptors in the virtualization translation tables define level 2 memory region attributes, that are combined with the attributes defined in the stage 1 translation. This section describes this combining of attributes.

  *VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-4586 describes the format of the entries in these tables.

**Note**

In a virtualization implementation, a hypervisor might usefully:

- Reduce the permitted Cacheability of a region.
- Increase the required Shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- The definition of the stage 2 SH[1:0] field is identical to the same field for a stage 1 translation, see *Shareability, Long-descriptor format* on page G4-4622.

- MemAttr[3:2] give a top-level definition of the memory type, and of the cacheability of a Normal memory region, as Table G4-17 shows:

<table>
<thead>
<tr>
<th>MemAttr[3:2]</th>
<th>Memory type</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Device, of type determined by MemAttr[1:0]</td>
<td>Not applicable</td>
</tr>
<tr>
<td>01</td>
<td>Normal, Inner cacheability determined by MemAttr[1:0]</td>
<td>Outer Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Write-Through Cacheable</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>Outer Write-Back Cacheable</td>
<td></td>
</tr>
</tbody>
</table>
The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

— When MemAttr[3:2] == 0b00, indicating a type of Device memory, Table G4-18 shows the encoding of MemAttr[1:0]:

Table G4-18 MemAttr[1:0] encoding for the types of Device memory

<table>
<thead>
<tr>
<th>MemAttr[1:0]</th>
<th>Meaning when MemAttr[3:2] == 0b00</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Region is Device-nGnRnE memory</td>
</tr>
<tr>
<td>01</td>
<td>Region is Device-nGnRE memory</td>
</tr>
<tr>
<td>10</td>
<td>Region is Device-nGRE memory</td>
</tr>
<tr>
<td>11</td>
<td>Region is Device-GRE memory</td>
</tr>
</tbody>
</table>

— When MemAttr[3:2] != 0b00, indicating Normal memory, Table G4-19 shows the encoding of MemAttr[1:0]:

Table G4-19 MemAttr[1:0] encoding for Normal memory

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Reserved, CONSTRAINED UNPREDICTABLE, See Reserved values in System and memory-mapped registers and translation table entries on page K1-6117 for the permitted behavior.</td>
</tr>
<tr>
<td>01</td>
<td>Inner Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Inner Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Write-Back Cacheable</td>
</tr>
</tbody>
</table>

--- Note ---

The stage 2 translation does not assign any allocation hints.

The following sections describe how the memory type attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- Combining the memory type attribute on page G4-4626.
- Combining the Cacheability attribute on page G4-4626.
- Combining the Shareability attribute on page G4-4627.

--- Note ---

- The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:
  — MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

- In addition to the attribute combinations described in this section, Access permissions for instruction execution on page G4-4609 describes how the stage 1 and stage 1 XN permission fields are combined, so that a region is execute-never if the value of the XN field is 1 in at least one stage of translation.
Combining the memory type attribute

Table G4-20 shows how the stage 1 and stage 2 memory type assignments are combined:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device-nGnRnE</td>
<td>Any</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td>Device-nGnRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Not Device-nGnRnE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td>Device-nGRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Device-nGnRE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td></td>
<td>Not (Device-nGnRnE or Device-nGnRE)</td>
<td>Device-nGRE</td>
</tr>
<tr>
<td>Device-GRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Device-nGnRE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td></td>
<td>Device-nGRE</td>
<td>Device-nGRE</td>
</tr>
<tr>
<td></td>
<td>Device-GRE or Normal</td>
<td>Device-GRE</td>
</tr>
<tr>
<td>Normal</td>
<td>Any type of Device</td>
<td>Device type assigned at stage 2</td>
</tr>
<tr>
<td></td>
<td>Normal</td>
<td>Normal</td>
</tr>
</tbody>
</table>

See Combining the Shareability attribute on page G4-4627 for information about the Shareability of:

- A region for which the resultant type is any Device type.
- A region with a resultant type of Normal for which the resultant cacheability, described in Combining the Cacheability attribute, is Inner Non-cacheable, Outer Non-cacheable.

The combining of the memory type attribute means a translation table walk for a stage 1 translation can be made to a type of Device memory. If this occurs, then:

- If the value of HCR.PTW is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be done speculatively.
- If the value of HCR.PTW is 1, then the memory access generates a stage 2 Permission fault.

Combining the Cacheability attribute

For a Normal memory region, Table G4-21 shows how the stage 1 and stage 2 Cacheability assignments are combined. This combination applies, independently, for the Inner Cacheability and Outer Cacheability attributes:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-cacheable</td>
<td>Any</td>
<td>Non-cacheable</td>
</tr>
<tr>
<td>Any</td>
<td>Non-cacheable</td>
<td>Non-cacheable</td>
</tr>
</tbody>
</table>
Note

Only Normal memory has a Cacheability attribute.

Combining the Shareability attribute

In the following cases, a memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation:

- The resultant memory type attribute, described in Combining the memory type attribute on page G4-4626, is any type of Device memory.

- The resultant memory type attribute is Normal memory, and the resultant Cacheability, described in Combining the Cacheability attribute on page G4-4626, is Inner Non-cacheable Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal that is not Inner Non-cacheable Outer Non-cacheable, Table G4-22 shows how the stage 1 and stage 2 shareability assignments are combined:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant Shareability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Outer Shareable</td>
<td>Any</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Non-shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Non-shareable</td>
<td>Non-shareable</td>
</tr>
</tbody>
</table>
G4.8 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement to perform a translation table walk in memory for every memory access. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.

- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.

- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.

- When address translation is enabled, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not from a translation regime for an Exception level that is lower than the current Exception level can be allocated to a TLB at any time. The only translation table entries guaranteed not to be held in the TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

  Note

A TLB can hold translation table entries that do not generate a Translation fault but point to subsequent tables in the translation table walk. This can be referred to as intermediate caching of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- Global and process-specific translation table entries.
- TLB matching.
- TLB behavior at reset.
- TLB lockdown.
- TLB conflict aborts.

See also TLB maintenance requirements on page G4-4632.

G4.8.1 Global and process-specific translation table entries

For VMSAv8-32, system software can divide a virtual memory map used by memory accesses at PL1 and PL0 into global and non-global regions, indicated by the nG bit in the translation table descriptors:

- nG == 0: The translation is global, meaning the region is available for all processes.
- nG == 1: The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined by:
  - TTBR0.ASID or TTBR1.ASID, if using the Long-descriptor translation table format. In this case, TTBCR.A1 selects which ASID is current.
  - CONTEXTIDR.ASID, if using the Short-descriptor translation table format.

Each non-global region has an associated ASID. These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.
For a symmetric multiprocessor cluster where a single operating system is running on the set of PEs, the architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all PEs in the system.

The translation regime used for accesses made at PL2 does not support ASIDs, and all pages are treated as global.

When a PE is using the Long-descriptor translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information see Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4593.

G4.8.2 TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in TLB maintenance requirements on page G4-4632 can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This can occur only if the architecturally-required break-before-make sequence described in Using break-before-make when updating translation table entries on page G4-4633 is not used. If the break-before make sequence is not used, the TLB can hold two mappings for the same address, and this:

- Might generate an exception that is reported using the TLB Conflict fault code, see TLB conflict aborts on page G4-4630.
- Might lead to CONSTRAINED UNPREDICTABLE behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for the access. See CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101.

G4.8.3 TLB behavior at reset

The ARM architecture does not require a reset to invalidate the TLBs, and recognizes that an implementation might require caches, including TLBs, to maintain context over a system reset. Possible reasons for doing so include power management and debug requirements.

Therefore, for ARMv8:

- All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
- All TLBs are disabled from reset. All stages of address translation that are used from the PE state entered on coming out of reset are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information see Enabling stages of address translation on page G4-4569.
- An implementation can require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device. ARM recommends that if an invalidation routine is required for this purpose, and the PE resets into AArch32 state, the routine is based on the AArch32 TLB maintenance instructions described in The scope of TLB maintenance instructions on page G4-4641.

Similar rules apply:

- To cache behavior, see Behavior of caches at reset on page G3-4531.
- To branch predictor behavior, see Behavior of the branch predictors at reset on page G3-4539.
G4.8.4 TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- The architecture does not require TLB lockdown support.
- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that:

- The TLB Type Register, TLBTR, does not define the lockdown scheme in use.
- In AArch32 state, a region of the \{coproc==0b1111, Crn==c18\} encodings is reserved for IMPLEMENTATION DEFINED TLB functions, such as TLB lockdown functions. The reserved encodings are those with:
  - \(<Crn>==\{c0, c1, c4, c8\}.
  - All values of \(<opc2>\) and \(<opc1>\).

An implementation might use some of the \{coproc==0b1111, Crn==c18\} encodings that are reserved for IMPLEMENTATION DEFINED TLB functions to implement additional TLB control functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the PLI and PLD hint instructions.

The inclusion of EL2 in an implementation does not affect the TLB lockdown requirements. However, in an implementation that includes EL2, exceptions generated as a result of TLB lockdown when executing in a Non-secure PL1 mode or in Non-secure User mode can be routed to either:

- Non-secure Abort mode, using the Non-secure Data Abort exception vector.
- Hyp mode, using the Hyp Trap exception vector.

For more information, see Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-4433.

G4.8.5 TLB conflict aborts

If an address matches multiple entries in the TLB, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses. A TLB conflict abort is classified as an MMU fault, see MMU faults in AArch32 state on page G4-4657. This means:

- A TLB conflict abort on an instruction fetch is reported as a Prefetch Abort exception,
- A TLB conflict abort on a data access is reported as a Data Abort exception,

Fault status codes for TLB conflict aborts are defined for both the Short-descriptor and Long-descriptor translation table formats, see:

- PL1 fault reporting with the Short-descriptor translation table format on page G4-4668
- PL1 fault reporting with the Long-descriptor translation table format on page G4-4670.

On a TLB conflict abort, the fault address register returns the address that generated the fault. That is, it returns the address that was being looked up in the TLB.

It is IMPLEMENTATION DEFINED whether a TLB conflict abort is a stage 1 abort or a stage 2 abort.

Note

- An address can hit multiple entries in the TLB if the TLB has been invalidated inappropriately, for example if TLB invalidation required by this manual has not been performed.
- A stage 2 abort cannot be generated if the Non-secure PL1&0 stage 2 address translation is disabled.
The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of any TLB that can generate the abort. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

If an address matches multiple entries in the TLB and no TLB conflict abort not generated, the resulting behavior is CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101. The CONSTRAINED UNPREDICTABLE behavior must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Privilege level.
G4.9 TLB maintenance requirements

Translation Lookaside Buffers (TLBs) on page G4-4628 describes the ARM architectural provision for TLBs. Although the ARM architecture does not specify the form of any TLB structures, it does define the mechanisms by which TLBs can be maintained. The following sections describe the VMSAv8-32 TLB maintenance instructions:

- General TLB maintenance requirements.
- Maintenance requirements on changing System register values on page G4-4637.
- Atomicity of register changes on changing virtual machine on page G4-4638.
- Synchronization of changes of ASID and TTBR on page G4-4639.
- The scope of TLB maintenance instructions on page G4-4641.

G4.9.1 General TLB maintenance requirements

TLB maintenance instructions provide a mechanism to invalidate entries from a TLB. As Translation Lookaside Buffers (TLBs) on page G4-4628 describes, when address translation is enabled translation table entries can be allocated to a TLB at any time. This means that software must perform TLB maintenance between updating translation table entries that apply in a particular context and accessing memory locations whose translation is determined by those entries in that context.

--- Note ---

This requirement applies to any translation table entry at any level of the translation tables, including an entry that points to further levels of the tables, provided that the entry in that level of the tables does not cause a Translation fault, an Address size fault, or an Access flag fault.

---

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see Cache maintenance requirement created by changing translation table attributes on page G4-4648.

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB or branch predictor invalidation.

Special considerations apply to translation table updates that change the memory type, cacheability, or output address of an entry, see Using break-before-make when updating translation table entries on page G4-4633.

In addition, software must perform TLB maintenance after updating the System registers if the update means that the TLB might hold information that applies to a current translation context, but is no longer valid for that context. Maintenance requirements on changing System register values on page G4-4637 gives more information about this maintenance requirement.

Each of the translation regimes defined in Figure G4-1 on page G4-4560 is a different context, and:

- For the Non-secure PL1&0 regime, a change in the VMID or ASID value changes the context.
- For the Secure PL1&0 regime, a change in the ASID value changes the context.

For operation in Non-secure PL1 or PL0 modes, a change of HCR.VM, unless made at the same time as a change of VMID, requires the invalidation of all TLB entries for the Non-secure PL1&0 translation regime that apply to the current VMID. Otherwise, there is no guarantee that the effect of the change of HCR.VM is visible to software executing in the Non-secure PL1 and PL0 modes.

Any TLB maintenance instruction can affect any other TLB entries that are not locked down.

AArch32 state defines \{coproc==0b1111, Crn==c8\} System instructions for TLB maintenance instructions, and supports the following operations:

- Invalidate all unlocked entries in the TLB.
- Invalidate a single TLB entry, by VA, or VA and ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.
- Operations that apply across multiprocessors in the same Inner Shareable domain.
A TLB maintenance instruction that specifies a virtual address that would generate any MMU fault, including a virtual address that is not in the range of virtual addresses that can be translated, does not generate an abort.

EL2 provides additional TLB maintenance instructions for use in AArch32 state at PL2, and has some implications for the effect of the other TLB maintenance instructions, see The scope of TLB maintenance instructions on page G4-4641.

In an implementation that includes EL3, the TLB maintenance instructions take account of the current Security state, as part of the address translation required for the TLB maintenance instruction.

Some TLB maintenance instructions are defined as operating only on instruction TLBs, or only on data TLBs. ARMv8 AArch32 state includes these instructions for backwards compatibility. However, more recent TLB maintenance instructions do not support this distinction. From the introduction of ARMv7, ARM deprecates any use of Instruction TLB maintenance instructions, or of Data TLB maintenance instructions, and developers must not rely on this distinction being maintained in future revisions of the ARM architecture.

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, for TLB invalidate instructions, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

The scope of TLB maintenance instructions on page G4-4641 describes the TLB maintenance instructions. The following subsections give more information about the general requirements for TLB maintenance:

- Using break-before-make when updating translation table entries.
- The interaction of TLB lockdown with TLB maintenance instructions on page G4-4634.
- Ordering and completion of TLB maintenance instructions on page G4-4635.
- Use of ASIDs and VMIDs to reduce TLB maintenance requirements on page G4-4636.

### Using break-before-make when updating translation table entries

To avoid possibly creating multiple TLB entries for the same address, and to avoid the effects of TLB caching possibly breaking coherency, ordering guarantees or uniprocessor semantics, or possibly failing to clear the Exclusives monitors, the architecture requires the use of a break-before-make sequence when changing translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation table entries involves any of:

- A change of the memory type.
- A change of the cacheability attributes.
- A change of the output address (OA), if the OA of at least one of the old translation table entries and the new translation table entry is writeable.
- A change to the size of block used by the translation system. This rule applies both:
  - When changing from a smaller size to a larger size, for example by replacing a table mapping with a block mapping in a stage 2 translation table.
  - When changing from a larger size to a smaller size, for example by replacing a block mapping with a table mapping in a stage 2 translation table.
- Creating a global entry when there might be non-global entries in a TLB that overlap with that global entry.
A break-before-make sequence on changing from an old translation table entry to a new translation table entry requires the following steps:

1. Replace the old translation table entry with an invalid entry, and execute a DSB instruction.
2. Invalidate the translation table entry with a broadcast TLB invalidation instruction, and execute a DSB instruction to ensure the completion of that invalidation.
3. Write the new translation table entry, and execute a DSB instruction to ensure that the new entry is visible.

This sequence ensures that at no time are both the old and new entries simultaneously visible to different threads of execution, and therefore the problems described at the start of this subsection cannot arise.

The interaction of TLB lockdown with TLB maintenance instructions

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

- The effect on locked entry of a TLB invalidate all unlocked entries instruction or a TLB invalidate by VA all ASID instruction that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  - The instructions have no effect on entries that are locked down.
  - The instructions generate an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down. For an invalidation instruction performed in AArch32 state, the \{coproc==0b1111, Crn==c5\} fault status register definitions include a Fault status code for cache and TLB lockdown faults, see Table G4-25 on page G4-4668 for the codes used with the Short-descriptor translation table formats, or Table G4-26 on page G4-4670 for the codes used with the Long-descriptor translation table formats.

In an implementation that includes EL2, if EL2 is using AArch32 and the value of HCR.TIDCP is 1, any such exceptions taken from a Non-secure PL1 mode are routed to Hyp mode, see Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-4433.

This permits a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.

- The effect on a locked TLB entry of a TLB invalidate by VA instruction or a TLB invalidate by ASID match instruction that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  - A locked entry is invalidated in the TLB.
  - The instruction has no effect on a locked entry in the TLB. In the case of the Invalidate single entry by VA, this means the PE treats the instruction as a NOP.
  - The instruction generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down. For an invalidate instruction performed in AArch32 state, the \{coproc==0b1111, Crn==c5\} fault status register definitions include a Fault status code for cache and TLB lockdown faults, see Table G4-25 on page G4-4668 and Table G4-26 on page G4-4670.

Note

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required invalidation on entries that are not locked down.
- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined maintenance instructions. This minimizes the number of customized maintenance operations required.
In addition, an implementation that uses an abort mechanism for handling TLB maintenance instructions on entries that can be locked down but are not actually locked down must also must provide a mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see The interaction of cache lockdown with cache maintenance instructions on page G3-4546.

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of a TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

Ordering and completion of TLB maintenance instructions

The following rules describe the relations between the memory order model and the TLB maintenance instructions:

• A TLB invalidate instruction is complete when all memory accesses using the invalidated TLB entries have been observed by all observers, to the extent that those accesses must be observed. The Shareability and Cacheability of the accessed memory locations determine the extent to which the accesses must be observed.

    **Note**

    For a TLB invalidate instruction that affects other PEs, the set of memory accesses that have been observed when the TLB maintenance instruction is complete must include the memory accesses from those processes that used the invalidated TLB entries.

    After the TLB invalidate instruction is complete, no new memory accesses using the invalidated TLB entries will be observed by those observers.

    **Note**

    This requirement does not mean that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.

• A TLB maintenance instruction is only guaranteed to be complete after the execution of a DSB instruction.

• An ISB instruction, or a return from an exception, causes the effect of all completed TLB maintenance instructions that appear in program order before the ISB or return from exception to be visible to all subsequent instructions, including the instruction fetches for those instructions.

• An exception causes all completed TLB maintenance instructions, that appear in the instruction stream before the point where the exception is taken, to be visible to all subsequent instructions, including the instruction fetches for those instructions.

• All TLB maintenance instructions are executed in program order relative to each other.

• The execution of a Data or Unified TLB maintenance instruction is only guaranteed to be visible to a subsequent explicit load or store instruction after both:
  — The execution of a DSB instruction to ensure the completion of the TLB maintenance instruction.
  — Execution of a subsequent *Context synchronization event*.

• The execution of an Instruction or Unified TLB maintenance instruction is only guaranteed to be visible to a subsequent instruction fetch after both:
  — The execution of a DSB instruction to ensure the completion of the TLB maintenance instruction.
  — Execution of a subsequent *Context synchronization event*.

In all cases in this section where a DMB or DSB is referred to, it refers to a DMB or DSB whose required access type is both loads and stores. A DSB NSH is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE. A DSB ISH is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

The following rules apply when writing translation table entries. They ensure that the updated entries are visible to subsequent accesses and cache maintenance instructions.
For TLB maintenance, the translation table walk is treated as a separate observer. This means:

- A write to the translation tables is only guaranteed to be seen by a translation table walk caused by an explicit load or store after the execution of both a DSB and an ISB.
  However, the architecture guarantees that any writes to the translation tables are not seen by any explicit memory access that occurs in program order before the write to the translation tables.
- A write to the translation tables is only guaranteed to be seen by a translation table walk caused by the instruction fetch of an instruction that follows the write to the translation tables after both a DSB and an ISB.

Therefore, in a uniprocessor system, an example instruction sequence for writing a translation table entry, covering changes to the instruction or data mappings is:

```
STR rx, [Translation table entry]          ; write new entry to the translation table
DSB            ; ensures visibility of the new entry
Invalidate TLB entry by VA (and ASID if non-global) [page address]
Invalidate BTC
DSB            ; ensure completion of the Invalidate TLB instruction
ISB            ; ensure table changes visible to instruction fetch
```

**Use of ASIDs and VMIDs to reduce TLB maintenance requirements**

To reduce the need for TLB maintenance on context switches, the lookups from some translation regimes can be associated with an ASID, or with an ASID and a VMID.

_____ Note _____

The use of ASIDs and VMIDs in VMSAv8-32 is generally similar to their use in VMSAv8-64, see *Use of ASIDs and VMIDs to reduce TLB maintenance requirements* on page D4-2113.

For more information about the use of ASIDs in VMSAv8-32 see *Global and process-specific translation table entries* on page G4-4628.

**Common not private translations in VMSAv8-32**

In an implementation that includes ARMv8.2-TTCNP, multiple PEs in the same Inner Shareable domain can use the same translation table entries for a given stage of address translation in a particular translation regime. This sharing is enabled by the TTBR.CnP field for the stage of address translation.

When the value of a TTBR.CnP field is 1, translation table entries pointed to by that TTBR are shared with all other PEs in the Inner Shareable domain for which the following conditions are met:

- The corresponding TTBR.CnP field has the value 1.
- That TTBR is using the Long-descriptor translation table format.
- If an ASID applies to the stage of translation corresponding to that TTBR then the current ASID value must be the same for all of the PEs that are sharing entries.
- If a VMID applies to the stage of translation corresponding to that TTBR then the current VMID value must be the same for all of the PEs that are sharing entries.

_____ Note _____

In an implementation that includes EL3, the Secure instances of TTBR0 and TTBR1 relate to the Secure PL1&0 translation regime, and the Non-secure instances of TTBR0 and TTBR1 relate to the Non-secure PL1&0 translation regime.

Where a TLB combines information from stage 1 and stage 2 translation table entries into a single entry, this entry can be shared between different PEs only if the value of the TTBR.CnP bit is 1 for both stage 1 and stage 2 of the translation table walk.

The TTBR.CnP bit can be cached in a TLB.
For a given TTBR, if the value of TTBR.CnP is 1 on multiple PEs in the same Inner Shareable domain, and those PEs meet the other conditions for sharing translation table entries as defined in this section, but those TTBRs do not point to the same translation table entries, then the system is misconfigured, and performing an address translation using that TTBR:

- Might generate multiple hits in the TLB, and as a result generate an exception that is reported using the TLB conflict fault code, see TLB conflict aborts on page G4-4630.
- Otherwise, has a CONSTRAINED UNPREDICTABLE result, as described in CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101.

### G4.9.2 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMID or ASID that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```markdown
; Change control bits in System registers
ISB ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The System register changes that this applies to are:

- Any change to the NMRR, PRRR, MAIR0, MAIR1, HMAIR0 or HMAIR1 registers.
- Any change to the SCTLR.AFE bit, see Changing the Access flag enable.
- Any change to any of the SCTLR.{TRE, WXN, UWXN} bits.
- Any change to the Translation table base 0 address in TTBR0.
- Any change to the Translation table base 1 address in TTBR1.
- Any change to HTTBR.BADDR.
- Any change to VTTBR.BADDR.
- Changing TTBCR.EAE, see Changing the current Translation table format on page G4-4638.
- In an implementation that includes EL3, any change to the SCR.SIF bit.
- In an implementation that includes EL2:
  - Any change to the HCR.VM bit.
  - Any change to HCR.PTW bit, see Changing HCR.PTW on page G4-4638.
- When using the Short-descriptor translation table format:
  - Any change to the RGN, IRGN, S, or NOS fields in TTBR0 or TTBR1.
  - Any change to the N, EAE, PD0 or PD1 fields in TTBCR
- When using the Long-descriptor translation table format:
  - Any change to the EAE, TnSZ, ORGn0, IRGn0, SHn, or EPDn fields in the TTBCR, where n is 0 or 1.
  - Any change to the TTBCR2.
  - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the HTCR.
  - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the VTCR.

#### Changing the Access flag enable

In a PE that is using the Short-descriptor translation table format, it is CONSTRAINED UNPREDICTABLE whether the TLB caches the effect of the SCTLR.AFE bit on translation tables. This means that, after changing the SCTLR.AFE bit software must invalidate the TLB before it relies on the effect of the new value of the SCTLR.AFE bit, otherwise behavior is CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101.

---

**Note**

There is no enable bit for use of the Access flag when using the Long-descriptor translation table format.
Changing HCR.PTW

When EL2 is using AArch32 and the value of the Protected table walk bit, HCR.PTW, is 1, a stage 1 translation table access in the Non-secure PL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMID might hold entries that depend on the effect of HCR.PTW. Therefore, if the value of HCR.PTW is changed without a change to the VMID value, all TLB entries associated with the current VMID must be invalidated before executing software in a Non-secure PL1 or PL0 mode. If this is not done, behavior is CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101.

Changing the current Translation table format

The effect of changing TTBCR.EAE when executing in the translation regime affected by TTBCR.EAE with any stage of address translation for that translation regime enabled is CONSTRAINED UNPREDICTABLE. This means that, when TTBCR.EAE is changed for a given context, the TLB must be invalidated before resuming execution in that context, otherwise the effect is CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101.

G4.9.3 Atomicity of register changes on changing virtual machine

From the viewpoint of software executing in a Non-secure PL1 or PL0 mode, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This rule applies to the registers for:

- Non-secure PL1&0 stage 1 address translations. This means that all of the following registers must change atomically:
  - PRRR and NMRR, if using the Short-descriptor translation table format.
  - MAIR0 and MAIR1, if using the Long-descriptor translation table format.
  - TTBR0, TTBR1, TTBCR, TTBCR2, DACR, and CONTEXTIDR.
  - The SCTLR.

- Non-secure PL1&0 stage 2 address translations. When EL2 is using AArch32, this means that all of the following registers and register fields must change atomically:
  - VTTBR and VTCR.
  - HMAIR0 and HMAIR1.
  - The HSCTLR.

--- Note ---

Only some bits of SCTLR affect the stage 1 translation, and only some bits of HSCTLR affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution in Non-secure PL1&0 modes. However, when updated as part of a switch of virtual machines they are updated by software executing in Hyp mode. This means the registers are out of context when they are updated, and no synchronization precautions are required.

--- Note ---

By contrast, a translation table change associated with a change of ASID, made by software executing at PL1, can require changes to registers that are in context. Synchronization of changes of ASID and TTBR on page G4-4639 describes appropriate precautions for such a change.

Software executing in Hyp mode, or in Secure state, must not use the registers that are associated with the Non-secure PL1&0 translation regime for speculative memory accesses.
G4.9.4 Synchronization of changes of ASID and TTBR

A common virtual memory management requirement is to change the ASID and TTBR together to associate the new ASID with different translation tables, without any change to the current translation regime. When using the Short-descriptor translation table format, different registers hold the ASID and the translation table base address, meaning these two values cannot be updated atomically. Since a PE can perform a speculative memory access at any time, this lack of atomicity is a problem that software must address. Such a change is complicated by:

- The depth of speculative fetch being IMPLEMENTATION DEFINED.
- The use of branch prediction.

When using the Short-descriptor translation table format, the virtual memory management operations must ensure the synchronization of changes of the ContextID and the translation table registers. For example, some or all of the TLBs, branch predictors, and other caching of ASID and translation information might become corrupt with invalid translations. Synchronization is required to avoid either:

- The old ASID being associated with translation table walks from the new translation tables.
- The new ASID being associated with translation table walks from the old translation tables.

There are a number of possible solutions to this problem, and the most appropriate approach depends on the system. Example G4-3, Example G4-4, and Example G4-5 on page G4-4640 describe three possible approaches.

Note

Another instance of the synchronization problem occurs if a branch is encountered between changing the ASID and performing the synchronization. In this case the value in the branch predictor might be associated with the incorrect ASID. Software can address this possibility using any of these approaches, but instead software might be written in a way that avoids such branches.

Example G4-3 Using a reserved ASID to synchronize ASID and TTBR changes

In this approach, a particular ASID value is reserved for use by the operating system, and is used only for the synchronization of the ASID and TTBR. This example uses the value of 0 for this purpose, but any value could be used.

This approach can be used only when the size of the mapping for any given virtual address is the same in the old and new translation tables.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

Change ASID to 0
ISB
Change TTBR
ISB
Change ASID to new value

This approach ensures that any non-global pages fetched at a time when it is uncertain whether the old or new translation tables are being accessed are associated with the unused ASID value of 0. Since the ASID value of 0 is not used for any normal operations these entries cannot cause corruption of execution.

Example G4-4 Using translation tables containing only global mappings when changing the ASID

A second approach involves switching the translation tables to a set of translation tables that only contain global mappings while switching the ASID.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

Change TTBR to the global-only mappings
ISB
Change ASID to new value
ISB
Change TTBR to new value

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

This approach works without the need for TLB invalidations in systems that have caching of intermediate levels of translation tables, as described in General TLB maintenance requirements on page G4-4632, provided that the translation tables containing only global mappings have only level 1 translation table entries of the following kinds:

- Entries that are global.
- Pointers to level 2 tables that hold only global entries, and that are the same level 2 tables that are used for accessing global entries by both:
  - The set of translation tables that were used under the old ASID value.
  - The set of translation tables that will be used with the new ASID value.
- Invalid level 1 entries.

In addition, all sets of translation tables in this example should have the same Shareability and Cacheability attributes, as held in the TTBR0.{ORGN, IRGN} or TTBR1.{ORGN, IRGN} fields.

If these rules are not followed, then the implementation might cache level 1 translation table entries that require explicit invalidation.

---

Example G4-5 Disabling non-global mappings when changing the ASID

In systems where only the translation tables indexed by TTBR0 hold non-global mappings, maintenance software can use the TTBCR.PD0 field to disable use of TTBR0 during the change of ASID. This means the system does not require a set of global-only mappings.

The maintenance software uses the following sequence, that must be executed from a memory region with a translation that is accessed using the base address in the TTBR1 register, and is marked as global:

Set TTBCR.PD0 = 1
ISB
Change ASID to new value
Change TTBR to new value
ISB
Set TTBCR.PD0 = 0

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

When using the Long-descriptor translation table format, TTBCR.A1 holds the number, 0 or 1, of the TTBR that holds the current ASID. This means the current TTBR can also hold the current ASID, and the current translation table base address and ASID can be updated atomically when:

- TTBR0 is the only TTBR being used. TTBCR.A1 must be set to 0.
- TTBR0 points to the only translation tables that hold non-global entries, and TTBCR.A1 is set to 0.
- TTBR1 points to the only translation tables that hold non-global entries, and TTBCR.A1 is set to 1.

In these cases, software can update the current translation table base address and ASID atomically, by updating the appropriate TTBR, and does not require a specific routine to ensure synchronization of the change of ASID and base address.

However, in all other cases using the Long-descriptor format, the synchronization requirements are identical to those when using the Short-descriptor formats, and the examples in this section indicate how synchronization might be achieved.
When using the Long-descriptor translation table format, CONTEXTIDR.ASID has no significance for address translation, and is only an extension of the Context ID value.

G4.9.5 The scope of TLB maintenance instructions

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures, to ensure that changes to the translation tables are reflected correctly in the TLB caching structures. To support TLB maintenance in multiprocessor systems, there are maintenance operations that apply to the TLBs of all PEs in the same Inner Shareable domain.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault and that does not, itself, cause a Translation Fault, an Address size fault, or an Access Flag fault. This means the TLB:

- Cannot hold an entry that, when used for a translation table lookup, causes a Translation fault, an Address size fault, or an Access Flag fault.
- Can hold an entry for a translation table lookup for a translation that causes a Translation Fault, an Address size fault, or an Access Flag fault at a subsequent level of translation table lookup. For example, it can hold an entry for the level 1 lookup of a translation that causes a Translation fault, an Address size fault, or an Access Flag fault at level 2 or level 3 of lookup.

This means that entries cached in the TLB can include:

- Translation table entries that point to a subsequent table to be used in the current stage of translation.
- In an implementation that includes EL2:
  - Stage 2 translation table entries that are used as part of a stage 1 translation table walk.
  - Stage 2 translation table entries for translating the output address of a stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are distinct from the data caches, in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction on the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries. In particular for translation regimes that involve two stages of translation, it recognizes that such caching structures might contain:

- At any level of the translation table walk, entries containing information from stage 1 translation table entries.
- In an implementation that includes EL2:
  - At any level of the translation table walk, entries containing information from stage 2 translation table entries.
  - At any level of the translation table walk, entries combining information from both stage 1 and stage 2 translation table entries.

For the purpose of TLB maintenance, the term TLB entry denotes any structure, including temporary working registers in translation table walk hardware, that holds a translation table entry.

For the TLB maintenance instructions:

- If a TLB maintenance instruction is required to apply to stage 1 entries then it must apply to any cached entry in the caching structures that includes any stage 1 information that would be used to translate the address being invalidated, including any entry that combines information from both stage 1 and stage 2 translation table entries.
Note

— Where stage 1 information has been cached in multiple TLB entries, as could occur from splintering a page when caching in the TLB, then the invalidation must apply to each cached entry containing stage 1 information from the page that is used to translate the address being invalidated, regardless of whether or not that cached entry would be used to translate the address being invalidated.

— As stated in Global and process-specific translation table entries on page G4-4628, translation table entries from levels of translation other than the final level are treated as being non-global. ARM expects that, in at least some implementations, cached copies of levels of the translation table walk other than the last level are tagged with their ASID, regardless of whether the final level is global. This means that TLB invalidations that involve the ASID require the ASID to match such entries to perform the required invalidation.

- If a TLB maintenance instruction is required to apply to stage 2 entries only, then:
  — It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
  — It must apply to caching structures that contain information only from stage 2 translation table entries.

- If a TLB maintenance instruction is required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Table G4-23 on page G4-4643 summarizes the required effect of the AArch32 TLB maintenance instructions, that operate only on TLBs on the PE that executes the instruction. Additional TLB maintenance instructions that:

- Apply across all PEs in the same Inner Shareable domain. Each instruction shown in the table has an Inner Shareable equivalent, identified by an IS suffix. For example, the Inner Shareable equivalent of TLB1ALL is TLB1ALLIS. See also EL2 forced broadcasting of TLB maintenance instructions on page G4-4644.

- Can apply to separate Instruction or Data TLBs. These instructions are indicated by a footnote to the table. ARM deprecates any use of these instructions.

Note

- The architecture permits a TLB invalidation instruction to affect any unlocked entry in the TLB. Table G4-23 on page G4-4643 defines only the entries that each instruction must invalidate.

- All TLB instructions, including those that operate on a VA match, operate as described regardless of the value of SCTLR.M.

When interpreting the table:

Related operations

Each instruction description applies also to any equivalent instruction that either:

- Applies to all PEs in the same Inner Shareable domain.
- Applies only to a data TLB, or only to an instruction TLB.

So, for example, the TLB1ALL instruction description applies also to TLB1ALLIS, ITLB1ALL, and DTLB1ALL.

TLB maintenance instructions, functional group on page G4-4735 lists all of the TLB maintenance instructions.

Matches the VA

Means the VA argument for the instruction must match the VA value in the TLB entry.

Matches the ASID

Means the ASID argument for the instruction must match the ASID in use when the TLB entry was assigned.

Matches the current VMID

Means the current VMID must match the VMID in use when the TLB entry was assigned.
The dependency on the VMID applies even when the value of HCR.VM is 0, including situations where there is no use of virtualization. However, VTTBR.VMID resets to zero, meaning there is a valid VMID from reset.

**Execution at PL2** Descriptions of operations at PL2 apply only to implementations that include EL2.

For the definitions of the translation regimes referred to in the table see *About VMSAv8-32* on page G4-4558.

### Table G4-23 Effect of the TLB maintenance instructions

</table>
EL2 forced broadcasting of TLB maintenance instructions

In an implementation that includes EL2, when the value of HCR.FB is 1, the TLB maintenance instructions that are not broadcast across the Inner Shareable domain are forced to operate across the Inner Shareable domain when executed in a Non-secure PL1 mode. For example, when the value of HCR.FB is 1, a TLBIMVA instruction executed in a Non-secure PL1 mode performs the same invalidation as the invalidation performed by a TLBIMVAI instruction.
TLB maintenance with different translation granule sizes

If a TLB maintenance instruction specifying a virtual address affecting the PL2 translation regime is broadcast from a PE using AArch32 to a PE using AArch64 using a translation granule size that is different from the AArch32 translation granule size for that same translation regime, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.

If a TLB maintenance instruction specifying a virtual address affecting the PL1 translation regime is broadcast from a PE using AArch32 using one translation granule size for that translation regime for a particular ASID, VMID (if applicable), and Security state, to a PE using AArch64 where EL1 for the same ASID, VMID (if applicable), and Security state, is using a translation granule size that is different from the AArch32 translation granule size, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.
G4.10 Caches in VMSAv8-32

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

Maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

• Summarizes the architectural requirements for the interaction between caches and memory translation.
• Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

• Data and unified caches.
• Instruction caches on page G4-4647.

In addition Cache maintenance requirement created by changing translation table attributes on page G4-4648 describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see:

• AArch32 cache and branch predictor support on page G3-4525. This section describes the ARM cache maintenance instructions.
• Cache maintenance instructions, functional group on page G4-4734. This section summarizes the System register encodings used for these operations when executing in AArch32 state.

G4.10.1 Data and unified caches

For data and unified caches, the use of memory address translation is entirely transparent to any data access other than as described in Mismatched memory attributes on page E2-2792.

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

• Two writes to the same PA occur in program order.
• A read of a PA returns the value of the last successful write to that PA.
• A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as Physically-indexed, physically-tagged (PIPT) caches.
G4.10.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture permits different behaviors for instruction caches. These are identified by descriptions of the associated expected implementation. The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of memory address translation transparent to the instruction cache:

- **PIPT (Physically-indexed, physically-tagged) instruction caches.**
- **VPIPT (VMID-aware PIPT) instruction caches.**
- **VIPT (Virtually-indexed, physically-tagged) instruction caches on page G4-4648.**
- **The IVIPT architecture Extension on page G4-4648.**

In AArch32 state, the CTR.L1Ip field identifies the form of the instruction caches.

--- Note ---
For software to be portable between implementations that might use any of PIPT instruction caches, VPIPT instruction caches, or VIPT instruction caches, software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

---

**PIPT (Physically-indexed, physically-tagged) instruction caches**

For a PIPT instruction cache:

- The use of memory address translation is entirely transparent to all instruction fetches other than as described in *Mismatched memory attributes* on page E2-2792.

- If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see *The IVIPT architecture Extension* on page G4-4648.

**VPIPT (VMID-aware PIPT) instruction caches**

An implementation that includes ARMv8.2-VPIPT can implement VPIPT instruction caches.

For a VPIPT instruction cache:

- Instruction fetches from Non-secure EL1 and Non-secure EL0 are only permitted to hit in the cache if the instruction fetch is made using the VMID that was used when the entry in the instruction cache was fetched.

- An instruction cache maintenance instruction executed at Non-secure EL0 or at Non-secure EL1 is required to have an effect on entries in the instruction cache only if those entries were fetched using the VMID that is current when the cache maintenance instruction is executed.

All other requirements for the use of cache maintenance instructions are the same as for PIPT (Physically-indexed, physically-tagged) instruction caches.

An implementation that provides VPIPT instruction caches implements the IVIPT Extension, see *The IVIPT architecture Extension* on page G4-4648.
VIPT (**Virtually-indexed, physically-tagged**) instruction caches

For a VIPT instruction cache:

- The use of memory address translation is transparent to all instruction fetches other than for the effect of memory address translation on instruction cache invalidate by address operations or as described in *Mismatched memory attributes* on page E2-2792.

--- **Note** ---

Cache invalidation is the only cache maintenance instruction that can be performed on an instruction cache.

---

- If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other virtual address aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see *The IVIPT architecture Extension*.

**The IVIPT architecture Extension**

In ARMv8, any permitted instruction cache implementation can be described as implementing the **IVIPT Extension** to the ARM architecture.

The formal definition of the ARM IVIPT Extension is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a physical address that holds an instruction.

--- **Note** ---

Previous versions of the ARM architecture have permitted an instruction cache option that does not implement the ARM IVIPT Extension.

**G4.10.3 Cache maintenance requirement created by changing translation table attributes**

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in *General TLB maintenance requirements* on page G4-4632. If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through.
- Write-Back to Non-cacheable.
- Write-Through to Non-cacheable.
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the Shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the Shareability attributes to the required new values.
G4.11 VMSAv8-32 memory aborts

In a VMSAv8-32 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

- **Debug exception**
  An exception caused by the debug configuration, see Chapter G2 AArch32 Self-hosted Debug.

- **Alignment fault**
  An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information see Unaligned data access on page E2-2777 and Alignment faults on page G4-4656.

- **MMU fault**
  An MMU fault is a fault generated by the fault checking sequence for the current translation regime. See MMU faults in AArch32 state on page G4-4657.

- **External abort**
  Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault.

Collectively, these mechanisms are called aborts. Chapter G2 AArch32 Self-hosted Debug and Chapter H3 Halting Debug Events describe Debug exceptions, and the remainder of this section describes Alignment faults, MMU faults, and External aborts.

The exception generated on a synchronous memory abort:
- On an instruction fetch is called the Prefetch Abort exception.
- On a data access is called the Data Abort exception.

**Note**
The Prefetch Abort exception applies to any synchronous memory abort on an instruction fetch. It is not restricted to speculative instruction fetches.

In AArch32 state, asynchronous memory aborts are a type of External abort, and are treated as a type of Data Abort exception.

The following sections describe the abort mechanisms:
- Routing of aborts taken to AArch32 state.
- VMSAv8-32 MMU fault terminology on page G4-4652.
- The MMU fault-checking sequence on page G4-4652.
- Alignment faults on page G4-4656.
- MMU faults in AArch32 state on page G4-4657.
- External abort on a translation table walk on page G4-4659.
- AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660.

An access that causes an abort is said to be aborted. On an abort, System registers are used to record context information. For more information see Exception reporting in a VMSAv8-32 implementation on page G4-4663.

G4.11.1 Routing of aborts taken to AArch32 state

A memory abort is either a Data Abort exception or a Prefetch Abort exception. When executing in AArch32 state, depending on the cause of the abort, and possibly on configuration settings, an abort is taken either:
- To the Exception level of the PE mode from which the abort is taken. In this case the abort is taken to AArch32 state.
- To a higher Exception level. In this case the Exception level to which the abort is taken is either:
  - Using AArch32. In this case, this chapter describes how the abort is handled.
  - Using AArch64. In this case, Chapter D4 The AArch64 Virtual Memory System Architecture describes how the abort is handled.
For an abort taken to an Exception level that is using AArch32, the mode to which a memory abort is taken depends on the reason for the exception, the mode the PE is in when it takes the exception, and configuration settings, as follows:

**Memory aborts taken to Monitor mode**

If an implementation includes EL3, when the value of SCR.EA is 1, all External aborts are taken to EL3, and if EL3 is using AArch32 they are taken to Monitor mode. This rule applies to aborts taken from Secure modes and from Non-secure modes. For more information see *Asynchronous exception routing controls* on page G1-4367.

--- **Note** ---

- Although the referenced section mostly describes the routing of asynchronous exceptions, it includes the SCR.EA control that applies to both synchronous external aborts and SError interrupts.
- The SCR is implemented only as part of EL3.

**Memory aborts taken to Secure Abort mode**

If an implementation includes EL3, when the PE is executing in Secure state, all memory aborts that are not routed to EL3 are taken to Secure Abort mode.

--- **Note** ---

The only memory aborts that can be routed to Monitor mode are External aborts.

**Memory aborts taken to Hyp mode**

If an implementation includes EL2, when the PE is executing in Non-secure state, the following aborts are taken to EL2. If EL2 is using AArch32 this means they are taken to Hyp mode:

- Alignment faults taken:
  - When the PE is in Hyp mode.
  - When the PE is in a Non-secure PL1 or PL0 mode and the exception is generated because the Non-secure PL1&0 stage 2 translation identifies the target of an unaligned access as any type of Device memory.
  - When the PE is in Non-secure User mode and HCR.TGE is set to 1. For more information see *Abort exceptions, when the value of HCR.TGE is 1* on page G1-4357.

- When the PE is using the Non-secure PL1&0 translation regime:
  - MMU faults from stage 2 translations, for which the stage 1 translation did not cause an MMU fault.
  - Any abort taken during the stage 2 translation of an address accessed in a stage 1 translation table walk that is not routed to Secure Monitor mode, see *Stage 2 fault on a stage 1 translation table walk* on page G4-4656.

- When the PE is using the Non-secure PL2 translation regime, MMU faults from stage 1 translations.

--- **Note** ---

The Non-secure PL2 translation regime has only one stage of translation.
• External aborts, if SCR.EA is set to 0 and any of the following applies:
  — The PE was executing in Hyp mode when it took the exception.
  — The PE was executing in a Non-secure PL0 or PL1 mode when it took the exception, the abort is asynchronous, and HCR.AMO is set to 1. For more information see *Asynchronous exception routing controls* on page G1-4367.
  — The PE was executing in the Non-secure User mode when it took the exception, the abort is synchronous, and HCR.TGE is set to 1. For more information see *Abort exceptions, when the value of HCR.TGE is 1* on page G1-4357.
  — The abort occurred on a stage 2 translation table walk.
• Debug exceptions, if HDCR.TDE is set to 1. For more information, see *Routing debug exceptions to EL2 using AArch32* on page G1-4358.

**Memory aborts taken to Non-secure Abort mode**

In an implementation that does not include EL3, all memory aborts that are taken to an Exception level that is using AArch32 are taken to Abort mode. Otherwise, when the PE is executing in Non-secure state, the following aborts are taken to Non-secure Abort mode:

• When the PE is in a Non-secure PL1 or PL0 mode, Alignment faults taken for any of the following reasons:
  — SCTLR.A is set to 1.
  — An instruction that does not support unaligned accesses is committed for execution, and the instruction accesses an unaligned address.
  — The PL1&0 stage 1 translation identifies the target of an unaligned access as any type of Device memory.

  ____________
  **Note**
  ____________

  In an implementation that does not include EL2, this case results in a **CONSTRAINED UNPREDICTABLE** memory access, see *Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE* on page E2-2778 and *Loads and Stores to unaligned locations* on page K1-6098.

  ____________
  **Note**
  ____________

If an implementation includes EL2 and the PE is in Non-secure User mode, these exceptions are taken to Abort mode only if the value of HCR.TGE is 0.

• When the PE is using the Non-secure PL1&0 translation regime, an MMU fault from a stage 1 translation.

• External aborts, if all of the following apply:
  — The abort is not on a stage 2 translation table walk.
  — The PE is not in Hyp mode.
  — The value of SCR.EA is 0.
  — The abort is asynchronous, and HCR.AMO is set to 0.
  — The abort is synchronous, and HCR.TGE is set to 0.

• Virtual Aborts, see *Virtual exceptions when an implementation includes EL2* on page G1-4365.

• When the value of HDCR.TDE is 0, Debug exceptions. For more information, see *Routing debug exceptions to EL2 using AArch32* on page G1-4358.

  ____________
  **Note**
  ____________

If EL0 is using AArch32 and EL1 is using AArch64 then any of these memory aborts taken from User mode are taken to EL1 as described in *Chapter D4 The AArch64 Virtual Memory System Architecture*. 
Memory aborts with IMPLEMENTATION DEFINED behavior

In addition, a PE can generate an abort for an IMPLEMENTATION DEFINED reason associated with lockdown. In an implementation that includes EL2, whether such an abort is taken to Non-secure Abort mode or is taken to EL2 is IMPLEMENTATION DEFINED, and an implementation might include a mechanism to select whether the abort is routed to Non-secure Abort mode or to EL2.

When the PE is in a Non-secure mode other than Hyp mode, if multiple factors cause an Alignment fault, the abort is taken to Non-secure Abort mode if any of the factors require the abort to be taken to Abort mode. For example, if the SCTLR.A bit is set to 1, and the access is an unaligned access to an address that the stage 2 translation tables mark as Device-nGnRnE, then the abort is taken to Non-secure Abort mode.

For more information see Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340.

G4.11.2 VMSAv8-32 MMU fault terminology

The ARMv7 Large Physical Address Extension introduced new terminology for faults on a stage of address translation, to provide consistent terminology across all implementations. Table G4-24 shows the terminology used in this manual for an MMU faults, compared with older ARM documentation. The current terms are the same for faults that occur with the Short-descriptor translation table format and with the Long-descriptor format, and also apply to faults in a level 3 lookup when using the Long-descriptor translation table format.

<table>
<thead>
<tr>
<th>Current term</th>
<th>Old term</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Level 1 Translation fault</td>
<td>Section Translation fault</td>
<td>-</td>
</tr>
<tr>

<tr>
<td>Level 2 Permission fault</td>
<td>Page Permission fault</td>
<td>-</td>
</tr>
<tr>
<td>Level 3 Permission fault</td>
<td>-</td>
<td>Long-descriptor translation table format only.</td>
</tr>
</tbody>
</table>

In an implementation that includes EL2, MMU faults are also classified by the translation stage at which the fault is generated. This means that a memory access from a Non-secure PL1 or PL0 mode can generate:

• A stage 1 MMU fault, for example, a stage 1 Translation fault.
• A stage 2 MMU fault, for example, a stage 2 Translation fault.

G4.11.3 The MMU fault-checking sequence

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

• If an instruction fetch faults, it generates a Prefetch Abort exception.
• If an data memory access faults, it generates a Data Abort exception.
For more information about Prefetch Abort exceptions and Data Abort exceptions see *Handling exceptions that are taken to an Exception level using AArch32* on page G1-4340.

In VMSAv8-32, all memory accesses require VA to PA translation. Therefore, when a corresponding stage of address translation is enabled, each access requires a lookup of the translation table descriptor for the accessed VA. For more information, see *Translation tables on page G4-4571* and subsequent sections of this chapter. MMU fault checking is performed for each level of translation table lookup. If an implementation includes EL2 and is operating in Non-secure state, MMU fault checking is performed for each stage of address translation.

--- Note ---

In an implementation that includes EL2, if a PE is executing in Non-secure state, the operating system or similar Non-secure system software defines the stage 1 translation tables in the IPA address map, and typically is unaware of the stage 2 translation from IPA to PA. However, each Non-secure stage 1 translation table access is subject to stage 2 address translation, and might be faulted at that stage.

The MMU fault checking sequence is largely independent of the translation table format, as the figures in this section show. The differences are:

**When using the Short-descriptor format**

- There are one or two levels of lookup.
- Lookup always starts at level 1.
- The final level of lookup checks the Domain field of the descriptor and:
  - Faults if there is no access to the Domain.
  - Checks the access permissions only for Client domains.

**When using the Long-descriptor format**

- There are one, two, or three levels of lookup.
- Lookup starts at either level 1 or level 2.
- Domains are not supported. All accesses are treated as Client domain accesses.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see *About address translation for VMSAv8-32 on page G4-4562*.

--- Note ---

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in *TLB conflict aborts on page G4-4630*.

*MMU faults in AArch32 state on page G4-4657* describes the faults that an MMU fault-checking sequence can report.

*Figure G4-15 on page G4-4654* shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, in an implementation that includes EL2, if the translation is stage 1 of the Non-secure PL1&0 translation regime, then the descriptor address is in the IPA address map, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

--- Note ---

*Figure G4-15 on page G4-4654* and *Figure G4-16 on page G4-4655* give an overview of the fault checking performed by the MMU. See *AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660* for the complete set of possible faults and their prioritization.
Figure G4-15 Fetching the descriptor in a VMSAv8-32 translation table walk
Figure G4-16 shows the full VMSAv8-32 fault checking sequence, including the alignment check on the initial access.

Figure G4-16 VMSAv8-32 fault checking sequence
Stage 2 fault on a stage 1 translation table walk

When an implementation that includes EL2 is operating in a Non-secure PL1 or PL0 mode, any memory access goes through two stages of translation:

• Stage 1, from VA to IPA.
• Stage 2, from IPA to PA.

Note

In a virtualized system that is using AArch32, typically, a Guest OS operating in a Non-secure PL1 mode defines the translation tables and translation table register entries controlling the Non-secure PL1&0 stage 1 translations. A Guest OS has no awareness of the stage 2 address translation, and therefore believes it is specifying translation table addresses in the physical address map. However, it actually specifies these addresses in its IPA map. Therefore, to support virtualization, translation table addresses for the Non-secure PL1&0 stage 1 translations are always defined in the IPA address map.

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

• A Translation fault, Access flag fault, or Permission fault.
• A synchronous external abort on the memory access.

If SCR.EA is set to 1, a synchronous external abort is taken to EL3, and if EL3 is using AArch32 it is taken to Secure Monitor mode. Otherwise, these faults are reported as stage 2 memory aborts. When EL2 is using AArch32, HSR.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see Use of the HSR on page G4-4677.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the any type of Device memory attribute assigned on the stage 2 translation of the address accessed. When the value of the HCR.PTW bit is 1, such an access generates a stage 2 Permission fault.

Note

On most systems, such a mapping to a Device memory type on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of HCR.PTW. Therefore, if HCR.PTW is changed without changing the current VMID, the TLBs must be invalidated before executing in a Non-secure PL1 or PL0 mode. For more information see Changing HCR.PTW on page G4-4638.

A cache maintenance instruction executed at Non-secure PL1 can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault. If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by VA instruction can generate a Permission fault in this way.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Permission fault in this way.

G4.11.4 Alignment faults

The ARM memory architecture requires support for strict alignment checking. This checking is controlled by SCTLR.A. In addition, some instructions do not support unaligned accesses, regardless of the value of SCTLR.A. Unaligned data access on page E2-2777 defines when Alignment faults are generated, for both values of SCTLR.A.

An Alignment fault can occur on an access for which the stage of address translation is disabled.

Any unaligned access to memory region with any Device memory type attribute generates an Alignment fault.

Routing of aborts taken to AArch32 state on page G4-4649 defines the mode to which an Alignment fault is taken.
The prioritization of Alignment faults depends on whether the fault was generated because of an access to a Device memory type, or for another reason. For more information see AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660.

G4.11.5 MMU faults in AArch32 state

This section describes the faults that might be detected during one of the fault-checking sequences described in The MMU fault-checking sequence on page G4-4652. Unless indicated otherwise, information in this section applies to the fault checking sequences for both the Short-descriptor translation table format and the Long-descriptor translation table format.

MMU faults are always synchronous.

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as any type of Device memory.

The following subsections describe the MMU faults that might be detected during a fault checking sequence:

- Permission fault
- Translation fault on page G4-4658.
- Address size fault on page G4-4658.
- Access flag fault on page G4-4659.
- Domain fault, Short-descriptor format translation tables only on page G4-4659.
- TLB conflict aborts on page G4-4630.

See also External abort on a translation table walk on page G4-4659.

Note

Although the TLB conflict abort is classified as an MMU fault, it is described in the section Translation Lookaside Buffers (TLBs) on page G4-4628.

In VMSAv8-64 an external abort on a translation table walk is classified as an MMU fault. However, in VMSAv8-32, for consistency with earlier versions of the architecture these aborts are not classified as MMU faults.

Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See About access permissions on page G4-4605 for information about conditions that cause a Permission fault.

Note

When using the Short-descriptor translation table format, the translation table descriptors are checked for Permission faults only for accesses to memory regions in Client domains.

A TLB might hold a translation table entry that cause a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in Ordering and completion of TLB maintenance instructions on page G4-4635.

Note

In an implementation that includes EL2, this maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.
Cache or branch predictor maintenance operations cannot cause a Permission fault, except that:

- A stage 1 translation table walk performed as part of a cache or branch predictor maintenance operation can generate a stage 2 Permission fault as described in *Stage 2 fault on a stage 1 translation table walk* on page G4-4656.

- A DCIMVAC issued in Non-secure state that attempts to update a location for which it does not have stage 2 write access can generate a stage 2 Permission fault, as described in *AArch32 data cache maintenance instructions (DC*)* on page G3-4537.

### Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information see:

- *VMSAv8-32 Short-descriptor translation table format descriptors* on page G4-4577.
- *VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-4586.

In addition, a Translation fault is generated if the input address for a translation either does not map onto an address range of a TTBR, or the TTBR range that it maps onto is disabled. In these cases the fault is reported as a level 1 Translation fault on the translation stage at which the mapping to a region described by a TTBR failed.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

A data or unified cache maintenance instruction by VA can generate a Translation fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate a Translation fault.

A data or unified cache maintenance by VA instruction can generate a Translation fault. If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA instruction can generate a Translation fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate a Translation fault.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Translation fault.

It is IMPLEMENTATION DEFINED whether a branch predictor maintenance operation can generate a Translation fault.

### Address size fault

An Address size fault can be generated at any level of lookup, and the reported fault code identifies the lookup level.

An Address size fault is generated if the translation table entries or the TTBR for the stage of translation have nonzero address bits above the most significant bit of the maximum output address size. Because VMSAv8-32 supports a maximum PA and IPA size of 40 bits, this means any case where a translation table entry or the TTBR holds an address for which A[47:40] is nonzero generates an Address size fault.

A data or unified cache maintenance by VA instruction can generate an Address size fault. If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA instruction can generate an Address size fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate an Address size fault.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate an Address size fault.

It is IMPLEMENTATION DEFINED whether a branch predictor maintenance operation can generate an Address size fault.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.
Access flag fault
An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if all of the following apply:

- The translation tables support an Access flag bit:
  - The Short-descriptor format supports an Access flag only when SCTLR.AFE is set to 1.
  - The Long-descriptor format always supports an Access flag.
- A translation table descriptor with the Access flag bit set to 0 is loaded.

For more information about the Access flag bit see:
- VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4577
- VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4586.

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance instruction by VA can generate Access flag faults is IMPLEMENTATION DEFINED.
Whether branch predictor invalidate by VA operations can generate Access flag faults is IMPLEMENTATION DEFINED.
For more information, see The Access flag on page G4-4613.

Domain fault, Short-descriptor format translation tables only
When using the Short-descriptor translation table format, a Domain fault can be generated at level 1 or level 2 of lookup. The reported fault code identifies the lookup level. The conditions for generating a Domain fault are:

Level 1 When a level 1 descriptor fetch returns a valid Section level 1 descriptor, the domain field of that descriptor is checked against the DACR. A level 1 Domain fault is generated if this check fails.

Level 2 When a level 2 descriptor fetch returns a valid level 2 descriptor, the domain field of the level 1 descriptor that required the level 2 fetch is checked against the DACR, and a level 2 Domain fault is generated if this check fails.

For more information, see Domains, Short-descriptor format only on page G4-4612.

Domain faults cannot occur on cache or branch predictor maintenance operations.
A TLB might hold a translation table entry that causes a Domain fault. Therefore, if the handling of a Domain fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in Ordering and completion of TLB maintenance instructions on page G4-4635.

Any change to the DACR must be synchronized by a Context synchronization event. For more information see Synchronization of changes to AArch32 System registers on page G6-4768.

G4.11.6 External abort on a translation table walk
An external abort on a translation table walk can be either synchronous or asynchronous. For more information on external aborts, see External aborts on page G3-4550.

An external abort on a translation table walk is reported:
- If the external abort is synchronous, using:
  - A synchronous Prefetch Abort exception if the translation table walk is for an instruction fetch.
  - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the external abort is asynchronous, using an SError interrupt, which is taken as an asynchronous Data Abort exception.
If an implementation reports the error in the translation table walk asynchronously from executing the instruction whose instruction fetch or memory access caused the translation table walk, these aborts behave essentially as interrupts. The aborts are masked when PSTATE.A is set to 1, otherwise they are reported using the Data Abort exception.

**Behavior of external aborts on a translation table walk caused by address translation instructions**

The address translation instructions summarized in *Address translation instructions, functional group on page G4-4737* require translation table walks. An external abort can occur in the translation table walk. The abort generates a Data Abort exception, and can be synchronous or asynchronous. For more information, see *Handling of faults and aborts during an address translation instruction on page G4-4686.*

**G4.11.7 AArch32 state prioritization of synchronous aborts from a single stage of address translation**

*Exception prioritization for exceptions taken to AArch32 state on page G1-4344* describes the prioritization of exceptions taken from an Exception level that is using AArch32. This section gives additional information about the prioritization of MMU faults from VMSAv8-32 translation regimes.

If a single instruction generates aborts on more than one memory access, the architecture does not define any prioritization between those aborts.

In general, the ARM architecture does not define when asynchronous events are taken, and therefore the prioritization of asynchronous events is IMPLEMENTATION DEFINED.

--- **Note** ---

The priority numbering in this list only shows the relative priorities of aborts from a single stage of address translation in a VMSAv8-32 translation regime. This numbering has no global significance and, for example, does not correlate with the equivalent AArch64 list in *AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-2110.*

For a single stage of translation in a VMSAv8-32 translation regime, the following numbered list shows the priority of the possible memory management faults on a memory access. In this list:

- For memory accesses that undergo two stages of translation, the *italic entries show where the faults from the stage 2 translation can occur.* A stage 2 fault within a stage 1 translation table walk follows the same prioritization of faults.
- For synchronous external aborts from translation table walks see also *Synchronous external abort errors from address translation caching structures on page G4-4661.*

The priority order, from highest priority to lowest priority, is:

1. Alignment fault not caused by memory type. This is possible for a stage 1 translation only.
2. Translation fault due to the input address being out of the address range to be translated or requiring an AArch32 TTBR that is disabled. This includes VTCR.SL0 being inconsistent with VTCR.T0SZ or programmed to a reserved value.
3. Address size fault on an AArch32 TTBR caused by the physical address being out of the range implemented.
4. Second stage abort on a level 1 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented. This is second stage abort during a first stage translation table walk.
5. Synchronous parity or ECC error on a level 1 lookup of a translation table walk.
6. Synchronous external abort on a level 1 lookup level of a translation table walk.
7. Translation fault on a level 1 translation table entry.
8. Address size fault on a level 1 lookup translation table entry caused by the output address being out of the range implemented.

9. Second stage abort on a level 2 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented. This is second stage abort during a first stage translation table walk.

10. Synchronous parity or ECC error on a level 2 lookup of a translation table walk.

11. Synchronous external abort on a level 2 lookup level of a translation table walk.

12. Translation fault on a level 2 translation table entry.

13. Address size fault on a level 2 lookup translation table entry caused by the output address being out of the range implemented.

14. Second stage abort on a level 3 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented. This is second stage abort during a first stage translation table walk.

15. Synchronous parity or ECC error on a level 3 lookup of a translation table walk.

16. Synchronous external abort on a level 3 lookup level of a translation table walk.

17. Translation fault on a level 3 translation table entry.

18. Address size fault on a level 3 lookup translation table entry caused by the output address being out of the range implemented.

19. Access Flag fault.

20. Alignment fault caused by the memory type.

--- Note ---

Domain faults are possible only when using the VMSAv8-32 Short-descriptor translation table format, see Domain fault, Short-descriptor format translation tables only on page G4-4659.

---

22. Permission fault.

23. A fault from the stage 2 translation of the memory access. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented.

24. Synchronous parity or ECC error on the memory access.

25. Synchronous External Abort on the memory access.

--- Note ---

- The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

- The prioritization of IMPLEMENTATION DEFINED MMU faults for a Load-Exclusive or Store-Exclusive to an unsupported memory type is IMPLEMENTATION DEFINED.

See also The MMU fault-checking sequence on page G4-4652.

**Synchronous external abort errors from address translation caching structures**

A caching structure used for caching translation table walks might support:

- An arbitrary number of levels of translation table lookup.
• One or more stages of translation, that might not correspond to the stages of an address translation lookup.

This might mean that, on a synchronous external abort arising from the caching structure, such as from a parity or ECC error, the PE cannot precisely determine one or both of the translation stage and level of lookup at which the error occurred. In this case:

• If the PE cannot determine precisely the translation stage at which the error occurred, it is reported and prioritized as a stage 1 error.

• If the PE cannot determine precisely the lookup level at which the error occurred, the level is reported and prioritized as either:
  — The lowest-numbered level that could have given rise to the error.
  — Level 1 if the PE cannot determine any information about the level.
G4.12 Exception reporting in a VMSAv8-32 implementation

This section describes exception reporting, in AArch32 state, in a VMSAv8-32 implementation. That is, it describes only the reporting of exceptions that are taken to an Exception level that is using AArch32. EL2 provides an enhanced reporting mechanism for exceptions taken to the Non-secure EL2 mode, Hyp mode. This means that, for VMSAv8-32, the exception reporting depends on the mode to which the exception is taken.

Note

The enhanced reporting mechanism for exceptions that are taken to Hyp mode is generally similar to the reporting of exceptions that are taken to an Exception level that is using AArch64.

About exception reporting

Introduces the general approach to exception reporting, and the following sections then describe exception reporting at different privilege levels:

- Reporting exceptions taken to PL1 modes on page G4-4664.
- Fault reporting in PL1 modes on page G4-4667.
- Summary of register updates on faults taken to PL1 modes on page G4-4671.
- Reporting exceptions taken to Hyp mode on page G4-4673.
- Use of the HSR on page G4-4677.
- Summary of register updates on exceptions taken to Hyp mode on page G4-4680.

Note

The registers used for exception reporting also report information about debug exceptions. For more information see:

- Data Abort exceptions, taken to a PL1 mode on page G4-4665.
- Prefetch Abort exceptions, taken to a PL1 mode on page G4-4667.
- Reporting exceptions taken to Hyp mode on page G4-4673.

G4.12.1 About exception reporting

In an implementation that includes EL2 and EL3, exceptions can be taken to:

- Monitor mode, if EL3 is using AArch32.
- Hyp mode, if EL2 is using AArch32.
- A Secure or Non-secure PL1 mode.

Monitor mode is a PL1 mode, but:

- It is accessible only when EL3 is using AArch32.
- It is present only in Secure state.
- When EL3 is using AArch32, System register controls route some exceptions from Non-secure state to Monitor mode. These are the only cases where taking an exception to an Exception level that is using AArch32 changes the Security state of the PE.

Exception reporting in Hyp mode differs significantly from that in the other modes, but in general, exception reporting returns:

- Information about the exception:
  - On taking an exception to Hyp mode, the Hyp Syndrome Register, HSR, returns syndrome information.
  - On taking an exception to any other mode, a Fault Status Register (FSR) returns status information.
- For synchronous exceptions, one or more addresses associated with the exceptions, returned in Fault Address Registers (FARs). For a permitted exception to this requirement see Fault address reporting on synchronous external aborts on page G4-4664.

In all modes, additional IMPLEMENTATION DEFINED registers can provide additional information about exceptions.
--- Note ---

- **PE mode for taking exceptions** on page G1-4350 describes how the mode to which an exception is taken is determined.

- **EL2** provides:
  - Specific exception types, that can only be taken from Non-secure PL1 and PL0 modes, and are always taken to Hyp mode.
  - Routing controls that can route some exceptions from Non-secure PL1 and PL0 modes to Hyp mode.

  These exceptions are reported using the same mechanism as the Hyp mode reporting of VMSAv8-32 memory aborts, as described in this section.

---

Memory system faults generate either a Data Abort exception or a Prefetch Abort exception, as summarized in:

- **Reporting exceptions taken to PL1 modes**.
- **Memory fault reporting in Hyp mode** on page G4-4675.

On an access that might have multiple aborts, the MMU fault checking sequence and the prioritization of aborts determine which abort occurs. For more information, see *The MMU fault-checking sequence* on page G4-4652 and AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660.

### Fault address reporting on synchronous external aborts

The general architectural requirement is that, on a synchronous abort, the faulting address is recorded in a Fault Address Register (FAR). This requirement is relaxed for the case of a synchronous external abort that is not a synchronous external abort on a translation table walk. In this case only:

- It is IMPLEMENTATION DEFINED whether the faulting address is recorded in a FAR.
- A bit in a fault reporting register, the FnV bit, indicates whether a valid address is recorded.

For exceptions taken to an Exception level that is using AArch32, the details of this reporting depend on whether the exception is taken to:

- A PL1 mode, as described in **Reporting exceptions taken to PL1 modes**.
- Hyp mode, as described in **Reporting exceptions taken to Hyp mode** on page G4-4673.

### G4.12.2 Reporting exceptions taken to PL1 modes

The following sections give general information about the reporting of exceptions when they are taken to a Secure or Non-secure PL1 mode:

- **Registers used for reporting exceptions taken to PL1 modes** on page G4-4665.
- **Data Abort exceptions, taken to a PL1 mode** on page G4-4655.
- **Prefetch Abort exceptions, taken to a PL1 mode** on page G4-4667.

**Fault reporting in PL1 modes** on page G4-4667 then describes the fault reporting in these modes, including the encodings used for reporting the faults.

--- Note ---

*Security state, Exception levels, and AArch32 execution privilege* on page G1-4318 describes how the Secure and Non-secure PL1 modes map onto the Exception levels.
Registers used for reporting exceptions taken to PL1 modes

AArch32 state defines the following registers, and register encodings, for exceptions taken to PL1 modes:

- The DFSR holds information about a Data Abort exception.
- The DFAR holds the faulting address for some synchronous Data Abort exceptions.
- The IFSR holds information about a Prefetch Abort exception.
- The IFAR holds the faulting address for some synchronous Prefetch Abort exceptions.

In addition, if implemented, the optional ADFSR and AIFSR can provide additional fault information, see Auxiliary Fault Status Registers.

Auxiliary Fault Status Registers

AArch32 state defines the following Auxiliary Fault Status Registers:

- The Auxiliary Data Fault Status Register, ADFSR.
- The Auxiliary Instruction Fault Status Register, AIFSR.

The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED. An implementation can use these registers to return additional fault status information. An example use of these registers is to return more information for diagnosing parity or ECC errors.

An implementation that does not need to report additional fault information must implement these registers as UNK/SBZP. This ensures that an attempt to access these registers from software executing at PL1 does not cause an Undefined Instruction exception.

Data Abort exceptions, taken to a PL1 mode

On taking a Data Abort exception to a PL1 mode:

- If the exception is on an instruction cache or branch predictor maintenance operation by VA, its reporting depends on the value of TTBCR.EAE. For more information about the registers used when reporting the exception, see Data Abort on an instruction cache or branch predictor maintenance instruction by VA on page G4-4666.

- Otherwise, the DFSR is updated with details of the fault, including the appropriate Fault status code. If the Data Abort exception is synchronous, DFSR.WnR is updated to indicate whether the faulted instruction was a read or a write. However, if the fault is on a cache maintenance instruction, or on an address translation instruction, WnR is set to 1, to indicate a fault on a write instruction, and the CM bit is set to 1.

See the register description for more information about the returned fault information. See also Data Abort on a Watchpoint exception on page G4-4666.

If the Data Abort exception is

- Synchronous, the DFAR is updated with the VA that caused the exception, but see Fault address reporting on synchronous external aborts on page G4-4664 for a permitted exception to this requirement.
- Asynchronous, the DFAR becomes UNKNOWN.

DFSR.WnR and DFSR.CM are UNKNOWN on an asynchronous Data Abort exception.

For all Data Abort exceptions, if the implementation includes EL3, the Security state of the PE in the mode to which the Data Abort exception is taken determines whether the Secure or Non-secure DFSR and DFAR are updated.
Data Abort on an instruction cache or branch predictor maintenance instruction by VA

If an instruction cache invalidation by VA or branch predictor invalidation by VA operation generates a Data Abort exception that is taken to a PL1 mode, the DFAR is updated to hold the faulting VA. However, the reporting of the fault depends on the value of TTBCR.EAE:

TTBCR.EAE == 0

When the value of TTBCR.EAE is 0, it is IMPLEMENTATION DEFINED which of the following is used when reporting the fault:

- The DFSR indicates an Instruction cache maintenance instruction fault, and the IFSR is valid and indicates the cause of the fault, a Translation fault or Access flag fault.
- The DFSR indicates the cause of the fault, a Translation fault or Access flag fault. The IFSR is UNKNOWN.

In either case:
- DFSR.WnR is set to 1.
- DFSR.CM is set to 1, to indicate a fault on a cache maintenance instruction.

TTBCR.EAE == 1

When the value of TTBCR.EAE is 1:

- DFSR.CM is set to 1, to indicate a fault on a cache maintenance instruction.
- DFSR.STATUS indicates the cause of the fault, a Translation or Access flag fault.
- DFSR.WnR is set to 1.
- The IFSR is UNKNOWN.

Data Abort on a Watchpoint exception

On taking a Data Abort exception caused by a watchpoint:

- DFSR.FS is updated to indicate a debug exception.
- DFSR.{WnR, Domain} are UNKNOWN.
- DFAR is set to the address that generated the watchpoint

--- Note ---

- LR_abt indicates the address of the instruction that triggered the watchpoint.
- In some ARMv7 AArch32 implementations, the DBGWFAR is set to the address of the instruction that triggered the watchpoint. In ARMv8 this register is RES0.

---

A watchpointed address can be any byte-aligned address. The address reported in DFAR might not be the watchpointed address, and:

- For a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:
  - The lowest address accessed by the instruction that triggered the watchpoint.
  - The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated. The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

--- Note ---

- In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.
- The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.
• For a watchpoint due to a Data Cache operation, the address is the address passed to the instruction. This might be an address that is above the watchpointed location.

**Prefetch Abort exceptions, taken to a PL1 mode**

For a Prefetch Abort exception generated by an instruction fetch, the Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

• If the PE attempts to execute the instruction a Prefetch Abort exception is generated.

• If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction, no Prefetch Abort exception is generated.

In addition, Breakpoint Instruction, Breakpoint, and Vector Catch exceptions, generate a Prefetch Abort exception, see the following for more information:

• *Exception syndrome information and preferred return address for a BKPT instruction* on page G2-4468.

• *Exception syndrome information and preferred return address for a Breakpoint exception* on page G2-4493.

• *Exception syndrome information and preferred return address for a Vector Catch exception* on page G2-4516.

**Note**

Usually, the term *exception syndrome* is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced sections use the term more generally, to include exception information reported in the IFSR.

On taking a Prefetch Abort exception to a PL1 mode:

• The IFSR is updated with details of the fault, including the appropriate fault code. If appropriate, the fault code indicates that the exception was generated by a debug exception. See the register description for more information about the returned fault information.

• For a Prefetch Abort exception generated by an instruction fetch, the IFAR is updated with the VA that caused the exception, but see *Fault address reporting on synchronous external aborts* on page G4-4664 for a permitted exception to this requirement.

• For a Prefetch Abort exception generated by a debug exception, the IFAR is UNKNOWN.

If the implementation includes EL3, the Security state of the PE in the mode to which it takes the Prefetch Abort exception determines whether the exception updates the Secure or Non-secure IFSR and IFAR.

**G4.12.3 Fault reporting in PL1 modes**

The FSRs provide fault information, including an indication of the fault that occurred. The following subsections describe fault reporting in PL1 modes for each of the translation table formats:

• *PL1 fault reporting with the Short-descriptor translation table format* on page G4-4668.

• *PL1 fault reporting with the Long-descriptor translation table format* on page G4-4670.

*Reserved encoding in the IFSR and DFSR encodings tables* on page G4-4671 gives some additional information about the encodings for both formats.

*Summary of register updates on faults taken to PL1 modes* on page G4-4671 shows which registers are updated on each of the reported faults.

*Reporting of External aborts taken from Non-secure state to Monitor mode* on page G4-4668 describes how the fault status register format is determined for those aborts. For all other aborts, the current translation table format determines the format of the fault status registers.
Reporting of External aborts taken from Non-secure state to Monitor mode

When an External abort is taken from Non-secure state to Monitor mode:

• For a Data Abort exception, the Secure DFSR and DFAR hold information about the abort.
• For a Prefetch Abort exception, the Secure IFSR and IFAR hold information about the abort.
• The abort does not affect the contents of the Non-secure copies of the fault reporting registers.

Normally, the current translation table format determines the format of the DFSR and IFSR. However, when SCR.EA is set to 1, to route external aborts to Monitor mode, and an external abort is taken from Non-secure state, this section defines the DFSR and IFSR format.

For an External abort taken from Non-secure state to Monitor mode, the DFSR or IFSR uses the format associated with the Long-descriptor translation table format, as described in *PL1 fault reporting with the Long-descriptor translation table format* on page G4-4670, if any of the following applies:

• The Secure TTBCR.EAE bit is set to 1.
• The External abort is synchronous and either:
  — It is taken from Hyp mode.
  — It is taken from a Non-secure PL1 or PL0 mode, and the Non-secure TTBCR.EAE bit is set to 1.

Otherwise, the DFSR or IFSR uses the format associated with the Short-descriptor translation table format, as described in *PL1 fault reporting with the Short-descriptor translation table format*.

PL1 fault reporting with the Short-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1 when address translation is using the Short-descriptor translation table format.

On taking an exception, bit[9] of the FSR is RAZ, or set to 0, if the PE is using this FSR format.

An FSR encodes the fault in a 5-bit FS field, that comprises FSR[10, 3:0]. Table G4-25 shows the encoding of that field. *Summary of register updates on faults taken to PL1 modes* on page G4-4671 shows:

• Whether the corresponding FAR is updated on the fault. That is:
  — For a fault reported in the IFSR, whether the IFAR holds a valid address.
  — For a fault reported in the DFSR, whether the DFAR holds a valid address.
• For faults that update DFSR, whether DFSR.Domain is valid

When reading Table G4-25:

• FS values not shown in the table are reserved.
• FS values shown as DFSR only are reserved for the IFSR.

<sup>a</sup> MMU fault
The level associated with MMU faults on a Short-descriptor translation table lookup

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, Permission fault, or Domain fault, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Supersection, Section, or Page descriptor.

Also see Synchronous external abort errors from address translation caching structures on page G4-4661.

The Domain field in the DFSR

The DFSR includes a Domain field. This is inherited from previous versions of the VMSA. The IFSR does not include a Domain field. Summary of register updates on faults taken to PL1 modes on page G4-4671 describes when DFSR Domain is valid.

ARM deprecates any use of the Domain field in the DFSR. The Long-descriptor translation table format does not support a Domain field, and future versions of the ARM architecture might not support a Domain field in the Short-descriptor translation table format. ARM strongly recommends that new software does not use this field.

For both Data Abort exceptions and Prefetch Abort exceptions, software can find the domain information by performing a translation table read for the faulting address and extracting the Domain field from the translation table entry.
PL1 fault reporting with the Long-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1 mode when address translation is using the Long-descriptor translation table format.

When the PE takes an exception, bit[9] of the FSR is set to 1 if the PE is using this FSR format.

The FSRs encode the fault in a 6-bit STATUS field, that comprises FSR[5:0]. Table G4-26 shows the encoding of that field. In addition:

- For a fault taken to a PL1 mode, Summary of register updates on faults taken to PL1 modes on page G4-4671 shows whether the corresponding FAR is updated on the fault. That is:
  - For a fault reported in the IFSR, whether the IFAR holds a valid address.
  - For a fault reported in the DFSR, whether the DFAR holds a valid address.

- For a fault taken to the Hyp mode, Summary of register updates on exceptions taken to Hyp mode on page G4-4680 shows what registers are updated on the fault.

<td>Level 3. When xFSR.STATUS indicates a Domain fault, this value is reserved.</td>
<td></td>
</tr>
</tbody>
</table>

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see Synchronous external abort errors from address translation caching structures on page G4-4661.

Reserved encoding in the IFSR and DFSR encodings tables

With both the Short-descriptor and the Long-descriptor FSR format, the fault encodings reserve a single encoding for Cache and TLB lockdown faults. The details of these faults and any associated subsidiary registers are IMPLEMENTATION DEFINED.

G4.12.4 Summary of register updates on faults taken to PL1 modes

For faults that generate exceptions that are taken to a PL1 mode, Table G4-28 on page G4-4672 shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.
For faults that update the DFSR using the Short-descriptor format FSR encodings, Table G4-29 on page G4-4673 shows whether DFSR.Domain is valid.

---

- **a.** IMPLEMENTATION DEFINED. The IFSR.FnV or DFSR.FnV bit indicates whether the register holds a valid address. See Fault address reporting on synchronous external aborts on page G4-4664.
- **b.** When using the Long-descriptor translation table format, there is not a specific fault code for a fault on an instruction cache maintenance instruction. For more information see Data Abort on an instruction cache or branch predictor maintenance instruction by VA on page G4-4666.
- **c.** The two lines of this entry show the alternative ways of reporting the fault when using the Short-descriptor translation table format. It is IMPLEMENTATION DEFINED which methods is used, see Data Abort on an instruction cache or branch predictor maintenance instruction by VA on page G4-4666.
- **d.** Generates a Prefetch Abort exception.
- **e.** Generates a Data Abort exception.
For those faults for which Table G4-28 on page G4-4672 shows that the DFSR is updated, if the fault is reported using the Short-descriptor FSR encodings, Table G4-29 shows whether DFSR.Domain is valid. In this table, UNK indicates that the fault makes DFSR.Domain UNKNOWN.

a. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use.

b. Including asynchronous external abort on a data access, a translation table walk, or an instruction fetch.

**G4.12.5 Reporting exceptions taken to Hyp mode**

Hyp mode is the Non-secure EL2 mode. It is entered by taking an exception to Hyp mode.

--- Note ---

Software executing in Monitor mode, or at EL3 when EL3 is using AArch64, can perform an exception return to Hyp mode. This means Hyp mode can be entered either by taking an exception, or by a permitted exception return.

When EL2 is using AArch32, the following exceptions are taken to Hyp mode:

- SError interrupt exceptions, IRQ exceptions, and FIQ exceptions, from Non-secure PL0 and PL1 modes, if not routed to Secure Monitor mode, and if configured by the AMO, FMO or IMO bits. For more information see Asynchronous exception routing controls on page G1-4367.

- When HCR.TGE is set to 1, all exceptions that would be routed to Non-secure PL1 modes.
For more information, see Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.

- When HDCR.TDE is set to 1, any debug exception that would otherwise be taken to a Non-secure PL1 mode, see Routing debug exceptions to EL2 using AArch32 on page G1-4358.

- The privilege rules for taking exceptions mean that any exception taken from Hyp mode, if not routed to EL3, must be taken to Hyp mode.

- Hypervisor Call exceptions, and Hyp Trap exceptions, are always taken to Hyp mode. These exceptions are supported only as part of EL2.

  When EL2 is implemented, various operations from Non-secure PL0 and PL1 modes can be trapped to Hyp mode, using the Hyp Trap exception. For more information, see EL2 configurable controls on page G1-4427.

These exceptions include any memory system fault that occurs:

- On a memory access from Hyp mode.
- On memory access from a Non-secure PL0 or PL1 mode:
  - On a stage 2 translation, from IPA to PA.
  - On the stage 2 translation of an address accessed in performing a stage 1 translation table walk.

Memory fault reporting in Hyp mode on page G4-4675 gives more information about these faults.

The following exceptions provide syndrome information in the HSR:

- Any synchronous exception taken to Hyp mode.
- Some exceptions taken from Debug state that would be taken to Hyp mode if the PE was in Non-debug state, see Exceptions in Debug state on page H2-5465.

  Note  
  - In Debug state, the PE does not change mode on taking an exception.
  - As Exceptions in Debug state on page H2-5465 describes, some other exceptions taken from Debug state make the HSR UNKNOWN.

The syndrome information in the HSR includes the Fault status code otherwise provided by the fault status register, and extends the fault reporting compared to that available for an exception taken to a PL1 mode. For more information, see Use of the HSR on page G4-4677.

In addition, for a Debug exception taken to Hyp mode, DBGDSR.int.MOE or DBGDTRRXext.MOE shows what caused the Debug exception. This bit is valid regardless of whether the Debug exception was taken from Hyp mode or from another Non-secure mode.

Registers used for reporting exceptions taken to Hyp mode lists all of the registers used for exception reporting in Hyp mode.

### Registers used for reporting exceptions taken to Hyp mode

The following registers are used for reporting exceptions taken to Hyp mode:

- The HSR holds syndrome information for the exception.
- The HDFAR holds the VA associated with a Data Abort exception.
- The HIFAR holds the VA associated with a Prefetch Abort exception.
- The HPFAR holds bits[39:12] of the IPA associated with some aborts on stage 2 address translations.

In addition, if implemented, the optional HADFSR and HAIFSR can provide additional fault information, see Hyp Auxiliary Fault Syndrome Registers.

### Hyp Auxiliary Fault Syndrome Registers

EL2 also defines encodings for the following Hyp Auxiliary Fault Syndrome Registers:

- The Hyp Auxiliary Data Fault Syndrome Register, HADFSR.
- The Hyp Auxiliary Instruction Fault Syndrome Register, HAIFSR.
An implementation can use these registers to return additional fault status information for aborts taken to Hyp mode. They are the Hyp mode equivalents of the registers described in Auxiliary Fault Status Registers on page G4-4665. An example use of these registers is to return more information for diagnosing parity or ECC errors.

The architectural requirements for the HADFSR and HAIFSR are:

- The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED.
- An implementation with no requirement for additional fault reporting can implement these registers as UNK/SBZP, but the architecture does not require it to do so.

**Memory fault reporting in Hyp mode**

Prefetch Abort and Data Abort exceptions taken to Hyp mode report memory faults. For these aborts, the HSR contains the following fault status information:

- The HSR.EC field indicates the type of abort, as Table G4-30 shows.
- The HSR.ISS field holds more information about the abort. In particular:
  - Bits[5:0] of this field hold the STATUS field for the abort, using the encodings defined in PL1 fault reporting with the Long-descriptor translation table format on page G4-4670.
  - Other subfields of the ISS give more information about the exception, equivalent to the information returned in the FSR for a memory fault reported at PL1.

See the descriptions of the ISS fields for the memory faults, referenced from the Syndrome description column of Table G4-30, for information about the returned fault information.

<table>
<thead>
<tr>
<th>HSR.EC</th>
<th>Abort</th>
<th>Syndrome description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x20</td>
<td>Prefetch Abort taken from Non-secure PL0 or PL1 mode</td>

</tr>
<tr>
<td>0x21</td>
<td>Prefetch Abort taken from Hyp mode</td>
<td></td>
</tr>
<tr>
<td>0x24</td>
<td>Data Abort taken from Non-secure PL0 or PL1 mode</td>
<td>ISS encoding for an exception from a Data Abort on page G6-4960</td>
</tr>
<tr>
<td>0x25</td>
<td>Data Abort taken from Hyp mode</td>
<td></td>
</tr>
</tbody>
</table>

For more information, see Use of the HSR on page G4-4677.

A Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction that would abort if the PE attempted to execute it, no Prefetch Abort exception is generated.

**Register updates on exception reporting in Hyp mode**

The use of the HSR, and of the other registers listed in Registers used for reporting exceptions taken to Hyp mode on page G4-4674, depends on the cause of the Abort. In reporting these faults, in general:

- If the fault generates a synchronous Data Abort exception, the HDFAR holds the associated VA, but see Fault address reporting on synchronous external aborts on page G4-4664 for a permitted exception to this requirement.
- If the fault generates a Prefetch Abort exception, the HIFAR holds the associated VA, but see Fault address reporting on synchronous external aborts on page G4-4664 for a permitted exception to this requirement.
In the following cases, the HPFAR holds the faulting IPA:

- A Translation or Access flag fault on a stage 2 translation.
- A Translation, Access flag, or Permission fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.
- A stage 2 Address size fault.

In all other cases, the HPFAR is UNKNOWN.

- On a Data Abort exception that is taken to Hyp mode, the HIFAR is UNKNOWN.
- On a Prefetch Abort exception that is taken to Hyp mode, the HDFAR is UNKNOWN.

In addition, the reporting of particular aborts is as follows:

Abort on the stage 1 translation for a memory access from Hyp mode

The HIFAR or HDFAR holds the VA that caused the fault. The STATUS subfield of HSR.ISS indicates the type of fault, Translation, Address size, Access flag, or Permission. The HPFAR is UNKNOWN.

Abort on the stage 2 translation for a memory access from a Non-secure PL1 or PL0 mode

This includes aborts on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation. The HIFAR or HDFAR holds the VA that caused the fault. The STATUS subfield of HSR.ISS indicates the type of fault, Translation, Address size, Access flag, or Permission.

For any Access flag fault or Translation fault, and also for any Permission fault on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation, the HPFAR holds the IPA that caused the fault. Otherwise, the HPFAR is UNKNOWN.

Abort caused by a synchronous external abort, or synchronous parity or ECC error, and taken to Hyp mode

The HDFAR or HIFAR holds the VA that caused the fault, but see Fault address reporting on synchronous external aborts on page G4-4664 for a permitted exception to this requirement. The HPFAR is UNKNOWN.

Data Abort caused by a Watchpoint exception and routed to Hyp mode because HDCR.TDE is set to 1

When HDCR.TDE is set to 1, a Watchpoint exception generated in a Non-secure PL1 or PL0 mode, that would otherwise generate a Data Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

HDFAR is set to the address that generated the watchpoint.

Note

ELR_hyp indicates the address of the instruction that triggered the watchpoint.

A watchpointed address can be any byte-aligned address. The address reported in HDFAR might not be the watchpointed address, and, for a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:

- The lowest address accessed by the instruction that triggered the watchpoint.
- The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

Note

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.
Note
The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.

See also Watchpoint exceptions on page G2-4496.
In all cases, HPFAR is UNKNOWN.

Prefetch Abort caused by a Breakpoint Instruction exception and taken to Hyp mode
This abort is generated if a BKPT instruction is executed in Hyp mode. The abort leaves the HIFAR and HPFAR UNKNOWN.
See also Breakpoint Instruction exceptions on page G2-4467.

Prefetch Abort caused by a Breakpoint Instruction, Breakpoint, or Vector Catch exception, and routed to Hyp mode because HDCR.TDE is set to 1
When HDCR.TDE is set to 1, a debug exception, generated in a Non-secure PL1 or PL0 mode, that would otherwise generate a Prefetch Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.
The abort leaves the HIFAR and HPFAR UNKNOWN. This is identical to the reporting of a Prefetch Abort exception caused by a Debug exception on a BKPT instruction that is executed in Hyp mode.

Note
The difference between these two cases is:
• The Debug exception on a BKPT instruction executed in Hyp mode generates a Prefetch Abort exception, taken to Hyp mode, and reported in the HSR using EC value 0x21.
• Aborts generated because HDCR.TDE is set to 1 generate a Hyp Trap exception, and are reported in the HSR using EC value 0x20.

Use of the HSR
The HSR holds syndrome information for any synchronous exception taken to Hyp mode. Compared with the reporting of exceptions taken to PL1 modes, the HSR:
• Always provides details of the fault. The DFSR and IFSR are not used.
• Provides more extensive information, for a wider range of exceptions.

Note
IRQ and FIQ exceptions taken to Hyp mode do not report any syndrome information in the HSR.

HSR, Hyp Syndrome Register on page G6-4945 describes the HSR, this section summarizes the general form of the register, to show how it encodes exception syndrome information. The register comprises:
• A 6-bit Exception class field, EC, that indicates the cause of the exception.
• An instruction length bit, IL. When an exception is caused by trapping an instruction to Hyp mode, this bit indicates the length of the trapped instruction, as follows:
  0  16-bit instruction trapped.
  1  32-bit instruction trapped.

In other cases the IL field is not valid and is RES1.
• An instruction specific syndrome field, ISS. Architecturally, this field could be defined independently for each defined Exception class (EC), but in practice several ISS formats are common to more than one EC.
The format of the HSR depends on the value of the EC field, as follows:

\[ 0b000000 \leq EC \leq 0b001100 \]

The ISS part of the returned value includes the CV and COND fields described in *Encoding of ISS[24:20] when 0b000000 \leq EC \leq 0b001100*. Figure G4-17 shows the HSR format in this case.

![HSR format](image)

**Figure G4-17 HSR format when the ISS includes CV and COND fields**

**EC==0b000000 or EC==0b001110** There are no generic fields within the ISS. Figure G4-18 shows the HSR format in this case.

![HSR format](image)

**Figure G4-18 HSR format when the ISS does not include a COND field**

*Encoding of ISS[24:20] when 0b000000 \leq EC \leq 0b001100*

For EC values that are nonzero and less than or equal to 0b001100, ISS[24:20] provides the Condition code field for the trapped instruction, together with a valid flag for this field. The encoding of this part of the ISS field is:

- **CV, ISS[24]** Condition code valid. Possible values of this bit are:
  - 0 The COND field is not valid.
  - 1 The COND field is valid

- **COND, ISS[23:20]**
  
  The Condition code for the trapped instruction. This field is valid only when CV is set to 1.

  If CV is set to 0, this field is UNK/SBZP.

The full descriptions of the HSR.ISS formats give more information about the CV field.

**Note**

In some circumstances, it is IMPLEMENTATION DEFINED whether a conditional instruction that fails its Condition code check generates an Undefined Instruction exception, see *Conditional execution of undefined instructions on page G1-4378*. 

---
HSR exception classes

Table G4-31 shows the encoding of the HSR exception class field, EC. Values of EC not shown in the table are reserved. For each EC value, the table references a subsection of the description of the HSR that describes the associated ISS format and gives information about the cause of the exception, for example the configuration required to enable the associated trap.

## Summary of register updates on exceptions taken to Hyp mode

For memory system faults that generate exceptions that are taken to Hyp mode, Table G4-32 shows the registers affected by each fault. In this table:

- **Yes** indicates that the register is updated.
- **UNK** indicates that the fault makes the register value **UNKNOWN**.
- A null entry, -, indicates that the fault does not affect the register.

Note

For a list of the MMU faults see **MMU faults in AArch32 state** on page G4-4657.

---

**Note**

Unlike Table G4-28 on page G4-4672, the Hyp mode fault reporting table does not include an entry for a fault on an instruction cache maintenance instruction. That is because, when the fault is taken to Hyp mode, the reporting indicates the cause of the fault, for example a Translation fault, and ISS.CM is set to 1 to indicate that the fault was on a cache maintenance instruction, see *ISS encoding for an exception from a Data Abort* on page G6-4960.

---

**Classification of MMU faults taken to Hyp mode**

This subsection gives more information about the MMU faults shown in Table G4-32 on page G4-4680.

---

**Note**

All MMU faults are synchronous.

The table uses the following descriptions for MMU faults taken to Hyp mode:

**MMU fault at stage 1**

This is an MMU fault generated on a stage 1 translation performed in the Non-secure PL2 translation regime.

**MMU fault at stage 2**

This is an MMU fault generated on a stage 2 translation performed in the Non-secure PL1&0 translation regime.

As the table shows, for the faults in this group:

- Translation and Access flag faults update the HPFAR
- Permission faults leave the HPFAR UNKNOWN.

**MMU stage 2 fault on a stage 1 translation**

This is an MMU fault generated on the stage 2 translation of an address accessed in a stage 1 translation table walk performed in the Non-secure PL1&0 translation regime. For more information about these faults see *Stage 2 fault on a stage 1 translation table walk* on page G4-4656.

Figure G4-1 on page G4-4560 shows the different translation regimes and associated stages of translation.
G4.13 Address translation instructions

The System register encoding space includes encodings for instructions that either:

- Translate a virtual address (VA) to a physical address (PA).
- Translate a virtual address (VA) to an intermediate physical address (IPA).

Address translation instructions, functional group on page G4-4737 summarizes these instructions.

When using the Short-descriptor translation table format, all translations performed by these instructions take account of TEX remap when this is enabled, see Short-descriptor format memory region attributes, with TEX remap on page G4-4619.

An address translation instruction that executes successfully returns the output address, a PA or an IPA, in the PAR. This is a 64-bit register, that can hold addresses of up to 40 bits.

It is IMPLEMENTATION DEFINED whether the address translation instructions return the values held in a TLB or the result of a translation table walk. Therefore, ARM recommends that these instructions are not used at a time when the TLB entries might be different from the underlying translation tables held in memory.

The following sections give more information about these instructions:

- Address translation instruction naming and operation summary.
- Encoding and availability of the address translation instructions on page G4-4684.
- Determining the PAR format on page G4-4686.
- Handling of faults and aborts during an address translation instruction on page G4-4686.

G4.13.1 Address translation instruction naming and operation summary

Some older documentation uses the original names for the address translation instructions that were included in the original ARMv7 documentation. Table G4-33 summarizes the instructions that are available in AArch32 state, and relates the old instruction names to the current names.

<table>
<thead>
<tr>
<th>Name</th>
<th>Old name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATS1CPR, ATS1CPW, ATS1CUR, ATS1CUW</td>
<td>V2PCWPR, V2PCWPW, V2PCWUR, V2PCWUW</td>
<td>See ATS1C**, Address translation stage 1, current Security state on page G4-4683</td>
</tr>
<tr>
<td>ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, ATS12NSOUW</td>
<td>V2POWPR, V2POWPW, V2POWUR, V2POWUW</td>
<td>See ATS12NSO**, Address translation stages 1 and 2, Non-secure state only on page G4-4683</td>

<td>ATS1HR, ATS1HW</td>
<td>Not applicablea</td>
<td>See ATS1H*, Address translation stage 1, Hyp mode on page G4-4684</td>
</tr>
</tbody>
</table>

a. Instructions are part of EL2 and have no equivalent in the older descriptions.

In an implementation that does not include EL2, there is no distinction between stage 1 translations and stage 1 and 2 combined translations.

For the stage 1 current state and stages 1 and 2 Non-secure state only instructions, the meanings of the last two letters of the names are:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PR</td>
<td>PL1 mode, read operation.</td>
</tr>
<tr>
<td>PW</td>
<td>PL1 mode, write operation.</td>
</tr>
<tr>
<td>UR</td>
<td>User mode, read operation.</td>
</tr>
<tr>
<td>UW</td>
<td>User mode, write operation.</td>
</tr>
</tbody>
</table>

--- Note ---

User mode can be described as the unprivileged mode. It is the only PL0 mode.
For the stage 1 Hyp mode instructions, the last letter of the instruction name is **R** for the read operation and **W** for the write operation.

See also *Encoding and availability of the address translation instructions* on page G4-4684.

**ATS1C**, Address translation stage 1, current Security state

Any VMSAv8-32 implementation supports the ATS1C** instructions. They can be executed by any software executing at PL1 or higher, in either Security state.

The ATS1C** instructions are **ATS1CPR, ATS1CPW, ATS1CUR, and ATS1CUW** and, when ARMv8.2-ATS1E1 is implemented, **ATS1CPRP and ATS1CPWP**. These instructions perform the address translations of the PL1&0 translation regime.

In an implementation that includes EL2, when executed in Non-secure state, these instructions return the IPA that is the output address of the stage 1 translation. **Figure G4-1 on page G4-4560** shows the different translation regimes.

--- Note ---
The Non-secure PL1 and PL0 modes have no visibility of the stage 2 address translations, that can be defined only at PL2, and translate IPAs to be PAs.

---

See *Determining the PAR format* on page G4-4686 for the format used when returning the result of these instructions.

**ATS12NSO**, Address translation stages 1 and 2, Non-secure state only

A VMSAv8-32 implementation supports the ATS12NSO** instructions only if it includes EL2. In an implementation that includes EL2, in AArch32 state, they can be executed:

- By software executing in Non-secure state at EL2. This means by software executing in Hyp mode.
- If the implementation includes EL3, when EL3 is using AArch32, by software executing in Secure state at PL1.

The ATS12NSO** instructions are **ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, and ATS12NSOUW**.

In an implementation that includes EL3, when EL3 is using AArch64 and EL1 is using AArch32, any execution of an ATS12NSO** instruction at Secure EL1 is trapped as an exception that is taken to EL3.

In an implementation that does not include EL2, but includes EL3, when EL3 is using AArch32 these instructions are not **UNDEFINED** but each instruction behaves in the same way as the equivalent ATS1C** instruction.

If an implementation does not include EL2 and does not include EL3 then these instructions are **CONSTRAINED UNPREDICTABLE**, with the permitted behavior that the instructions are **UNDEFINED**, see *Unallocated System register access instructions* on page K1-6100.

ARM deprecates use of these instructions from any Secure PL1 mode other than Monitor mode.

In Secure state and in Non-secure Hyp mode these instructions perform the translations made by the Non-secure PL1&0 translation regime.

These instructions always return the PA and final attributes generated by the translation. That is, for an implementation that includes EL2, they return:

- The result of the two stages of address translation for the specified Non-secure input address.
- The memory attributes obtained by the combination of the stage 1 and stage 2 attributes.
Note

From Hyp mode, the ATS1C** and ATS12NSO** instructions both return the results of address translations that would be performed in the Non-secure modes other than Hyp mode. The difference is:

- The ATS1C** instructions return the Non-secure PL1 view of the associated address translation. That is, they return the IPA output address corresponding to the VA input address.
- The ATS12NSO** instructions return the EL2, or Hyp mode, view of the associated address translation. That is, they return the PA output address corresponding to the VA input address, generated by two stages of translation.

See Determining the PAR format on page G4-4686 for the format used when returning the result of these instructions.

ATS1H*, Address translation stage 1, Hyp mode

A VMSAv8-32 implementation supports the ATS1H* instructions only if it includes EL2. They can be executed by:

- Software executing in Non-secure state at PL2. This means by software executing in Hyp mode.
- Software executing in Secure state in Monitor mode.

The ATS1H* instructions are ATS1HR and ATS1HW. In an implementation that includes EL3, these instructions are CONSTRAINED UNPREDICTABLE if executed in a Secure PL1 mode other than Monitor mode, see Hyp mode VA to PA address translation instructions on page K1-6116.

If an implementation does not include EL2 then these instructions are CONSTRAINED UNPREDICTABLE, with the permitted behavior that the instructions are UNDEFINED, see Unallocated System register access instructions on page K1-6100.

These instructions perform the translations made by the Non-secure EL2 translation regime. The instruction takes a VA input address and returns a PA output address.

These instructions always return a result in a 64-bit format PAR.

G4.13.2 Encoding and availability of the address translation instructions

Software executing at PL0 never has any visibility of the address translation instructions, but software executing at PL1 or higher can use the unprivileged address translation instructions to find the address translations used for memory accesses by software executing at PL0 and PL1.

Note

For information about translations when the stage of address translation is disabled see The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4567.

Table G4-34 shows the encodings for the address translation instructions, and their availability in different implementations in different PE modes and states.

Table G4-34 Address translation instructions in AArch32 state

<table>
<thead>
<tr>
<th>opc1</th>
<th>CRm</th>
<th>opc2</th>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>All VMSAv8-32 implementations, in all modes, at PL1 or higher, see ATS1C**, Address translation stage 1, current Security state on page G4-4683</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The result of an instruction is always returned in the PAR. The PAR is a RW register and:

- In all implementations, the 32-bit format PAR is accessed using an MCR or MRC instruction with CRn set to c7, CRm set to c4, and opc1 and opc2 both set to 0.
- The 64-bit format PAR is accessed using an MCRR or MRRC instruction with CRm set to c7, and opc1 set to 0.

Address translation instructions that are not available in a particular implementation are reserved and CONSTRAINED UNPREDICTABLE. For example:

- In an implementation that does not include EL2, the encodings with an opc1 value of 4 are reserved and CONSTRAINED UNPREDICTABLE. These are the ATS1H* instructions.
- In an implementation that does not include either EL2 or EL3, the encodings with opc2 values of 4-7 are reserved and CONSTRAINED UNPREDICTABLE. These are the ATS12NSO** instructions.

The CONSTRAINED UNPREDICTABLE behavior of these encodings is that they are UNDEFINED, see Unallocated System register access instructions on page K1-6100.
G4.13.3 Determining the PAR format

The PAR is a 64-bit register, that supports both 32-bit and 64-bit PAR formats. This section describes how the PAR format is determined, for returning a result from each of the groups of address translation instructions. The returned result might be the translated address, or might indicate a fault on the translation, see Handling of faults and aborts during an address translation instruction.

ATS1C** instructions

Address translations for the current state. From modes other than Hyp mode:
- TTBCR.EAE determines whether the result is returned using the 32-bit or the 64-bit PAR format.
- If the implementation includes EL3, the translation performed is for the current Security state and, depending on that state:
  - The Secure or Non-secure TTBCR.EAE determines the PAR format.
  - The result is returned to the Secure or Non-secure instance of the PAR

Instructions executed in Hyp mode always return a result to the Non-secure PAR, using the 64-bit format.

ATS12NSO** instructions

Address translations for the Non-secure PL1 and PL0 modes. These instructions return a result using the 64-bit PAR format if at least one of the following is true:
- The Non-secure TTBCR.EAE bit is set to 1.
- The implementation includes EL2, and the value of HCR.VM is 1.

Otherwise, the instruction returns a result using the 32-bit PAR format.

Instructions executed in a Secure PL1 mode return a result to the Secure PAR. Instructions executed in Hyp mode return a result to the Non-secure PAR.

ATS1H* instructions

Address translations from Hyp mode. These instructions always return a result using the 64-bit PAR format.

Instructions executed in Secure Monitor mode return a result to the Secure PAR. Instructions executed in Non-secure Hyp mode return a result to the Non-secure PAR.

G4.13.4 Handling of faults and aborts during an address translation instruction

When a stage of address translation is enabled, any corresponding address translation instruction requires a translation table lookup, and this might require a translation table walk. However, the input address for the translation might be a faulting address, either because:
- The translation table entries used for the translation indicate a fault.
- A stage 2 fault or an external abort occurs on the required translation table walk.

VMSAv8-32 memory aborts on page G4-4649 describes the faults that might occur on a translation table walk in AArch32 state.

How the fault is handled, and whether it generates an exception, depends on the cause of the fault, as described in:
- MMU fault on an address translation instruction.
- External abort during an address translation instruction on page G4-4687.
- Stage 2 fault on a current state address translation instruction on page G4-4688.

MMU fault on an address translation instruction

In the following cases, an MMU fault on an address translation is reported in the PAR, and no abort is taken. This rule applies:
- To a faulting address translation instruction executed in Hyp mode, or in a Secure PL1 mode.
• To a faulting address translation instruction executed in a Non-secure PL1 mode, for cases where the fault would generate a stage 1 abort if it occurred on the equivalent load or store operation.

Using the PAR to report a fault on an address translation instruction gives more information about how these faults are reported.

——— Note ————

• The Domain fault encodings shown in Table G4-26 on page G4-4670 are used only for reporting a fault on an address translation instruction that uses the 64-bit PAR format. That is, they are used only in an implementation that includes EL2, and are used for reporting a Domain fault on either:
  — An ATS1C** instruction executed in Hyp mode.
  — An ATS12NSO** instruction executed when the value of HCR.VM is 1.

These encodings are never used for fault reporting in the DFSR, IFSR, or HSR.

• For an address translation instruction executed in a Non-secure PL1 mode, for a fault that would generate a stage 2 abort if it occurred on the equivalent load or store operation, the stage 2 abort is generated as described in Stage 2 fault on a current state address translation instruction on page G4-4688.

Using the PAR to report a fault on an address translation instruction

For a fault on an address translation instruction for which no abort is taken, the PAR is updated with the following information, to indicate the fault:

• The fault code, that would normally be written to the Fault status register. The code used depends on the current translation table format, as described in either:
  — PL1 fault reporting with the Short-descriptor translation table format on page G4-4668.
  — PL1 fault reporting with the Long-descriptor translation table format on page G4-4670.

See also the Note at the start of Determining the PAR format on page G4-4686 about the Domain fault encodings shown in Table G4-26 on page G4-4670.

• A status bit, that indicates that the translation operation failed.

The fault does not update any Fault Address Register.

External abort during an address translation instruction

As stated in External abort on a translation table walk on page G4-4659, an external abort on a translation table walk generates a Data Abort exception. The abort can be synchronous or asynchronous, and behaves as follows:

Synchronous external abort on a translation table walk

The fault status and fault address registers of the Security state to which the abort is taken are updated. The fault status register indicates the appropriate external abort on a Translation fault, and the fault address register indicates the input address for the translation.

The PAR is UNKNOWN.

Asynchronous external abort on a translation table walk

The fault status register of the Security state to which the abort is taken is updated, to indicate the asynchronous external abort. No fault address registers are updated.

The PAR is UNKNOWN.
Stage 2 fault on a current state address translation instruction

If the PE is in a Non-secure PL1 mode and executes one of the ATS1C** instructions, then a fault in the stage 2 translation of an address accessed in a stage 1 translation table lookup generates an exception. This is equivalent to the case described in *Stage 2 fault on a stage 1 translation table walk* on page G4-4656. When this fault occurs on an ATS1C** address translation instruction:

- A Hyp Trap exception is taken to Hyp mode.
- The PAR is UNKNOWN.
- The HSR indicates that:
  - The fault occurred on a translation table walk.
  - The operation that faulted was a cache maintenance instruction.
- The HPFAR holds the IPA that faulted.
- The HDFAR holds the VA that the executing software supplied to the address translation instruction.
G4.14 About the System registers for VMSAv8-32

The System registers and System instructions that are accessible in AArch32 state are almost all in the encoding space described in The AArch32 System register interface on page G1-4408. This section gives general information about these registers, which comprise:

- Registers in the (coproc==0b1111) encoding space, that provide control and status information for the PE in Non-debug state.
- Registers in the (coproc==0b1110) encoding space, including:
  - Debug registers.
  - Trace registers.
  - Legacy execution environment registers.

VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space on page G4-4704 summarizes the registers in the (coproc==0b1110) encoding space, and indicates where these registers are described, either in this manual or in other architecture specifications.

VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G4-4707 summarizes the registers in the (coproc==0b1111) encoding space, and indicates where in this manual these registers are described.

This section gives general information about the AArch32 System registers, and the conventions used in describing these registers.

Note

Many implementations include other interfaces to some System registers, for example a memory-mapped interface to some debug System registers. These are described in the appropriate sections of this manual.

This section is organized as follows:

- About AArch32 System register accesses.
- Classification of System registers on page G4-4692.
- Synchronization of changes to AArch32 System registers on page G6-4768.
- Fixed values in register diagrams on page G4-4701.
- Principles of the ID scheme for fields in ID registers on page G4-4701.

G4.14.1 About AArch32 System register accesses

The following subsections give more information about accesses to the AArch32 System registers:

- Ordering of reads of System registers.
- Accessing 32-bit System registers on page G4-4690.
- Accessing 64-bit System registers on page G4-4691.

Ordering of reads of System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

- Any data dependencies between the instructions, as specified in Synchronization of changes to AArch32 System registers on page G6-4768, including read-after-read dependencies, are respected.
- The reads to the register do not occur earlier than the most recent Context synchronization event to its architectural position in the instruction stream.

Note

In particular, the values read from System registers that hold self-incrementing counts, such as the Performance Monitors counters or the Generic Timer counter or timers, could be accessed from any time after the previous Context synchronization event. For example, where a memory access is used to communicate a read of such counts.
counters, an ISB must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the write being completed, and the read of the Generic Timer counter, if it is necessary that the Generic Timer counter returns a count value after the memory communication.

Accessing 32-bit System registers

Software accesses most 32-bit System registers using the generic MCR and MRC System register access instructions, specifying some or all of the parameters \{coproc, CRn, opc1, CRm, opc2\}, where:

- **coproc** Identifies the primary region of the System register encoding space. Takes one of the values:
  - p14 Encoded as 0b1110.
  - p15 Encoded as 0b1111.
- **CRn** Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111.
  - In the \(coproc==0b1110\) encoding space, the opc1 value identifies the System register functional group, and CRn is the most significant identifier for the required register within that group.
  - In the \(coproc==0b1111\) encoding space, CRn is the most significant identifier for the required register.
- **opc1** Takes a value in the range 0-7, encoded as its 3-bit binary value.
  - In the \(coproc==0b1110\) encoding space, the opc1 value identifies the System register functional group, and can take the following values:
    - 0 Debug System registers.
    - 1 Trace System registers.
    - 7 Legacy Jazelle System registers.
  - In the \(coproc==0b1111\) encoding space, opc1 can take any value in the range 0-7.
- **CRm** Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111.
- **opc2** Takes a value in the range 0-7, encoded as its 3-bit binary value.
  - opc2 is optional in the MCR and MRC instruction syntax, and if no value is specified the encoding defaults to 0b000.
- **Rt** A general-purpose register to hold a 32-bit value to transfer to or from the System register. Takes a value in the range R0-R14, encoded as the corresponding 4-bit binary value, 0b0000-0b1110.

This means an MCR or MRC access to a specific 32-bit System register uses:
- A unique combination of coproc, CRn, opc1, CRm, and opc2, to specify the required System register.
- A general-purpose register, Rt, for the transferred 32-bit value.

See also:
- **MCR** on page F5-3249.
- **MRC** on page F5-3271.

A small number of AArch32 debug System registers are accessed using LDC or STC instructions. In these cases, the register to be accessed is identified in the instruction syntax by the use of p14, c5 where:

- **p14** Identifies that the access is to the \(coproc==0b1110\) encoding space.
- **c5** Identifies the target debug System register.

See the instruction descriptions:
- **LDC (immediate)** on page F5-3140.
- **LDC (literal)** on page F5-3142.
- **STC** on page F5-3478.

The only uses of LDC and STC permitted in ARMv8-A are:
- An LDC access to load data from memory to DBGDTRTXint, see **LDC (immediate)** on page F5-3140 and **LDC (literal)** on page F5-3142.
- An STC access to store data to memory from DBGDTRRXint, see **STC** on page F5-3478.
A small number of AArch32 System registers are accessed using MRS, MSR, VMRS, or VMSR instructions, see the appropriate register and instruction description for more information, see:

- **MRS** on page F5-3275.
- **MSR (immediate)** on page F5-3285.
- **MSR (register)** on page F5-3287.
- **VMRS** on page F6-4017.
- **VMSR** on page F6-4020.

---

**Note**

- For example:
  - The APSR, CPSR, and SPSR are accessed using MRS or MSR instructions.
  - The MVFR0, MVFR1, and MVFR2 are accessed using VMRS or VMSR instructions.

- In addition, the banked register forms of the MRS and MSR instructions can be used to access some System registers that are associated with PE modes other than the mode in which the PE is currently executing, see **MRS (Banked register)** on page F5-3277 and **MSR (Banked register)** on page F5-3281.

---

**Accessing 64-bit System registers**

Software accesses a 64-bit System register using the generic **MCRR** and **MRRC** System register access instructions, specifying the parameters `{coproc, Crm, opc1}`, where:

- **coproc** Identifies the primary region of the System register encoding space. Takes one of the values:
  - p14 Encoded as 0b1110.
  - p15 Encoded as 0b1111.

- **Crm** Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111.
  - In the (`coproc==0b1110`) encoding space, the opc1 value identifies the System register functional group, and Crm is the most significant identifier for the required register within that group.
  - In the (`coproc==0b1111`) encoding space, Crm is the most significant identifier for the required register.

- **opc1** Takes a value in the range 0-15, encoded as its 3-bit binary value.
  - In the (`coproc==0b1110`) encoding space, the opc1 value identifies the System register functional group, and can take the following values:
    - 0 Debug System registers.
    - 1 Trace System registers.
  - In the (`coproc==0b1111`) encoding space, opc1 can take any value in the range 0-15.

- **Rt** A general-purpose register to hold bits[31:0] of the value to transfer to or from the System register.
  - Takes a value in the range R0-R14, encoded as the corresponding 4-bit binary value, 0b0000-0b1110.

- **Rt2** A general-purpose register to hold bits[63:32] of the value to transfer to or from the System register.
  - Takes a value in the range R0-R14, encoded as the corresponding 4-bit binary value, 0b0000-0b1110.

This means an **MCRR** or **MRRC** access to a specific 64-bit System register uses:

- A unique combination of coproc, Crm and opc1, to specify the required 64-bit System register.
- Two general-purpose registers, each holding 32 bits of the value to transfer.

This means a PE can access a 64-bit System register using:

- An **MCRR** instruction to write to a System register, see **MCRR** on page F5-3251.
- An **MRRC** instruction to read a System register, see **MCRR** on page F5-3251.

When using an **MCRR** or **MRRC** instruction the System register access is 64-bit atomic.

Some 64-bit registers also have an **MCR** and **MRC** encoding. The **MCR** and **MRC** encodings for these registers access the least significant 32 bits of the register. For example, to access the **PAR**, software can:

- Use the following instructions to access all 64 bits of the register:
  ```assembly
  MRRC p15, 0, <Rt>, <Rt2>, c7 ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)
  MCRR p15, 0, <Rt>, <Rt2>, c7 ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR
  ```
• Use the following instructions to access the least significant 32 bits of the register:
  MRC p15, 0, <Rt>, c7, c4, 0 ; Read PAR[31:0] into Rt
  MCR p15, 0, <Rt>, c7, c4, 0 ; Write Rt to PAR[31:0]

G4.14.2 Classification of System registers

Features provided by EL3 and EL2 integrate with many features of the architecture. Therefore, the descriptions of the individual System registers include information about how these Exception levels affect the register. This section:
• Summarizes how EL3 and EL2 affect the implementation of the System registers, and the classification of those registers.
• Summarizes how EL3 controls access to the System registers.
• Describes an EL3 signal that can control access to some registers in the (coproc==0b1111) encoding space.

It contains the following subsections:
• Banked System registers.
• Restricted access System registers on page G4-4694.
• Configurable access System registers on page G4-4694.
• EL2-mode System registers on page G4-4695.
• Common System registers on page G4-4698.
• The CP15SDISABLE input signal on page G4-4699.
• Access to registers from Monitor mode on page G4-4700.

Note
EL3 defines the register classifications of Banked, Restricted access, Configurable, and Common. EL2 defines the EL2-mode classification.

It is IMPLEMENTATION DEFINED whether each IMPLEMENTATION DEFINED register is Banked, Restricted access, Configurable, EL2-mode, or Common.

Banked System registers

In an implementation that includes EL3 using AArch32, some System registers are Banked. Banked System registers have two copies, one Secure and one Non-secure. The SCR.NS bit selects the Secure or Non-secure instance of the register. Table G4-35 shows which registers in the (coproc==0b1111) encoding space are Banked in this way, and the permitted access to each register. No registers in the (coproc==0b1110) encoding space are Banked.

<table>
<thead>
<tr>
<th>Banked register</th>
<th>Permitted accesses</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
A Banked System register can contain a mixture of:

- Fields that are Banked.
- Fields that are read-only in Non-secure PL1 or PL2 modes but read/write in the Secure state.

The System Control Register `SCTLR` is an example of a register that contains this mixture of fields.

The Secure copies of the Banked System registers are sometimes referred to as the Secure Banked System registers. The Non-secure copies of the Banked System registers are sometimes referred to as the Non-secure Banked System registers.
Restricted access System registers

In an implementation that includes EL3, some System registers are present only in Secure state. These are called *Restricted access* registers, and their read/write access permissions are:

- In Non-secure state, software cannot modify Restricted access registers.
- For the NSACR, in Non-secure state:
  - Software running at PL1 or higher can read the register.
  - Unprivileged software, meaning software running at PL0, cannot read the register.

  This means that Non-secure software running at PL1 or higher can read the access permissions for System registers that have Configurable access.

  If EL3 is using AArch64 then any read of the NSACR from Non-secure EL2 using AArch32, or Non-secure EL1 using AArch32, returns the value **0x00000C00**.

  - For all other Restricted access registers, Non-secure software cannot read the register.

In an implementation that does not include EL3:

- **SDER** is implemented only in Secure state.
- Any read of the NSACR returns the value **0x00000C00**.
- All other accesses to Restricted access System registers are UNDEFINED.

Table G4-36 shows the Restricted access System registers in the (*coproc == 0b1111*) encoding space. There are no Restricted access registers in the (*coproc == 0b1110*) encoding space.

</tbody>
</table>

- Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

Configurable access System registers

Secure software can configure the access to some System registers. These registers are called Configurable access registers, and the control can be:

- A bit in the control register determines whether the register is:
  - Accessible from Secure state only.
  - Accessible from both Secure and Non-secure states.

- A bit in the control register changes the accessibility of a register bit or field. For example, setting a bit in the control register might mean that a RW field behaves as RAZ/WI when accessed from Non-secure state.

Bits in the NSACR control access.

In an AArch32 implementation that includes EL3:

- There are no Configurable access System registers in the (*coproc == 0b1110*) encoding space.
- The only required Configurable access register in the (*coproc == 0b1111*) encoding space is the CPACR.
- The following Advanced SIMD and floating point System registers are Configurable access:
  - Floating-point Status and Control Register, FPSCR
EL2-mode System registers

In an implementation that includes EL2, if EL2 can use AArch32, the implementation provides a number of registers for use in the EL2 mode, Hyp mode. As with other System register encodings, some of these register encodings provide write-only operations. When the implementation includes EL3 and EL3 is using AArch32, these registers are also accessible from Monitor mode when the value of SCR.NS is 1.

The following subsections describe the EL2-mode registers:

• Hyp mode read/write registers in the (coproc==0b1111) encoding space.
• Hyp mode encodings for shared (coproc==0b1111) System registers on page G4-4696.
• Hyp mode (coproc==0b1111) write-only System instructions on page G4-4697.

There are no EL2-mode registers in the (coproc==0b1110) encoding space.

Hyp mode read/write registers in the (coproc==0b1111) encoding space

These registers are implemented only in Non-secure state, and in Non-secure state they are accessible only from Hyp mode.

Except for accesses to CNTVOFF in an implementation that includes EL3 but not EL2, the behavior of accesses to these registers is as follows:

• In Secure state, the registers can be accessed from EL3 when SCR.NS is set to 1, see Access to registers from Monitor mode on page G4-4700.

• The following accesses are UNDEFINED:
  — Accesses from Non-secure PL1 modes.
  — Accesses in Secure state when SCR.NS is set to 0.

In an implementation that includes EL3 but not EL2, the behavior of accesses to CNTVOFF is as follows:

• Any access from Secure Monitor mode is CONSTRAINED UNPREDICTABLE, regardless of the value of SCR.NS. The CONSTRAINED UNPREDICTABLE behavior is that the access is UNDEFINED, see Unallocated System register access instructions on page K1-6100.

• All other accesses are UNDEFINED.

Note

Except for CNTVOFF, the Hyp mode registers are part of EL2, meaning they are implemented only if the implementation includes EL2. However, conceptually, CNTVOFF is part of any implementation of the Generic Timer, see Status of the CNTVOFF register on page G5-4757. This means the behavior of CNTVOFF in an implementation that does not include EL2 is not covered by the general definition of the behavior of the Hyp mode (coproc==0b1111) read/write registers.
Table G4-37 shows the Hyp mode read/write System registers, in the (coproc==0b1111) encoding space:

</table>

ᵃ. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
ᵇ. Implemented in any implementation of the Generic Timer. See, also, the Note earlier in this section.

**Hyp mode encodings for shared (coproc==0b1111) System registers**

Some Hyp mode registers share the Secure instance of an existing Banked register. In this case the implementation includes an encoding for the register that is accessible only in Hyp mode, or in Monitor mode when SCR.NS is set to 1.
For these registers, the following accesses are UNDEFINED:
• Accesses from Non-secure PL1 modes.
• Accesses in Secure state when SCR.NS is set to 0.

Table G4-38 lists the Hyp mode encodings for shared registers.

<table>
<thead>
<tr>
<th>Register</th>
<th>Permitted accesses°</th>
<th>Shared register</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDFAR</td>
<td>Read/write. Accessible from Hyp mode, or from Monitor mode when SCR.NS is set to 1.</td>
<td>Secure DFAR</td>
</tr>
<tr>
<td>HIFAR</td>
<td>Read/write. Accessible from Hyp mode, or from Monitor mode when SCR.NS is set to 1.</td>
<td>Secure IFAR</td>
</tr>
</tbody>
</table>

° Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

In Monitor mode, the Secure copies of these registers can be accessed either:
• Using the DFAR or IFAR encoding with SCR.NS set to 0.
• Using the HDFAR or HIFAR encoding with SCR.NS set to 1.

However, between accessing a register using one alias and accessing the register using the other alias, a Context synchronization event is required to ensure the ordering of the accesses.

**Hyp mode (coproc==0b1111) write-only System instructions**

Architecturally, these encodings are an extension of the Banked register encodings described in Banked System registers on page G4-4692, where:
• The implementation does not implement the operation in Secure state.
• In Non-secure state, the operation is accessible only at EL2, that is, only from Hyp mode.

In Secure state:
• These instructions can be accessed from Monitor mode regardless of the value of SCR.NS, see Access to registers from Monitor mode on page G4-4700.
• Accesses to these instructions are CONSTRAINED UNPREDICTABLE if executed in a Secure mode other than Monitor mode, see Hyp mode TLB maintenance instructions on page K1-6116 and Hyp mode VA to PA address translation instructions on page K1-6116.

Accesses to these instructions are UNDEFINED if accessed from a Non-secure PL1 mode.

Table G4-39 shows the EL2-mode write-only instructions in the (coproc==0b1111) encoding space:

</table>
Common System registers

Some System registers and operations are common to the Secure and Non-secure Security states. These are described as the Common access registers, or simply as the Common registers. These registers include:

- Read-only registers that hold configuration information.
- Register encodings used for various memory system operations, rather than to access registers.
- The ISR.
- All System registers in the (coproc==0b1110) encoding space.

Table G4-40 shows the Common System registers in the (coproc==0b1111) encoding space. These registers are not affected by whether EL3 is implemented.

^a. This section describes the behavior of write accesses that are not permitted. See also Read-only and write-only register encodings on page G6-4766.

Table G4-40 Common (coproc==0b1111) System registers
Secure System registers for the (coproc==0b1111) encoding space

The Secure System registers in the (coproc==0b1111) encoding space comprise:

- The Secure copies of the Banked System registers in the (coproc==0b1111) encoding space.
- The Restricted access System registers in the (coproc==0b1111) encoding space.
- The Configurable access System registers in the (coproc==0b1111) encoding space that are configured to be accessible only from Secure state.

In an implementation that includes EL3, the Non-secure System registers are the System registers other than the Secure System registers.

The CP15SDISABLE input signal

When EL3 is using AArch32, it provides an input signal, CP15SDISABLE, that disables write access to some of the Secure registers when asserted HIGH. The CP15SDISABLE signal has no effect on:

- Register accesses from AArch64 state.
- Register accesses from Secure EL1 when EL3 is using AArch64 and EL1 is using AArch32.

Note

When EL3 is using AArch32, the interaction between CP15SDISABLE and any IMPLEMENTATION DEFINED register is IMPLEMENTATION DEFINED.

Table G4-41 shows the registers and operations affected.

</tr>
</tbody>
</table>
On a reset by the external system that resets the PE into EL3 using AArch32, the CP15SDISABLE input signal must be taken LOW. This permits the Reset code to set up the configuration of EL3 features. When the input is asserted HIGH, any attempt to write to the Secure registers shown in Table G4-41 on page G4-4699 results in an Undefined Instruction exception.

The CP15SDISABLE input does not affect reading Secure registers, or reading or writing Non-secure registers. It is IMPLEMENTATION DEFINED how the input is changed and when changes to this input are reflected in the PE, and an implementation might not provide any mechanism for driving the CP15SDISABLE input HIGH. However, in an implementation in which the CP15SDISABLE input can be driven HIGH, changes in the state of CP15SDISABLE must be reflected as quickly as possible. Any change must occur before completion of an Instruction Synchronization Barrier operation, issued after the change, is visible to the PE with respect to instruction execution boundaries. Software must perform an Instruction Synchronization Barrier operation meeting the above conditions to ensure all subsequent instructions are affected by the change to CP15SDISABLE.

When EL3 is using AArch32, use of CP15SDISABLE means key Secure features that are accessible only at PL1 can be locked in a known state. This provides an additional level of overall system security. ARM expects control of CP15SDISABLE to reside in the system, in a block dedicated to security.

Access to registers from Monitor mode

When the PE is in Monitor mode, the PE is in Secure state regardless of the value of the SCR.NS bit. In Monitor mode, the SCR.NS bit determines whether, for System registers in the (coproc==0b1111) encoding space, valid uses of the MRC, MCR, MRRC and MCRR instructions access the Secure Banked System registers or the Non-secure Banked System registers. That is, when:

NS == 0  Common, Restricted access, and Secure Banked System registers are accessed by MRC, MCR, MRRC and MCRR instructions that target the (coproc==0b1111) encoding space.

If the implementation includes EL2, the registers listed in Hyp mode read/write registers in the (coproc==0b1111) encoding space on page G4-4695 and Hyp mode encodings for shared (coproc==0b1111) System registers on page G4-4696 are not accessible, and any attempt to access them generates an Undefined Instruction exception.

—- Note —-

The operations listed in Hyp mode (coproc==0b1111) write-only System instructions on page G4-4697 are accessible in Monitor mode regardless of the value of SCR.NS.

System instructions in the (coproc==0b1111) encoding space use the Security state to determine all resources used, that is, all operations performed by these instructions are performed in Secure state.

NS == 1  Common, Restricted access and Non-secure Banked System registers are accessed by MRC, MCR, MRRC and MCRR instructions that target the (coproc==0b1111) encoding space.

If the implementation includes EL2, all the registers and operations listed in the subsections of EL2-mode System registers on page G4-4695 are accessible, using the MRC, MCR, MRRC, or MCRR instructions required to access them from Hyp mode.

System instructions in the (coproc==0b1111) encoding space use the Security state to determine all resources used, that is, all operations by these instructions are performed in Secure state.

The Security state determines whether the Secure or Non-secure Banked registers determine the control state.

—- Note —-

Where the contents of a register select the value accessed by an MRC or MCR access to a different register, then the register that is used for selection is being used as control state. For example, CSSELR selects the current CCSIDR, and therefore CSSELR is used as control state. Therefore, in Monitor mode:

- SCR.NS determines whether the Secure or Non-secure CSSELR is accessible.
- Because the PE is in Secure state, the Secure CSSELR selects the current CCSIDR.
G4.14.3 Fixed values in register diagrams

In register diagrams, a fixed bit can be indicated by one of 0, (0), 1, or (1), with the following meanings:

0
   In any implementation:
   • The bit must read as 0.
   • Writes to the bit must be ignored.
   • Software:
     — Can rely on the bit reading as 0.
     — Must use an SBZP policy to write to the bit.

(0)
   The bit should-be-zero. In AArch32 state there are a small number of cases where a bit is (0) in some contexts, and has a different defined behavior in other contexts. See RES0.

1
   In any implementation:
   • The bit must read as 1.
   • Writes to the bit must be ignored.
   • Software:
     — Can rely on the bit reading as 1.
     — Must use an SBOP policy to write to the bit.

(1)
   The bit is should-be-one. In AArch32 state there are a small number of cases where a bit is (1) in some contexts, and has a different defined behavior in other contexts. See RES1.

Note
In register diagrams, (0) is a synonym for RES0, and (1) is a synonym for RES1, where RES0 and RES1 are defined in the Glossary. However, when used in an instruction encoding diagram, (0) and (1) have the narrower definition that behavior is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE if either:
• A bit marked as (0) has the value 1.
• A bit marked as (1) has the value 0.

G4.14.4 Principles of the ID scheme for fields in ID registers

The ARM architecture specifies a number of ID registers that are characterized as comprising a set of 4-bit ID fields. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. AArch32 ID registers to which this scheme applies on page G4-4702 identifies the set of ID registers that are accessible from AArch32 state.

Note
These fields are distinct from register fields that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors, or the amount of memory.

Note
The presence of an ID register field for a feature does not imply that the feature is optional.

To provide forward compatibility, software can rely on the features of these fields that are described in this section.

The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, if a value of 0x1 indicates the presence of some instructions, then the value 0x2 will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```c
if (value >= number) {
    // do something that relies on the value of the feature
}
```
For ID fields where the value \(0x0\) defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value \(0xF\) indicates that the feature is not implemented.
- The field value \(0x0\) indicates that the feature is implemented.
- Software that depends on the feature can use the test:
  ```c
  if value >= 0 {
    // Software features that depend on the presence of the hardware feature
  }
  ```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a fractional field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. Example G4-6 shows the use of such a field.

**Example G4-6 Example of the use of a fractional field**

For a field describing some class of functionality:

- The value \(0x1\) was defined as indicating that item A is present.
- The value \(0x2\) was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value \(0x1\) when A and B only are present. This fractional field is valid only when the original ID field has the value \(0x1\).

This approach means that:

- Software that depends on the test if \((value >= 0x2)\) can rely on features A, B, and C being present,
- Software that depends on the test if \((value >= 0x1)\) can rely on feature A being present.
- If new software needs to check only that features A and B are present then it can test:
  ```c
  if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {
    // Software features that depend on A and B only
  }
  ```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

**AArch32 ID registers to which this scheme applies**

This scheme applies to the following AArch32 system registers:

- The Auxiliary Feature register ID_AFR0.
- The Processor Feature registers ID_PFR0 and ID_PFR1.
- The Debug Feature register ID_DFR0.
- The Memory Model Feature registers ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4.
• The Instruction Set Attribute registers ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

• The Media and VFP Feature registers MVFR0, MVFR1, and MVFR2.

**Note**

*Principles of the ID scheme for fields in ID registers on page D7-2195* includes information about the AArch64 System registers and the memory-mapped registers to which this scheme applies.
G4.15  **VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space**

The System registers in the (coproc==0b1110) encoding space provide a number of distinct control functions, covering:

- Debug.
- Trace.
- Execution environment control, for identification of the trivial Jazelle implementation.

Because these functions are distinct, the descriptions of these registers are distributed, as follows:

- In this manual *[Debug registers on page G6-5239]* describes the Debug registers.
- The *Embedded Trace Macrocell Architecture Specification* describes the Trace registers.

This section summarizes the allocation of the System registers in the (coproc==0b1110) encoding space between these different functions, and the register encodings in this space that are reserved.

The 32-bit System register encodings are classified by the \{opc1, CRn, opc2, CRm\} values required to access them using an MCR or an MRC instruction. The 64-bit System register encodings are classified by the \{opc1, CRm\} values required to access them using an MCRR or an MRRC instruction. For the registers in the (coproc==0b1110) encoding space, the opc1 value determines the primary allocation of these registers, as follows:

- **opc1==0**  Debug registers.
- **opc1==1**  Trace registers.
- **opc1==7**  Jazelle registers. Jazelle registers are implemented as required for a trivial Jazelle implementation.

**Other opc1 values**

Reserved.

--- **Note** ---

Primary allocation of (coproc==0b1110) register function by opc1 value differs from the allocation of (coproc==0b1111) registers, where primary allocation is by CRn value for 32-bit register accesses, or CRm value for 64-bit register accesses.

---

For the Debug and Jazelle registers, *[Table G4-42 on page G4-4705]* defines:

- The \{opc1, CRn, opc2, CRm\} values used for accessing the 32-bit registers using the MRC and MCR instructions.
- The \{opc1, CRm\} values used for accessing the 64-bit register using the MRRC instruction.

Some Debug registers can also be accessed using the LDC and STC instructions. *[Table G4-43 on page G4-4706]* defines the CRn values used for accessing the registers using these instructions.

--- **Note** ---

The only permitted uses of the LDC and STC instructions are:

- An LDC access to load data from memory to DBGDTRTXint.
- An STC access to store data to memory from DBGDTRRXint.

In the LDC and STC syntax descriptions in this Manual, the required coproc value of p14 and CRn value of c5 are given explicitly.
G4.15.1 Register access instruction arguments, (coproc==0b1110) registers

Table G4-42 shows the MCR, MRC, and MRRC instruction arguments required for accesses to each register that can be visible in the System register interface in the (coproc==0b1110) encoding.

G4.16 VMSAv8-32 organization of registers in the \((\text{coproc}=\text{0b1111})\) encoding space

For 32-bit accesses to the System registers in the \((\text{coproc}=\text{0b1111})\) encoding space, the ordered set of parameters \{\(\text{CRn}, \text{opc1}, \text{CRm}, \text{opc2}\)\} determine the register order. Within this ordering, the \(\text{CRn}\) value originally provided a functional grouping of these registers. As the number of System registers has increased this ordering has become less appropriate.

This document now:

- Groups the ARMv8.0 System registers in the \((\text{coproc}=\text{0b1111})\) encoding space by functional group, see Functional grouping of VMSAv8-32 System registers on page G4-4726.
- Describes all of the ARMv8.0 System registers for VMSAv8-32, in Chapter G6 AArch32 System Register Descriptions.
- Gives additional information about the organization of the VMSAv8-32 System registers in the \((\text{coproc}=\text{0b1111})\) encoding space, in the remainder of this section.

_____ Note _____

Not all System registers introduced by architectural extensions to ARMv8.0 are described in Chapter G6 AArch32 System Register Descriptions. For information about the System registers introduced by architectural extensions to ARMv8.0, see ARMv8 architecture extensions on page A1-55.

This section presents information as follows:

Register ordering by \{\(\text{CRn}, \text{opc1, CRm, opc2}\)\}

See:

- System register summary for \((\text{coproc}=\text{0b1111})\) encodings by \(\text{CRn}\) value on page G4-4708.
- Full list of VMSAv8-32 System registers in the \((\text{coproc}=\text{0b1111})\) encoding space on page G4-4710.

_____ Note _____

The ordered listing of \((\text{coproc}=\text{0b1111})\) registers by the \{\(\text{CRn, opc1, CRm, opc2}\)\} encoding of the 32-bit registers is most likely to be useful to those implementing AArch32 state, and to those validating such implementations. However, otherwise, the grouping of registers by function is more logical.

_____ Note _____

The different register views are particularly significant in implementations that include EL2.

Views of the registers, that depend on the current state of the PE

See AArch32 views of the System registers in the \((\text{coproc}=\text{0b1111})\) encoding space on page G4-4723.

In addition, the indexes in Appendix K11 Registers Index include all of the System registers.
G4.16.1 System register summary for (coproc==0b1111) encodings by CRn value

Figure G4-19 summarizes the grouping of the System registers in the (coproc==0b1111) encoding space, for a VMSAv8-32 implementation, by the value of CRn used for a 32-bit access to the register.

Note

Figures G4-19 gives only an overview of the assigned encodings for 32-bit registers for each of the CRn values c0-c15. For more information, see:

- The full list of registers in the (coproc==0b1111) encoding space, in Full list of VMSAv8-32 System registers in the (coproc==0b1111) encoding space on page G4-4710, for the definition of the assigned and unassigned encodings for that register.
- The register definitions in Chapter G6 AArch32 System Register Descriptions for any dependencies on the implemented Exception levels.

In general, System register accesses using an unallocated set of \{CRn, opc1, CRm, opc2\} values are UNDEFINED.

Behavior of VMSAv8-32 32-bit System registers with (coproc==0b1111, CRn==c0) on page G4-4709 described the only exceptions to this rule.

The 32-bit System registers with (coproc==0b1111, CRn==c15), and the corresponding 64-bit System registers, are reserved for implementation defined registers. For more information see Reserved encodings in the VMSAv8-32 System register (coproc == 0b1111) space on page G4-4709.

The HSTR.Tn trap on (coproc==0b1111) System registers

As General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space on page G1-4440 describes, when the value of HSTR.Tn is 1, Non-secure PL1 accesses to System registers in the (coproc==0b1111) encoding space using a CRn or CRm value that corresponds to the value of Tn are trapped to PL2, even if the encoding is UNDEFINED when the value of HSTR.Tn is 0. This rule applies:

- For 32 bit register accesses when the value of Rn in the MCR or MRC instruction corresponds to Tn.
- For 64 bit register accesses when the value of Rn in the MCRR or MRRC instruction corresponds to Tn.

If there are matching System register encodings that are accessible from Non-secure PL0 then those accesses are also trapped to PL2 when the value of HSTR.Tn is 1.
Behavior of VMSAv8-32 32-bit System registers with \((\text{coproc}=0b1111, \text{CRn}=c0)\)

In the \((\text{coproc}=0b1111)\) encoding space, the 32-bit System registers with \((\text{CRn}=c0)\) provide device and feature identification. That is, they provide registers in the functional group described in Identification registers, functional group on page G4-4727.

Table G4-44 on page G4-4711 shows all of the architecturally required System registers with \({\text{coproc}=0b1111, \text{CRn}=c0}\). The behavior of 32-bit System register encodings in this group that are not shown in the table, and encodings that are part of an unimplemented Exception level, depends on the value of \(\text{opc1}\), and possibly on the value of \(\text{CRm}\) and \(\text{opc2}\), as follows:

- \(\text{opc1} = 0\)
  - All write accesses to the encodings are UNDEFINED.
  - For read accesses:
    - The following encodings return an UNKNOWN value:
      - \(\text{CRm}=3, \text{opc2}={0, 1, 2}\).
      - \(\text{CRm}={4, 6, 7}, \text{opc2}={0, 1}\).
      - \(\text{CRm}=5, \text{opc2}={0, 1, 4, 5}\).
    - All other encodings are RES0.
- \(\text{opc1} > 0\)
  - All accesses to the encodings are UNDEFINED.

See also Accesses to unallocated encodings in the \((\text{coproc}=0b111x)\) encoding space on page G6-4765.

---

**Note**

Some of these registers were previously described as being part of the CPUID identification scheme, see The CPUID identification scheme on page G4-4728.

---

**Reserved encodings in the VMSAv8-32 System register \((\text{coproc}=0b1111)\) space**

AArch32 state reserves a number of regions in the \((\text{coproc}=0b1111)\) encoding space for IMPLEMENTATION DEFINED System registers. These reservations are defined in terms of the encoding of 32-bit accesses to the System register encoding space. That is, they are defined by the reserved 32-bit \({\text{CRn}, \text{opc1}, \text{CRn}, \text{opc2}}\) encodings.

In ARMv8, reserved encodings that do not have an IMPLEMENTATION DEFINED function are UNDEFINED.

The following subsections give more information about these reserved encodings:

- **Reserved 32-bit encodings with \({\text{coproc}=0b1111, \text{CRn}=c9}\).**
- **Reserved 32-bit encodings with \({\text{coproc}=0b1111, \text{CRn}=c10}\) on page G4-4710.
- **Reserved 32-bit encodings with \({\text{coproc}=0b1111, \text{CRn}=c11}\) on page G4-4710.
- **Reserved 32-bit encodings with \({\text{coproc}=0b1111, \text{CRn}=c15}\) on page G4-4710.

**Reserved 32-bit encodings with \({\text{coproc}=0b1111, \text{CRn}=c9}\)**

In the AArch32 encoding space, for 32-bit encodings with \({\text{coproc}=0b1111, \text{CRn}=c9}\), the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with \({\text{coproc}=0b1111, \text{CRn}=c9, \text{opc}={0-7}, \text{CRm}={c0-c2, c5-c8}}\) are reserved for IMPLEMENTATION DEFINED branch predictor, cache, and TCM operations.
- Encodings with \({\text{coproc}=0b1111, \text{CRn}=c9, \text{opc}={0-7}, \text{CRm}=c15}\) are reserved for IMPLEMENTATION DEFINED performance monitors.

---

**Note**

These are distinct from the OPTIONAL ARM Performance Monitors Extension, the registers for which use the encoding space \({\text{coproc}=0b1111, \text{CRn}=c9, \text{opc}={0-7}, \text{CRm}={c12-c14}}\).
Reserved 32-bit encodings with \{coproc==0b1111, CRn==c10\}

In the AArch32 encoding space, for 32-bit encodings with \{coproc==0b1111, CRn==c10\}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with \{coproc==0b1111, CRn==c10, opc=={0-7}, CRm=={c0, c1, c4, c8}\} are reserved for IMPLEMENTATION DEFINED TLB lockdown operations.

Reserved 32-bit encodings with \{coproc==0b1111, CRn==c11\}

In the AArch32 encoding space, for 32-bit encodings with \{coproc==0b1111, CRn==c11\}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with \{coproc==0b1111, CRn==c11, opc=={0-7}, CRm=={c0-c8, c15}\} are reserved for IMPLEMENTATION DEFINED DMA operations for TCM access.

In ARMv8, the remainder of the AArch32 \{coproc==0b1111, CRn==c11\} encoding space is UNDEFINED.

Reserved 32-bit encodings with \{coproc==0b1111, CRn==c15\}

ARMv8 reserves the AArch32 System register encodings with \{coproc==0b1111, CRn==c15\} for IMPLEMENTATION DEFINED purposes, and does not impose any restrictions on the use of the these encodings. The documentation of the ARM implementation must describe fully any registers implemented in the \{coproc==0b1111, CRn==c15\} encoding space. Normally, for processor implementations by ARM, this information is included in the Technical Reference Manual for the processor.

Typically, an implementation uses the \{coproc==0b1111, CRn==c15\} encodings to provide test features, and any required configuration options that are not covered by this Manual.

This reservation means that the AArch32 64-bit encodings with \{coproc==0b1111, CRn==c15\} are also reserved for IMPLEMENTATION DEFINED purposes, without any restrictions on the use of the these encodings.

G4.16.2 Full list of VMSAv8-32 System registers in the (coproc==0b1111) encoding space

Table G4-44 on page G4-4711 shows the System registers in the (coproc==0b1111) encoding space in VMSAv8-32, in the order of the \{CRn, opc1, CRm, opc2\} parameter values used in MCR or MRC accesses to the 32-bit registers:

- For MCR or MRC accesses to the 32-bit registers, CRn is the primary identifier of the target System register for the access. This rule applies, also, to MCR or MRC instructions that provide 32-bit accesses to a single word of a 64-bit System register.

- For MCRR or MRRC accesses to the 64-bit registers, CRn is the primary identifier of the target System register for the access. Table G4-44 on page G4-4711 orders the 64-bit registers with the 32-bit registers accessed using the same primary register identifier. For example, the 64-bit encoding of TTBR0, that is accessed with (CRn==c2), is listed with the 32-bit registers that are accessed with (CRn==c2).

</table>

a. **REVIDR** is an optional register. If it is not implemented, the encoding with opc2 set to 6 is an alias of **MIDR**.
b. Implemented only as part of EL2, when EL2 is using AArch32. Otherwise, encoding is unallocated and **CONSTRAINED UNPREDICTABLE**, see **Accesses to unallocated encodings in the (coproc==0b111x) encoding space** on page G6-4765.
c. Implemented only as part of the EL3, when EL3 is using AArch32. Otherwise, as described in **Accesses to unallocated encodings in the (coproc==0b111x) encoding space** on page G6-4765, encoding is unallocated and:
   • **UNDEFINED**, for the registers accessed using CRn set to c12.
   • **CONSTRAINED UNPREDICTABLE**, for the register accessed using CRn values other than c12.
d. Introduced in ARMv8.
e. Introduced in ARMv8. Implemented only if the implementation includes the GIC System registers. For information see **Generic Interrupt Controller System registers, functional groups** on page G4-4740. As that subsection describes, each ICV_* register uses the same encoding as the corresponding ICC_* register.
f. This register is only accessible in Debug state.
h. For performance reasons, ARM deprecates any use of these memory barrier operations.

i. When an implementation is using the Long descriptor translation table format these encodings access the MAIR0 and MAIR1 registers. Otherwise, they access the PRRR and NMRR.

j. Introduced in ARMv8. Only one of RMR and HRMR is implemented, corresponding to the highest implemented Exception level, and the register is implemented only if that Exception level is using AArch32.

k. Implemented as part of the Generic Timer.

l. Implemented as RW as part of the Generic Timer on an implementation that includes EL2 and when EL2 is using AArch32. For more information see Status of the CNTYOFF register on page G5-4757.
G4.16.3 AArch32 views of the System registers in the (coproc==0b1111) encoding space

The following sections summarize the different software views of the System registers in the (coproc==0b1111) encoding space, for VMSAv8-32:

- PL0 views of the System registers in the (coproc==0b1111) encoding space.
- PL1 views of the System registers in the (coproc==0b1111) encoding space on page G4-4725.
- Non-secure PL2 view of the System registers in the (coproc==0b1111) encoding space on page G4-4725.

**Note**

In previous versions of the ARM architecture, the behavior of accesses to the System registers in the (coproc==0b1111) encoding space were described in relation to the PE modes. In Secure state, the Exception level of the privileged PE modes depends on whether EL3 is using AArch32, or is using AArch64. This means it is simpler to describe the views of the registers in terms of privilege levels, PL0-PL2, rather than the Exception levels EL1-EL3. This is because each AArch32 PE mode is associated with a particular privilege level, but in Secure state its Exception level can depend on the EL3 Execution state. For more information see Security state, Exception levels, and AArch32 execution privilege on page G1-4318.

### PL0 views of the System registers in the (coproc==0b1111) encoding space

Software executing at PL0, unprivileged, can access only a small subset of the System registers in the (coproc==0b1111) encoding space, as Table G4-45 shows. This table excludes possible PL0 access to the following registers:

- The Performance Monitors Extension, see Possible PL0 access to the Performance Monitors Extension System registers on page G4-4724.
- The Generic Timer registers, see Possible PL0 access to the Generic Timer System registers on page G4-4724.

Possible PL0 access to the Performance Monitors Extension System registers

In a VMSAv8-32 implementation that includes the Performance Monitors Extension, when using the System register interface to the Performance Monitors:

- The PMUSERENR is RO from PL0.
- When:
  - The value of PMUSERENR.EN is 1, PMCNTENSENSET, PMCNTENCLR, PMOVSRR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMCEVTYPEPER, PMCEVCNTR, PMUSERENR, PMOSVSET, PMEVCNTR<n>, PMEVTYPEPER<n>, and PMCCFILTR are accessible by reads and writes from PL0.
  - The value of PMUSERENR.ER is 1, PMEVCNTR and PMEVCNTR<n>. are accessible by reads and from PL0, and PMSLR is accessible by reads and writes from PL0.
  - The value of PMUSERENR.CR is 1, PMCCNTR is accessible by reads from PL0.
  - The value of PMUSERENR.SW is 1, PMSWINC is accessible by writes from PL0.

In general, when the value of a PMUSERENR.{EN, ER, CR, SW} bit is 1, the enabled registers have the same access permissions from PL0 as they do from PL1.

For more information, see:
- Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1850.
- Chapter D5 The Performance Monitors Extension, in particular Access permissions on page D5-2176.

Possible PL0 access to the Generic Timer System registers

In a VMSAv8-32 implementation, when using the System register interface to the Generic Timer registers:

- If CNTKCTL.PL0PCTEN is set to 1, then if the physical counter register CNTPCT is accessible from PL1 it is also accessible from PL0. For more information see Accessing the physical counter on page D6-2184.
- If CNTKCTL.PL0PVTEN is set to 1, the virtual counter register CNTVCT is accessible from PL0. For more information, see Accessing the virtual counter on page D6-2185.
- If at least one of CNTKCTL.{PL0PCTEN, PL0PVTEN} is set to 1, the CNTFRQ register is RO from PL0.
- If:
  - CNTKCTL.PL0PTEN is set to 1, the physical timer registers CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are accessible from PL0.
  - CNTKCTL.PL0VTEN is set to 1, the virtual timer registers CNTV_CTL, CNTV_CVAL, and CNTV_TVAL are accessible from PL0.

For more information, see Accessing the timer registers on page G5-4759.
PL1 views of the System registers in the (coproc==0b1111) encoding space

Software executing at PL1 can access all System registers in the (coproc==0b1111) encoding space, with the following exceptions:

Non-secure PL1 software

EL3 restricts or prevents access to some registers by Non-secure PL1 software. In particular:

- The Restricted access System registers are either not accessible to Non-secure PL1 software, or are read-only to Non-secure PL1 software, see Restricted access System registers on page G4-4694.
- Configuration settings determine whether Non-secure PL1 software can access the Configurable access System registers, see Configurable access System registers on page G4-4694.

The individual register descriptions identify these access restrictions.

In an implementation that includes EL2, Non-secure PL1 software has no visibility of the PL2-mode registers summarized in Hyp mode read/write registers in the (coproc==0b1111) encoding space on page G4-4695. The individual register descriptions identify these registers as EL2-mode registers.

Secure PL1 software

In general, Secure PL1 software has access to all System registers. However:

- When EL3 is using AArch32, the CP15SDISABLE signal disables write access to a number of Secure registers, see The CP15SDISABLE input signal on page G4-4699.
- The PL2-mode registers are accessible from Secure state only if EL3 is using AArch32. When this is the case, Secure PL1 software can access these registers by moving into Monitor mode, and setting SCR.NS to 1. Hyp mode read/write registers in the (coproc==0b1111) encoding space on page G4-4695 summarizes these registers.

The individual register descriptions identify:

- The registers affected by the CP15SDISABLE signal.
- The PL2-mode registers.

Non-secure PL2 view of the System registers in the (coproc==0b1111) encoding space

Non-secure software executing at PL2 can access:

- The registers that are accessible to Non-secure software executing at PL1, as defined in PL1 views of the System registers in the (coproc==0b1111) encoding space. Access permissions for these registers are identical to those for Non-secure software executing at EL1.
- The PL2-mode registers summarized in Hyp mode read/write registers in the (coproc==0b1111) encoding space on page G4-4695, and described in Virtualization registers, functional group on page G4-4730.
G4.17 Functional grouping of VMSAv8-32 System registers

This section describes how the System registers in an VMSAv8-32 implementation divide into functional groups.

Chapter G6 AArch32 System Register Descriptions describes each of these registers.

Note

• Table G4-44 on page G4-4711 lists all of the VMSAv8-32 System registers in the (coproc==0b1111) encoding space, ordered by:
  1. The CRn primary register used when using a 32-bit access to the register.
     For 64-bit register accesses using an MCRR or MRRC instruction, the instruction arguments that identify the target register are \{coproc, Rm, opc1\}. The value of Rm determines where these registers appear in Table G4-44 on page G4-4711, so that these registers appear with the 32-bit registers accessed using that value for CRn. So, for example, the 64-bit access to TTBR0, that uses (CRn==c2), appears with the 32-bit access to TTBR0, that uses (CRn==c2).
  2. The opc1 value used when accessing the register.
  3. For 32-bit registers, the \{CRm, opc2\} values used when accessing the register.

• The functional groups defined in this section mainly consist of the VMSAv8-32 System registers, but include some additional System registers.

• Some registers belong to more than one functional group.

For other related information see:

• The AArch32 System register interface on page G1-4408 for general information about the access to the AArch32 System registers, including the main register access instructions MRC and MCR.

• About the System registers for VMSAv8-32 on page G4-4689.

• VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space on page G4-4704.

• VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G4-4707.

• About the AArch32 System registers on page G4-4764.

The remainder of this chapter, and the register descriptions in Chapter G6 AArch32 System Register Descriptions, assume you are familiar with these sections, and use conventions and other information from them without any explanation.

Each of the following sections summarizes a functional group of VMSAv8-32 System registers:

• Identification registers, functional group on page G4-4727.

• General system control registers, functional group on page G4-4728.

• Virtual memory control registers, functional group on page G4-4729.

• Virtualization registers, functional group on page G4-4730.

• Security registers, functional group on page G4-4732.

• Exception and fault handling registers, functional group on page G4-4733.

• Reset management registers, functional group on page G4-4734.

• Thread and process ID registers, functional group on page G4-4734.

• Cache maintenance instructions, functional group on page G4-4734.

• TLB maintenance instructions, functional group on page G4-4735.

• Address translation instructions, functional group on page G4-4737.

• Lockdown, DMA, and TCM features, functional group on page G4-4738.

• Performance Monitors Extension registers, functional group on page G4-4738.

• Generic Timer registers, functional group on page G4-4740.

• Generic Interrupt Controller System registers, functional group on page G4-4740.

• Legacy feature registers, functional group on page G4-4744.
G4.17 Functional grouping of VMAv8-32 System registers

- **IMPLEMENTATION DEFINED registers, functional group** on page G4-4744.
- **Advanced SIMD and floating-point registers, functional group** on page G4-4745.
- **Debug registers, functional group** on page G4-4745.

### G4.17.1 Identification registers, functional group

Table G4-46 shows the VMAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Identification registers functional group.

</tbody>
</table>
The other registers in this group are the FPSID, MVFR0, MVFR1, and MVFR2.
The JIDR holds legacy identification information.

### The CPUID identification scheme

The ID_* registers were originally called the CPUID identification scheme registers. A footnote to Table G4-46 on page G4-4727 identifies these registers. However, functionally, there is no value in separating these registers from the slightly larger Identification registers functional group.

### G4.17.2 General system control registers, functional group

Table G4-47 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the General system control registers functional group.

</table>

The PE returns fault information using the fault status registers and the fault address registers. For details of how these registers are used see Exception reporting in a VMSAv8-32 implementation on page G4-4663.
Note

These registers also report information about debug exceptions. For more information see:

- Data Abort exceptions, taken to a PL1 mode on page G4-4665.
- Prefetch Abort exceptions, taken to a PL1 mode on page G4-4667.
- Reporting exceptions taken to Hyp mode on page G4-4673.

G4.17.7 Reset management registers, functional group

Table G4-53 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Reset management registers functional group.

a. See the register descriptions for more information. Accessibility can depend on configuration settings as well as on the current Exception level.

b. Implemented as RW as part of the Generic Timer on an implementation that includes EL2 and when EL2 is using AArch32. For more information see Status of the CNTVOFF register on page G5-4757.

G4.17.15   Generic Interrupt Controller System registers, functional groups

From version 3.0 of the GIC architecture specification, the specification defines three groups of System registers, identified by the prefix of the register name:

- **ICC** - GIC physical CPU interface System registers.
- **ICH** - GIC virtual interface control System registers.
- **ICV** - GIC Virtual CPU interface System registers.

Note

These registers are in addition to the GIC memory-mapped register groups GICC_, GICD_, GICH_, GICR_, GICV_, and GITS_.

In VMSAv8-32, the GIC System registers are all in the (coproc==0b1111) encoding space with (CRn==c12). The ICV_* registers have the same {CRn, opc1, CRm, opc2} encodings as the corresponding ICC_* registers. For these encodings, GIC register configuration fields determine which register is accessed.

For more information see the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0.
Table G4-62 shows the functional groups of GIC System registers.

</tbody>
</table>

- a. PL0 in a Type description indicates that the encoding is accessible by software executing at PL0. See the register description for more information.
- b. For performance reasons, ARM deprecates any use of these memory barrier operations.
- c. In ARMv8, the PE does not implement the FCSEIDR, and therefore the register is RAZ/WI. See the register description for more information.

Table G4-64 shows the VMSAv8-32 System registers in the \((\text{coproc} == 0b1110)\) encoding space that are in the Legacy features registers functional group.

G4.18 Pseudocode description of VMSAv8-32 memory system operations

This section contains a list of pseudocode functions describing VMSAv8-32 memory operations. The following subsections describe the pseudocode functions:

- **Alignment fault.**
- **Address translation.**
- **Domain checking.**
- **TLB operations.**
- **Translation table walk.**
- **Reporting syndrome information** on page G4-4749.
- **Memory access decode when TEX remap is enabled** on page G4-4749.

See also the descriptions of pseudocode for general memory system operations in *Pseudocode description of general memory system instructions* on page G3-4553.

### G4.18.1 Alignment fault

The `AArch32.AlignmentFault()` pseudocode function describes the generation of an Alignment fault Data Abort exception.

See also *Abort exceptions* on page G3-4555.

### G4.18.2 Address translation

The `AArch32.TranslateAddress()` and `AArch32.FullTranslate()` pseudocode functions describe a VMSAv8-32 address translation.

The `AArch32.FullTranslate()` function calls either:

- The function described in *Address translation when the stage 1 address translation is disabled*.
- One of the functions described in *Translation table walk*.

See also *Stage 2 translation table walk* on page G4-4749.

#### Address translation when the stage 1 address translation is disabled

The `AArch32.TranslateAddressS1Off()` pseudocode function describes the address translation performed when the stage 1 address translation is disabled.

### G4.18.3 Domain checking

The `AArch32.CheckDomain()` pseudocode function describes domain checking.

### G4.18.4 TLB operations

The `TLBRecord` type represents the contents of a TLB entry:

### G4.18.5 Translation table walk

Because of the complexity of a translation table walk, the following sections describe the different cases:

- **Translation table walk using the Short-descriptor translation table format for stage 1.**
- **Translation table walk using the Long-descriptor translation table format for stage 1** on page G4-4749.
- **Stage 2 translation table walk** on page G4-4749.

#### Translation table walk using the Short-descriptor translation table format for stage 1

The `AArch32.TranslationTableWalkSD()` pseudocode function describes the translation table walk when the stage 1 translation tables use the Short-descriptor format. It calls the function described in *Stage 2 translation table walk* on page G4-4749 if necessary.
The `ShortConvertAttrsHints()` pseudocode function converts the Normal memory cacheability attribute, from the TTBR or the translation table TEX field, into the separate cacheability attribute and cache allocation hint defined in a Long-descriptor translation table descriptor.

**Translation table walk using the Long-descriptor translation table format for stage 1**

The `AArch32.TranslationTableWalkLD()` pseudocode function describes the translation table walk when the stage 1 translation tables use the Long-descriptor format. It calls the function described in *Stage 2 translation table walk* if necessary.

`AArch32.TranslationTableWalkLD()` calls the `ConvertAttrsHints()` pseudocode function that is defined in *Translation table walk using the Short-descriptor translation table format for stage 1* on page G4-4748.

The `AArch32.S1AttrDecode()` pseudocode function uses the MAIR0 and MAIR1 registers to decode the Attr[2:0] value from a stage 1 translation table descriptor.

The `S2AttrDecode()` pseudocode function decodes the Attr[3:0] value from a stage 2 translation table descriptor.

**Stage 2 translation table walk**

In the Non-secure EL1&0 translation regime, a descriptor address returned by stage 1 lookup is in the IPA address map, and must be mapped to a PA by a stage 2 translation. When EL2 is using AArch32, function `AArch32.SecondStageWalk()` performs this translation, by calling the `AArch32.SecondStageTranslate()` function.

When called from `AArch32.SecondStageWalk()`, the `AArch32.SecondStageTranslate()` function performs a second stage translation, from IPA to PA, of the supplied address, including checking that the access has read permission at the second stage. If the access does not have second stage read permission it generates a second stage Permission fault on the first stage translation table walk. The second stage translation might hit in a TLB, or might involve a translation table walk, which will use the algorithm described in this section. Stage 2 translations tables always use the Long-descriptor translation table format.

The `AArch32.CheckPermission()` pseudocode function checks the access permissions for the stage 1 translation.

The `AArch32.CheckS2Permission()` pseudocode function checks the access permissions for the stage 2 translation.

The `CombineS1S2Desc()` pseudocode function combines the stage 1 and stage 2 access descriptors:

**G4.18.6 Reporting syndrome information**

The `AArch32.ReportHypEntry()`, `AArch32.ReportDataAbort()`, and `AArch32.ReportPrefetchAbort()` pseudocode functions write syndrome value information to the appropriate registers for the current mode.

**G4.18.7 Memory access decode when TEX remap is enabled**

When using the Short-descriptor translation table format, the function `AArch32.RemappedTEXDecode()` decodes the texcb and S attributes derived from the translation tables when TEX remap is enabled. *Short-descriptor format memory region attributes, with TEX remap* on page G4-4619 shows the interpretation of the arguments.
Chapter G5
The Generic Timer in AArch32 state

This chapter describes the implementation of the ARM Generic Timer as an extension to an ARMv8 implementation. It includes an overview of the AArch32 System register interface to an ARM Generic Timer.

It contains the following sections:

•  About the Generic Timer in AArch32 state on page G5-4752.
•  The AArch32 view of the Generic Timer on page G5-4756.

Chapter D6 The Generic Timer in AArch64 state describes the AArch64 view of the Generic Timer, including an additional timer that can be implemented in AArch64 state, and Chapter I1 System Level Implementation of the Generic Timer describes the system level implementation of the Generic Timer.
G5.1 About the Generic Timer in AArch32 state

Figure G5-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The ARM Generic Interrupt Controller Architecture Specification defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

The Generic Timer:

- Provides a system counter, that measures the passing of time in real-time.

  **Note**

  The Generic Timer can also provide other components at a system level, but Figure G5-1 does not show any such components.

- Supports *virtual counters* that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.

- Timers, that can trigger events after a period of time has passed. The timers:
  - Can be used as count-up or as count-down timers.
  - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure G5-1 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch32 state. Chapter D6 The Generic Timer in AArch64 state describes access to this component from AArch64 state.

**Note**

The reset requirements of Generic Timer registers are more strict when they are accessed from AArch32 state than when they are accessed from AArch64 state.
A Generic Timer implementation must also include a memory-mapped system component, see *The full set of Generic Timer components*.

### G5.1.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

#### The system counter

This provides a uniform view of system time, see *The system counter* on page G5-4754. Because this must be implemented at the system level, it is accessed through *The system level memory-mapped implementation of the Generic Timer*. However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

#### PE implementations of the Generic Timer

Each PE implementation of the Generic Timer provides the following components:

- A physical counter, that gives access to the count value of the system counter.
- A virtual counter, that gives access to virtual time. In AArch32 state, the CNTVOFF register defines the offset between physical time, as defined by the value of the system counter, and virtual time.
- A number of timers. In an implementation where all Exception levels are implemented and can use AArch32 state, the timers that are accessible from AArch64 state are:
  - A Secure PL1 physical timer.
  - A Non-secure EL1 physical timer.
  - An EL2 physical timer.
  - A virtual timer.

______ Note ________

The Secure PL1 physical timer uses the Secure banked instances of the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL registers, and the Non-secure EL1 physical timer uses the Non-secure instances of the same registers.

*The AArch32 view of the Generic Timer* on page G5-4756 describes these components.

#### The system level memory-mapped implementation of the Generic Timer

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into frames. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.

Each system level component has one or two register frames. The possible system level components are:

**The memory-mapped counter module, required**

This module controls the system counter. It has two frames:

- A control frame, CNTControlBase.
- A status frame, CNTReadBase.

**The memory-mapped timer control module, required**

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, CNTCTLBase.

**Memory-mapped timers, optional**

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the CNTBaseN frame.
G5.1 About the Generic Timer in AArch32 state

Chapter II System Level Implementation of the Generic Timer describes these components.

G5.1.2 The system counter

The Generic Timer provides a system counter with the following specification:

- **Width**: At least 56 bits wide.
  - The value returned by any 64-bit read of the counter is zero-extended to 64 bits.

- **Frequency**: Increments at a fixed frequency, typically in the range 1-50MHz.
  - Can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving.

- **Roll-over**: Roll-over time of not less than 40 years.

- **Accuracy**: ARM does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period.
  - Use of lower-frequency modes must not affect the implemented accuracy.

- **Start-up**: Starts operating from zero.

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

The CNTFRQ register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information see *Initializing and reading the system counter frequency*.

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

--- Note ---

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. *Gray-count scheme for timer distribution scheme on page II-5736* gives more information about this possibility.

---

**Initializing and reading the system counter frequency**

The CNTFRQ register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the system counter frequency to the CNTFRQ register. Only software executing at the highest implemented Exception level can write to CNTFRQ.
The CNTFRQ register is UNKNOWN at reset, and therefore the counter frequency must be set as part of the system boot process.

Software can read the CNTFRQ register, to determine the current system counter frequency, in the following states and modes:

- Hyp mode.
- Secure PL1 modes and Non-secure EL1 modes.
- When CNTKCTL.PL0PCTEN is set to 1, Secure and Non-secure EL0 modes.

Memory-mapped controls of the system counter

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see Chapter 11 System Level Implementation of the Generic Timer.
G5.2  The AArch32 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch32 state:

- The physical counter.
- The virtual counter.
- Event streams on page G5-4757.
- Timers on page G5-4758.

G5.2.1  The physical counter

The PE includes a physical counter that contains the count value of the system counter. The CNTPCT register holds the current physical counter value.

Accessing the physical counter

Software with sufficient privilege can read CNTPCT using a 64-bit System register read.

CNTPCT:

- Is always accessible from Secure PL1 modes and from Non-secure Hyp mode.
- Is accessible from Non-secure EL1 modes when the value of CNTHCTL.PL1PCTEN is 1. When the value of CNTHCTL.PL1PCTEN is 0, any attempt to access CNTPCT from Non-secure EL1 modes is trapped to Hyp mode.
- Is accessible from Secure User mode when the value of CNTKCTL.PL0PCTEN is 1. When the value of CNTKCTL.PL0PCTEN is 0, any attempt to access CNTPCT generates an UNDEFINED exception.
- Is accessible from Non-secure User mode when the value of CNTHCTL.PL1PCTEN is 1 and the value of CNTKCTL.PL0PCTEN is 1. Otherwise:
  - When the value of CNTKCTL.PL0PCTEN is 0, any attempt to access CNTPCT from Non-secure User mode generates an UNDEFINED exception.
  - When the value of CNTKCTL.PL0PCTEN is 1 and the value of CNTHCTL.PL1PCTEN is 0, any attempt to access CNTPCT from Non-secure User mode is trapped to Hyp mode.

Reads of CNTPCT can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that CNTPCT must be read, an ISB is used to ensure that the read of CNTPCT occurs after the signal has been read from memory, as shown in the following code sequence:

```assembly
loop    ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]    
    CMP R1, #1      
    BNE loop
    ISB             ; without this, the CNTPCT could be read before the memory location in [R2] has had the value 1 written to it
    MRS R1, CNTPCT
```

G5.2.2  The virtual counter

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time.

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing in a Non-secure EL1 or EL0 mode, the virtual offset value relates to the current virtual machine.

The CNTVOFF register contains the virtual offset. CNTVOFF is only accessible:

- From Hyp mode.
- From Monitor mode only when SCR.NS is set to 1.

For more information see Status of the CNTVOFF register on page G5-4757.
The **CNTVCT** register holds the current virtual counter value.

### Accessing the virtual counter

Software with sufficient privilege can read **CNTVCT** using a 64-bit System register read. **CNTVCT** is always accessible from Secure PL1 modes and from Non-secure EL1 and EL2 modes.

In addition, when **CNTKCTL.PL0VCTEN** is set to 1, **CNTVCT** is accessible from EL0. When **CNTKCTL.PL0VCTEN** is set to 0, any attempt to access **CNTVCT** from EL0 is UNDEFINED.

Reads of **CNTVCT** can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that **CNTVCT** must be read, an ISB is used to ensure that the read of **CNTVCT** occurs after the signal has been read from memory, as shown in the following code sequence:

```assembly
loop ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]  
    CMP R1, #1
    BNE loop
    ISB          ; without this, the CNTVCT could be read before the memory location in [R2]
                 ; has had the value 1 written to it
    MRS R1, CNTVCT
```

### Status of the **CNTVOFF** register

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the **CNTVOFF** register that defines the virtual offset between the physical count and the virtual count. **CNTVOFF** is only accessible at EL2 or above. If EL2 is not implemented, the virtual counter uses a fixed virtual offset of zero.

### G5.2.3 Event streams

Any implementation of the Generic Timer can use the system counter to generate one or more event streams, to generate periodic wake-up events as part of the mechanism described in *Wait for Event mechanism and Send event on page D1-1879*.

---

**Note**

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

---

An event stream is configured by:

- Selecting which bit, from the bottom 16 bits of a counter, triggers the event. This determines the frequency of the events in the stream.
- Selecting whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

The **CNTKCTL.[EVNTEN, EVNTDIR, EVNTI]** fields define an event stream that is generated from the virtual counter.

In all implementations the **CNTHCTL.[EVNTEN, EVNTDIR, EVNTI]** fields define an event stream that is generated from the physical counter.

The operation of an event stream is as follows:

- The pseudocode variables `PreviousCNTVCT` and `PreviousCNTPCT` are initialized as:

```assembly
// Variables used for generation of the timer event stream.
```
The pseudocode functions TestEventCNTV() and TestEventCNTP() are called on each cycle of the PE clock.

The TestEventCNTx() pseudocode template defines the functions TestEventCNTV() and TestEventCNTP():

```c
// TestEventCNTx()
// ===============
// Template for the TestEventCNTV() and TestEventCNTP() functions
// Describes operation when all Exception Levels are using AArch32:
//   CNTxCT         is  CNTVCT          or  CNTPCT          64-bit count value
//   CNTx_CTL       is  CNTV_CTL        or  CNTP_CTL        Control register
//   PreviousCNTxCT is  PreviousCNTVCT  or  PreviousCNTPCT
TestEventCNTx()
if CNTx_CTL.EVTNEN == '1' then
    n = UInt(CNTx_CTL.EVTI);
    SampleBit   = CNTxCT<n>;
    PreviousBit = PreviousCNTxCT<n>;
    if CNTx_CTL.EVTDIR == '0' then
        if PreviousBit == '0' && SampleBit == '1' then EventRegisterSet();
        else
            if PreviousBit == '1' && SampleBit == '0' then EventRegisterSet();
    PreviousCNTxCT = CNTxCT;
return;
```

### G5.2.4 Timers

In an implementation that includes EL3, in any implementation of the Generic Timer, the following timers are accessible from AArch32 state, provided the appropriate Exception level can use AArch32:

- A Non-secure EL1 physical timer. A Non-secure EL1 control determines whether this register is accessible from Non-secure EL0.

- A Secure PL1 physical timer. This timer:
  - Is accessible from Secure EL1 using AArch32 when EL3 is using AArch64.
  - Is accessible from Secure EL3 when EL3 is using AArch32.

A Secure PL1 control determines whether this register is accessible from Secure EL0.

- A Non-secure EL2 physical timer.

- A virtual timer.

The output of each implemented timer:

- Provides an output signal to the system.

- If the PE interfaces to a **Generic Interrupt Controller (GIC)**, signals a **Private Peripheral Interrupt (PPI)** to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer:

- Is based around a 64-bit CompareValue that provides a 64-bit unsigned upcounter.

- Provides an alternative view of the CompareValue, called the TimerValue, that appears to operate as a 32-bit downcounter.

- Has, in addition, a 32-bit Control register.
In all implementations, the AArch32 System registers for the EL1 (or PL1) physical timer are Banked, to provide the Secure and Non-secure implementations of the timer. Table G5-1 shows the Timer registers.

**Table G5-1 Timer registers summary for the Generic Timer**

<table>
<thead>
<tr>
<th>Timer register</th>
<th>Secure PL1 or Non-secure EL1 physical timer</th>
<th>EL2 physical timer</th>
<th>Virtual timer</th>
</tr>

</tbody>
</table>

* In AArch32 state, these registers are Banked to provide the Non-secure EL1 physical timer and the Secure PL1 physical timer.

The following sections describe:

- Accessing the timer registers
- Operation of the CompareValue views of the timers on page G5-4760
- Operation of the TimerValue views of the timers on page G5-4760.

### Accessing the timer registers

For each timer, all timer registers have the same access permissions, as follows:

#### Secure PL1 and Non-secure EL1 physical timer

The Secure PL1 physical timer is accessible from Secure PL1 modes.

Non-secure software executing at EL2 controls access to the Non-secure EL1 physical timer from Non-secure EL1 modes. The Non-secure EL1 physical timer is accessible from Monitor mode when the value of SCR.NS is 1.

When access from PL1 or EL1 modes is permitted, CNTKCTL.PL0PTEN determines whether the registers are accessible from EL0. If an access is not permitted because CNTKCTL.PL0PTEN is set to 0, an attempted access from EL0 is UNDEFINED.

In all implementations:

- Except for accesses from Monitor mode, accesses are to the registers for the current Security state.
- For accesses from Monitor mode, the value of SCR.NS determines whether accesses are to the Secure or the Non-secure registers.

---

**Note**

Monitor mode is present only when EL3 is using AArch32.

---

- The Non-secure registers are accessible from Hyp mode.
- CNTHCTL.PL1PCEN determines whether the Non-secure registers are accessible from Non-secure EL1 modes. If this bit is set to 1, to enable access from Non-secure EL1 modes, CNTKCTL.PL0PTEN determines whether the registers are accessible from Non-secure EL0.

If an access is not permitted because CNTHCTL.PL1PCEN is set to 0, an attempted access from a Non-secure EL1 or EL0 mode generates a Hyp Trap exception. However, if CNTKCTL.PL0PTEN is set to 0, this control takes priority, and an attempted access from EL0 is UNDEFINED.

#### EL2 physical timer

Accessible from Hyp mode, and from Secure Monitor mode when SCR_EL3.NS is set to 1.
Virtual timer Accessible from Secure PL1 modes and Non-secure EL1 modes, and from Hyp mode. CNTKCTL.PL0VTEN determines whether the registers are accessible from EL0 modes. If an access is not permitted because CNTKCTL.PL0VTEN is set to 0, an attempted access from EL0 is undefined.

Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register. When the timer condition is met an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL, CNTHP_CTL, or CNTV_CTL. For CNTP_CTL, the interrupt is the same as the interrupt asserted by the Non-secure instance of the AArch64 register CNTP_CTL_EL0.

The operation of this view of a timer is:

\[
\text{TimerConditionMet} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) \geq 0)
\]

Where:

- **TimerConditionMet** Is TRUE if the timer condition for this counter is met, and FALSE otherwise.
- **Counter** The physical counter value, that can be read from the CNTPCT register.

Note

The virtual counter value, that can be read from the CNTVCT register, is the value:

\[
\text{(Counter} - \text{Offset})
\]

- **Offset** For a physical timer it is zero, and for the virtual timer it is the virtual offset, held in the CNTVOFF register.
- **CompareValue** The value of the appropriate CompareValue register, CNTP_CVAL, CNTHP_CVAL, or CNTV_CVAL.

In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.

Note

This means that a timer with a CompareValue of, or close to, 0xFFFF_FFFF_FFFF_FFFF might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.

Operation of the TimerValue views of the timers

The TimerValue view of a timer appears to operate as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL, CNTHP_CTL, or CNTV_CTL.

This view of a timer depends on the following behavior of accesses to TimerValue registers:

- **Reads** TimerValue = (CompareValue - (Counter - Offset)[31:0]
- **Writes** CompareValue = ((Counter - Offset)[63:0] + SignExtend(TimerValue))[63:0]

Where the arguments other than TimerValue have the definitions used in *Operation of the CompareValue views of the timers*, and in addition:

- **TimerValue** The value of a TimerValue register, CNTP_TV_AL, CNTHP_TV_AL, or CNTV_TV_AL.

In this view of a timer, values are signed, in standard two’s complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.
Note

- Operation of the CompareValue views of the timers on page G5-4760 gives a strict definition of TimerConditionMet. However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from 0x80000000, the TimerValue view can be used as giving an effect equivalent to:
  
  \[ \text{TimerConditionMet} = (\text{TimerValue} \leq 0) \]

- Programming TimerValue to a negative number with magnitude greater than (Counter–Offset) can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays meeting the timer condition for an extremely long period of time.
Chapter G6
AArch32 System Register Descriptions

This chapter describes each of the AArch32 System registers.

It contains the following sections:

• *About the AArch32 System registers* on page G6-4764.
• *General system control registers* on page G6-4774.
• *Debug registers* on page G6-5239.
• *Performance Monitors registers* on page G6-5331.
• *Generic Timer registers* on page G6-5383.
G6.1  About the AArch32 System registers

For general information about the AArch32 System registers, see:

- About the System registers for VMSAv8-32 on page G4-4689.
- VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space on page G4-4704.
- VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G4-4707.
- Functional grouping of VMSAv8-32 System registers on page G4-4726.

The remainder of this chapter describes the AArch32 System registers, in the following sections:

- General system control registers on page G6-4774.
- Debug registers on page G6-5239.
- Performance Monitors registers on page G6-5331.
- Generic Timer registers on page G6-5383.

G6.1.1  General behavior of System registers

Except where indicated, System registers are 32-bits wide. As stated in About the System registers for VMSAv8-32 on page G4-4689, there are some 64-bit registers, and these include cases where software can access either a 32-bit view or a 64-bit view of a register. The register summaries, and the individual register descriptions, identify the 64-bit registers and how they can be accessed.

The following sections give information about the general behavior of these registers. Unless otherwise indicated, information applies to all AArch32 System registers:

- Register names.
- Read-only bits in read/write registers.
- UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses.
- Read-only and write-only register encodings on page G6-4766.
- Reset behavior of AArch32 System registers on page G6-4767.

See also About AArch32 System register accesses on page G4-4689 and Fixed values in register diagrams on page G4-4701.

Register names

The ARM architecture guarantees not to define any register name prefixed with IMP_ as part of the standard ARM architecture.

Note

ARM strongly recommends that any register names created in the IMPLEMENTATION DEFINED register spaces be prefixed with IMP_, where appropriate.

Read-only bits in read/write registers

Some read/write registers include bits that are read-only. These bits ignore writes.

An example of this is the SCTLR.NMFI bit, SCTLR[27].

UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses

This section defines UNPREDICTABLE and UNDEFINED behaviors for accesses to System registers, including those cases where the ARMv8 behavior is CONSTRAINED UNPREDICTABLE.
In AArch32 state the following operations are UNDEFINED:

- All LDC and STC accesses, except for the LDC access to DBGDTRTXint and the STC access to DBGDTRRXint specified in Table G4-43 on page G4-4706.
- All MCR and MRC operations to the (coproc==0b111x) encoding space, except for those explicitly defined as accessing 64-bit System registers specified in Table G4-42 on page G4-4705 and Table G4-44 on page G4-4711.

Unless otherwise indicated in the individual register descriptions:

- Reserved fields in registers are RES0.
- Assigning a reserved value to a field has a CONSTRAINED UNPREDICTABLE effect, see Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.

The following subsections give more information about UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for accesses to the (coproc==0b111x) encoding space:

- Accesses to unallocated encodings in the (coproc==0b111x) encoding space.
- Additional rules for MCR and MRC accesses to System registers.
- Effects of EL3 and EL2 on System register accesses.

**Accesses to unallocated encodings in the (coproc==0b111x) encoding space**

In ARMv8-A, accesses to unallocated register encodings in the (coproc==0b111x) encoding space are UNDEFINED, see Unallocated System register access instructions on page K1-6100.

**Additional rules for MCR and MRC accesses to System registers**

The following operations are CONSTRAINED UNPREDICTABLE for all encodings in the (coproc==0b111x) encoding space:

- All MCR operations from the PC.
- All MRC operations to APSR_nzcv, except for the (coproc==0b1110) MRC operation to APSR_nzcv from DBGDSCRInt.

The CONSTRAINED UNPREDICTABLE behavior of these operations is that they are UNDEFINED, see Unallocated System register access instructions on page K1-6100.

For registers and operations that are accessible from a particular Privilege level, any attempt to access those registers from a lower Privilege level is UNDEFINED.

Some individual registers can be made inaccessible by setting configuration bits, possibly including IMPLEMENTATION DEFINED configuration bits, to disable access to the register. The effects of the architecturally-defined configuration bits are defined individually in this manual. Unless explicitly stated otherwise in this manual, setting a configuration bit to disable access to a register results in the register becoming UNDEFINED for MRC and MCR accesses.

See also Read-only and write-only register encodings on page G6-4766.

**Effects of EL3 and EL2 on System register accesses**

EL2 and EL3 introduce classes of System registers, described in Classification of System registers on page G4-4692. Some of these classes of register are either:

- Accessible only from certain modes or states.
- Accessible from certain modes or states only when configuration settings permit the access.

Accesses to these registers that are not permitted are UNDEFINED, meaning execution of the register access instruction generates an Undefined Instruction exception.

--- **Note** ---

This section applies only to registers that are accessible from some modes and states. That is, it applies only to register access instructions using an encoding that, under some circumstances, would perform a valid register access.
The following register classes restrict access in this way:

**Restricted access System registers**

This register class is defined in any implementation that includes EL3.

Restricted access registers other than the NSACR are accessible only from Secure EL3 modes. All other accesses to these registers are UNDEFINED.

The NSACR is a special case of a Restricted access register and:

- The NSACR is:
  - Read/write accessible from Secure PL1 modes.
  - Is Read-only accessible from Non-secure PL2 and PL1 modes.
- All other accesses to the NSACR are UNDEFINED.

For more information, including behavior when EL3 is using AArch64 or is not implemented, see Restricted access System registers on page G4-4694.

**Configurable access System registers**

This register class is defined in any implementation that includes EL3.

Most Configurable access registers are accessible from Non-secure state only if control bits in the NSACR permit Non-secure access to the register. Otherwise, a Non-secure access to the register is UNDEFINED.

For other Configurable access registers, control bits in the NSACR control the behavior of bits or fields in the register when it is accessed from Non-secure state. That is, Non-secure accesses to the register are permitted, but the NSACR controls how they behave. The only architecturally-defined register of this type is the CPACR.

For more information, see Configurable access System registers on page G4-4694.

**EL2-mode System registers**

This register class is defined only in an implementation that includes EL2.

EL2-mode registers are accessible only from:

- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode when SCR.NS is set to 1.

All other accesses to these registers are UNDEFINED.

For more information, see Hyp mode read/write registers in the (coproc == 0b1111) encoding space on page G4-4695 and Hyp mode encodings for shared (coproc == 0b1111) System registers on page G4-4696.

**EL2-mode write-only operations**

This register class is defined only in an implementation that includes EL2.

EL2-mode write-only operations are accessible only from:

- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode, regardless of the value of SCR.NS.

Write accesses to these operations are:

- CONSTRAINED UNPREDICTABLE in Secure EL3 modes other than Monitor mode.
- UNDEFINED in Non-secure modes other than Hyp mode.

For more information, see Hyp mode (coproc == 0b1111) write-only System instructions on page G4-4697.

In addition, in any implementation that includes EL3, when EL3 is using AArch32, if write access to a register is disabled by the CP15SDISABLE signal then any MCR access to that register is UNDEFINED.

**Read-only and write-only register encodings**

Some System registers are read-only (RO) or write-only (WO). For example:

- Most identification registers are read-only.
• Most encodings that perform an operation, such as a cache maintenance instruction, are write-only.

If a particular Privilege level defines a register to be:

• RO, then any attempt to write to that register, at that Privilege level, is UNDEFINED. This means that any access to that register with \( L = 0 \) is UNDEFINED.

• WO, then any attempt to read from that register, at that Privilege level, is UNDEFINED. This means that any access to that register with \( L = 1 \) is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED.

Note

This section applies only to registers that this manual defines as RO or WO. It does not apply to registers for which other access permissions are explicitly defined.

Reset behavior of AArch32 System registers

Reset values apply only to RW registers and fields, however:

• Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.

• Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.

• Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.

• WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.

• IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch32, see:

• PE state on reset into AArch32 state on page G1-4400.

• The appropriate Trace architecture specification, for the Trace System registers.

When the PE resets into an Exception level that is using AArch64, PE state that relates to execution in AArch32 state, including the System register values, is UNKNOWN. The only exception to this is state that applies to execution in both AArch64 state and AArch32 state and that has a defined reset value on the reset into AArch64 state. An example of such PE state is the EDPRSR.SR bit.

For a PE reset into an Exception level that is using AArch32, the architecture defines which AArch32 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and PE state on reset into AArch32 state on page G1-4400 summarizes these architectural requirements. Otherwise, RW registers reset to an architecturally unknown value.

Note

In an implementation that includes EL3, unless this manual explicitly states otherwise, only the Secure instance of a Banked register is reset to the defined value. This means that software must program the Non-secure instance of the register with the required values. Typically, this programming is part of the PE boot sequence.

Pseudocode description of resetting System registers

The AArch32.ResetControlRegisters() pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and PE state on reset into AArch32 state on page G1-4400.
For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

**Note**

Synchronization of changes to AArch32 System registers

In this section, *this PE* means the PE on which accesses are being synchronized.

**Note**

See *Definitions of direct and indirect reads and writes and their side-effects on page G6-4772* for definitions of the terms *direct write*, *direct read*, *indirect write*, and *indirect read*.

A *direct write* to a System register might become visible at any point after the change to the register, but without a *Context synchronization event* there is no guarantee that the change becomes visible. Any direct write to a System register is guaranteed not to affect any instruction that appears, in program order, before the instruction that performed the direct write, and any direct write to a System register must be synchronized before any instruction that appears after the direct write, in program order, can rely on the effect of that write. The only exceptions to this are:

- All direct writes to the same register, using the same encoding, are guaranteed to occur in program order.
- All direct writes to a register are guaranteed to occur in program order relative to all direct reads of the same register using the same encoding.
- Any System register access that an ARM *Architecture Specification* or equivalent specification defines as not requiring synchronization.
- If an instruction that appears in program order before the direct write performs a memory access, such as a memory-mapped register access, that causes an indirect read or write to a register, that memory access is subject to the memory order model. In this case, if permitted by the memory order model, the instruction that appears in program order before the direct write can be affected by the direct write. For information about the memory order model, see *Definition of the ARMv8 memory model on page E2-2762*.

These rules mean that an instruction that writes to one of the address translation instructions described in *Address translation instructions on page G4-4682* must be explicitly synchronized to guarantee that the result of the address translation instruction is visible in the PAR.

**Note**

In this case, the direct write to the encoding of the address translation instruction causes an *indirect write* to the PAR. Without a *Context synchronization event* after the direct write, there is no guarantee that the indirect write to the PAR is visible.

Conceptually, the explicit synchronization occurs as the first step of any *Context synchronization event*. This means that if the operation uses the state that had been changed but not synchronized before the operation occurred, the operation is guaranteed to use the state as if it had been synchronized.

**Note**

- This explicit synchronization is applied as the first step of the execution of any instruction that causes the synchronization operation. This means it does not synchronize any effect of changes to the System registers that might affect the fetch and decode of the instructions that cause the operation, such as breakpoints or changes to translation tables.
- For a synchronous exception, the control state in use at the time the exception is generated determines the exception syndrome information, and this syndrome information is not changed by this synchronization at the start of taking the exception.
Except for the register reads listed in *Registers with some architectural guarantee of ordering or observability* on page G6-4771, if no *Context synchronization event* is performed, direct reads of System registers can occur in any order.

Table G6-1 shows the synchronization requirement between two reads or writes that access the same System register. In the column headings, *First* and *Second* refer to:

- Program order, for any read or write caused by the execution of an instruction by this PE, other than a read or write caused by a memory access made by that instruction.
- The order of arrival of asynchronous reads or writes made by this PE relative to the execution of instructions by this PE.

In addition:

- For indirect reads or writes caused by an external agent, such as a debugger, the mechanism that determines the order of the reads or writes is defined by that external agent. The external agent can provide mechanisms that ensure that any read or write it makes arrives at the PE. These indirect reads and writes are asynchronous to software execution on the PE.
- For indirect reads or writes caused by memory-mapped reads or writes made by this PE, the ordering of the memory accesses is subject to the memory order model, including the effect of the memory type of the accessed memory address. This applies, for example, if this PE reads or writes one of its registers in a memory-mapped register interface. The mechanism for ensuring completion of these memory accesses, including ensuring the arrival of the asynchronous read or write at the PE, is defined by the system.

**Note**

Such accesses are likely to be given a Device memory attribute, but requiring this is outside the scope of the architecture.

- For indirect reads or writes caused by autonomous asynchronous events that are counted, for example events caused by the passage of time, the events are ordered so that:
  - Counts progress monotonically.
  - The events arrive at the PE in finite time and without undue delay.

</tr>
</tbody>
</table>
If the indirect write is to a register that Registers with some architectural guarantee of ordering or observability on page G6-4771 shows as having some guarantee of the visibility of an indirect write, synchronization might not be required.

If a direct read or a direct write to a register is followed by an indirect write to that register that is caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the indirect write relative to the direct read or direct write.

If an indirect write caused by a direct write is followed by an indirect write caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the two indirect writes.

If a direct read causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct read, before any subsequent direct or indirect read or write.

If a direct write causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct write, before any subsequent direct or indirect read or write.

Note

Where a register has more than one encoding, a direct write to the register using a particular encoding is not an indirect write to the same register with a different encoding.

Where an indirect write is caused by the action of an external agent, such as a debugger, or by a memory-mapped read or write by the PE, then an indirect write by that agent to a register using a particular access mechanism, followed by an indirect read by that agent to the same register using the same access mechanism and address does not need synchronization.

For information about the additional synchronization requirements for memory-mapped registers, see Synchronization requirements for AArch64 System registers on page D7-2191.

To guarantee the visibility of changes to some registers, additional operations might be required before the Context synchronization event. For such a register, the definition of the register identifies these additional requirements.

In this manual, unless the context indicates otherwise:

- **Accessing** a System register refers to a direct read or write of the register.
- **Using** a System register refers to an indirect read or write of the register.
**Registers with some architectural guarantee of ordering or observability**

For the registers for which Table G6-2 shows that the ordering of direct reads is guaranteed, multiple direct reads of a single register, using the same encoding, occur in program order without any explicit ordering.

For the registers for which Table G6-2 shows that some observability of indirect writes is guaranteed, an indirect write to the register caused by an external agent, an autonomous asynchronous event, or as a result of a memory-mapped write, is both:

- Observable to direct reads of the register, in finite time, without explicit synchronization.
- Observable to subsequent indirect reads of the register without explicit synchronization.

These two sets of registers are similar, as Table G6-2 shows:

</tbody>
</table>

In addition to the requirements shown in Table G6-2:

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
  - OSLAR_EL1. OSLAR_EL1 is indirectly read to determine whether the subsequent access is permitted.

  **Note**

  OSLAR_EL1 maps to the AArch32 System register DBGOSLAR.
EDLAR, if implemented. EDLAR is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

--- Note ---
This requirement is stricter than the general requirement for the observability of indirect writes.

- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See DCC and ITR access in Debug state on page H4-5513.

The possibility that direct reads can occur early, in the absence of context synchronization, described in Ordering of reads of System registers on page G4-4689, still applies to the registers listed in Table G6-2 on page G6-4771.

Definitions of direct and indirect reads and writes and their side-effects

Direct and indirect reads and writes are defined as follows:

**Direct read**
Is a read of a register, using an MRC, MRRC, or STC instruction, that the architecture permits for the current PE state.

If a direct read of a register has a side-effect of changing the value of a register, the effect of a direct read on that register is defined to be an indirect write, and has the synchronization requirements of an indirect write. This means the indirect write is guaranteed to have occurred, and to be visible to subsequent direct or indirect reads and writes only if synchronization is performed after the direct read.

--- Note ---
The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.

**Direct write**
Is a write to a register, using an MCR, MCRR, or LDC instruction, that the architecture permits for the current PE state.

In the following cases, the side-effect of the direct write is defined to be an indirect write of the affected register, and has the synchronization requirements of an indirect write:

- If the direct write has a side-effect of changing the value of a register other than the register accessed by the direct write.
- If the direct write has a side-effect of changing the value of the register accessed by the direct write, so that the value in that register might not be the value that the direct write wrote to the register.

In both cases, this means that the indirect write is not guaranteed to be visible to subsequent direct or indirect reads and writes unless synchronization is performed after the direct write.

--- Note ---
- As an example of a direct write to a register having an effect that is an indirect write of that register, writing 1 to a PMCNTENCLR.Px bit is also an indirect write, because if the Px bit had the value 1 before the direct write, the side-effect of the write changes the value of that bit to 0.
- The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.

For example, writing 1 to a PMCNTENCLR.Px bit that is set to 1 also changes the corresponding PMCNTENSET.Px bit from 1 to 0. This means that the direct write to the PMCNTENCLR defines indirect writes to both itself and to the PMCNTENSET.

--- Indirect read ---
Is a use of the register by an instruction to establish the operating conditions for the instruction. Examples of operating conditions that might be determined by an indirect read are the translation table base address, or whether memory accesses are forced to be Non-cacheable.
Indirect reads include situations where the value of one register determines what value is returned by a second register. This means that any read of the second register is an indirect read of the register that determines what value is returned.

Indirect reads also include:

- Reads of the System registers by external agents, such as debuggers, as described in Debug registers on page G6-5239.
- Memory-mapped reads of the System registers made by the PE on which the System registers are implemented.

Where an indirect read of a register has a side-effect of changing the value of a register, that change is defined to be an indirect write, and has the synchronization requirements of an indirect write.

**Indirect write** is an update to the value of a register as a consequence of either:

- An exception, operation, or execution of an instruction that is not a direct write to that register.
- The asynchronous operation of an external agent.

This can include:

- The passage of time, as seen in counters or timers, including performance counters.
- The assertion of an interrupt.
- A write from an external agent, such as a debugger.

However, for some registers, the architecture gives some guarantee of visibility without any explicit synchronization, see Registers with some architectural guarantee of ordering or observability on page G6-4771.

Note

Taking an exception is a context-synchronizing operation. Therefore, any indirect write performed as part of an exception entry does not require additional synchronization. This includes the indirect writes to the registers that report the exception, as described in Exception reporting in a VMSAv8-32 implementation on page G4-4663.
G6.2 General system control registers

This section lists the System registers in AArch32 state that are not part of one of the other listed groups.
G6.2.1 ACTLR, Auxiliary Control Register

The ACTLR characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

**Configurations**

AArch32 System register ACTLR is architecturally mapped to AArch64 System register ACTLR_EL1[31:0].

Some bits might define global configuration settings, and be common to the Secure and Non-secure instances of the register.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ACTLR is a 32-bit register.

**Field descriptions**

The ACTLR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

**IMPLEMENTATION DEFINED, bits [31:0]**

IMPLEMENTATION DEFINED.

**Accessing the ACTLR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TACR==1, Non-secure accesses to this register from EL1 are trapped to EL2 using AArch64.
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TACR==1, Non-secure accesses to this register from EL1 are trapped to EL2 using AArch64.
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TAC==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.2 ACTLR2, Auxiliary Control Register 2

The ACTLR2 characteristics are:

**Purpose**

Provides additional space to the ACTLR register to hold **IMPLEMENTATION DEFINED** trap functionality for execution at EL1 and EL0.

**Configurations**

AArch32 System register ACTLR2 is architecturally mapped to AArch64 System register `ACTLR_EL1[63:32]`.

In ARMv8.0 and ARMv8.1, it is **IMPLEMENTATION DEFINED** whether this register is implemented, or whether it causes **UNDEFINED** exceptions when accessed. The implementation of this register can be detected by examining `ID_MMFR4.AC2`.

From ARMv8.2 this register must be implemented.

**Attributes**

RW fields in this register reset to architecturally **UNKNOWN** values.

**Field descriptions**

The ACTLR2 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td><strong>IMPLEMENTATION DEFINED</strong></td>
</tr>
</tbody>
</table>

**Accessing the ACTLR2**

This register can be read using MRC with the following syntax:

`MRC <syntax>`

This register can be written using MCR with the following syntax:

`MCR <syntax>`

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TACR==1, Non-secure accesses to this register from EL1 are trapped to EL2 using AArch64.
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TACR==1, Non-secure accesses to this register from EL1 are trapped to EL2 using AArch64.
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TAC==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.3 ADFSR, Auxiliary Data Fault Status Register

The ADFSR characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for Data Abort exceptions taken to EL1 modes, and EL3 modes when EL3 is implemented and is using AArch32.

**Configurations**

AArch32 System register ADFSR is architecturally mapped to AArch64 System register AFSR0_EL1.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ADFSR is a 32-bit register.

**Field descriptions**

The ADFSR bit assignments are:

![Field descriptions](image)

**IMPLEMENTATION DEFINED, bits [31:0]**

IMPLEMENTATION DEFINED.

**Accessing the ADFSR**

This register can be read using MRC with the following syntax:

\[ \text{MRC } \text{<syntax>} \]

This register can be written using MCR with the following syntax:

\[ \text{MCR } \text{<syntax>} \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c5, c1, 0</td>
<td>000</td>
<td>000</td>
<td>0101</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>
### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T5==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
### G6.2.4 AIDR, Auxiliary ID Register

The AIDR characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED identification information.
The value of this register must be used in conjunction with the value of MIDR.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register AIDR is architecturally mapped to AArch64 System register AIDR_EL1.

**Attributes**

AIDR is a 32-bit register.

**Field descriptions**

The AIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

**Accessing the AIDR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 1, &lt;R&gt;, c0, c0, 7</td>
<td>001</td>
<td>111</td>
<td>0000</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EL0</td>

<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID1==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
### G6.2.5 AIFSR, Auxiliary Instruction Fault Status Register

The AIFSR characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for Prefetch Abort exceptions taken to EL1 modes, and EL3 modes when EL3 is implemented and is using AArch32.

**Configurations**

AArch32 System register AIFSR is architecturally mapped to AArch64 System register AFSR1_EL1.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AIFSR is a 32-bit register.

**Field descriptions**

The AIFSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:0]</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

**Accessing the AIFSR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c5, cl, l</td>
<td>000</td>
<td>001</td>
<td>0101</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>✓</td>
<td>1</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T5==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.6 AMAIR0, Auxiliary Memory Attribute Indirection Register 0

The AMAIR0 characteristics are:

**Purpose**

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR0.

**Configurations**

AArch32 System register AMAIR0 is architecturally mapped to AArch64 System register AMAIR_EL1[31:0].

When EL3 is using AArch32, write access to AMAIR0(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMAIR0 is a 32-bit register.

**Field descriptions**

The AMAIR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

This register is RES0 in the following cases:

- When an implementation does not provide any IMPLEMENTATION DEFINED memory attributes.
- When the Long-descriptor translation table format is not used.

If EL3 is implemented and is using AArch32:

- AMAIR0(S) gives the value for memory accesses from Secure state.
- AMAIR0(NS) gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

**Accessing the AMAIR0**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c10, c3, 0</td>
<td>000</td>
<td>000</td>
<td>1010</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL3 is not implemented.</td>
<td>x  x  0</td>
<td>-  RW  n/a  n/a</td>
<td>AMAIR0</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x  0  1</td>
<td>-  RW  RW  n/a</td>
<td>AMAIR0</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x  1  1</td>
<td>-  n/a  RW  n/a</td>
<td>AMAIR0</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x  x  0</td>
<td>-  RW  n/a  n/a</td>
<td>AMAIR0</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x  0  1</td>
<td>-  RW  RW  n/a</td>
<td>AMAIR0</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x  1  1</td>
<td>-  n/a  RW  n/a</td>
<td>AMAIR0</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x  0  1</td>
<td>-  RW  RW  RW</td>
<td>AMAIR0 ns</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x  1  1</td>
<td>-  n/a  RW  RW</td>
<td>AMAIR0 ns</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x  x  0</td>
<td>-  n/a  n/a  RW</td>
<td>AMAIR0 s</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to AMAIR0_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state*. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.7 AMAIR1, Auxiliary Memory Attribute Indirection Register 1

The AMAIR1 characteristics are:

**Purpose**

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR1.

**Configurations**

AArch32 System register AMAIR1 is architecturally mapped to AArch64 System register AMAIR_EL1[63:32].

When EL3 is using AArch32, write access to AMAIR1(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMAIR1 is a 32-bit register.

**Field descriptions**

The AMAIR1 bit assignments are:

<table>
<thead>
<tr>
<th>Field Assignment</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:0</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

This register is RES0 in the following cases:

- When an implementation does not provide any IMPLEMENTATION DEFINED memory attributes.
- When the Long-descriptor translation table format is not used.

If EL3 is implemented and is using AArch32:

- AMAIR1(S) gives the value for memory accesses from Secure state.
- AMAIR1(NS) gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architectured behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

**Accessing the AMAIR1**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

\[
\begin{array}{cccccccc}
\text{<syntax>} & \text{opc1} & \text{opc2} & \text{CRn} & \text{coproc} & \text{CRm} \\
p15, 0, \langle \text{Rt} \rangle, c10, c3, 1 & 000 & 001 & 1010 & 1111 & 0011 \\
\end{array}
\]

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL3 is not implemented.</td>
<td>x x 0</td>
<td>- RW n/a n/a</td>
<td>AMAIR1</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 0 1</td>
<td>- RW RW n/a</td>
<td>AMAIR1</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 1 1</td>
<td>- n/a RW n/a</td>
<td>AMAIR1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x x 0</td>
<td>- RW n/a n/a</td>
<td>AMAIR1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 0 1</td>
<td>- RW RW n/a</td>
<td>AMAIR1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 1 1</td>
<td>- n/a RW n/a</td>
<td>AMAIR1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x 0 1</td>
<td>- RW RW RW</td>
<td>AMAIR1_ns</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x 1 1</td>
<td>- n/a RW RW</td>
<td>AMAIR1_ns</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x x 0</td>
<td>- n/a n/a RW</td>
<td>AMAIR1_s</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to AMAIR1\_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If HCR\_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR\_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR\_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If HCR\_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR\_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR\_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR\_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
### G6.2.8 APSR, Application Program Status Register

The APSR characteristics are:

**Purpose**

Hold program status and control information.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

APSR is a 32-bit register.

**Field descriptions**

The APSR bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Z</td>
<td>C</td>
<td>V</td>
<td>Q</td>
<td>RES0</td>
<td>GE</td>
<td>RES0</td>
<td>RES0</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

- **N**, bit [31]
  
  Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then N is set to 1 if the result was negative, and N is set to 0 if the result was positive or zero.

- **Z**, bit [30]
  
  Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

- **C**, bit [29]
  
  Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

- **V**, bit [28]
  
  Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

- **Q**, bit [27]
  
  Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

- **Bits [26:20]**
  
  Reserved, RES0.

- **GE**, bits [19:16]
  
  Greater than or Equal flags, for parallel addition and subtraction.

- **Bits [15:5]**
  
  Reserved, RES0.

- **Bit [4]**
  
  Reserved, RES1.
Bits [3:0]

Reserved, RES0.
G6.2.9  ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read

The ATS12NSOPR characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if reading from the given virtual address.

**Configurations**

There are no configuration notes.

**Attributes**

ATS12NSOPR is a 32-bit System instruction.

**Field descriptions**

The ATS12NSOPR input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>Input address for translation. The resulting address can be read from the PAR. This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.</td>
</tr>
</tbody>
</table>

**Executing the ATS12NSOPR instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c8, 4</td>
<td>000</td>
<td>100</td>
<td>0111</td>
<td>1111</td>
<td>1000</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- - n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- - WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, execution of ATS12NSOPR in Secure EL1 using AArch32 is trapped as an exception to EL3.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.10 ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write

The ATS12NSOPW characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if writing to the given virtual address.

**Configurations**

There are no configuration notes.

**Attributes**

ATS12NSOPW is a 32-bit System instruction.

**Field descriptions**

The ATS12NSOPW input value bit assignments are:

```
<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Input address for translation</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:0]**

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

**Executing the ATS12NSOPW instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c8, 5</td>
<td>000</td>
<td>101</td>
<td>0111</td>
<td>1111</td>
<td>1000</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

```
Control | Accessibility
---------|-------------------
E2 TGE NS | EL0 EL1 EL2 EL3
x x 0 | - - n/a WO
x 0 1 | - - WO WO
x 1 1 | - n/a WO WO
```

If EL3 is implemented and is using AArch64, execution of ATS12NSOPW in Secure EL1 using AArch32 is trapped as an exception to EL3.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read

The ATS12NSOUR characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for PL0 and the Non-secure state, with permissions as if reading from the given virtual address.

**Configurations**

There are no configuration notes.

**Attributes**

ATS12NSOUR is a 32-bit System instruction.

**Field descriptions**

The ATS12NSOUR input value bit assignments are:

```
+---+---+---+---+---+---+---+
| 31| 30| 29| 28| 27| 26| 25 |
+---+---+---+---+---+---+---+
|   |   |   |   |   |   |   |
+---+---+---+---+---+---+---+
```

**Bits [31:0]**

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

**Executing the ATS12NSOUR instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c8, 6</td>
<td>000</td>
<td>110</td>
<td>0111</td>
<td>1111</td>
<td>1000</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- - n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- - WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, execution of ATS12NSOUR in Secure EL1 using AArch32 is trapped as an exception to EL3.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.12   ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write

The ATS12NSOUW characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for PL0 and the Non-secure state, with
permissions as if writing to the given virtual address.

**Configurations**

There are no configuration notes.

**Attributes**

ATS12NSOUW is a 32-bit System instruction.

**Field descriptions**

The ATS12NSOUW input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:0</td>
<td>Input address for translation. The resulting address can be read from the PAR. This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.</td>
</tr>
</tbody>
</table>

**Executing the ATS12NSOUW instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c8, 7</td>
<td>000</td>
<td>111</td>
<td>0111</td>
<td>1111</td>
<td>1000</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>TGE</td>
<td>- - n/a WO</td>
</tr>
<tr>
<td>NS</td>
<td>x x 0</td>
</tr>
<tr>
<td></td>
<td>x 0 1</td>
</tr>
<tr>
<td></td>
<td>x 1 1</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, execution of ATS12NSOUW in Secure EL1 using AArch32 is trapped as an exception to EL3.
Traps and Enables

For a description of the prioritization of any generated exceptions, see "Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state." Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.13 ATS1CPR, Address Translate Stage 1 Current state PL1 Read

The ATS1CPR characteristics are:

**Purpose**

Performs stage 1 address translation as defined for PL1 and the current Security state, with permissions as if reading from the given virtual address.

**Configurations**

There are no configuration notes.

**Attributes**

ATS1CPR is a 32-bit System instruction.

**Field descriptions**

The ATS1CPR input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Input address for translation</td>
</tr>
</tbody>
</table>

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

**Executing the ATS1CPR instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c8, 0</td>
<td>000</td>
<td>000</td>
<td>0111</td>
<td>1111</td>
<td>1000</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EL0</td>
</tr>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.14 ATS1CPRP, Address Translate Stage 1 Current state PL1 Read PAN

The ATS1CPRP characteristics are:

**Purpose**

When ARMv8.2-ATS1E1 is implemented, performs a stage 1 address translation at PL1 and in the current Security state, where the value of PSTATE.PAN determines if a read from a location will generate a permission fault for a privileged access.

**Configurations**

This instruction is introduced in ARMv8.2.

**Attributes**

ATS1CPRP is a 32-bit System instruction.

**Field descriptions**

The ATS1CPRP input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Input address for translation</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>0</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.15  ATS1CPW, Address Translate Stage 1 Current state PL1 Write

The ATS1CPW characteristics are:

**Purpose**

Performs stage 1 address translation as defined for PL1 and the current Security state, with permissions as if writing to the given virtual address.

**Configurations**

There are no configuration notes.

**Attributes**

ATS1CPW is a 32-bit System instruction.

**Field descriptions**

The ATS1CPW input value bit assignments are:

```
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
</tr>
<tr>
<td>Input address for translation</td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:0]**

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

**Executing the ATS1CPW instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

```
<syntax> opc1 opc2 CRn coproc CRm
p15, 0, <Rt>, c7, c8, 1 000 001 0111 1111 1000
```

**Accessibility**

The instruction is executable as follows:

```
<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>
```
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.16  ATS1CPWP, Address Translate Stage 1 Current state PL1 Write PAN

The ATS1CPWP characteristics are:

**Purpose**

When ARMv8.2-ATS1E1 is implemented, performs a stage 1 address translation at PL1 and in the current Security state, where the value of PSTATE.PAN determines if a write to the location will generate a permission fault for a privileged access.

**Configurations**

This instruction is introduced in ARMv8.2.

**Attributes**

ATS1CPWP is a 32-bit System instruction.

**Field descriptions**

The ATS1CPWP input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Input address for translation</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td></td>
</tr>
</tbody>
</table>

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

**Executing the ATS1CPWP instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c9, 1</td>
<td>000</td>
<td>001</td>
<td>0111</td>
<td>1111</td>
<td>1001</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>WO n/a WO WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>WO WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>n/a WO WO</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.17   ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read

The ATS1CUR characteristics are:

**Purpose**

Performs stage 1 address translation as defined for PL0 and the current Security state, with permissions as if reading from the given virtual address.

**Configurations**

There are no configuration notes.

**Attributes**

ATS1CUR is a 32-bit System instruction.

**Field descriptions**

The ATS1CUR input value bit assignments are:

![Input address for translation](image)

**Bits [31:0]**

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

**Executing the ATS1CUR instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c8, 2</td>
<td>000</td>
<td>010</td>
<td>0111</td>
<td>1111</td>
<td>1000</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>
**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.18  ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write

The ATS1CUW characteristics are:

**Purpose**

Performs stage 1 address translation as defined for PL0 and the current Security state, with permissions as if writing to the given virtual address.

**Configurations**

There are no configuration notes.

**Attributes**

ATS1CUW is a 32-bit System instruction.

**Field descriptions**

The ATS1CUW input value bit assignments are:

```
+-------------------+--------+
| Bits [31:0]       | Value  |
+-------------------+--------+
| Input address for translation | 000    |
+-------------------+--------+
```

**Bits [31:0]**

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

**Executing the ATS1CUW instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

```
<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c8, 3</td>
<td>000</td>
<td>011</td>
<td>0111</td>
<td>1111</td>
<td>1000</td>
</tr>
</tbody>
</table>
```

**Accessibility**

The instruction is executable as follows:

```
<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>
```
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.19 ATS1HR, Address Translate Stage 1 Hyp mode Read

The ATS1HR characteristics are:

**Purpose**

Performs stage 1 address translation as defined for PL2 and the Non-secure state, with permissions as if reading from the given virtual address.

**Configurations**

There are no configuration notes.

**Attributes**

ATS1HR is a 32-bit System instruction.

**Field descriptions**

The ATS1HR input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td>Input address for translation</td>
</tr>
</tbody>
</table>

This instruction takes a VA as input. The resulting address is the PA that is the output address of the translation.

**Executing the ATS1HR instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c7, c8, 0</td>
<td>100</td>
<td>000</td>
<td>0111</td>
<td>1111</td>
<td>1000</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- - n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- - WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>
If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.20 ATS1HW, Address Translate Stage 1 Hyp mode Write

The ATS1HW characteristics are:

**Purpose**
Performs stage 1 address translation as defined for PL2 and the Non-secure state, with permissions as if writing to the given virtual address.

**Configurations**
There are no configuration notes.

**Attributes**
ATS1HW is a 32-bit System instruction.

**Field descriptions**
The ATS1HW input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Input address for translation</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td>Input address for translation. The resulting address can be read from the PAR. This instruction takes a VA as input. The resulting address is the PA that is the output address of the translation.</td>
</tr>
</tbody>
</table>

**Executing the ATS1HW instruction**
This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c7, c8, 1</td>
<td>100</td>
<td>001</td>
<td>0111</td>
<td>1111</td>
<td>1000</td>
</tr>
</tbody>
</table>

**Accessibility**
The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- - n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- - WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>
If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is
CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.21 BPIALL, Branch Predictor Invalidate All

The BPIALL characteristics are:

**Purpose**
Invalidate all entries from branch predictors.

**Configurations**
In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

**Attributes**
BPIALL is a 32-bit System instruction.

**Field descriptions**
BPIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the BPIALL instruction**
This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c5, 6</td>
<td>000</td>
<td>110</td>
<td>1111</td>
<td>1111</td>
<td>0101</td>
</tr>
</tbody>
</table>

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

**Accessibility**
The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a BPIALLIS.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.22 BPIALLIS, Branch Predictor Invalidate All, Inner Shareable

The BPIALLIS characteristics are:

Purpose

Invalidate all entries from branch predictors Inner Shareable.

Configurations

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

Attributes

BPIALLIS is a 32-bit System instruction.

Field descriptions

BPIALLIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the BPIALLIS instruction

This instruction is executed using MCR with the following syntax:

\[ \text{MCR} <\text{syntax}> \]

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c1, 6</td>
<td>000</td>
<td>110</td>
<td>0111</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) &&
  (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.23  BPIMVA, Branch Predictor Invalidate by VA

The BPIMVA characteristics are:

**Purpose**

Invalidate virtual address from branch predictors.

**Configurations**

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

**Attributes**

BPIMVA is a 32-bit System instruction.

**Field descriptions**

The BPIMVA input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
</tr>
</tbody>
</table>

**Executing the BPIMVA instruction**

This instruction is executed using MCR with the following syntax:

`MCR <syntax>`

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c5, 7</td>
<td>000</td>
<td>111</td>
<td>0111</td>
<td>1111</td>
<td>0101</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
**G6.2.24 CCSIDR, Current Cache Size ID Register**

The CCSIDR characteristics are:

**Purpose**

Provides information about the architecture of the currently selected cache.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states. AArch32 System register CCSIDR is architecturally mapped to AArch64 System register CCSIDR_EL1.

The implementation includes one CCSIDR for each cache that it can access. CSSELR and the Security state select which Cache Size ID Register is accessible.

**Attributes**

CCSIDR is a 32-bit register.

**Field descriptions**

The CCSIDR bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNKNOWN</td>
<td>[31:28]</td>
<td>Reserved, UNKNOWN.</td>
</tr>
<tr>
<td>NumSets</td>
<td>[27:13]</td>
<td>(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.</td>
</tr>
<tr>
<td>Associativity</td>
<td>[12:3]</td>
<td>(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.</td>
</tr>
<tr>
<td>LineSize</td>
<td>[2:0]</td>
<td>(Log₂(Number of bytes in cache line)) - 4. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For a line length of 16 bytes: Log₂(16) = 4, LineSize entry = 0. This is the minimum line length.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For a line length of 32 bytes: Log₂(32) = 5, LineSize entry = 1.</td>
</tr>
</tbody>
</table>

--- **Note**

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

--- **Accessing the CCSIDR**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 1, &lt;R&gt;, c0, 0</td>
<td>001</td>
<td>000</td>
<td>0000</td>
<td>1111</td>
<td>000</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If CSSELR.Level is programmed to a cache level that is not implemented, then on a read of the CCSIDR the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR read is treated as NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state*. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID2==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.25   CLIDR, Cache Level ID Register

The CLIDR characteristics are:

**Purpose**

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states. AArch32 System register CLIDR is architecturally mapped to AArch64 System register CLIDR_EL1.

**Attributes**

CLIDR is a 32-bit register.

**Field descriptions**

The CLIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>ICB</td>
</tr>
<tr>
<td>30</td>
<td></td>
</tr>
<tr>
<td>29</td>
<td>LoUU</td>
</tr>
<tr>
<td>28</td>
<td>LoC</td>
</tr>
<tr>
<td>27</td>
<td>LoUIS</td>
</tr>
<tr>
<td>26</td>
<td>Ctype7</td>
</tr>
<tr>
<td>25</td>
<td>Ctype6</td>
</tr>
<tr>
<td>24</td>
<td>Ctype5</td>
</tr>
<tr>
<td>23</td>
<td>Ctype4</td>
</tr>
<tr>
<td>22</td>
<td>Ctype3</td>
</tr>
<tr>
<td>21</td>
<td>Ctype2</td>
</tr>
<tr>
<td>20</td>
<td>Ctype1</td>
</tr>
</tbody>
</table>

**ICB, bits [31:30]**

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The possible values are:

- 00: Not disclosed by this mechanism.
- 01: L1 cache is the highest Inner Cacheable level.
- 10: L2 cache is the highest Inner Cacheable level.
- 11: L3 cache is the highest Inner Cacheable level.

**LoUU, bits [29:27]**

Level of Unification Uniprocessor for the cache hierarchy.

**LoC, bits [26:24]**

Level of Coherence for the cache hierarchy.

**LoUIS, bits [23:21]**

Level of Unification Inner Shareable for the cache hierarchy.

**Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 1 to 7**

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

- 000: No cache.
- 001: Instruction cache only.
- 010: Data cache only.
- 011: Separate instruction and data caches.
Unified cache.
All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no caches that can be managed using the architected cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

Accessing the CLIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 1, &lt;Rt&gt;, c0, c0, l</td>
<td>001</td>
<td>001</td>
<td>0000</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td></td>
</tr>
<tr>
<td>NS</td>
<td></td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID2==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.26 CONTEXTIDR, Context ID Register

The CONTEXTIDR characteristics are:

**Purpose**

- Identifies the current Process Identifier and, when using the Short-descriptor translation table format, the Address Space Identifier.
- The value of the whole of this register is called the Context ID and is used by:
  - The debug logic, for Linked and Unlinked Context ID matching.
  - The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

**Configurations**

AArch32 System register CONTEXTIDR is architecturally mapped to AArch64 System register CONTEXTIDR_EL1.

The register format depends on whether address translation is using the Long-descriptor or the Short-descriptor translation table format.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CONTEXTIDR is a 32-bit register.

**Field descriptions**

The CONTEXTIDR bit assignments are:

*When TTBCR.EAE==0:*

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PROCID</td>
<td></td>
<td>ASID</td>
</tr>
</tbody>
</table>

**PROCID, bits [31:8]**

Process Identifier. This field must be programmed with a unique value that identifies the current process.

**ASID, bits [7:0]**

Address Space Identifier. This field is programmed with the value of the current ASID.

*When TTBCR.EAE==1:*

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PROCID</td>
</tr>
</tbody>
</table>

**PROCID, bits [31:0]**

Process Identifier. This field must be programmed with a unique value that identifies the current process.

**Accessing the CONTEXTIDR**

This register can be read using MRC with the following syntax:
MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c13, c0, 1</td>
<td>000</td>
<td>001</td>
<td>1110</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H</td>
<td>EL0</td>
<td>EL1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>

</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
If HSTR.T13==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.27 CP15DMB, Data Memory Barrier System instruction

The CP15DMB characteristics are:

**Purpose**

Performs a Data Memory Barrier.

ARM deprecates any use of this operation, and strongly recommends that software use the DMB instruction instead.

**Configurations**

There are no configuration notes.

**Attributes**

CP15DMB is a 32-bit System instruction.

**Field descriptions**

CP15DMB ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the CP15DMB instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c10, 5</td>
<td>000</td>
<td>101</td>
<td>0111</td>
<td>1111</td>
<td>1010</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>WO</td>
</tr>
<tr>
<td>NS</td>
<td>WO</td>
</tr>
<tr>
<td>x</td>
<td>WO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If SCTLR.CP15BEN==0, execution of this instruction at PL0 and PL1 is UNDEFINED.
  - If SCTLR_EL1.CP15BEN==0, execution of this instruction at PL0 is UNDEFINED.
  - If HSCTLR.CP15BEN==0, execution of this instruction at PL2 is UNDEFINED.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) &&
  (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T7==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to Hyp mode.
G6.2.28 CP15DSB, Data Synchronization Barrier System instruction

The CP15DSB characteristics are:

**Purpose**

Performs a Data Synchronization Barrier.

ARM deprecates any use of this operation, and strongly recommends that software use the DSB instruction instead.

**Configurations**

There are no configuration notes.

**Attributes**

CP15DSB is a 32-bit System instruction.

**Field descriptions**

CP15DSB ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the CP15DSB instruction**

This instruction is executed using MCR with the following syntax:

\[ \text{MCR <syntax>} \]

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c10, 4</td>
<td>000</td>
<td>100</td>
<td>0111</td>
<td>1111</td>
<td>1010</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.* Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If SCTLR.CP15BEN==0, execution of this instruction at PL0 and PL1 is undefined.
  - If SCTLR_EL1.CP15BEN==0, execution of this instruction at PL0 is undefined.
  - If HSCTLR.CP15BEN==0, execution of this instruction at PL2 is undefined.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) &&
  (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T7==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to Hyp mode.
G6.2.29 CP15ISB, Instruction Synchronization Barrier System instruction

The CP15ISB characteristics are:

**Purpose**

Performs an Instruction Synchronization Barrier.

ARM deprecates any use of this operation, and strongly recommends that software use the ISB instruction instead.

**Configurations**

There are no configuration notes.

**Attributes**

CP15ISB is a 32-bit System instruction.

**Field descriptions**

CP15ISB ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the CP15ISB instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>  

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c5, 4</td>
<td>000</td>
<td>100</td>
<td>0111</td>
<td>1111</td>
<td>0101</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>TGE</td>
<td>WO WO WO WO</td>
</tr>
<tr>
<td>NS</td>
<td>x x 0</td>
</tr>
<tr>
<td></td>
<td>WO WO n/a WO</td>
</tr>
<tr>
<td></td>
<td>x 0 1</td>
</tr>
<tr>
<td></td>
<td>WO WO WO WO</td>
</tr>
<tr>
<td></td>
<td>x 1 1</td>
</tr>
<tr>
<td></td>
<td>WO WO WO WO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If SCTLR.CP15BEN==0, execution of this instruction at PL0 and PL1 is UNDEFINED.
  - If SCTLR_EL1.CP15BEN==0, execution of this instruction at PL0 is UNDEFINED.
  - If HSCTLR.CP15BEN==0, execution of this instruction at PL2 is UNDEFINED.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) &&
  (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T7==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to Hyp mode.
G6.2.30 CPACR, Architectural Feature Access Control Register

The CPACR characteristics are:

**Purpose**

Controls access to trace, and to Advanced SIMD and floating-point functionality from EL0, EL1, and EL3.

In an implementation that includes EL2, the CPACR has no effect on instructions executed at EL2.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CPACR is architecturally mapped to AArch64 System register CPACR_EL1.

Bits in the NSACR control Non-secure access to the CPACR fields. See the field descriptions for more information.

--- Note ---

In the register field descriptions, controls are described as applying at specified Privilege levels. This is because, in Secure state, a PL1 control:

- Applies to execution in a Secure EL3 mode when EL3 is using AArch32.
- Applies to execution in a Secure EL1 mode when EL3 is using AArch64.

See Security state, Exception levels, and AArch32 execution privilege on page G1-4318.

---

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CPACR is a 32-bit register.

**Field descriptions**

The CPACR bit assignments are:

```
31 30 29 28 27 24 23 22 21 20 19 0
| RES0 | cp11 | cp10 | RES0 |
```

ASEDIS, bit [31]

Disables PL0 and PL1 execution of Advanced SIMD instructions.

- 0 This control permits execution of Advanced SIMD instructions at PL0 and PL1.
- 1 All instruction encodings that are Advanced SIMD instruction encodings, but are not also floating-point instruction encodings, are UNDEFINED at PL0 and PL1.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSASEDIS is 1, this field behaves as RAO/WI in Non-secure state, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.
For the list of instructions affected by this field, see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2746.

See the description of CPACR.cp10 for a list of other controls that can disable or trap execution of Advanced SIMD instructions in AArch32 state.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**Bits [30:29]**

Reserved, RES0.

**TRCDIS, bit [28]**

Traps PL0 and PL1 System register accesses to all implemented trace registers to Undefined mode.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>This control has no effect on PL0 and PL1 System register accesses to trace registers.</td>
</tr>
<tr>
<td>1</td>
<td>PL0 and PL1 System register accesses to all implemented trace registers are trapped to Undefined mode.</td>
</tr>
</tbody>
</table>

If the implementation does not include a trace macrocell, or does not include a System register interface to the trace macrocell registers, this field is RES0. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSTRCDIS is 1, this field behaves as RAO/WI in Non-secure state, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

---

**Note**

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- The architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

**Bits [27:24]**

Reserved, RES0.

**cp11, bits [23:22]**

The value of this field is ignored. If this field is programmed with a different value to the cp10 field then this field is UNKNOWN on a direct read of the CPACR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In Non-secure state, if EL3 is implemented and is using AArch32, when the value of NSACR.cp10 is 0, this field behaves as RAZ/WI, regardless of its actual value.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**cp10, bits [21:20]**

Defines the access rights for the floating-point and Advanced SIMD functionality. Possible values of the field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>PL0 and PL1 accesses to floating-point and Advanced SIMD registers or instructions are UNDEFINED.</td>
</tr>
</tbody>
</table>
PL0 accesses to floating-point and Advanced SIMD registers or instructions are **UNDEFINED**.

Reserved. The effect of programming this field to this value is **CONSTRAINED UNPREDICTABLE**. See [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-6117.

This control permits full access to the floating-point and Advanced SIMD functionality from PL0 and PL1.

The floating-point and Advanced SIMD features controlled by these fields are:

- Execution of any floating-point or Advanced SIMD instruction.
- Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- Any access to the FPSCR, FPSID, MVFR0, MVFR1, MVFR2, or FPEXC System registers.

**Note**

The CPACR has no effect on floating-point and Advanced SIMD accesses from PL2. These can be disabled by the HCPTR.TCP10 field.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In Non-secure state, if EL3 is implemented and is using AArch32, when the value of NSACR.cp10 is 0, this field behaves as RAZ/WI, regardless of its actual value.

Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:

- CPACR.cp10, or, if executing at EL0, CPACR_EL1.FPEN.
- FPEXC.EN.
- If executing in Non-secure state:
  - HCPTR.TCP10, or if EL2 is using AArch64, CPTR_EL2.TFP.
  - NSACR.cp10, or if EL3 is using AArch64, CPTR_EL3.TFP.
- For Advanced SIMD instructions only:
  - CPACR.ASEDIS.
  - If executing in Non-secure state, HCPTR.TASE and NSACR.NSTRCDIS.

See the descriptions of the controls for more information.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**Bits [19:0]**

Reserved, RES0.

**Accessing the CPACR**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c1, c0, 2</td>
<td>000</td>
<td>010</td>
<td>0001</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.* Subject to the prioritization rules:

- When EL2 is implemented and using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CPTR_EL2.TCPAC==1, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CPTR_EL2.TCPAC==1, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and using AArch32 and SCR_EL3.NS == 1:
  - If HCPTR.TCPAC==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If CPTR_EL3.TCPAC==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.2.31 CPSR, Current Program Status Register

The CPSR characteristics are:

**Purpose**
Holds PE status and control information.

**Configurations**
There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**
CPSR is a 32-bit register.

**Field descriptions**
The CPSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>N, Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then N is set to 1 if the result was negative, and N is set to 0 if the result was positive or zero.</td>
</tr>
<tr>
<td>30</td>
<td>Z, Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.</td>
</tr>
<tr>
<td>29</td>
<td>C, Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.</td>
</tr>
<tr>
<td>28</td>
<td>V, Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.</td>
</tr>
<tr>
<td>27</td>
<td>Q, Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.</td>
</tr>
<tr>
<td>26</td>
<td>IT[1:0], IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.</td>
</tr>
<tr>
<td>24</td>
<td>J, RES0. In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.</td>
</tr>
</tbody>
</table>
Bit [23]

Reserved, RES0.

PAN, bit [22]

_In ARMv8.2 and ARMv8.1_

Privileged Access Never. When ARMv8.1-PAN is implemented, defined values are:

0 The translation system is the same as ARMv8.0.
1 Disables privileged read and write accesses to addresses accessible at EL0.

The value of this bit is usually preserved on taking an exception, except in the following situations:

• When the target of the exception is EL1, and the value of the SCTLR.SPAN bit for the current
  Security state is 0, this bit is set to 1.

• When the target of the exception is EL3, from Secure state, and the value of the Secure
  SCTLR.SPAN is 0, this bit is set to 1.

• When the target of the exception is EL3, from Non-secure state, this bit is set to 0 regardless
  of the value of the Secure SCTLR.SPAN bit.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bits [21:20]

Reserved, RES0.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

• IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the
  condition code specified by the first condition field of the IT instruction.

• IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be
  conditionally executed, by the position of the least significant 1 in this field. It also encodes
  the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation
1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also
applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide
Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception
return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to
any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

0 Exception not masked.
1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Indicates the AArch32 instruction set state. Possible values of this bit are:
0 A32 state.
1 T32 state.

Bit [4]

Reserved, RES1.

M[3:0], bits [3:0]

Current PE mode. Possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.
G6.2.32 CSSELR, Cache Size Selection Register

The CSSELR characteristics are:

**Purpose**

Selects the current Cache Size ID Register, CCSIDR, by specifying the required cache level and the cache type (either instruction or data cache).

**Configurations**

AArch32 System register CSSELR is architecturally mapped to AArch64 System register CSSELR_EL1.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CSSELR is a 32-bit register.

**Field descriptions**

The CSSELR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:4] RES0</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>[3:1] Level</td>
<td>Cache level of required cache. Permitted values are:</td>
</tr>
<tr>
<td></td>
<td>000 Level 1 cache</td>
</tr>
<tr>
<td></td>
<td>001 Level 2 cache</td>
</tr>
<tr>
<td></td>
<td>010 Level 3 cache</td>
</tr>
<tr>
<td></td>
<td>011 Level 4 cache</td>
</tr>
<tr>
<td></td>
<td>100 Level 5 cache</td>
</tr>
<tr>
<td></td>
<td>101 Level 6 cache</td>
</tr>
<tr>
<td></td>
<td>110 Level 7 cache</td>
</tr>
<tr>
<td>[0] InD</td>
<td>Instruction not Data bit. Permitted values are:</td>
</tr>
<tr>
<td></td>
<td>0 Data or unified cache.</td>
</tr>
<tr>
<td></td>
<td>1 Instruction cache.</td>
</tr>
</tbody>
</table>

If CSSELR.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

If CSSELR.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

**Accessing the CSSELR**

This register can be read using MRC with the following syntax:
MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 2, &lt;Rt&gt;, c0, c0, 0</td>
<td>010</td>
<td>000</td>
<td>0000</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL3 is not implemented.</td>
<td>x x 0</td>
<td>- RW n/a n/a</td>
<td>CSSELR</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 0 1</td>
<td>- RW RW n/a</td>
<td>CSSELR</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 1 1</td>
<td>- n/a RW n/a</td>
<td>CSSELR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x x 0</td>
<td>- RW n/a n/a</td>
<td>CSSELR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 0 1</td>
<td>- RW RW n/a</td>
<td>CSSELR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 1 1</td>
<td>- n/a RW n/a</td>
<td>CSSELR</td>
</tr>
<tr>

<td>CSSELR_ns</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on* page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.33 CTR, Cache Type Register

The CTR characteristics are:

**Purpose**

Provides information about the architecture of the caches.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CTR is architecturally mapped to AArch64 System register CTR_EL0.

**Attributes**

CTR is a 32-bit register.

**Field descriptions**

The CTR bit assignments are:

<table>
<thead>
<tr>
<th>Bit [31]</th>
<th>Reserved, RES1.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [30:28]</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
| CWG, bits [27:24] | Cache writeback granule. Log2 of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified. A value of 0b0000 indicates that this register does not provide Cache writeback granule information and either:
  • The architectural maximum of 512 words (2KB) must be assumed.
  • The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers. Values greater than 0b1001 are reserved. ARM recommends that an implementation that does not support cache write-back implements this field as 0b0001. This applies, for example, to an implementation that supports only write-through caches. |
| ERG, bits [23:20] | Exclusives reservation granule. Log2 of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions. A value of 0b0000 indicates that this register does not provide Exclusives reservation granule information and the architectural maximum of 512 words (2KB) must be assumed. Values greater than 0b1001 are reserved. |
| DminLine, bits [19:16] | Log2 of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE. |
L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

- **00**: VMID aware Physical Index, Physical tag (VPIPT)
- **01**: ASID-tagged Virtual Index, Virtual Tag (AIVIVT)
- **10**: Virtual Index, Physical Tag (VIPT)
- **11**: Physical Index, Physical Tag (PIPT)

The value 0b01 is reserved in ARMv8.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

Log₂ of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

Accessing the CTR

This register can be read using MRC with the following syntax:

**MRC <syntax>**

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c0, l</td>
<td>000</td>
<td>001</td>
<td>0000</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>-</td>
</tr>
<tr>
<td>x 0 1</td>
<td>-</td>
</tr>
<tr>
<td>x 1 1</td>
<td>-</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- **When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):**
  - If HCR_EL2.TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HCR_EL2.TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  — If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HCR.TID2==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  — If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.34 DACR, Domain Access Control Register

The DACR characteristics are:

Purpose

Defines the access permission for each of the sixteen memory domains.

Configurations

AArch32 System register DACR is architecturally mapped to AArch64 System register DACR32_EL2.

When EL3 is using AArch32, write access to DACR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

This register has no function when TTBCR.EAE is set to 1, to select the Long-descriptor translation table format.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DACR is a 32-bit register.

Field descriptions

The DACR bit assignments are:

D<n>, bits [2n+1:2n], for n = 0 to 15

Domain n access permission, where n = 0 to 15. Permitted values are:

00 No access. Any access to the domain generates a Domain fault.
01 Client. Accesses are checked against the permission bits in the translation tables.
11 Manager. Accesses are not checked against the permission bits in the translation tables.

The value 10 is reserved.

Accessing the DACR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c3, c0, 0</td>
<td>000</td>
<td>000</td>
<td>0011</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>x</td>
<td>-</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>0</td>
<td>1</td>
<td>-</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>1</td>
<td>1</td>
<td>-</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>x</td>
<td>-</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>0</td>
<td>1</td>
<td>-</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>1</td>
<td>1</td>
<td>-</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>x</td>
<td>-</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>0</td>
<td>1</td>
<td>-</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>1</td>
<td>1</td>
<td>-</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to DACR_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  — If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  — If HSTR_EL2.T3==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  — If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  — If HSTR_EL2.T3==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  — If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  — If HSTR.T3==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.35   DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC

The DCCIMVAC characteristics are:

**Purpose**

Clean and Invalidate data or unified cache line by virtual address to PoC.

**Configurations**

AArch32 System instruction DCCIMVAC performs the same function as AArch64 System instruction DC CIV AC.

**Attributes**

DCCIMVAC is a 32-bit System instruction.

**Field descriptions**

The DCCIMVAC input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
</table>

**Executing the DCCIMVAC instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c14, l</td>
<td>000</td>
<td>001</td>
<td>0111</td>
<td>1111</td>
<td>1110</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TPC==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.36 DCCISW, Data Cache line Clean and Invalidate by Set/Way

The DCCISW characteristics are:

**Purpose**

Clean and Invalidate data or unified cache line by set/way.

**Configurations**

AArch32 System instruction DCCISW performs the same function as AArch64 System instruction DC CISW.

**Attributes**

DCCISW is a 32-bit System instruction.

**Field descriptions**

The DCCISW input value bit assignments are:

```
31 4 3 1 0

SetWay        Level

RES0
```

**SetWay, bits [31:4]**

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

**Executing the DCCISW instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c14, 2</td>
<td>000</td>
<td>010</td>
<td>0111</td>
<td>1111</td>
<td>1110</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TSW==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.37 DCCMVAC, Data Cache line Clean by VA to PoC

The DCCMVAC characteristics are:

**Purpose**

Clean data or unified cache line by virtual address to PoC.

**Configurations**

AArch32 System instruction DCCMVAC performs the same function as AArch64 System instruction DCVAC.

**Attributes**

DCCMVAC is a 32-bit System instruction.

**Field descriptions**

The DCCMVAC input value bit assignments are:

```
<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>
```

**Executing the DCCMVAC instruction**

This instruction is executed using MCR with the following syntax:

`MCR <syntax>`

This syntax uses the following encoding in the System instruction encoding space:

```
<syntax> | opc1 | opc2 | CRn | coproc | CRm |
---------|------|------|-----|--------|-----|
0111 1111 1010 |
```

**Accessibility**

The instruction is executable as follows:

```
<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>
```
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TPC==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.38  DCCMVAU, Data Cache line Clean by VA to PoU

The DCCMVAU characteristics are:

**Purpose**
Clean data or unified cache line by virtual address to PoU.

**Configurations**
AArch32 System instruction DCCMVAU performs the same function as AArch64 System instruction DC CV AU.

**Attributes**
DCCMVAU is a 32-bit System instruction.

**Field descriptions**
The DCCMVAU input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
</table>

**Executing the DCCMVAU instruction**
This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c11, 1</td>
<td>000</td>
<td>001</td>
<td>0111</td>
<td>1111</td>
<td>1011</td>
</tr>
</tbody>
</table>

**Accessibility**
The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TPU==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.39  DCCSW, Data Cache line Clean by Set/Way

The DCCSW characteristics are:

Purpose
Clean data or unified cache line by set/way.

Configurations
AArch32 System instruction DCCSW performs the same function as AArch64 System instruction DC CSW.

Attributes
DCCSW is a 32-bit System instruction.

Field descriptions
The DCCSW input value bit assignments are:

SetWay, bits [31:4]
Contains two fields:
• Way, bits[31:32-A], the number of the way to operate on.
• Set, bits[31:B-1], the number of the set to operate on.
Bits[31:B-1] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).
ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]
Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]
Reserved, RES0.

Executing the DCCSW instruction
This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c10, 2</td>
<td>000</td>
<td>010</td>
<td>0111</td>
<td>1111</td>
<td>1010</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TSW==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.40 DCIMVAC, Data Cache line Invalidate by VA to PoC

The DCIMVAC characteristics are:

**Purpose**

Invalidate data or unified cache line by virtual address to PoC.

**Configurations**

AArch32 System instruction DCIMVAC performs the same function as AArch64 System instruction DCIVAC.

**Attributes**

DCIMVAC is a 32-bit System instruction.

**Field descriptions**

The DCIMVAC input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual address to use</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Virtual address to use.

**Executing the DCIMVAC instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c6, 1</td>
<td>000</td>
<td>001</td>
<td>0111</td>
<td>1111</td>
<td>0110</td>
</tr>
</tbody>
</table>

It is IMPLEMENTATION DEFINED whether, when this instruction is executed, it can generate a watchpoint. If this instruction can generate a watchpoint this is prioritized in the same way as other watchpoints.

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>WO</td>
</tr>
<tr>
<td>NS</td>
<td>n/a</td>
</tr>
</tbody>
</table>
At EL1, this instruction performs a cache clean and invalidate, meaning it performs the same invalidation as a DCCIMVAC instruction, if all of the following apply:

- EL2 is implemented and either:
  - EL2 is using AArch64 and the value of HCR_EL2.VM is 1.
  - EL2 is using AArch32 and the value of HCR.VM is 1.

- Execution is in Non-secure state, or EL3 is not implemented.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and using AArch64 and (SCR_EL3.NS == 1) & (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) & (HCR_EL2.E2H == 1) & (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TPC==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.41  DCISW, Data Cache line Invalidate by Set/Way

The DCISW characteristics are:

Purpose

Invalidate data or unified cache line by set/way.

Configurations

AArch32 System instruction DCISW performs the same function as AArch64 System instruction DCISW.

Attributes

DCISW is a 32-bit System instruction.

Field descriptions

The DCISW input value bit assignments are:

31 4 3 1 0
SetWay Level RES0

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DCISW instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c6, 2</td>
<td>000</td>
<td>010</td>
<td>0111</td>
<td>1111</td>
<td>0110</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

At EL1, this instruction performs a cache clean and invalidate, meaning it performs the same invalidation as a DCCISW instruction, if all of the following apply:

- EL2 is implemented and either:
  - EL2 is using AArch64 and the value of HCR_EL2. {SWIO, VM} is not {0, 0}.
  - EL2 is using AArch32 and the value of HCR. {SWIO, VM} is not {0, 0}.
- Execution is in Non-secure state, or EL3 is not implemented.

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TSW==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.42 DFAR, Data Fault Address Register

The DFAR characteristics are:

**Purpose**
Holds the virtual address of the faulting address that caused a synchronous Data Abort exception.

**Configurations**
- AArch32 System register DFAR(NS) is architecturally mapped to AArch64 System register FAR_EL1[31:0].
- AArch32 System register DFAR(S) is architecturally mapped to AArch32 System register HDFAR when EL2 is implemented.
- AArch32 System register DFAR(S) is architecturally mapped to AArch64 System register FAR_EL2[31:0] when EL2 is implemented.
- RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
DFAR is a 32-bit register.

**Field descriptions**
The DFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>VA of faulting address of synchronous Data Abort exception</td>
</tr>
</tbody>
</table>

**Accessing the DFAR**
This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c6, c0, 0</td>
<td>000</td>
<td>000</td>
<td>0110</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
<td></td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x x 0</td>
<td>n/a n/a RW</td>
<td>DFAR_s</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x x 0</td>
<td>RW n/a n/a</td>
<td>DFAR</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 0 1</td>
<td>RW RW n/a</td>
<td>DFAR</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 1 1</td>
<td>n/a RW n/a</td>
<td>DFAR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x x 0</td>
<td>RW n/a n/a</td>
<td>DFAR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 0 1</td>
<td>RW RW n/a</td>
<td>DFAR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 1 1</td>
<td>n/a RW n/a</td>
<td>DFAR</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x 0 1</td>
<td>RW RW RW</td>
<td>DFAR_ns</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x 1 1</td>
<td>n/a RW RW</td>
<td>DFAR_ns</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T6==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.43 DFSR, Data Fault Status Register

The DFSR characteristics are:

Purpose

Holds status information about the last data fault.

Configurations

AArch32 System register DFSR is architecturally mapped to AArch64 System register ESR_EL1. The current translation table format determines which format of the register is used. RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DFSR is a 32-bit register.

Field descriptions

The DFSR bit assignments are:

When TTBCR.EAE==0:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>

</tbody>
</table>

Bits [31:17]

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0  DFAR is valid.
1  DFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Data Abort exceptions.

AET, bits [15:14]

Asynchronous Error Type. When the RAS Extension is implemented, this field describes the state of the PE after taking an asynchronous Data Abort exception. Possible values are:

00  Uncontainable error (UC) or uncategorized.
01  Unrecoverable error (UEU).
10  Restartable error (UEO) or Corrected error (CE).
11  Recoverable error (UER).

When the RAS Extension is not implemented, or on a synchronous Data Abort, this field is RES0.
Note

ARMv8.2 requires the implementation of the RAS Extension.

In the event of multiple errors taken as a single SError interrupt exception, the overall state of the PE is reported.

Note

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

CM, bit [13]

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance instruction generated the fault. The possible values of this bit are:

0 Abort not caused by execution of a cache maintenance instruction.
1 Abort caused by execution of a cache maintenance instruction.

On a synchronous Data Abort on a translation table walk, this bit is UNKNOWN.

On an asynchronous fault, this bit is UNKNOWN.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0.

For aborts other than external aborts this bit always returns 0.

Write not Read bit. Indicates whether the abort was caused by a write or a read instruction. The possible values of this bit are:

0 Abort caused by a read instruction.
1 Abort caused by a write instruction.

For faults on the cache maintenance and address translation System instructions in the (coproc==1111) encoding space this bit always returns a value of 1.

FS[4], bit [10]

See FS[3:0], bits [3:0] for description of the FS field.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.
1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bit [8]

Reserved, RES0.

Domain, bits [7:4]

The domain of the fault address.

ARM deprecates any use of this field, see The Domain field in the DFSR on page G4-4669.

This field is UNKNOWN for certain faults where the DFSR is updated and reported using the Short-descriptor FSR encodings, see Table G4-29 on page G4-4673.
FS[3:0], bits [3:0]
Fault status bits. Interpreted with bit [10]. Possible values of FS[4:0] are:
- 00001: Alignment fault
- 00010: Debug exception
- 00011: Access flag fault, level 1
- 00100: Fault on instruction cache maintenance
- 00101: Translation fault, level 1
- 00110: Access flag fault, level 2
- 00111: Translation fault, level 2
- 01000: Synchronous external abort, not on translation table walk
- 01001: Domain fault, level 1
- 01011: Domain fault, level 2
- 01100: Synchronous external abort, on translation table walk, level 1
- 01111: Synchronous external abort, on translation table walk, level 2
- 10000: TLB conflict abort
- 10100: IMPLEMENTATION DEFINED fault (Lockdown fault)
- 10101: IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
- 11000: SError interrupt
- 11001: Synchronous parity or ECC error on memory access
- 11011: Synchronous parity or ECC error on memory access, not on translation table walk
- 11100: Synchronous parity or ECC error on translation table walk, level 1
- 11110: Synchronous parity or ECC error on translation table walk, level 2

All other values are reserved.

When the RAS Extension is implemented, 11000, 11001, 11100, and 11110 are reserved.

For more information about the lookup level associated with a fault, see *The level associated with MMU faults on a Short-descriptor translation table lookup* on page G4-4669.

</tbody>
</table>

FnV

Bits [31:17]
Reserved, RES0.
FnV, bit [16]
FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0  DFAR is valid.
1  DFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Data Abort exceptions.

AET, bits [15:14]
Asynchronous Error Type. When the RAS Extension is implemented, this field describes the state of the PE after taking an asynchronous Data Abort exception. Possible values are:

00  Uncontainable error (UC) or uncategorized.
01  Unrecoverable error (UEU).
10  Restartable error (UEO) or Corrected error (CE).
11  Recoverable error (UER).

When the RAS Extension is not implemented, or on a synchronous Data Abort, this field is RES0.

Note
ARMv8.2 requires the implementation of the RAS Extension.

In the event of multiple errors taken as a single SError interrupt exception, the overall state of the PE is reported.

Note
Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

CM, bit [13]
Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance instruction generated the fault. The possible values of this bit are:

0  Abort not caused by execution of a cache maintenance instruction.
1  Abort caused by execution of a cache maintenance instruction.

On a synchronous Data Abort on a translation table walk, this bit is UNKNOWN. On an asynchronous fault, this bit is UNKNOWN.

ExT, bit [12]
External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0. For aborts other than external aborts this bit always returns 0.

Write not Read bit. Indicates whether the abort was caused by a write or a read instruction. The possible values of this bit are:

0  Abort caused by a read instruction.
1  Abort caused by a write instruction.

For faults on the cache maintenance and address translation System instructions in the (coproc==1111) encoding space this bit always returns a value of 1.
Bit [10]
Reserved, RES0.

LPAE, bit [9]
On taking a Data Abort exception, this bit is set as follows:
0 Using the Short-descriptor translation table formats.
1 Using the Long-descriptor translation table formats.
Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]
Reserved, RES0.

STATUS, bits [5:0]
Fault status bits. Possible values of this field are:
000000 Address size fault in TTBR0 or TTBR1
000001 Address size fault, level 1
000010 Address size fault, level 2
000011 Address size fault, level 3
000101 Translation fault, level 1
000110 Translation fault, level 2
000111 Translation fault, level 3
001001 Access flag fault, level 1
001010 Access flag fault, level 2
001011 Access flag fault, level 3
001101 Permission fault, level 1
001110 Permission fault, level 2
001111 Permission fault, level 3
010000 Synchronous external abort, not on translation table walk
010001 SError interrupt
010101 Synchronous external abort, on translation table walk, level 1
010110 Synchronous external abort, on translation table walk, level 2
010111 Synchronous external abort, on translation table walk, level 3
011000 Synchronous parity or ECC error on memory access, not on translation table walk
011001 SError interrupt, from a parity or ECC error on memory access
011101 Synchronous parity or ECC error on memory access on translation table walk, level 1
011110 Synchronous parity or ECC error on memory access on translation table walk, level 2
011111 Synchronous parity or ECC error on memory access on translation table walk, level 3
100001 Alignment fault
100010 Debug exception
110000 TLB conflict abort
110100 IMPLEMENTATION DEFINED fault (Lockdown fault)
110101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
All other values are reserved.
When the RAS Extension is implemented, 011000, 011001, 011101, 011110, and 011111 are reserved.
For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Long-descriptor translation table lookup on page G4-4671.

**Accessing the DFSR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c5, c0, 0</td>
<td>000</td>
<td>000</td>
<td>0101</td>
<td>1111</td>
<td>000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H</td>
<td>EL0</td>
<td>EL1</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
— If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
— If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  — If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  — If HSTR.T5==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.44 DTLBIALL, Data TLB Invalidate All

The DTLBIALL characteristics are:

Purpose

Invalidate all cached copies of translation table entries from data TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

Configurations

There are no configuration notes.

Attributes

DTLBIALL is a 32-bit System instruction.

Field descriptions

DTLBIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the DTLBIALL instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c6, 0</td>
<td>000</td>
<td>000</td>
<td>1000</td>
<td>1111</td>
<td>0110</td>
</tr>
</tbody>
</table>

Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>TGE</td>
<td></td>
</tr>
<tr>
<td>NS</td>
<td></td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>
When HCR.FB is 1, at Non-secure EL1 this instruction executes as a TLBIALLIS operating on data TLBs only.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
DTLBIASID, Data TLB Invalidate by ASID match

The DTLBIASID characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from data TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

**Configurations**

There are no configuration notes.

**Attributes**

DTLBIASID is a 32-bit System instruction.

**Field descriptions**

The DTLBIASID input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td><strong>RES0</strong></td>
</tr>
<tr>
<td>8-7</td>
<td>ASID</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

**Executing the DTLBIASID instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```
This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c6, 2</td>
<td>000</td>
<td>010</td>
<td>1000</td>
<td>1111</td>
<td>0110</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a TLBIASIDIS operating on data TLBs only.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.46  DTLBIMVA, Data TLB Invalidate by VA

The DTLBIMVA characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from data TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

**Configurations**

There are no configuration notes.

**Attributes**

DTLBIMVA is a 32-bit System instruction.

**Field descriptions**

The DTLBIMVA input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.
Executing the DTLBIMVA instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c6, l</td>
<td>000</td>
<td>001</td>
<td>1000</td>
<td>1111</td>
<td>0110</td>
</tr>
</tbody>
</table>

Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a TLBIMVAIS operating on data TLBs only.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.47 ELR_hyp, Exception Link Register (Hyp mode)

The ELR_hyp characteristics are:

**Purpose**

When taking an exception to Hyp mode, holds the address to return to.

**Configurations**

AArch32 System register ELR_hyp is architecturally mapped to AArch64 System register ELR_EL2.

On a reset into an Exception level that is using AArch32 ELR_hyp is UNKNOWN.

**Attributes**

ELR_hyp is a 32-bit register.

**Field descriptions**

The ELR_hyp bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Return address</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
</tr>
</tbody>
</table>

**Accessing the ELR_hyp**

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;banked_reg&gt;</th>
<th>R</th>
<th>M</th>
<th>M1</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELR_hyp</td>
<td>0</td>
<td>1</td>
<td>1110</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- - n/a -</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- - RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>
G6.2.48 FCSEIDR, FCSE Process ID register

The FCSEIDR characteristics are:

**Purpose**

Identifies whether the Fast Context Switch Extension (FCSE) is implemented.

In ARMv8, the FCSE is not implemented, so this register is RAZ/WI. Software can access this register to determine that the implementation does not include the FCSE.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

FCSEIDR is a 32-bit register.

**Field descriptions**

The FCSEIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RAZ/WI. Hardware must implement this as RAZ/WI. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.</td>
</tr>
</tbody>
</table>

**Accessing the FCSEIDR**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c13, c0, 0</td>
<td>000</td>
<td>000</td>
<td>1101</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T13==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
### G6.2.49  FPEXC, Floating-Point Exception Control register

The FPEXC characteristics are:

**Purpose**

Provides a global enable for the implemented Advanced SIMD and floating-point functionality, and reports floating-point status information.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register FPEXC is architecturally mapped to AArch64 System register FPEXC32_EL2.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

FPEXC is a 32-bit register.

**Field descriptions**

The FPEXC bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>EX</td>
</tr>
<tr>
<td>30</td>
<td>EN</td>
</tr>
<tr>
<td>29</td>
<td>DEX</td>
</tr>
<tr>
<td>28</td>
<td>FP2V</td>
</tr>
<tr>
<td>27</td>
<td>TFV</td>
</tr>
<tr>
<td></td>
<td>RES0</td>
</tr>
<tr>
<td></td>
<td>VECITR</td>
</tr>
<tr>
<td>11</td>
<td>IXF</td>
</tr>
<tr>
<td>10</td>
<td>OFF</td>
</tr>
<tr>
<td>8</td>
<td>UFF</td>
</tr>
<tr>
<td>7</td>
<td>DZF</td>
</tr>
<tr>
<td>6</td>
<td>IOF</td>
</tr>
<tr>
<td>5</td>
<td>IDF</td>
</tr>
</tbody>
</table>
```

**EX, bit [31]**

Exception bit. In ARMv8, this bit is RAZ/WI.

**EN, bit [30]**

Enables access to the Advanced SIMD and floating-point functionality from all Exception levels, except that setting this field to 0 does not disable the following:

- VMSR accesses to the FPEXC or FPSID.
- VMRS accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

0  Accesses to the FPSCR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are **UNDEFINED** at all Exception levels.

1  This control permits access to the Advanced SIMD and floating-point functionality at all Exception levels.

Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:

- CPACR.cp10, or, if executing at EL0, CPACR_EL1.FPEN.
• FPEXC.EN.
• If executing in Non-secure state:
  — HCPTR.TCP10, or if EL2 is using AArch64, CPTR_EL2.TFP.
  — NSACR.cp10, or if EL3 is using AArch64, CPTR_EL3.TFP.
• For Advanced SIMD instructions only:
  — CPACR.ASEDIS.
  — If executing in Non-secure state, HCPTR.TASE and NSACR.NSTRCDIS.

See the descriptions of the controls for more information.

——— Note ————

When executing at EL0 using AArch32:

• If EL1 is using AArch64 then behavior is as if the value of FPEXC.EN is 1.
• In Non-secure state, if EL2 is using AArch64 and the value of HCR_EL2.{RW, TGE} is \{1, 1\} then behavior is as if the value of FPEXC.EN is 1.
• In Non-secure state, if EL2 is using AArch64 and the value of HCR_EL2.{RW, TGE} is \{0, 1\} then it is IMPLEMENTATION DEFINED whether the behavior is:
  — As if the value of FPEXC.EN is 1.
  — Determined by the value of FPEXC.EN, as described in this field description.
  — ARM deprecates using the value of FPEXC.EN to determine behavior.

When this register has an architecturally-defined reset value, this field resets to 0.

DEX, bit [29]

Defined synchronous exception on floating-point execution.
This field identifies whether a synchronous exception generated by the attempted execution of an instruction was generated by an unallocated encoding. The instruction must be in the encoding space that is identified by the pseudocode function ExecutingCP10or11Instr() returning TRUE. This field also indicates whether the FPEXC.TFV field is valid.

The meaning of this bit is:

\[ \begin{align*}
0 & \quad \text{The exception was generated by the attempted execution of an unallocated instruction in the encoding space that is identified by the pseudocode function ExecutingCP10or11Instr(). If FPEXC.TFV is RW then it is invalid and UNKNOWN. If FPEXC.\{IDF, IXF, UFF, OFF, DZF, IOF\} are RW then they are invalid and UNKNOWN.} \\
1 & \quad \text{The exception was generated during the execution of an unallocated encoding. FPEXC.TFV is valid and indicates the cause of the exception.}
\end{align*} \]

On an exception that sets this bit to 1 the exception-handling routine must clear this bit to 0.
On an implementation that both does not support trapping of floating-point exceptions and implements the FPSR.\{Stride, Len\} fields as RAZ, this bit is RES0.
If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

FP2V, bit [28]

FPINST2 instruction valid bit. In ARMv8, this bit is RES0.

VV, bit [27]

VECITR valid bit. In ARMv8, this bit is RES0.
TFV, bit [26]
Trapped Fault Valid bit. Valid only when the value of FPEXC.DEX is 1. When valid, it indicates the cause of the exception and therefore whether the FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} bits are valid.

0 The exception was caused by the execution of a floating-point VABS, VADD, VDIV, VFMA, VFMS, VFNMA, VFNMS, VMLA, VMLS, VMOV, VMUL, VNEG, VNMLA, VNMUL, VNMUL, VSQRT, or VSUB instruction when one or both of FPSCR. {Stride, Len} was non-zero. If the FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} bits are RW then they are invalid and UNKNOWN.

1 FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} indicate the presence of trapped floating-point exceptions that had occurred at the time of the exception. Bits are set for all trapped exceptions that had occurred at the time of the exception.

This bit returns a status value and ignores writes.
When the value of FPEXC.DEX is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
On an implementation that supports the trapping of floating-point exceptions and implements FPSCR. {Stride, Len} as RAZ, this bit is RAO/WI.

Bits [25:11]
Reserved, RES0.

VECITR, bits [10:8]
Vector iteration count. In ARMv8, this field is RES1.

IDF, bit [7]
Input Denormal trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

0 Input denormal exception has not occurred.
1 Input denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.
This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [6:5]
Reserved, RES0.

IXF, bit [4]
Inexact trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

0 Inexact exception has not occurred.
1 Inexact exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.
UFF, bit [3]
Underflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

0  Underflow exception has not occurred.
1  Underflow exception has occurred.

Underflow trapped exceptions can occur only when FPSCR.FZ is 0.
This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

OFF, bit [2]
Overflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

0  Overflow exception has not occurred.
1  Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

DZF, bit [1]
Divide by Zero trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether a Divide by Zero exception occurred while FPSCR.DZE was 1:

0  Divide by Zero exception has not occurred.
1  Divide by Zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

IOF, bit [0]
Invalid Operation trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

0  Invalid Operation exception has not occurred.
1  Invalid Operation exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Accessing the FPEXC
This register can be read using VMRS with the following syntax:

VMRS <Rt>, <spec_reg>
This register can be written using VMSR with the following syntax:

\[ \text{VMSR} \langle \text{spec\_reg} \rangle, \langle \text{Rt} \rangle \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>(&lt;\text{spec_reg})&gt;</th>
<th>reg</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>FPEXC</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RW</td>
</tr>
<tr>
<td>NS</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>x</td>
</tr>
<tr>
<td></td>
<td>x</td>
</tr>
<tr>
<td></td>
<td>x</td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CPACR.cp10==0, accesses to this register from PL1 are UNDEFINED.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CPTR_EL2.TFP==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CPTR_EL2.FPEN==00, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If CPTR_EL2.FPEN==10, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCPR.TRCP10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If NSACR.cp10==0, Non-secure accesses to this register from EL1 and EL2 are UNDEFINED.
- When EL3 is implemented and is using AArch64:
  - If CPTR_EL3.TFP==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.2.50 FPSCR, Floating-Point Status and Control Register

The FPSCR characteristics are:

**Purpose**

Provides floating-point system status information and control.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

The named fields in this register map to the equivalent fields in the AArch64 FPCR and FPSR.

It is **IMPLEMENTATION DEFINED** whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be **UNDEFINED**, or whether these fields are **RAZ**.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

FPSCR is a 32-bit register.

**Field descriptions**

The FPSCR bit assignments are:

```
   31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
   N  Z  C  V  FZ  Stride  Len
QC   AHP   DN   RMode   FZ16
```

**N, bit [31]**

Negative condition flag. This is updated by floating-point comparison operations.

**Z, bit [30]**

Zero condition flag. This is updated by floating-point comparison operations.

**C, bit [29]**

Carry condition flag. This is updated by floating-point comparison operations.

**V, bit [28]**

Overflow condition flag. This is updated by floating-point comparison operations.
QC, bit [27]
Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

AHP, bit [26]
Alternative half-precision control bit:

0  IEEE half-precision format selected.
1  Alternative half-precision format selected.

This bit is only used for conversions between half-precision floating-point and other floating-point formats.
The data-processing instructions added as part of the ARMv8.2-FP16 extension always use the IEEE half-precision format, and ignore the value of this bit.

DN, bit [25]
Default NaN mode control bit:

0  NaN operands propagate through to the output of a floating-point operation.
1  Any operation involving one or more NaNs returns the Default NaN.

The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Default NaN setting, regardless of the value of the DN bit.

FZ, bit [24]
Flush-to-zero mode control bit:

0  Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
1  Flush-to-zero mode enabled.

The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Flush-to-zero setting, regardless of the value of the FZ bit.

This bit has no effect on half-precision calculations.

RMode, bits [23:22]
Rounding Mode control field. The encoding of this field is:

00  Round to Nearest (RN) mode
01  Round towards Plus Infinity (RP) mode
10  Round towards Minus Infinity (RM) mode
11  Round towards Zero (RZ) mode.

The specified rounding mode is used by almost all scalar floating-point instructions. Advanced SIMD arithmetic always uses the Round to Nearest setting, regardless of the value of the RMode bits.

Stride, bits [21:20]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.
The value of this field is ignored when processing Advanced SIMD instructions.

FZ16, bit [19]

In ARMv8.2
When ARMv8.2-FP16 is implemented, flush-to-zero mode control bit on half-precision data-processing instructions:

0    Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
1    Flush-to-zero mode enabled.

The value of this bit applies to both scalar and Advanced SIMD floating-point half-precision calculations.

When ARMv8.2-FP16 is not implemented, this bit is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Len, bits [18:16]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

IDE, bit [15]

Input Denormal floating-point exception trap enable. Possible values are:

0    Untrapped exception handling selected. If the floating-point exception occurs then the IDC bit is set to 1.
1    Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IDC bit. The trap handling software can decide whether to set the IDC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

Bits [14:13]

Reserved, RES0.

IXE, bit [12]

Inexact floating-point exception trap enable. Possible values are:

0    Untrapped exception handling selected. If the floating-point exception occurs then the IXC bit is set to 1.
1    Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IXC bit. The trap handling software can decide whether to set the IXC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

UFE, bit [11]

Underflow floating-point exception trap enable. Possible values are:

0    Untrapped exception handling selected. If the floating-point exception occurs then the UFC bit is set to 1.
1    Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the UFC bit. The trap handling software can decide whether to set the UFC bit to 1.
This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

**OFE, bit [10]**

Overflow floating-point exception trap enable. Possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Untrapped exception handling selected. If the floating-point exception occurs then the OFC bit is set to 1.</td>
</tr>
<tr>
<td>1</td>
<td>Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the OFC bit. The trap handling software can decide whether to set the OFC bit to 1.</td>
</tr>
</tbody>
</table>

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

**DZE, bit [9]**

Divide by Zero floating-point exception trap enable. Possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Untrapped exception handling selected. If the floating-point exception occurs then the DZC bit is set to 1.</td>
</tr>
<tr>
<td>1</td>
<td>Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the DZC bit. The trap handling software can decide whether to set the DZC bit to 1.</td>
</tr>
</tbody>
</table>

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

**IOE, bit [8]**

Invalid Operation floating-point exception trap enable. Possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Untrapped exception handling selected. If the floating-point exception occurs then the IOC bit is set to 1.</td>
</tr>
<tr>
<td>1</td>
<td>Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IOC bit. The trap handling software can decide whether to set the IOC bit to 1.</td>
</tr>
</tbody>
</table>

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

**IDC, bit [7]**

Input Denormal cumulative floating-point exception bit. This bit is set to 1 to indicate that the Input Denormal floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IDE bit.

Advanced SIMD instructions set this bit if the Input Denormal floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IDE bit.

**Bits [6:5]**

Reserved, RES0.
IXC, bit [4]
Inexact cumulative floating-point exception bit. This bit is set to 1 to indicate that the Inexact floating-point exception has occurred since 0 was last written to this bit.
How VFP instructions update this bit depends on the value of the IXE bit.
Advanced SIMD instructions set this bit if the Inexact floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IXE bit.

UFC, bit [3]
Underflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Underflow floating-point exception has occurred since 0 was last written to this bit.
How VFP instructions update this bit depends on the value of the UFE bit.
Advanced SIMD instructions set this bit if the Underflow floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the UFE bit.

OFC, bit [2]
Overflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Overflow floating-point exception has occurred since 0 was last written to this bit.
How VFP instructions update this bit depends on the value of the OFE bit.
Advanced SIMD instructions set this bit if the Overflow floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the OFE bit.

DZC, bit [1]
Divide by Zero cumulative floating-point exception bit. This bit is set to 1 to indicate that the Divide by Zero floating-point exception has occurred since 0 was last written to this bit.
How VFP instructions update this bit depends on the value of the DZE bit.
Advanced SIMD instructions set this bit if the Divide by Zero floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the DZE bit.

IOC, bit [0]
Invalid Operation cumulative floating-point exception bit. This bit is set to 1 to indicate that the Invalid Operation floating-point exception has occurred since 0 was last written to this bit.
How VFP instructions update this bit depends on the value of the IOE bit.
Advanced SIMD instructions set this bit if the Invalid Operation floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IOE bit.

Accessing the FPSCR
This register can be read using VMRS with the following syntax:
VMRS <Rt>, <spec_reg>
This register can be written using VMSR with the following syntax:
VMSR <spec_reg>, <Rt>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;spec_reg&gt;</th>
<th>reg</th>

</tbody>
</table>

## Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CPACR.cp10==00, accesses to this register from PL0 and PL1 are UNDEFINED.
  - If CPACR.cp10==01, accesses to this register from PL0 are UNDEFINED.
  - If CPACR_EL1.FPEN==00, accesses to this register from PL0 are trapped to EL1.
  - If CPACR_EL1.FPEN==01, accesses to this register from PL0 are trapped to EL1.
  - If CPACR_EL1.FPEN==10, accesses to this register from PL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CPTR_EL2.TFP==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CPACR_EL1.FPEN==00, Non-secure accesses to this register from EL0 are trapped to EL1.
  - If CPACR_EL1.FPEN==01, Non-secure accesses to this register from EL0 are trapped to EL1.
  - If CPACR_EL1.FPEN==10, Non-secure accesses to this register from EL0 are trapped to EL1.
  - If CPTR_EL2.FPEN==00, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
  - If CPTR_EL2.FPEN==10, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CPTR_EL2.FPEN==00, Non-secure accesses to this register from EL0 are trapped to EL2.
  - If CPTR_EL2.FPEN==01, Non-secure accesses to this register from EL0 are trapped to EL2.
  - If CPTR_EL2.FPEN==10, Non-secure accesses to this register from EL0 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCPTR.TCP10==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  - If HCPTR.TCP10==1, Non-secure accesses to this register from EL2 are UNDEFINED.

- When EL3 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If NSACR.cp10==0, Non-secure accesses to this register from EL0, EL1, and EL2 are UNDEFINED.
• When EL3 is implemented and is using AArch64:
  — If CPTR_EL3.TFP==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.2.51 FPSID, Floating-Point System ID register

The FPSID characteristics are:

**Purpose**

Provides top-level information about the floating-point implementation.

This register largely duplicates information held in the MIDR. ARM deprecates use of it.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

**Attributes**

FPSID is a 32-bit register.

**Field descriptions**

The FPSID bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-24</td>
<td>Implementer</td>
</tr>
<tr>
<td>23</td>
<td>SW</td>
</tr>
<tr>
<td>22-16</td>
<td>Subarchitecture</td>
</tr>
<tr>
<td>15-8</td>
<td>PartNum</td>
</tr>
<tr>
<td>7-3</td>
<td>Variant</td>
</tr>
<tr>
<td>2</td>
<td>Revision</td>
</tr>
</tbody>
</table>

**Implementer, bits [31:24]**

Implementer codes are the same as those used for the MIDR.

For an implementation by ARM this field is 0x41, the ASCII code for A.

**SW, bit [23]**

Software bit. Defined values are:

0 The implementation provides a hardware implementation of the floating-point instructions.

1 The implementation supports only software emulation of the floating-point instructions.

In ARMv8-A the only permitted value is 0.

**Subarchitecture, bits [22:16]**

Subarchitecture version number. For an implementation by ARM, defined values are:

00000000 VFPv1 architecture with an IMPLEMENTATION DEFINED subarchitecture.

00000001 VFPv2 architecture with Common VFP subarchitecture v1.

00000010 VFPv3 architecture, or later, with Common VFP subarchitecture v2. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers.

00000011 VFPv3 architecture, or later, with Null subarchitecture. The entire floating-point implementation is in hardware, and no software support code is required. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers. This value can be used only by an implementation that does not support the trap enable bits in the FPSCR.

00000100 VFPv3 architecture, or later, with Common VFP subarchitecture v3, and support for trap enable bits in FPSCR. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers.
For a subarchitecture designed by ARM the most significant bit of this field, register bit[22], is 0. Values with a most significant bit of 0 that are not listed here are reserved.

When the subarchitecture designer is not ARM, the most significant bit of this field, register bit[22], must be 1. Each implementer must maintain its own list of subarchitectures it has designed, starting at subarchitecture version number 0x40.

In ARMv8-A the permitted values are 0000011 and 0000100.

**PartNum, bits [15:8]**

An IMPLEMENTATION DEFINED part number for the floating-point implementation, assigned by the implementer.

**Variant, bits [7:4]**

An IMPLEMENTATION DEFINED variant number. Typically, this field distinguishes between different production variants of a single product.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the floating-point implementation.

### Accessing the FPSID

This register can be read using VMRS with the following syntax:

VMRS <Rt>, <spec_reg>

This register can be written using VMSR with the following syntax:

VMSR <spec_reg>, <Rt>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;spec_reg&gt;</th>
<th>reg</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPSID</td>
<td>0000</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

When access to this register is permitted, write accesses are ignored.
Traps and Enables

For a description of the prioritization of any generated exceptions, see **Synchronous exception prioritization for exceptions taken to AArch32 state** on page G1-4344 for exceptions taken to AArch32 state and **Synchronous exception prioritization for exceptions taken to AArch64** on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CPACR.cp10==00, accesses to this register from PL1 are **undefined**.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CPTR_EL2.TFP==1, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TID0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CPTR_EL2.FPEN==00, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If CPTR_EL2.FPEN==10, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TID0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCPTR.TCP10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
  - If HCPTR.TCP10==1, Non-secure accesses to this register from EL2 are **undefined**.
  - If HCR.TID0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If NSACR.cp10==0, Non-secure accesses to this register from EL1 and EL2 are **undefined**.

- When EL3 is implemented and is using AArch64:
  - If CPTR_EL3.TFP==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.2.52  HACR, Hyp Auxiliary Configuration Register

The HACR characteristics are:

**Purpose**

Controls trapping to Hyp mode of IMPLEMENTATION DEFINED aspects of Non-secure EL1 or EL0 operation.

**Configurations**

AArch32 System register HACR is architecturally mapped to AArch64 System register HACR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HACR is a 32-bit register.

**Field descriptions**

The HACR bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

**Accessing the HACR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c1, c1, 7</td>
<td>100</td>
<td>111</td>
<td>0001</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td></td>
</tr>
<tr>
<td>NS</td>
<td></td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.53 HACTLR, Hyp Auxiliary Control Register

The HACTLR characteristics are:

**Purpose**

Controls IMPLEMENTATION DEFINED features of Hyp mode operation.

**Configurations**

AArch32 System register HACTLR is architecturally mapped to AArch64 System register ACTLR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HACTLR is a 32-bit register.

**Field descriptions**

The HACTLR bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>
```

**Accessing the HACTLR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

```
<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c1, c0, 1</td>
<td>100</td>
<td>001</td>
<td>0001</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
```

**Accessibility**

The register is accessible in software as follows:

```
<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td></td>
<td>x</td>
</tr>
<tr>
<td></td>
<td>x</td>
</tr>
</tbody>
</table>
```

Implementation Defined, bits [31:0]

IMPLEMENTATION DEFINED.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.54 HACTLR2, Hyp Auxiliary Control Register 2

The HACTLR2 characteristics are:

**Purpose**

Provides additional space to the HACTLR register to hold IMPLEMENTATION DEFINED trap functionality.

**Configurations**

AArch32 System register HACTLR2 is architecturally mapped to AArch64 System register ACTLR_EL2[63:32].

In ARMv8.0 and ARMv8.1, it is IMPLEMENTATION DEFINED whether this register is implemented, or whether it causes UNDEFINED exceptions when accessed. The implementation of this register can be detected by examining ID_MMFR4.AC2.

From ARMv8.2 this register must be implemented.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HACTLR2 is a 32-bit register.

**Field descriptions**

The HACTLR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
<tr>

</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.55  HADFSR, Hyp Auxiliary Data Fault Status Register

The HADFSR characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED syndrome information for Data Abort exceptions taken to Hyp mode.

**Configurations**

AArch32 System register HADFSR is architecturally mapped to AArch64 System register 
AFSR0_EL2.

This is an optional register. An implementation that does not require this register can implement it as RES0.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HADFSR is a 32-bit register.

**Field descriptions**

The HADFSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>

</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T5==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.57 HAMAIR0, Hyp Auxiliary Memory Attribute Indirection Register 0

The HAMAIR0 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by HMAIR0. These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in HMAIR0.

Configurations

AArch32 System register HAMAIR0 is architecturally mapped to AArch64 System register AMAIR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HAMAIR0 is a 32-bit register.

Field descriptions

The HAMAIR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HAMAIR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.58  HAMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1

The HAMAIR1 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by HMAIR1. These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in HMAIR1.

**Configurations**

AArch32 System register HAMAIR1 is architecturally mapped to AArch64 System register AMAIR_EL2[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HAMAIR1 is a 32-bit register.

**Field descriptions**

The HAMAIR1 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>IMPLEMENTATION DEFINED</td>

</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
### G6.2.59 HCPTR, Hyp Architectural Feature Trap Register

The HCPTR characteristics are:

**Purpose**

Controls:
- Trapping to Hyp mode of Non-secure access, at EL1 or EL0, to trace, and to Advanced SIMD and floating-point functionality.
- Hyp mode access to trace, and to Advanced SIMD and floating-point functionality.

Note

Accesses to this functionality:
- From Non-secure modes other than Hyp mode are also affected by settings in the CPACR and NSACR.
- From Hyp mode are also affected by settings in the NSACR.

Exceptions generated by the CPACR and NSACR controls are higher priority than those generated by the HCPTR controls.

**Configurations**

AArch32 System register HCPTR is architecturally mapped to AArch64 System register CPTR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HCPTR is a 32-bit register.

**Field descriptions**

The HCPTR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>RES0</td>
<td>RES1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**TCPAC, bit [31]**

Traps Non-secure EL1 accesses to the CPACR to Hyp mode.

0  This control does not cause any instructions to be trapped.
1  Non-secure EL1 accesses to the CPACR are trapped to Hyp mode.

Note

The CPACR is not accessible at EL0.

When this register has an architecturally-defined reset value, this field resets to 0.
Bits [30:21]
Reserved, RES0.

TTA, bit [20]
Traps Non-secure System register accesses to all implemented trace registers to Hyp mode.
0 This control does not cause any instructions to be trapped.
1 Any Non-secure System register access to an implemented trace register is trapped to Hyp mode, unless the access is trapped to EL1 by a CPACR or NSACR control, or the access is from Non-secure EL0 and the definition of the register in the appropriate trace architecture specification indicates that the register is not accessible from EL0. A trapped instruction generates:
- A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
- An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

If the implementation does not include a trace macrocell, or does not include a System register interface to the trace macrocell registers, it is IMPLEMENTATION DEFINED whether this bit:
- Is RES0.
- Is RES1.
- Can be written from Hyp mode, and from Secure Monitor mode when SCR.NS is 1.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSTRCDIS is 1, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

Note
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and a resulting Undefined Instruction exception is higher priority than a HCPTR.TTA Hyp Trap exception.
- The architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [19:16]
Reserved, RES0.

TASE, bit [15]
Traps Non-secure execution of Advanced SIMD instructions to Hyp mode when the value of HCPTR.TCP10 is 0.
0 This control does not cause any instructions to be trapped.
1 When the value of HCPTR.TCP10 is 0, any attempt to execute an Advanced SIMD instruction in Non-secure state is trapped to Hyp mode, unless it is trapped to EL1 by a CPACR or NSACR control. A trapped instruction generates:
- A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
- An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

When the value of HCPTR.TCP10 is 1, the value of this field is ignored.
If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, then it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSASEDIS is 1, in Non-secure state this field behaves as RAO/WI, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

For the list of instructions affected by this field, see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2746.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**Bit [14]**  
Reserved, RES0.

**Bits [13:12]**  
Reserved, RES1.

**TCP11, bit [11]**

The value of this field is ignored. If this field is programmed with a different value to the TCP10 bit then this field is UNKNOWN on a direct read of the HCPTTR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1.

If EL3 is implemented and is using AArch32, and the value of NSACR.cp10 is 0, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**TCP10, bit [10]**

Trap Non-secure accesses to Advanced SIMD and floating-point functionality to Hyp mode:

0  
This control does not cause any instructions to be trapped.

1  
Any attempted access to Advanced SIMD and floating-point functionality from Non-secure state is trapped to Hyp mode, unless it is trapped to EL1 by a CPACR or NSACR control. A trapped instruction generates:

- A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
- An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

The Advanced SIMD and floating-point features controlled by these fields are:

- Execution of any floating-point or Advanced SIMD instruction.
- Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- Any access to the FPSCR, FPSID, MVFR0, MVFR1, MVFR2, or FPEXC System registers.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1.

If EL3 is implemented and is using AArch32, and the value of NSACR.cp10 is 0, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**Bits [9:8]**  
Reserved, RES1.
Accessing the HCPTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c1, c1, 2</td>
<td>100</td>
<td>010</td>
<td>0001</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL3 is implemented and is using AArch64:
  - If CPTR_EL3.TCPAC==1, accesses to this register from EL2 are trapped to EL3.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
HCR, Hyp Configuration Register

The HCR characteristics are:

**Purpose**

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to Hyp mode.

**Configurations**

AArch32 System register HCR is architecturally mapped to AArch64 System register HCR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HCR is a 32-bit register.

**Field descriptions**

The HCR bit assignments are:

- **Res0**: Reserved, RES0.
- **TRVM**: Trap Reads of Virtual Memory controls. Traps Non-secure EL1 reads of the virtual memory control registers to Hyp mode. The registers for which read accesses are trapped are as follows:
  - SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, Dacr, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.
  - 0: This control does not cause any instructions to be trapped.
1 Non-secure EL1 read accesses to the specified Virtual Memory controls are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

**HCD, bit [29]**

HVC instruction disable. Disables Non-secure state execution of HVC instructions.

0 HVC instruction execution is enabled at EL2 and Non-secure EL1.

1 HVC instructions are UNDEFINED at EL2 and Non-secure EL1. The Undefined Instruction exception is taken to the Exception level at which the HVC instruction is executed.

--- Note ---

HVC instructions are always UNDEFINED at EL0.

---

This bit is only implemented if EL3 is not implemented. Otherwise, it is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**Bit [28]**

Reserved, RES0.

**TGE, bit [27]**

Trap General Exceptions, from Non-secure EL0.

0 This control has no effect on execution at EL0.

1 When the value of SCR.NS is 0, this control has no effect on execution at EL0.

When the value of SCR.NS is 1, then:

- All exceptions that would be routed to EL1 are routed to EL2.
- The SCTLR.M bit is treated as being 0 for all purposes other than returning the result of a direct read of SCTLR.
- The HCR.{FMO, IMO, AMO} bits are treated as being 1 for all purposes other than returning the result of a direct read of HCR.
- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.
- Monitor mode execution of an MSR or CPS instruction that changes CPSR.M to a Non-secure EL1 mode is an illegal change to PSTATE.M. For more information see *Illegal changes to PSTATE.M* on page G1-4336.

Also, when HCR.TGE is 1:

- If EL3 is using AArch32, an attempt to change from a Secure PL1 mode to a Non-secure EL1 mode by changing SCR.NS from 0 to 1 results in SCR.NS remaining as 0.
- The HIDCR.{TDRA, TDOSA, TDA, TDE} bits are ignored and treated as being 1 other than for the purpose of a direct read of HIDCR.

In the following cases the field resets to 0:

- The PE resets into EL3 with EL3 using AArch32.
- The PE resets into EL2 with EL2 using AArch32.

Otherwise, the field reset value is architecturally UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to 0.
TVM, bit [26]

Trap Virtual Memory controls. Traps Non-secure EL1 writes to the virtual memory control registers to Hyp mode. The registers for which write accesses are trapped are as follows:

\[
\text{SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR,}
\text{ AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.}
\]

0  This control does not cause any instructions to be trapped.
1  Non-secure EL1 write accesses to EL1 virtual memory control registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TTLB, bit [25]

Trap TLB maintenance instructions. Traps Non-secure EL1 execution of a TLBI instruction to Hyp mode. This applies to the following instructions:

\[
\text{TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAAIS, TLBIMVALIS,}
\text{ TLBIMVAL, ITLBIA, ITLBIMVA, ITLBIA, DTBLIMV, DTLBIMV, DTLBIASID, TBLIA,}
\text{ DTLBM, DTLMV, DTLI, DTLBIMVA, DTLMVAL, TLBMVAAL}
\]

0  This control does not cause any instructions to be trapped.
1  Non-secure EL1 accesses to TLB maintenance instructions are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps Non-secure EL1 execution of those cache maintenance instructions to Hyp mode. This applies to the following instructions:

\[
\text{ICIMVAU, ICIALLU, ICIALLUS, DCCMVAC.}
\]

——— Note ————

An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0  This control does not cause any instructions to be trapped.
1  Non-secure EL1 execution of the specified instructions is trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TPC, bit [23]

Trap data or unified cache maintenance instructions that operate to the Point of Coherency. Traps Non-secure EL1 execution of those cache maintenance instructions to Hyp mode. This applies to the following instructions:

\[
\text{DCIMVAC, DCCIMVAC, DCCMVAC.}
\]

——— Note ————

An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0  This control does not cause any instructions to be trapped.
1  Non-secure execution of the specified instructions is trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TSW, bit [22]

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps Non-secure EL1 execution of those cache maintenance instructions by set/way to Hyp mode. This applies to the following instructions:

\[
\text{DCISW, DCCSW, DCCISW.}
\]
Note

An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

TAC, bit [21]

Trap Auxiliary Control Registers. Traps Non-secure EL1 accesses to the Auxiliary Control Registers to Hyp mode, from both Execution states. This applies to the following register accesses: ACTLR and, if implemented, ACTLR2.

0 This control does not cause any instructions to be trapped.
1 Non-secure execution of the specified instructions is trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps Non-secure EL1 accesses to the encodings for IMPLEMENTATION DEFINED System Registers to Hyp mode.

MCR and MRC instructions accessing the following encodings:
- All coproc==p15, CRn==c9, Opcode1 = {0-7}, CRm == {c0-c2, c5-c8}, opcode2 == {0-7}.
- All coproc==p15, CRn==c10, Opcode1 == {0-7}, CRm == {c0, c1, c4, c8}, opcode2 == {0-7}.
- All coproc==p15, CRn==c11, Opcode1== {0-7}, CRm == {c0-c8, c15}, opcode2 == {0-7}.

When HCR.TIDCP is set to 1, it is IMPLEMENTATION DEFINED whether any of this functionality accessed from Non-secure EL0 is trapped to Hyp mode. If it is not, it is UNDEFINED, and the PE takes an Undefined Instruction exception to Non-secure Undefined mode.

0 This control does not cause any instructions to be trapped.
1 Non-secure EL1 accesses to the specified System register encodings for IMPLEMENTATION DEFINED functionality are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TSC, bit [19]

Trap SMC instructions. Traps Non-secure EL1 execution of SMC instructions to Hyp mode.

0 This control does not cause any instructions to be trapped.
1 Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of SCR.SCD.

The ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

Note

- This trap is only implemented if the implementation includes EL3.
- SMC instructions are always UNDEFINED at PL0.
- This bit traps execution of the SMC instruction. It is not a routing control for the SMC exception. Hyp Trap exceptions and SMC exceptions have different preferred return addresses.

When this register has an architecturally-defined reset value, this field resets to 0.
TID3, bit [18]

Trap ID group 3. Traps Non-secure EL1 reads of the following registers to Hyp mode:

- ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3,
- ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5, MVFR0, MVFR1,
- MVFR2, and ID_MMFR4, except that if ID_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether accesses to ID_MMFR4 are trapped.

Also an MRC access to any of the following encodings:

- \( \text{coproc} == \text{p15}, \text{opc1} == 0, \text{CRn} == 0, \text{CRm} == \{c3-c7\}, \text{opc2} == \{0,1\} \).
- \( \text{coproc} == \text{p15}, \text{opc1} == 0, \text{CRn} == 0, \text{CRm} == 3, \text{opc2} == 2 \).
- \( \text{coproc} == \text{p15}, \text{opc1} == 0, \text{CRn} == 0, \text{CRm} == 5, \text{opc2} == \{4,5\} \).

It is IMPLEMENTATION DEFINED whether this bit traps MRC accesses to the following encodings:

- \( \text{coproc} == \text{p15}, \text{opc1} == 0, \text{CRn} == 0, \text{CRm} == 2, \text{opc2} == 7 \).
- \( \text{coproc} == \text{p15}, \text{opc1} == 0, \text{CRn} == 0, \text{CRm} == 3, \text{opc2} == \{3-7\} \).
- \( \text{coproc} == \text{p15}, \text{opc1} == 0, \text{CRn} == 0, \text{CRm} == \{c4, c6, c7\}, \text{opc2} == \{2-7\} \).
- \( \text{coproc} == \text{p15}, \text{opc1} == 0, \text{CRn} == 0, \text{CRm} == 5, \text{opc2} == \{2, 3, 6, 7\} \).

0 This control does not cause any instructions to be trapped.

1 The specified Non-secure EL1 read accesses to ID group 3 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TID2, bit [17]

Trap ID group 2. Traps the following register accesses to Hyp mode:

- Non-secure EL1 and EL0 reads of the CTR, CCSIDR, CLIDR, and CSSELR.
- Non-secure EL1 and EL0 writes to the CSSELR.

0 This control does not cause any instructions to be trapped.

1 The specified Non-secure EL1 and EL0 accesses to ID group 2 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TID1, bit [16]

Trap ID group 1. Traps Non-secure EL1 reads of the following registers to Hyp mode:

- TCMTR, TLBTR, REVIDR, AIDR.

0 This control does not cause any instructions to be trapped.

1 The specified Non-secure EL1 read accesses to ID group 1 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TID0, bit [15]

Trap ID group 0. Traps the following register accesses to Hyp mode:

- Non-secure EL1 reads of the JIDR and FPSID.
- If the JIDR is RAZ from Non-secure EL0, Non-secure EL0 reads of the JIDR.

--- Note ---

- It is IMPLEMENTATION DEFINED whether the JIDR is RAZ or UNDEFINED at EL0. If it is UNDEFINED at EL0 then the Undefined Instruction exception takes precedence over this trap.
- The FPSID is not accessible at EL0.
- Writes to the FPSID are ignored, and not trapped by this control.

0 This control does not cause any instructions to be trapped.
The specified Non-secure EL1 read accesses to ID group 0 registers are trapped to Hyp mode. When this register has an architecturally-defined reset value, this field resets to 0.

**TWE, bit [14]**

Traps Non-secure EL0 and EL1 execution of WFE instructions to Hyp mode:

- **0** This control does not cause any instructions to be trapped.
- **1** Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWE.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

--- **Note** ---

Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 0.

**TWI, bit [13]**

Traps Non-secure EL0 and EL1 execution of WFI instructions to Hyp mode.

- **0** This control does not cause any instructions to be trapped.
- **1** Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWI.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- **Note** ---

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 0.

**DC, bit [12]**

Default Cacheability.

- **0** This control has no effect on the Non-secure EL1&0 translation regime.
- **1** In Non-secure state:
  - The SCTLR.M field behaves as 0 for all purposes other than a direct read of the value of the field.
  - The HCR.VM field behaves as 1 for all purposes other than a direct read of the value of the field.
  - The memory type produced by the first stage of the EL1&0 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate.

This field has no effect on the EL2 and EL3 translation regimes.

This field is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.
BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from Non-secure EL1 or Non-secure EL0:

- **00**: No effect
- **01**: Inner Shareable
- **10**: Outer Shareable
- **11**: Full system

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

When this register has an architecturally-defined reset value, this field resets to 0.

FB, bit [9]

Force broadcast. Causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:

- BPIALL, TLBIALL, TLBIMVA, TLBISID, DTLBIALL, DTLBIMVA, DTLBISID,
- ITLBIALL, ITLBIMVA, ITLBISID, TLBIMVAA, ICIALLU, TLBIMVAL, TLBIMVAAL.

- **0**: This field has no effect on the operation of the specified instructions.
- **1**: When one of the specified instruction is executed at Non-secure EL1, the instruction is broadcast within the Inner Shareable shareability domain.

When this register has an architecturally-defined reset value, this field resets to 0.

VA, bit [8]

Virtual SError interrupt exception.

- **0**: This mechanism is not making a virtual SError interrupt pending.
- **1**: A virtual SError interrupt is pending because of this mechanism.

The virtual SError interrupt is enabled only when the value of HCR.{TGE, AMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

When this register has an architecturally-defined reset value, this field resets to 0.

VI, bit [7]

Virtual IRQ exception.

- **0**: This mechanism is not making a virtual IRQ pending.
- **1**: A virtual IRQ is pending because of this mechanism.

The virtual IRQ is enabled only when the value of HCR.{TGE, IMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

When this register has an architecturally-defined reset value, this field resets to 0.

VF, bit [6]

Virtual FIQ exception.

- **0**: This mechanism is not making a virtual FIQ pending.
- **1**: A virtual FIQ is pending because of this mechanism.

The virtual FIQ is enabled only when the value of HCR.{TGE, FMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

When this register has an architecturally-defined reset value, this field resets to 0.

AMO, bit [5]

SError interrupt Mask Override. When this bit is set to 1, it overrides the effect of CPSR.A, and enables virtual exception signaling by the VA bit.

If the value of HCR.TGE is 0, then Virtual SError Interrupts are enabled in Non-secure state.
If the value of HCR.TGE is 1, then in Non-secure state the HCR.AMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.

**IMO, bit [4]**

IRQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.I, and enables virtual exception signaling by the VI bit.

If the value of HCR.TGE is 0, then Virtual IRQ interrupts are enabled in the Non-secure state.

If the value of HCR.TGE is 1, then in Non-secure state the HCR.IMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.

**FMO, bit [3]**

FIQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.F, and enables virtual exception signaling by the VF bit.

If the value of HCR.TGE is 0, then Virtual FIQ interrupts are enabled in the Non-secure state.

If the value of HCR.TGE is 1, then in Non-secure state the HCR.FMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.

**PTW, bit [2]**

Protected Table Walk. In the Non-secure PL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs then the value of this bit determines the behavior:

0 The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.

1 The memory access generates a stage 2 Permission fault.

This field is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

**SWIO, bit [1]**

Set/Way Invalidation Override. Causes Non-secure EL1 execution of the data cache invalidate by set/way instructions to perform a data cache clean and invalidate by set/way.

0 This control has no effect on the operation of data cache invalidate by set/way instructions.

1 Data cache invalidate by set/way instructions perform a data cache clean and invalidate by set/way.

When this bit is set to 1, DCISW performs the same invalidation as a DCCISW instruction.

As a result of changes to the behavior of DCISW, this bit is redundant in ARMv8. This bit can be implemented as RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**VM, bit [0]**

Virtualization enable. Enables stage 2 address translation for the Non-secure EL1&0 translation regime. Possible values of this bit are:

0 Non-secure EL1&0 stage 2 address translation disabled.

1 Non-secure EL1&0 stage 2 address translation enabled.

If the HCR.DC bit is set to 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with HCR.VM being 1, regardless of the actual value of HCR.VM, other than the value returned by an explicit read of HCR.VM.
When the value of this bit is 1, data cache invalidate instructions executed at Non-secure EL1 perform a data cache clean and invalidate. For the invalidate by set/way instruction this behavior applies regardless of the value of the HCR.SWIO bit.

This bit is permitted to be cached in a TLB. When this register has an architecturally-defined reset value, this field resets to 0.

**Accessing the HCR**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, cl, cl, 0</td>
<td>100</td>
<td>000</td>
<td>0001</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.61  HCR2, Hyp Configuration Register 2

The HCR2 characteristics are:

Purpose

Provides additional configuration controls for virtualization.

Configurations

AArch32 System register HCR2 is architecturally mapped to AArch64 System register HCR_EL2[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HCR2 is a 32-bit register.

Field descriptions

The HCR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:7]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>For the Non-secure PL1&amp;0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there must be no loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.</td>
</tr>
<tr>
<td>1</td>
<td>For the Non-secure PL1&amp;0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there might be a loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.</td>
</tr>
</tbody>
</table>

For more information see Mismatched memory attributes on page E2-2792.

The value of this field has no effect on translation regimes other than the Non-secure PL1&0 translation regime.

This field can be implemented as RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.
TEA, bit [5]

Route synchronous External Abort exceptions to EL2. If the RAS Extension is implemented, the possible values of this bit are:

0  Do not route synchronous External Abort exceptions from Non-secure EL0 and EL1 to EL2.
1  Route synchronous External Abort exceptions from Non-secure EL0 and EL1 to EL2, if not routed to EL3.

This bit resets to zero on a Warm reset into AArch32 state.
When the RAS Extension is not implemented, this field is RES0.
When this register has an architecturally-defined reset value, this field resets to 0.

TERR, bit [4]

Trap Error record accesses. If the RAS Extension is implemented, the possible values of this bit are:

0  Do not trap accesses to error record registers from Non-secure EL1 to EL2.
1  Accesses to the ER* registers from Non-secure EL1 generate a Trap exception to EL2.

This bit resets to zero on a Warm reset into AArch32 state.
When the RAS Extension is not implemented, this field is RES0.
When this register has an architecturally-defined reset value, this field resets to 0.

Bits [3:2]

Reserved, RES0.

ID, bit [1]

Stage 2 Instruction access cacheability disable. For the Non-secure PL1&0 translation regime, when HCR.VM==1, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

0  This control has no effect on stage 2 of the Non-secure PL1&0 translation regime.
1  For the Non-secure PL1&0 translation regime, forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.
When this register has an architecturally-defined reset value, this field resets to 0.

CD, bit [0]

Stage 2 Data access cacheability disable. When HCR.VM==1, this forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the Non-secure PL1&0 translation regime.

0  This control has no effect on stage 2 of the Non-secure PL1&0 translation regime for data accesses and translation table walks.
1  For the Non-secure PL1&0 translation regime, forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.
When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HCR2

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c1, c1, 4</td>
<td>100</td>
<td>100</td>
<td>0001</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>

</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) & (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1 == 1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) & (HCR_EL2.E2H == 1) & (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1 == 1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1 == 1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.62 HDFAR, Hyp Data Fault Address Register

The HDFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception that is taken to Hyp mode.

Configurations

AArch32 System register HDFAR is architecturally mapped to AArch64 System register FAR_EL2[31:0].

AArch32 System register HDFAR is architecturally mapped to AArch32 System register DFAR (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HDFAR is a 32-bit register.

Field descriptions

The HDFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>VA of faulting address of synchronous Data Abort exception taken to Hyp mode</td>
</tr>
</tbody>
</table>

Accessing the HDFAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c6, c0, 0</td>
<td>100</td>
<td>000</td>
<td>0110</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>

</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T6==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.63 HIFAR, Hyp Instruction Fault Address Register

The HIFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception that is taken to Hyp mode.

**Configurations**

AArch32 System register HIFAR is architecturally mapped to AArch64 System register FAR_EL2[63:32].

AArch32 System register HIFAR is architecturally mapped to AArch32 System register IFAR (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HIFAR is a 32-bit register.

**Field descriptions**

The HIFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>VA of faulting address of synchronous Prefetch Abort exception taken to Hyp mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
</tr>
</tbody>
</table>

On a Data Abort exception, this register is UNKNOWN.

Any execution in a Non-secure EL1 or Non-secure EL0 mode makes this register UNKNOWN.

**Accessing the HIFAR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c6, c0, 2</td>
<td>100</td>
<td>010</td>
<td>0110</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2E  TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x   x   0</td>
<td>-   -</td>
</tr>
<tr>
<td>x   0   1</td>
<td>-   -</td>
</tr>
<tr>
<td>x   1   1</td>
<td>-</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR.EL3.NS == 1) && (HCR.EL2.E2H == 0):
  - If HSTR.EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR.EL3.NS == 1) && (HCR.EL2.E2H == 1) && (HCR.EL2.TGE == 0):
  - If HSTR.EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR.EL3.NS == 1:
  - If HSTR.T6==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.64 HMAIR0, Hyp Memory Attribute Indirection Register 0

The HMAIR0 characteristics are:

**Purpose**

Along with HMAIR1, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

AttrIndx[2] indicates the HMAIR register to be used:
- When AttrIndx[2] is 0, HMAIR0 is used.
- When AttrIndx[2] is 1, HMAIR1 is used.

**Configurations**

AArch32 System register HMAIR0 is architecturally mapped to AArch64 System register MAIR_EL2[31:0].

If EL2 is not implemented, this register is RESO from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HMAIR0 is a 32-bit register.

**Field descriptions**

The HMAIR0 bit assignments are:

*When TTBCR.EAE==1:*

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>16 15</th>
<th>8 7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr3</td>
<td>Attr2</td>
<td>Attr1</td>
<td>Attr0</td>
<td></td>
</tr>
</tbody>
</table>

Attr<n>, bits [8n+7:8n], for n = 0 to 3

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:
- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>00RW, RW not 00</td>
<td>Normal memory, Outer Write-Through Transient</td>
</tr>
<tr>
<td>0100</td>
<td>Normal memory, Outer Non-cacheable</td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>Normal memory, Outer Write-Back Transient</td>
</tr>
<tr>
<td>10RW</td>
<td>Normal memory, Outer Write-Through Non-transient</td>
</tr>
<tr>
<td>11RW</td>
<td>Normal memory, Outer Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.
The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>00RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>1000</td>
<td>Device-nGRE memory</td>
<td>Normal memory, Inner Write-Through Non-transient (RW=00)</td>
</tr>
<tr>
<td>10RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>1100</td>
<td>Device-GRE memory</td>
<td>Normal memory, Inner Write-Back Non-transient (RW=00)</td>
</tr>
<tr>
<td>11RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.
The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

**Accessing the HMAIR0**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c10, c2, 0</td>
<td>100</td>
<td>000</td>
<td>1010</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>

<tr>
<td>NS</td>
<td></td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td></td>
</tr>
<tr>
<td>x</td>
<td></td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.65  HMAIR1, Hyp Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

Purpose

Along with HMAIR0, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

AttrIndx[2] indicates the HMAIR register to be used:

- When AttrIndx[2] is 0, HMAIR0 is used.
- When AttrIndx[2] is 1, HMAIR1 is used.

Configurations

AArch32 System register HMAIR1 is architecturally mapped to AArch64 System register MAIR_EL2[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HMAIR1 is a 32-bit register.

Field descriptions

The HMAIR1 bit assignments are:

When TTBRC.EAE==1:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr7</td>
<td>Attr6</td>
<td>Attr5</td>
<td>Attr4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Attr<n>, bits [8(n-4)+7:8(n-4)], for n = 4 to 7

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>00RW, RW not 00</td>
<td>Normal memory, Outer Write-Through Transient</td>
</tr>
<tr>
<td>0100</td>
<td>Normal memory, Outer Non-cacheable</td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>Normal memory, Outer Write-Back Transient</td>
</tr>
<tr>
<td>10RW</td>
<td>Normal memory, Outer Write-Through Non-transient</td>
</tr>
<tr>
<td>11RW</td>
<td>Normal memory, Outer Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.
The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>00RW, RW not 00</td>

<td>001</td>
<td>1010</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.66   HPFAR, Hyp IPA Fault Address Register

The HPFAR characteristics are:

**Purpose**

Holds the faulting IPA for some aborts on a stage 2 translation taken to Hyp mode.

**Configurations**

AArch32 System register HPFAR is architecturally mapped to AArch64 System register HPFAR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HPFAR is a 32-bit register.

**Field descriptions**

The HPFAR bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>FIPA[39:12]</td>
</tr>
<tr>
<td>4-0</td>
<td>RES0</td>
</tr>
</tbody>
</table>

Execution in any Non-secure mode other than Hyp mode makes this register UNKNOWN.

**FIPA[39:12], bits [31:4]**

Bits [39:12] of the faulting intermediate physical address.

**Bits [3:0]**

Reserved, RES0.

**Accessing the HPFAR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;R&gt;, c6, c0, 4</td>
<td>100</td>
<td>100</td>
<td>0110</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- - n/a -</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- - RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T6==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
HRMR, Hyp Reset Management Register

The HRMR characteristics are:

**Purpose**

If EL2 is the highest implemented Exception level and this register is implemented:

- A write to the register at EL2 can request a Warm reset.
- If EL2 can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

**Configurations**

AArch32 System register HRMR is architecturally mapped to AArch64 System register RMR_EL2. Only implemented if EL2 is the highest implemented Exception level. In this case:

- If EL2 can use AArch32 and AArch64 then this register must be implemented.
- If EL2 cannot use AArch64 then it is IMPLEMENTATION DEFINED whether the register is implemented.

See the field descriptions for the reset values. These apply whenever the register is implemented.

**Attributes**

HRMR is a 32-bit register.

**Field descriptions**

The HRMR bit assignments are:

<table>

**Bits [31:2]**

Reserved, RES0.

**RR, bit [1]**

Reset Request. Setting this bit to 1 requests a Warm reset. This field resets to 0 on a Warm or Cold reset.

**AA64, bit [0]**

When EL2 can use AArch64, determines which Execution state the PE boots into after a Warm reset:

- 0: AArch32.
- 1: AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL2 cannot use AArch64 this bit is RAZ/WI.

When implemented as a RW field, this field resets to 0 on a Cold reset.

**Accessing the HRMR**

This register can be read using MRC with the following syntax:
MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c12, c0, 2</td>
<td>100</td>
<td>010</td>
<td>1100</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL2 is the highest implemented Exception level.</td>
<td>E2H x TGE 0 NS 1</td>
<td>EL0 - EL1 - EL2 RW EL3 n/a</td>
</tr>
<tr>
<td>EL2 is the highest implemented Exception level.</td>
<td>E2H x TGE 0 NS 1</td>
<td>EL0 - n/a EL2 RW n/a</td>
</tr>
</tbody>
</table>

When HRMR is not implemented, the encoding for this register is UNDEFINED.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T12==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.68 HSCTLR, Hyp System Control Register

The HSCTLR characteristics are:

**Purpose**

Provides top level control of the system operation in Hyp mode.

**Configurations**

AArch32 System register HSCTLR is architecturally mapped to AArch64 System register SCTLR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HSCTLR is a 32-bit register.

**Field descriptions**

The HSCTLR bit assignments are:

| Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9  | Bit 8  | Bit 7  | Bit 6  | Bit 5  | Bit 4  | Bit 3  | Bit 2  | Bit 1  | Bit 0  |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| RES0   | RES1   | RES0   | EE     | RES0   | RES1   | RES0   | RES0   | RES0   | RES0   | RES0   | RES0   | RES0   | RES1   | RES1   | RES0   | RES1   |

**Bit [31]**

Reserved, RES0.

**TE, bit [30]**

T32 Exception Enable. This bit controls whether exceptions to EL2 are taken to A32 or T32 state:

- 0: Exceptions, including reset, taken to A32 state.
- 1: Exceptions, including reset, taken to T32 state.

This field resets to a value that is architecturally UNKNOWN.

**Bits [29:28]**

Reserved, RES1.

**Bits [27:26]**

Reserved, RES0.
EE, bit [25]
The value of the PSTATE.E bit on entry to Hyp mode, the endianness of stage 1 translation table walks in the EL2 translation regime, and the endianness of stage 2 translation table walks in the PL1&0 translation regime.
The possible values of this bit are:
0 Little-endian. PSTATE.E is cleared to 0 on entry to Hyp mode. Stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the PL1&0 translation regime are little-endian.
1 Big-endian. PSTATE.E is set to 1 on entry to Hyp mode. Stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the PL1&0 translation regime are big-endian.
If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.
If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.
When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to an IMPLEMENTATION DEFINED value.

Bit [24]
Reserved, RES0.

Bits [23:22]
Reserved, RES1.

Bits [21:20]
Reserved, RES0.

WXN, bit [19]
Write permission implies XN (Execute-never). For the EL2 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:
0 This control has no effect on memory access permissions.
1 Any region that is writable in the EL2 translation regime is forced to XN for accesses from software executing at EL2.
The WXN bit is permitted to be cached in a TLB.
This field resets to a value that is architecturally UNKNOWN.

Bit [18]
Reserved, RES1.

Bit [17]
Reserved, RES0.

Bit [16]
Reserved, RES1.

Bits [15:13]
Reserved, RES0.

I, bit [12]
Instruction access Cacheability control, for accesses at EL2:
0 All instruction access to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache.
If the value of HSCTLR.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

1  All instruction access to Normal memory from EL2 can be cached at all levels of instruction and unified cache.

If the value of HSCTLR.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the PL1&0 translation regime.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [11]
Reserved, RES1.

Bits [10:9]
Reserved, RES0.

SED, bit [8]
SETEND instruction disable. Enables SETEND instructions at EL2.
0  SETEND instruction execution is enabled at EL2.
1  SETEND instructions are UNDEFINED at EL2.

If the implementation does not support mixed-endian operation at EL2, this bit is RES1.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

ITD, bit [7]
IT Disable. Enables some uses of IT instructions at EL2.
0  All IT instruction functionality is enabled at EL2.
1  Any attempt at EL2 to execute any of the following is UNDEFINED:
   • All encodings of the IT instruction with hw1[3:0]!=1000.
   • All encodings of the subsequent instruction with the following values for hw1:
     11xxxxxxxxxxxx
     All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
     1011xxxxxxxxxxxx
     All instructions in Miscellaneous 16-bit instructions on page F3-2883.
     10100xxxxxxxx
     ADD Rd, PC, #imm
     01001xxxxxxxx
     LDR Rd, [PC, #imm]
     0100x1xxx1111xxx
     ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
     010001xx1xxxx111
     ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn.

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:
   • A 16-bit instruction, that can only be followed by another 16-bit instruction.
   • The first half of a 32-bit instruction.
This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information see Changes to an ITD control by an instruction in an IT block on page E1-2738

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the HSCTLR. If it is not implemented then this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bit [6]

Reserved, RES0.

CP15BEN, bit [5]

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==1111) encoding space from EL2:

0 EL2 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is UNDEFINED.
1 EL2 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is enabled.

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the HSCTLR. If it is not implemented then this bit is RAO/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

LSMAOE, bit [4]

In ARMv8.2

Load Multiple and Store Multiple Atomicity and Ordering Enable. When the OPTIMAL feature ARMv8.2-LSMAOC is implemented, defined values are:

0 For all memory accesses at EL2, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.
1 The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL2 is as defined for ARMv8.0.

This bit is permitted to be cached in a TLB.

If this bit is not implemented, it is RES1.

When this register has an architecturally-defined reset value, this field resets to 1.

In ARMv8.1 and ARMv8.0.

Reserved, RES1.

nTLSMD, bit [3]

In ARMv8.2

No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory. When the OPTIMAL feature ARMv8.2-LSMAOC is implemented, defined values are:

0 All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL2 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.
1 All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL2 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.

This bit is permitted to be cached in a TLB.

If this bit is not implemented, it is RES1.

When this register has an architecturally-defined reset value, this field resets to 1.
In ARMv8.1 and ARMv8.0.

Reserved, RES1.

C, bit [2]

Cacheability control, for data accesses at EL2:

0  All data access to Normal memory from EL2, and all accesses to the EL2 translation tables, are Non-cacheable for all levels of data and unified cache.

1  All data access to Normal memory from EL2, and all accesses to the EL2 translation tables, can be cached at all levels of data and unified cache.

This bit has no effect on the PL1&0 translation regime.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL2:

0  Alignment fault checking disabled when executing at EL2.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element or data elements being accessed.

1  Alignment fault checking enabled when executing at EL2.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element or data elements being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

This field resets to a value that is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:

0  EL2 stage 1 address translation disabled.

See the HSCTLR.I field for the behavior of instruction accesses to Normal memory.

1  EL2 stage 1 address translation enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HSCTLR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, cl, c0, 0</td>
<td>100</td>
<td>000</td>
<td>0001</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td></td>

<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see "Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.69   HSR, Hyp Syndrome Register

The HSR characteristics are:

**Purpose**

Holds syndrome information for an exception taken to Hyp mode.

**Configurations**

AArch32 System register HSR is architecturally mapped to AArch64 System register ESR_EL2. If EL2 is not implemented, this register is RES0 from EL3. RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HSR is a 32-bit register.

**Field descriptions**

The HSR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>26 25 24</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>EC</td>
<td>IL</td>
<td>ISS</td>
</tr>
</tbody>
</table>

Execution in any Non-secure PE mode other than Hyp mode makes this register UNKNOWN.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of HSR is UNKNOWN. The value written to HSR must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**EC, bits [31:26]**

Exception Class. Indicates the reason for the exception that this register holds information about. Possible values of this field are:

EC $= 000000$

Unknown reason.

See ISS encoding for exceptions with an unknown reason.

EC $= 000001$

Trapped WFI or WFE instruction execution.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

See ISS encoding for an exception from a WFI or WFE instruction.

EC $= 000011$

Trapped MCR or MRC access with (coproc==1111) that is not reported using EC 0b000000.

See ISS encoding for an exception from an MCR or MRC access.

EC $= 000100$

Trapped MCRR or MRRC access with (coproc==1111) that is not reported using EC 0b000000.

See ISS encoding for an exception from an MCRR or MRRC access.

EC $= 000101$

Trapped MCR or MRC access with (coproc==1110).

See ISS encoding for an exception from an MCR or MRC access.
EC == 000110
Trapped LDC or STC access.
The only architected uses of these instructions are:
• An STC to write data to memory from DBGDTRRXint.
• An LDC to read data from memory to DBGDTRTXint.
See ISS encoding for an exception from an LDC or STC instruction.

EC == 000111
Access to Advanced SIMD or floating-point functionality trapped by a HCPTR.\{TASE, TCP10\} control.
Excludes exceptions generated because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.
See ISS encoding for an exception from an access to SIMD or floating-point functionality, resulting from HCPTR.

EC == 001000
Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.
See ISS encoding for an exception from an MCR or MRC access.

EC == 001100
Trapped MRRC access with \{coproc==1110\}.
See ISS encoding for an exception from an MCRR or MRRC access.

EC == 001110
Illegal exception return to AArch32 state.
See ISS encoding for an exception from an Illegal state or PC alignment fault.

EC == 010001
Exception on SVC instruction execution in AArch32 state routed to EL2.
See ISS encoding for an exception from HVC or SVC instruction execution.

EC == 010010
HVC instruction execution in AArch32 state, when HVC is not disabled.
See ISS encoding for an exception from HVC or SVC instruction execution.

EC == 010011
Trapped execution of SMC instruction in AArch32 state.
See ISS encoding for an exception from SMC instruction execution.

EC == 100000
Prefetch Abort from a lower Exception level.
See ISS encoding for an exception from a Prefetch Abort.

EC == 100001
Prefetch Abort taken without a change in Exception level.
See ISS encoding for an exception from a Prefetch Abort.

EC == 100010
PC alignment fault exception.
See ISS encoding for an exception from an Illegal state or PC alignment fault.

EC == 100100
Data Abort from a lower Exception level.
See ISS encoding for an exception from a Data Abort.

EC == 100101
Data Abort taken without a change in Exception level.
See ISS encoding for an exception from a Data Abort.

All other EC values are reserved by ARM, and:
• Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
• Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-6133.

IL, bit [25]
Instruction length bit. Indicates the size of the instruction that has been trapped to Hyp mode. When this bit is valid, possible values of this bit are:
0 16-bit instruction trapped.
1 32-bit instruction trapped.

This field is RES1 and not valid for the following cases:
• When the EC field is 0b000000, indicating an exception with an unknown reason.
• Prefetch Aborts.
• Data Aborts for which the HSR.ISS.ISV field is 0.
• When the EC value is 0b001110, indicating an Illegal state exception.

Note
This is a change from the behavior in ARMv7, where the IL field is UNK/SBZP for the corresponding cases.

The IL field is not valid and is UNKNOWN on an exception from a PC alignment fault.

ISS, bits [24:0]
Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

The following subsections describe each ISS format.

ISS encoding for exceptions with an unknown reason
This encoding is used by:
• Unknown reason.

The ISS encoding for these exceptions is:

```
24 0
RES0
```

Bits [24:0]
Reserved, RES0.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:
• The attempted execution of an instruction bit pattern that has no allocated instruction in the current PE mode in the current Security state, including:
  — A read access using a System register encoding pattern that is not allocated for reads at the current Exception level and Security state.
  — A write access using a System register encoding pattern that is not allocated for writes at the current Exception level and Security state.
  — Instruction encodings for instructions not implemented in the implementation.
• In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
• In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
• The attempted execution of a short vector floating-point instruction.
• In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
• An exception generated because of the value of one of the SCTLR.{ITD, SED, CP15BEN} control bits.
• Attempted execution of:
  — An HVC instruction when disabled by HCR.HCD, SCR.HCE, or SCR_EL3.HCE.
  — An SMC instruction when disabled by SCR.SCD or SCR_EL3.SMD.
  — An HLT instruction when disabled by EDSCR.HDE.
• An exception generated because of the attempted execution of an MSR (Banked register) or MRS (Banked register) instruction that would access a Banked register that is not accessible from the Security state and PE mode at which the instruction was executed.

—— Note ———
An exception is generated only if the CONSTRAINED UNPREDICTABLE behavior of the instruction is that it is UNDEFINED, see MSR/MRS Banked registers on page K1-6117.

• Attempted execution, in Debug state, of:
  — A DCPS1 instruction in Non-secure state from EL0 when EL2 is using AArch32 and the value of HCR.TGE is 1.
  — A DCPS2 instruction at EL1 or EL0 when EL2 is not implemented, or when EL3 is using AArch32 and the value of SCR.NS is 0, or when EL3 is using AArch64 and the value of SCR_EL3.NS is 0.
  — A DCPS3 instruction when EL3 is not implemented, or when the value of EDSCR.SDD is 1.
• In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.

Undefined Instruction exception, when the value of HCR.TGE is 1 on page G1-4357 describes the configuration settings for a trap that returns an HSR.EC value of 0b000000.

ISS encoding for an exception from a WFI or WFE instruction

This encoding is used by:
• Trapped WFI or WFE instruction execution.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

The ISS encoding for these exceptions is:
CV, bit [24]

Condition code valid. Possible values of this bit are:

0  The COND field is not valid.
1  The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

• If the instruction is conditional, COND is set to the condition code field value from the instruction.
• If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

• With COND set to 0b1110, the value for unconditional.
• With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

• CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
• CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Bits [19:1]

Reserved, RES0.

TI, bit [0]

Trapped instruction. Possible values of this bit are:

0  WFI trapped.
1  WFE trapped.

Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437 describes the configuration settings for this trap.

ISS encoding for an exception from an MCR or MRC access

This encoding is used by:

• Trapped MCR or MRC access with (coproc==1111) that is not reported using EC 0b000000.
• Trapped MCR or MRC access with (coproc==1110).
• Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.

The ISS encoding for these exceptions is:

```
   24 23 20 19 17 16 14 13 10  9  8  5  4  1  0
    COND  Opc2  Opc1  CRn    Rt    CRm
```

CV, bit [24]

Condition code valid. Possible values of this bit are:

0  The COND field is not valid.
1  The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

• If the instruction is conditional, COND is set to the condition code field value from the instruction.
• If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

• With COND set to 0b1110, the value for unconditional.
• With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

• CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
• CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value 0b000.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value 0b111.

CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.
Bit [9]
Reserved, RES0.

Rt, bits [8:5]
The Rt value from the issued instruction, the general-purpose register used for the transfer.

CRm, bits [4:1]
The CRm value from the issued instruction.
For a trapped VMRS access, holds the value 0b0000.

Direction, bit [0]
Indicates the direction of the trapped instruction. The possible values of this bit are:
0 Write to System register space. MCR instruction.
1 Read from System register space. MRC or VMRS instruction.

The following sections describe configuration settings for traps that are reported using EC value 0b000011:

• Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers on page G1-4434.
• Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-4433.
• Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions on page G1-4432.
• Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions on page G1-4431.
• Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register on page G1-4432.
• Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page G1-4444.
• Traps to Hyp mode of Non-secure EL1 accesses to the CPICR on page G1-4439.
• Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers on page G1-4430.
• General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space on page G1-4440.

The following sections describe configuration settings for traps that are reported using EC value 0b000101:

• ID group 0, Primary device identification registers on page G1-4435.
• Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-4439.
• Trapping Non-secure System register accesses to Debug ROM registers on page G1-4442.
• Trapping Non-secure System register accesses to powerdown debug registers on page G1-4442.
• Trapping general Non-secure System register accesses to debug registers on page G1-4443.

The following sections describes configuration settings for traps that are reported using EC value 0b001000:

• ID group 0, Primary device identification registers on page G1-4435.
• ID group 3, Detailed feature identification registers on page G1-4436.

**ISS encoding for an exception from an MCRR or MRRC access**

This encoding is used by:

• Trapped MCRR or MRRC access with (coproc==1111) that is not reported using EC 0b000000.
• Trapped MRRC access with (coproc==1110).
The ISS encoding for these exceptions is:

```
<table>
<thead>
<tr>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>13</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>5</th>
<th>4</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

CV, bit [24]

Condition code valid. Possible values of this bit are:

0 The COND field is not valid.
1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

Bits [15:14]

Reserved, RES0.

Rt2, bits [13:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

Bit [9]

Reserved, RES0.

Rt, bits [8:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer.
CRm, bits [4:1]

The CRm value from the issued instruction.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

0  Write to System register space. MCRR instruction.
1  Read from System register space. MRRC instruction.

The following sections describe configuration settings for traps that are reported using EC value 0b000100:

•  *Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers* on page G1-4430.

•  *General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc = 0b1111) encoding space* on page G1-4440.

The following sections describe configuration settings for traps that are reported using EC value 0b001100:

•  *Traps to Hyp mode of Non-secure System register accesses to trace registers* on page G1-4439.

•  *Trapping Non-secure System register accesses to Debug ROM registers* on page G1-4442.

**ISS encoding for an exception from an LDC or STC instruction**

This encoding is used by:

•  Trapped LDC or STC access.

The only architected uses of these instructions are:

— An STC to write data to memory from DBGDTRRXint.
— An LDC to read data from memory to DBGDTRTXint.

The ISS encoding for these exceptions is:

```
24  COND  19  imm8  12  RES0  9  Rn  8  AM  5  4  3  1  0
   CV          Direction  Offset
```

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

0  The COND field is not valid.
1  The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

**COND, bits [23:20]**

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

•  If the instruction is conditional, COND is set to the condition code field value from the instruction.
•  If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

•  With CV set to 0b1110, the value for unconditional.
• With the COND value held in the instruction.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
• CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT
field to determine the condition, if any, of the T32 instruction.
• CV is set to 1 and COND is set to the condition code for the condition that applied to the
instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped
conditional instruction only if the instruction passes its condition code check, these definitions mean
that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110,
or to the value of any condition that applied to the instruction.

**imm8, bits [19:12]**
The immediate value from the issued instruction.

**Bits [11:9]**
Reserved, RES0.

**Rn, bits [8:5]**
The Rn value from the issued instruction. Valid only when AM[2] is 0, indicating an immediate
form of the LDC or STC instruction.
When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

**Offset, bit [4]**
Indicates whether the offset is added or subtracted:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Subtract offset.</td>
</tr>
<tr>
<td>1</td>
<td>Add offset.</td>
</tr>
</tbody>
</table>

This bit corresponds to the U bit in the instruction encoding.

**AM, bits [3:1]**
Addressing mode. The permitted values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>Immediate unindexed.</td>
</tr>
<tr>
<td>001</td>
<td>Immediate post-indexed.</td>
</tr>
<tr>
<td>010</td>
<td>Immediate offset.</td>
</tr>
<tr>
<td>011</td>
<td>Immediate pre-indexed.</td>
</tr>
<tr>
<td>100</td>
<td>Literal unindexed.</td>
</tr>
<tr>
<td>101</td>
<td>Literal offset.</td>
</tr>
<tr>
<td>110</td>
<td>LDC instruction only.</td>
</tr>
</tbody>
</table>

For a trapped STC instruction or a trapped T32 LDC instruction this encoding is
reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is
that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and
memory-mapped registers and translation table entries on page K1-6117.*

**Bit [2]** in this subfield indicates the instruction form, immediate or literal.

**Bits [1:0]** in this subfield correspond to the bits {P, W} in the instruction encoding.

**Direction, bit [0]**
Indicates the direction of the trapped instruction. The possible values of this bit are:

<table>
<thead>
<tr>
<th>Direction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Write to memory. STC instruction.</td>
</tr>
<tr>
<td>1</td>
<td>Read from memory. LDC instruction.</td>
</tr>
</tbody>
</table>
Trapping general Non-secure System register accesses to debug registers on page G1-4443 describes the configuration settings for the trap that is reported using EC value 0b0000110.

**ISS encoding for an exception from an access to SIMD or floating-point functionality, resulting from HCPTR**

This encoding is used by:

- Access to Advanced SIMD or floating-point functionality trapped by a HCPTR, {TASE, TCP10} control. Excludes exceptions generated because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.

The ISS encoding for these exceptions is:

```
+---+---+---+---+---+---+
| CV | RES0 | TA | coproc |
+---+---+---+---+---+
```

Excludes exceptions that occur because Advanced SIMD and floating-point functionality is not implemented, or because the value of HCR.TGE or HCR_EL2.TGE is 1. These are reported with EC value 0b000000.

**CV, bit [24]**

Condition code valid. Possible values of this bit are:

- 0: The COND field is not valid.
- 1: The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

**COND, bits [23:20]**

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

**Bits [19:6]**

Reserved, RES0.
TA, bit [5]
Indicates trapped use of Advanced SIMD functionality. The possible values of this bit are:
- 0 Exception was not caused by trapped use of Advanced SIMD functionality.
- 1 Exception was caused by trapped use of Advanced SIMD functionality.

Any use of an Advanced SIMD instruction that is not also a floating-point instruction that is trapped to Hyp mode because of a trap configured in the HCPTR sets this bit to 1.

For a list of these instructions, see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2746.

Bit [4]
Reserved, RES0.

coproc, bits [3:0]
When the TA field returns the value 1, this field returns the value 1010, otherwise this field is RES0.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:
- General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-4437.
- Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality on page G1-4438.

ISS encoding for an exception from HVC or SVC instruction execution
This encoding is used by:
- Exception on SVC instruction execution in AArch32 state routed to EL2.
- HVC instruction execution in AArch32 state, when HVC is not disabled.

The ISS encoding for these exceptions is:

<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td>imm16</td>
</tr>
</tbody>
</table>

Bits [24:16]
Reserved, RES0.

imm16, bits [15:0]
The value of the immediate field from the HVC or SVC instruction.
For an HVC instruction, this is the value of the imm16 field of the issued instruction.
For an SVC instruction:
- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-4357 describes the configuration settings for the trap reported with EC value 0b010001.
ISS encoding for an exception from SMC instruction execution

This encoding is used by:

- Trapped execution of SMC instruction in AArch32 state.

The ISS encoding for these exceptions is:

<table>
<thead>
<tr>
<th>24 23</th>
<th>20 19 18</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>COND</td>
<td></td>
<td>RES0</td>
</tr>
<tr>
<td>CV</td>
<td>CCKNOWNPASS</td>
<td></td>
</tr>
</tbody>
</table>

CV, bit [24]
Condition code valid. Possible values of this bit are:

0 The COND field is not valid.
1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.
This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:
- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.
A conditional A32 instruction that is known to pass its condition code check can be presented either:
- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.
This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

CCKNOWNPASS, bit [19]
Indicates whether the instruction might have failed its condition code check.
0 The instruction was unconditional, or was conditional and passed its condition code check.
1 The instruction was conditional, and might have failed its condition code check.

Bits [18:0]
Reserved, RES0.
Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-4434 describes the configuration settings for this trap, for instructions executed in Non-secure PL1 modes.

**ISS encoding for an exception from a Prefetch Abort**

This encoding is used by:

- Prefetch Abort from a lower Exception level.
- Prefetch Abort taken without a change in Exception level.

The ISS encoding for these exceptions is:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>24:11</td>
<td>Reserved, RES0</td>

</tbody>
</table>

All other values are reserved.

When the RAS Extension is implemented, 011000, 011101, 011110 and 011111 are reserved.

--- Note ---

ARMv8.2 requires the implementation of the RAS Extension.

---

For more information about the lookup level associated with a fault, see *The level associated with MMU faults on a Long-descriptor translation table lookup on page G4-4671.*

The following sections describe cases where Prefetch Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0b100000:

- *Abort exceptions, when the value of HCR.TGE is 1* on page G1-4357.
- *Routing debug exceptions to EL2 using AArch32* on page G1-4358.

**ISS encoding for an exception from an Illegal state or PC alignment fault**

This encoding is used by:

- Illegal exception return to AArch32 state.
- PC alignment fault exception.

The ISS encoding for these exceptions is:
Bits [24:0]

Reserved, RES0.

For more information about the Illegal state exception, see:

• Illegal changes to PSTATE.M on page G1-4336.
• Illegal return events from AArch32 state on page G1-4361.
• Legal returns that set PSTATE.IL to 1 on page G1-4363.
• The Illegal Execution state exception on page G1-4363.

For more information about the PC alignment fault exception, see Branching to an unaligned PC on page K1-6098.

ISS encoding for an exception from a Data Abort

This encoding is used by:

• Data Abort from a lower Exception level.
• Data Abort taken without a change in Exception level.

The ISS encoding for these exceptions is:

ISV, bit [24]

Instruction syndrome valid. Indicates whether the syndrome information in ISS[23:14] is valid.

0  No valid instruction syndrome. ISS[23:14] are RES0.
1  ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults except Data Aborts generated by stage 2 address translations for which all the following apply to the instruction that generated the Data Abort exception:

• The instruction is an LDR, LDA, LDRT, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STL, STRHT, STRB, STL, or STRBT instruction.
• The instruction is not performing register writeback.
• The instruction is not using the PC as a source or destination register.

For these cases, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, as described in Data Aborts in Memory access mode on page H4-5504, and otherwise indicates whether ISS[23:14] hold a valid syndrome.
Note

In the A32 instruction set, LDR*T and STR*T instructions always perform register writeback and therefore never return a valid instruction syndrome.

When the RAS Extension is implemented, ISV is 0 for any Synchronous external abort. ISV is set to 0 on a stage 2 abort on a stage 1 translation table walk.

When the RAS Extension is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a Synchronous external abort on stage 2 translation table walk.

SAS, bits [23:22]

Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.

00  Byte
01  Halfword
10  Word
11  Doubleword

This field is UNKNOWN when the value of ISV is UNKNOWN.
This field is RES0 when the value of ISV is 0.

SSE, bit [21]

Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

0  Sign-extension not required.
1  Data item must be sign-extended.

For all other operations this bit is 0.
This field is UNKNOWN when the value of ISV is UNKNOWN.
This field is RES0 when the value of ISV is 0.

Bit [20]

Reserved, RES0.

SRT, bits [19:16]

Syndrome Register transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction.

This field is UNKNOWN when the value of ISV is UNKNOWN.
This field is RES0 when the value of ISV is 0.

Bit [15]

Reserved, RES0.

AR, bit [14]

Acquire/Release. When ISV is 1, the possible values of this bit are:

0  Instruction did not have acquire/release semantics.
1  Instruction did have acquire/release semantics.

This field is UNKNOWN when the value of ISV is UNKNOWN.
This field is RES0 when the value of ISV is 0.

Bits [13:12]

Reserved, RES0.
AET, bit [11:10]

Asynchronous Error Type.

When the RAS Extension is implemented and the value returned in the DFSC field is 010001, describes the state of the PE after taking the SError interrupt exception. The possible values of this field are:

- 00: Uncontainable error (UC) or uncategorized.
- 01: Unrecoverable error (UEU).
- 10: Restartable error (UEO) or Corrected error (CE).
- 11: Recoverable error (UER).

On a synchronous Data Abort, this field is RES0.

If multiple errors are taken as a single SError interrupt exception, the overall state of the PE is reported. For example, if both a Recoverable and Unrecoverable error occurred, the state is Unrecoverable.

--- Note ---

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

---

When RAS Extension is not implemented, or when DFSC is not 010001:

- Bit[11] is RES0.
- Bit[10] forms the FnV field.

--- Note ---

ARMv8.2 requires the implementation of the RAS Extension.

FnV, bit [10]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0: HDFAR is valid.
- 1: HDFAR is not valid, and holds an UNKNOWN value.

When the RAS Extension is not implemented, this field is valid only if DFSC is 010000. It is RES0 for all other aborts.

When the RAS Extension is implemented:

- If DFSC is 010000, this field is valid.
- If DFSC is 010001, this bit forms part of the AET field.
- This field is RES0 for all other aborts.

--- Note ---

ARMv8.2 requires the implementation of the RAS Extension.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

CM, bit [8]

Cache maintenance. For a synchronous fault, identifies fault that comes from a cache maintenance or address translation instruction. For synchronous faults, the possible values of this bit are:

- 0: Fault not generated by a cache maintenance or address translation instruction.
Fault generated by a cache maintenance or address translation instruction. For an asynchronous Data Abort exception, this bit is 0.

**SIPTW, bit [7]**

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- **0** Fault not on a stage 2 translation for a stage 1 translation table walk.
- **1** Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

--- **Note** ---

ARMv8.2 requires the implementation of the RAS Extension.

**WnR, bit [6]**

Write not Read. Indicates whether a synchronous abort was caused by a write instruction or a read instruction. The possible values of this bit are:

- **0** Abort caused by a read instruction.
- **1** Abort caused by a write instruction.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

On an asynchronous Data Abort:

- When the RAS Extension is not implemented this bit is UNKNOWN.
- When the RAS Extension is implemented this bit is RES0.

--- **Note** ---

ARMv8.2 requires the implementation of the RAS Extension.

**DFSC, bits [5:0]**

Data Fault Status Code. Possible values of this field are:

- **000000** Address size fault, translation table base register
- **000001** Address size fault, level 1
- **000010** Address size fault, level 2
- **000011** Address size fault, level 3
- **000101** Translation fault, level 1
- **000110** Translation fault, level 2
- **001111** Translation fault, level 3
- **001001** Access flag fault, level 1
- **001010** Access flag fault, level 2
- **001011** Access flag fault, level 3
- **001101** Permission fault, level 1
- **001110** Permission fault, level 2
- **001111** Permission fault, level 3
- **010000** Synchronous external abort, not on translation table walk
- **011000** Synchronous parity or ECC error on memory access, not on translation table walk
- **010001** SError interrupt
- **011001** SError interrupt from a parity or ECC error on memory access
- **010101** Synchronous external abort, on translation table walk, level 1
010110  Synchronous external abort, on translation table walk, level 2
010111  Synchronous external abort, on translation table walk, level 3
011101  Synchronous parity or ECC error on memory access on translation table walk, level 1
011110  Synchronous parity or ECC error on memory access on translation table walk, level 2
011111  Synchronous parity or ECC error on memory access on translation table walk, level 3
100000  Alignment fault
100010  Debug exception, only when the EC value is 0b100100
110000  TLB conflict abort
110100  IMPLEMENTATION DEFINED fault (Lockdown fault)
110101  IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
All other values are reserved.
When the RAS Extension is implemented, 011000, 011001, 011101, 011110, and 011111 are reserved.
For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Long-descriptor translation table lookup on page G4-4671.
The following describe cases where Data Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0b100100:

• *Abort exceptions, when the value of HCR.TGE is 1* on page G1-4357.
• *Routing debug exceptions to EL2 using AArch32* on page G1-4358.
The following describe cases that can cause a Data Abort exception that is taken to Hyp mode, and reported in the HSR with EC value of 0b100000 or 0b100100:

• *Hyp mode control of Non-secure access permissions* on page G4-4614.
• *Memory fault reporting in Hyp mode* on page G4-4675.

**Accessing the HSR**

This register can be read using MRC with the following syntax:

**MRC** <syntax>

This register can be written using MCR with the following syntax:

**MCR** <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c5, c2, 0</td>
<td>100</td>
<td>000</td>
<td>0101</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>E2H</th>
<th>TGE</th>
<th>NS</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>
</tr>
</thead>
<tbody>

<td>1</td>
<td>1</td>
<td>-</td>
<td>n/a</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T5==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.70  HSTR, Hyp System Trap Register

The HSTR characteristics are:

**Purpose**

Controls trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to the System register in the coproc == 1111 encoding space, by the CRn value used to access the register using MCR or MRC instruction. When the register is accessible using an MCRR or MRRC instruction, this is the CRm value used to access the register.

**Configurations**

AArch32 System register HSTR is architecturally mapped to AArch64 System register HSTR_EL2. If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HSTR is a 32-bit register.

**Field descriptions**

The HSTR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>T9</td>
<td>T8</td>
<td>T7</td>
<td>T6</td>
<td>T5</td>
<td>T4</td>
<td>T3</td>
<td>T2</td>
<td>T1</td>
<td>T0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:16]**

Reserved, RES0.

T<n>, bit [n], for n = 0 to 15

Fields T14 and T4 are RES0.

The remaining fields control whether Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, and MRRC instructions, to the System registers in the coproc == 1111 encoding space are trapped to Hyp mode:

0  This control has no effect on Non-secure EL0 or EL1 accesses to System registers.

1  Any Non-secure EL1 MCR, MRC access with coproc == 1111 and CRn == <n> is trapped to Hyp mode if the access is not UNDEFINED when the value of this field is 0.

   Any Non-secure EL1 MCRR, MRRC access with coproc == 1111 and CRm == <n> is trapped to Hyp mode if the access is not UNDEFINED when the value of this field is 0.

For example, when HSTR.T7 is 1:

- Any 32-bit access from a Non-secure EL1 mode, using an MCR or MRC instruction with coproc set to 1111 and <Crn> set to c7, and that is not UNDEFINED when HSTR.T7 is 0, is trapped to Hyp mode.
• Any 64-bit access from a Non-secure EL1 mode, using an MCRR or MRRC instruction with coproc set to 1111 and <CRm> set to c7, and that is not UNDEFINED when HSTR.T7 is 0, is trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HSTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c1, c1, 3</td>
<td>100</td>
<td>011</td>
<td>0001</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.71 HTCR, Hyp Translation Control Register

The HTCR characteristics are:

**Purpose**

The control register for stage 1 of the EL2 translation regime.

--- Note ---

This stage of translation always uses the Long-descriptor translation table format.

**Configurations**

AArch32 System register HTCR is architecturally mapped to AArch64 System register TCR_EL2. If EL2 is not implemented, this register is RES0 from EL3. RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HTCR is a 32-bit register.

**Field descriptions**

The HTCR bit assignments are:

- **Bit [31]**
  - Reserved, RES1.

- **IMP DEF, bit [30]**
  - IMPLEMENTATION DEFINED.

- **Bit [29]**
  - Reserved, RES0.

- **HWU62, bit [28]**
  - In ARMv8.2
    - Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table block or level 3 entry if the HTCR.HPD value is 1.
    - Defined values are:
      - 0: The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

---
The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the HTCR.HPD value is 1.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

**In ARMv8.1 and ARMv8.0.**

Reserved, RES0.

**HWU61, bit [27]**

**In ARMv8.2**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table block or level 3 entry if the HTCR.HPD value is 1.

Defined values are:

0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if HTCR.HPD bit value is 1.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

**In ARMv8.1 and ARMv8.0.**

Reserved, RES0.

**HWU60, bit [26]**

**In ARMv8.2**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table block or level 3 entry.

Defined values are:

0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the HTCR.HPD bit value is 1.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

**In ARMv8.1 and ARMv8.0.**

Reserved, RES0.

**HWU59, bit [25]**

**In ARMv8.2**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table block or level 3 entry.

Defined values are:

0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the HTCR.HPD bit value is 1.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

**In ARMv8.1 and ARMv8.0.**

Reserved, RES0.

**HPD, bit [24]**

**In ARMv8.2**

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the PL2 translation regime.
Defined values are:

0  Hierarchical permissions are enabled.
1  Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.
This bit is RES0 if ARMv8.2-AA32HPD is not implemented.

*In ARMv8.1 and ARMv8.0.*

Reserved, RES0.

**Bit [23]**

Reserved, RES1.

**Bits [22:14]**

Reserved, RES0.

**SH0, bits [13:12]**

Shareability attribute for memory associated with translation table walks using HTTBR.

00  Non-shareable
10  Outer Shareable
11  Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6117.

**ORGN0, bits [11:10]**

Outer cacheability attribute for memory associated with translation table walks using HTTBR.

00  Normal memory, Outer Non-cacheable
01  Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable
10  Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable
11  Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable

**IRGN0, bits [9:8]**

Inner cacheability attribute for memory associated with translation table walks using HTTBR.

00  Normal memory, Inner Non-cacheable
01  Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable
10  Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable
11  Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable

**Bits [7:3]**

Reserved, RES0.

**T0SZ, bits [2:0]**

The size offset of the memory region addressed by HTTBR. The region size is \(2^{(32-T0SZ)}\) bytes.

**Accessing the HTCR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

\[
\begin{array}{cccccc}
\text{<syntax>} & \text{opc1} & \text{opc2} & \text{CRn} & \text{coproc} & \text{CRm} \\
\text{p15, 4, <Rt>, c2, c0, 2} & 100 & 010 & 0010 & 1111 & 0000 \\
\end{array}
\]

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>E2H</th>
<th>TGE</th>
<th>NS</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>

</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.72 HTPIDR, Hyp Software Thread ID Register

The HTPIDR characteristics are:

**Purpose**

Provides a location where software running in Hyp mode can store thread identifying information that is not visible to Non-secure software executing at EL0 or EL1, for hypervisor management purposes.

The PE makes no use of this register.

**Configurations**

AArch32 System register HTPIDR is architecturally mapped to AArch64 System register TPIDR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

The PE never updates this register. This means the register is always UNKNOWN on reset.

**Attributes**

HTPIDR is a 32-bit register.

**Field descriptions**

The HTPIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Thread ID</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Thread ID. Thread identifying information stored by software running at this Exception level.

**Accessing the HTPIDR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>

</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T13==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.73  HTTBR, Hyp Translation Table Base Register

The HTTBR characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of an address
translation in the EL2 translation regime, and other information for this translation regime.

Configurations

AArch32 System register HTTBR is architecturally mapped to AArch64 System register
TTBR0_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HTTBR is a 64-bit register.

Field descriptions

The HTTBR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:48]</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
| [47:1]         | Translation table base address, Bits[47:x], Bits [x-1:1] are RES0, with the additional requirement that
                if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are
                CONSTRAINED UNPREDICTABLE, and must be one of the following:
                • Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits
                  is either the value written or zero.
                • The result of the calculation of an address for a translation table walk using this register can
                  be corrupted in those bits that are nonzero.
                x is determined from the value of HTCR.T0SZ as follows:
                • If HTCR.T0SZ is 0 or 1, x = 5 - HTCR.T0SZ.
                • If HTCR.T0SZ is greater than 1, x = 14 - HTCR.T0SZ.
                If bits[47:40] of the translation table base address are not zero, an Address size fault is generated. |
| [0]            | CnP, bit [0] Common not Private. In an implementation that includes ARMv8.2-TTCNP, indicates whether each
                entry that is pointed to by HTTBR is a member of a common set that can be used by every PE in the
                Inner Shareable domain for which the value of HTTBR.CnP is 1. |

In ARMv8.2

Common not Private. In an implementation that includes ARMv8.2-TTCNP, indicates whether each
entry that is pointed to by HTTBR is a member of a common set that can be used by every PE in the
Inner Shareable domain for which the value of HTTBR.CnP is 1.

0 The translation table entries pointed to by HTTBR are permitted to differ from
 corresponding entries for HTTBR for other PEs in the Inner Shareable domain. This is
 not affected by the value of HTTBR.CnP on those other PEs.
The translation table entries pointed to by HTTBR are the same as the translation table entries pointed to by HTTBR on every other PE in the Inner Shareable domain for which the value of HTTBR.CnP is 1.

**Note**

If the value of the HTTBR.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those HTTBRs do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRANGED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101.

In an implementation that does not include ARMv8.2-TTCNP this field is RES0.

**In ARMv8.1 and ARMv8.0.**

Reserved, RES0.

### Accessing the HTTBR

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, &lt;Rt2&gt;, c2</td>
<td>0100</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- - n/a -</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- - RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.74  HVBAR, Hyp Vector Base Address Register

The HVBAR characteristics are:

**Purpose**

Holds the vector base address for any exception that is taken to Hyp mode.

**Configurations**

AArch32 System register HVBAR is architecturally mapped to AArch64 System register VBAR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HVBAR is a 32-bit register.

**Field descriptions**

The HVBAR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector Base Address</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:5]**

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

**Bits [4:0]**

Reserved, RES0.

**Accessing the HVBAR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c12, c0, 0</td>
<td>100</td>
<td>000</td>
<td>1100</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td></td>
</tr>
<tr>
<td>NS</td>
<td></td>
</tr>
</tbody>
</table>

| x | x | 0 | - | - | n/a | - |
| x | 0 | 1 | - | - | RW  | RW |
| x | 1 | 1 | - | n/a | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T12==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.75  ICIALLU, Instruction Cache Invalidate All to PoU

The ICIALLU characteristics are:

**Purpose**

Invalidate all instruction caches to PoU. If branch predictors are architecturally visible, also flush branch predictors.

**Configurations**

AArch32 System instruction ICIALLU performs the same function as AArch64 System instruction IC IALLU.

**Attributes**

ICIALLU is a 32-bit System instruction.

**Field descriptions**

ICIALLU ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the ICIALLU instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c5, 0</td>
<td>000</td>
<td>000</td>
<td>0111</td>
<td>1111</td>
<td>0101</td>
</tr>
</tbody>
</table>

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td></td>
</tr>
<tr>
<td>NS</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>E2H</th>
<th>TGE</th>
<th>NS</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>x</td>
<td>x</td>
<td>0</td>
<td>-</td>
<td>WO</td>
<td>n/a</td>
<td>WO</td>
</tr>
<tr>
<td></td>
<td>x</td>
<td>0</td>
<td>1</td>
<td>-</td>
<td>WO</td>
<td>WO</td>
<td>WO</td>
</tr>
<tr>
<td></td>
<td>x</td>
<td>1</td>
<td>1</td>
<td>-</td>
<td>n/a</td>
<td>WO</td>
<td>WO</td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a ICIALLUIS.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TPU==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.76 ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The ICIALLUIS characteristics are:

**Purpose**

Invalidate all instruction caches Inner Shareable to PoU. If branch predictors are architecturally visible, also flush branch predictors.

**Configurations**

AArch32 System instruction ICIALLUIS performs the same function as AArch64 System instruction IC IALLUIS.

**Attributes**

ICIALLUIS is a 32-bit System instruction.

**Field descriptions**

ICIALLUIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the ICIALLUIS instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c1, 0</td>
<td>000</td>
<td>000</td>
<td>0111</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
— If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  — If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HCR.TPU==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  — If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.77 ICIMVAU, Instruction Cache line Invalidate by VA to PoU

The ICIMVAU characteristics are:

**Purpose**

Invalidate instruction cache line by virtual address to PoU.

**Configurations**

AArch32 System instruction ICIMVAU performs the same function as AArch64 System instruction IC IVAU.

**Attributes**

ICIMVAU is a 32-bit System instruction.

**Field descriptions**

The ICIMVAU input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
</table>

**Executing the ICIMVAU instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c7, c5, 1</td>
<td>000</td>
<td>001</td>
<td>0111</td>
<td>1111</td>
<td>0101</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>n/a</td>

<tr>
<td>EL0</td>
<td>WO</td>
</tr>
<tr>
<td>EL1</td>
<td>WO</td>
</tr>
<tr>
<td>EL2</td>
<td>WO</td>
</tr>
<tr>
<td>EL3</td>
<td>WO</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TPU==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
### G6.2.78 ID_AFR0, Auxiliary Feature Register 0

The ID_AFR0 characteristics are:

**Purpose**

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch32 state.

Must be interpreted with the Main ID Register, MIDR.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_AFR0 is architecturally mapped to AArch64 System register ID_AFR0_EL1.

**Attributes**

ID_AFR0 is a 32-bit register.

**Field descriptions**

The ID_AFR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Bit 16</th>
<th>Bit 15</th>
<th>Bit 12</th>
<th>Bit 11</th>
<th>Bit 8</th>
<th>Bit 7</th>
<th>Bit 4</th>

</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.79  ID_DFR0, Debug Feature Register 0

The ID_DFR0 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch32 state.

Must be interpreted with the Main ID Register, MIDR.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_DFR0 is architecturally mapped to AArch64 System register ID_DFR0_EL1.

**Attributes**

ID_DFR0 is a 32-bit register.

**Field descriptions**

The ID_DFR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit positions</th>
<th>Field name</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>RES0</td>
</tr>
<tr>
<td>27-24</td>
<td>PerfMon</td>

<td>CopTrc</td>
</tr>
<tr>
<td>11-8</td>
<td>MMapDbg</td>
</tr>
<tr>
<td>7-4</td>
<td>CopSDbg</td>
</tr>
<tr>
<td>3-0</td>
<td>CopDbg</td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**PerfMon, bits [27:24]**

Performance Monitors. Support for System registers-based ARM Performance Monitors Extension, using registers in the coproc == 1111 encoding space, for A and R profile processors. Defined values are:

0000  Performance Monitors Extension System registers not implemented.
0001  Support for Performance Monitors Extension version 1 (PMUv1) System registers.
0010  Support for Performance Monitors Extension version 2 (PMUv2) System registers.
0011  Support for Performance Monitors Extension version 3 (PMUv3) System registers.
0100  Support for Performance Monitors Extension version 3 (PMUv3) System registers, with a 16-bit evtCount field.
1111  IMPLEMENTATION DEFINED form of Performance Monitors System registers supported. PMUv3 not supported.

All other values are reserved.

In ARMv8.0 the permitted values are 0000, 0011, and 1111.

From ARMv8.1 the permitted values are 0000, 0100, and 1111.

In ARMv7, the value 0000 can mean that PMUv1 is implemented. PMUv1 is not permitted in an ARMv8 implementation.

**MProfDbg, bits [23:20]**

M Profile Debug. Support for memory-mapped debug model for M profile processors. Defined values are:

0000  Not supported.
0001 Support for M profile Debug architecture, with memory-mapped access.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

MMapTrc, bits [19:16]
Memory Mapped Trace. Support for memory-mapped trace model. Defined values are:
0000 Not supported.
0001 Support for ARM trace architecture, with memory-mapped access.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.
In the Trace registers, the ETMIDR gives more information about the implementation.

CopTrc, bits [15:12]
Support for System registers-based trace model, using registers in the coproc == 1110 encoding space. Defined values are:
0000 Not supported.
0001 Support for ARM trace architecture, with System registers access.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.
In the Trace registers, the ETMIDR gives more information about the implementation.

MMapDbg, bits [11:8]
Memory Mapped Debug. Support for v7 memory-mapped debug model, for A and R profile processors.
In ARMv8-A this field is res0.
The optional memory map defined by ARMv8 is not compatible with ARMv7.

CopSDbg, bits [7:4]
Support for a System registers-based Secure debug model, using registers in the coproc = 1110 encoding space, for an A profile processor that includes EL3.
If EL3 is not implemented and the implemented Security state is Non-Secure state, this field is res0.
Otherwise, this field reads the same as bits [3:0].

CopDbg, bits [3:0]
Support for System registers-based debug model, using registers in the coproc == 1110 encoding space, for A and R profile processors. Defined values are:
0000 Not supported.
0010 Support for ARMv6, v6 Debug architecture, with System registers access.
0011 Support for ARMv6, v6.1 Debug architecture, with System registers access.
0100 Support for ARMv7, v7 Debug architecture, with System registers access.
0101 Support for ARMv7, v7.1 Debug architecture, with System registers access.
0110 Support for ARMv8 debug architecture, with System registers access.
0111 Support for ARMv8 debug architecture, with System registers access, and Virtualization Host extensions.
1000 Support for ARMv8.2 debug architecture.
All other values are reserved.
In an ARMv8.0 implementation, the only permitted value is 0b0110.
In an ARMv8.1 implementation that does not include ARMv8.1-VHE, the permitted values are 0b0110 and 0b0111.
In an ARMv8.1 implementation that includes ARMv8.1-VHE, the only permitted value is 0b0111.
In an ARMv8.2 implementation, the only permitted value is 0b1000.

**Accessing the ID_DFR0**

This register can be read using MRC with the following syntax:

\[ \text{MRC } <\text{syntax}> \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;R&gt;, c0, c1, 2</td>
<td>000</td>
<td>010</td>
<td>0000</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.80  ID_ISAR0, Instruction Set Attribute Register 0

The ID_ISAR0 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.
Must be interpreted with ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.
For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register ID_ISAR0 is architecturally mapped to AArch64 System register ID_ISAR0_EL1.

**Attributes**

ID_ISAR0 is a 32-bit register.

**Field descriptions**

The ID_ISAR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [31:28]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>Divide, bits [27:24]</td>
<td>Indicates the implemented Divide instructions. Defined values are:</td>
</tr>
<tr>
<td>0000</td>
<td>None implemented.</td>
</tr>
<tr>
<td>0001</td>
<td>Adds SDIV and UDIV in the T32 instruction set.</td>
</tr>
<tr>
<td>0010</td>
<td>As for 0001, and adds SDIV and UDIV in the A32 instruction set.</td>
</tr>
<tr>
<td>All other values are reserved.</td>
<td></td>
</tr>
<tr>
<td>In ARMv8-A the only permitted value is 0010.</td>
<td></td>
</tr>
<tr>
<td>Debug, bits [23:20]</td>
<td>Indicates the implemented Debug instructions. Defined values are:</td>
</tr>
<tr>
<td>0000</td>
<td>None implemented.</td>
</tr>
<tr>
<td>0001</td>
<td>Adds BKPT.</td>
</tr>
<tr>
<td>All other values are reserved.</td>
<td></td>
</tr>
<tr>
<td>In ARMv8-A the only permitted value is 0001.</td>
<td></td>
</tr>
<tr>
<td>Coproc, bits [19:16]</td>
<td>Indicates the implemented System register access instructions. Defined values are:</td>
</tr>
<tr>
<td>0000</td>
<td>None implemented, except for instructions separately attributed by the architecture to provide access to AArch32 System registers and System instructions.</td>
</tr>
<tr>
<td>0001</td>
<td>Adds generic CDP, LDC, MCR, MRC, and STC.</td>
</tr>
<tr>
<td>0010</td>
<td>As for 0001, and adds generic CDP2, LDC2, MCR2, MRC2, and STC2.</td>
</tr>
<tr>
<td>0011</td>
<td>As for 0010, and adds generic MCRR and MRRC.</td>
</tr>
</tbody>
</table>
0100  As for 0011, and adds generic MCRR2 and MRRC2.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

CmpBranch, bits [15:12]
Indicates the implemented combined Compare and Branch instructions in the T32 instruction set.
Defined values are:
0000  None implemented.
0001  Adds CBNZ and CBZ.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

BitField, bits [11:8]
Indicates the implemented BitField instructions. Defined values are:
0000  None implemented.
0001  Adds BFC, BFI, SBFX, and UBFX.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

BitCount, bits [7:4]
Indicates the implemented Bit Counting instructions. Defined values are:
0000  None implemented.
0001  Adds CLZ.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

Swap, bits [3:0]
Indicates the implemented Swap instructions in the A32 instruction set. Defined values are:
0000  None implemented.
0001  Adds SWP and SWPB.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

Accessing the ID_ISAR0
This register can be read using MRC with the following syntax:

MRC <syntax>  

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c2, 0</td>
<td>000</td>
<td>000</td>
<td>0000</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>

</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.81   ID_ISAR1, Instruction Set Attribute Register 1

The ID_ISAR1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_ISAR1 is architecturally mapped to AArch64 System register ID_ISAR1_EL1.

**Attributes**

ID_ISAR1 is a 32-bit register.

**Field descriptions**

The ID_ISAR1 bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>Jazelle</th>
<th>Interwork</th>
<th>Immediate</th>
<th>IfThen</th>
<th>Extend</th>
<th>Except_AR</th>
<th>Except</th>
<th>Endian</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>28</td>
<td>27</td>
<td>24 23</td>
<td>20 19</td>
<td>16 15</td>
<td>12 11</td>
<td>8 7</td>
<td>4 3 0</td>
</tr>
</tbody>
</table>

**Jazelle, bits [31:28]**

Indicates the implemented Jazelle extension instructions. Defined values are:

<table>
<thead>
<tr>
<th></th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>No support for Jazelle.</td>
<td></td>
</tr>
<tr>
<td>0001</td>
<td>Adds the BXJ instruction, and the J bit in the PSR. This setting might indicate a trivial implementation of the Jazelle extension.</td>
<td></td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

**Interwork, bits [27:24]**

Indicates the implemented Interworking instructions. Defined values are:

<table>
<thead>
<tr>
<th></th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>None implemented.</td>
<td></td>
</tr>
<tr>
<td>0001</td>
<td>Adds the BX instruction, and the T bit in the PSR.</td>
<td></td>
</tr>
<tr>
<td>0010</td>
<td>As for 0001, and adds the BLX instruction. PC loads have BX-like behavior.</td>
<td></td>
</tr>
<tr>
<td>0011</td>
<td>As for 0010, and guarantees that data-processing instructions in the A32 instruction set with the PC as the destination and the S bit clear have BX-like behavior.</td>
<td></td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

**Immediate, bits [23:20]**

Indicates the implemented data-processing instructions with long immediates. Defined values are:

<table>
<thead>
<tr>
<th></th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>None implemented.</td>
<td></td>
</tr>
<tr>
<td>0001</td>
<td>Adds:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The MOVT instruction.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The MOV instruction encodings with zero-extended 16-bit immediates.</td>
<td></td>
</tr>
</tbody>
</table>
• The T32 ADD and SUB instruction encodings with zero-extended 12-bit immediates, and the other ADD, ADR, and SUB encodings cross-referenced by the pseudocode for those encodings.

All other values are reserved.
In ARMv8-A the only permitted value is \texttt{0001}.

**IfThen, bits [19:16]**
Indicates the implemented If-Then instructions in the T32 instruction set. Defined values are:
- \texttt{0000} None implemented.
- \texttt{0001} Adds the IT instructions, and the IT bits in the PSRs.
All other values are reserved.
In ARMv8-A the only permitted value is \texttt{0001}.

**Extend, bits [15:12]**
Indicates the implemented Extend instructions. Defined values are:
- \texttt{0000} No scalar sign-extend or zero-extend instructions are implemented, where scalar instructions means non-Advanced SIMD instructions.
- \texttt{0001} Adds the SXTB, SXTH, UXTB, and UXTH instructions.
- \texttt{0010} As for \texttt{0001}, and adds the SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH instructions.
All other values are reserved.
In ARMv8-A the only permitted value is \texttt{0010}.

**Except_AR, bits [11:8]**
Indicates the implemented A and R profile exception-handling instructions. Defined values are:
- \texttt{0000} None implemented.
- \texttt{0001} Adds the SRS and RFE instructions, and the A and R profile forms of the CPS instruction.
All other values are reserved.
In ARMv8-A the only permitted value is \texttt{0001}.

**Except, bits [7:4]**
Indicates the implemented exception-handling instructions in the ARM instruction set. Defined values are:
- \texttt{0000} Not implemented. This indicates that the User bank and Exception return forms of the LDM and STM instructions are not implemented.
- \texttt{0001} Adds the LDM (exception return), LDM (user registers), and STM (user registers) instruction versions.
All other values are reserved.
In ARMv8-A the only permitted value is \texttt{0001}.

**Endian, bits [3:0]**
Indicates the implemented Endian instructions. Defined values are:
- \texttt{0000} None implemented.
- \texttt{0001} Adds the SETEND instruction, and the E bit in the PSRs.
All other values are reserved.
In ARMv8-A the permitted values are \texttt{0000} and \texttt{0001}.
Accessing the ID_ISAR1

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c2, 1</td>
<td>000</td>
<td>001</td>
<td>0000</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>

</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](page G1-4344) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 state](page D1-1827) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.82 ID_ISAR2, Instruction Set Attribute Register 2

The ID_ISAR2 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_ISAR2 is architecturally mapped to AArch64 System register ID_ISAR2_EL1.

**Attributes**

ID_ISAR2 is a 32-bit register.

**Field descriptions**

The ID_ISAR2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reversal</td>
<td>PSR_AR</td>
<td>MultU</td>
<td>MultS</td>
<td>Mult</td>
<td>MemHint</td>
<td>LoadStore</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Reversal, bits [31:28]**

Indicates the implemented Reversal instructions. Defined values are:

- **0000** None implemented.
- **0001** Adds the REV, REV16, and REVSH instructions.
- **0010** As for 0001, and adds the RBIT instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

**PSR_AR, bits [27:24]**

Indicates the implemented A and R profile instructions to manipulate the PSR. Defined values are:

- **0000** None implemented.
- **0001** Adds the MRS and MSR instructions, and the exception return forms of data-processing instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

The exception return forms of the data-processing instructions are:

- In the A32 instruction set, data-processing instructions with the PC as the destination and the S bit set. These instructions might be affected by the WithShifts attribute.
- In the T32 instruction set, the SUBS PC,LR,#N instruction.
**MultU, bits [23:20]**

Indicates the implemented advanced unsigned Multiply instructions. Defined values are:

- **0000**: None implemented.
- **0001**: Adds the UMULL and UMLAL instructions.
- **0010**: As for 0001, and adds the UMAAL instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

**MultS, bits [19:16]**

Indicates the implemented advanced signed Multiply instructions. Defined values are:

- **0000**: None implemented.
- **0001**: Adds the SMULL and SMLAL instructions.
- **0010**: As for 0001, and adds the SMLABB, SMLABT, SMLALBB, SMLALBT, SMLALT, SMLAT, SMLAWB, SMLAWT, SMLUBB, SMLUBT, SMLUTB, SMLUTT, SMULWB, and SMULWT instructions. Also adds the Q bit in the PSRs.
- **0011**: As for 0010, and adds the SMLAD, SMLADX, SMLAD, SMLADX, SMLSD, SMLSDX, SMLSDT, SMLSDX, SMLSDT, SMMUL, SMMULR, SMMUL, SMMULR, SMULWB, and SMULWD instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

**Mult, bits [15:12]**

Indicates the implemented additional Multiply instructions. Defined values are:

- **0000**: No additional instructions implemented. This means only MUL is implemented.
- **0001**: Adds the MLA instruction.
- **0010**: As for 0001, and adds the MLS instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

**MultiAccessInt, bits [11:8]**

Indicates the support for interruptible multi-access instructions. Defined values are:

- **0000**: No support. This means the LDM and STM instructions are not interruptible.
- **0001**: LDM and STM instructions are restartable.
- **0010**: LDM and STM instructions are continuable.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

**MemHint, bits [7:4]**

Indicates the implemented Memory Hint instructions. Defined values are:

- **0000**: None implemented.
- **0001**: Adds the PLD instruction.
- **0010**: Adds the PLD instruction. (0001 and 0010 have identical effects.)
- **0011**: As for 0001 (or 0010), and adds the PLI instruction.
- **0100**: As for 0011, and adds the PLDW instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0100.
LoadStore, bits [3:0]

Indicates the implemented additional load/store instructions. Defined values are:

0000  No additional load/store instructions implemented.
0001  Adds the LDRD and STRD instructions.
0010  As for 0001, and adds the Load Acquire (LDAB, LDAH, LDA, LDAEXB, LDAEXH, LDAEX, LDAEXD) and Store Release (STLB, STLH, STL, STLEXB, STLEXH, STLEX, STLEXD) instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Accessing the ID_ISAR2

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c2, 2</td>
<td>000</td>
<td>010</td>
<td>0000</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.83 ID_ISAR3, Instruction Set Attribute Register 3

The ID_ISAR3 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_ISAR3 is architecturally mapped to AArch64 System register ID_ISAR3_EL1.

**Attributes**

ID_ISAR3 is a 32-bit register.

**Field descriptions**

The ID_ISAR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
<th>Defined Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>T32EE</td>
<td>None implemented.</td>
</tr>
<tr>
<td>27-24</td>
<td>TrueNOP</td>
<td>None implemented. This means there are no NOP instructions that do not have any register dependencies.</td>
</tr>
<tr>
<td>23-20</td>
<td>T32Copy</td>
<td>Adds support for T32 instruction set encoding T1 of the MOV (register) instruction, copying from a low register to a low register.</td>
</tr>
<tr>
<td>19-16</td>
<td>TabBranch</td>
<td>Not supported. This means that in the T32 instruction set, encoding T1 of the MOV (register) instruction does not support a copy from a low register to a low register.</td>
</tr>
<tr>
<td>15-12</td>
<td>SynchPrim</td>
<td>Adds true NOP instructions in both the T32 and A32 instruction sets. This also permits additional NOP-compatible hints.</td>
</tr>
<tr>
<td>11-8</td>
<td>SVC</td>
<td>All other values are reserved.</td>
</tr>
<tr>
<td>7</td>
<td>SIMD</td>
<td>In ARMv8-A the only permitted value is 0001.</td>
</tr>
<tr>
<td>4</td>
<td>Saturate</td>
<td>All other values are reserved.</td>
</tr>
</tbody>
</table>

In ARMv8-A the only permitted value is 0000.

In ARMv8-A the only permitted value is 0001.
TabBranch, bits [19:16]
Indicates the implemented Table Branch instructions in the T32 instruction set. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>None implemented</td>
</tr>
<tr>
<td>0001</td>
<td>Adds the TBB and TBH instructions</td>
</tr>
</tbody>
</table>

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

SynchPrim, bits [15:12]
Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>If SynchPrim_frac == 0000, no Synchronization Primitives implemented.</td>
</tr>
<tr>
<td>0001</td>
<td>If SynchPrim_frac == 0000, adds the LDREX and STREX instructions. If SynchPrim_frac == 0011, also adds the CLREX, LDREXB, STREXB, and STREXH instructions.</td>
</tr>
<tr>
<td>0010</td>
<td>If SynchPrim_frac == 0000, as for [0001, 0011] and also adds the LDREXD and STREXD instructions.</td>
</tr>
</tbody>
</table>

All other combinations of SynchPrim and SynchPrim_frac are reserved.
In ARMv8-A the only permitted value is 0010.

SVC, bits [11:8]
Indicates the implemented SVC instructions. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Not implemented</td>
</tr>
<tr>
<td>0001</td>
<td>Adds the SVC instruction.</td>
</tr>
</tbody>
</table>

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

SIMD, bits [7:4]
Indicates the implemented SIMD instructions. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>None implemented.</td>
</tr>
<tr>
<td>0001</td>
<td>Adds the SSAT and USAT instructions, and the Q bit in the PSRs.</td>
</tr>
<tr>
<td>0011</td>
<td>As for 0001, and adds the PKHBT, PKHTB, QADD16, QADD8, QASX, QSUB16, QSUB8, QAX, SADD16, SADD8, SASX, SEL, SHADD16, SHADD8, SHASX, SHSUB16, SHSUB8, SHSAX, SSAT16, SSUB16, SSUB8, SSAX, SXTAB16, SXTB16, UADD16, UADD8, UASX, UHADD16, UHADD8, UHASX, UHSUB16, UHSUB8, UHSAX, UQADD16, UQADD8, UQASX, UQSUB16, UQSUB8, UQAX, USAD8, USADA8, USAT16, USUB16, USUB8, USAX, UXTAB16, and UXTB16 instructions. Also adds support for the GE[3:0] bits in the PSRs.</td>
</tr>
</tbody>
</table>

All other values are reserved.
In ARMv8-A the only permitted value is 0011.
The SIMD field relates only to implemented instructions that perform SIMD operations on the general-purpose registers. In an implementation that supports floating-point and Advanced SIMD instructions, MVFR0, MVFR1, and MVFR2 give information about the implemented Advanced SIMD instructions.

Saturate, bits [3:0]
Indicates the implemented Saturate instructions. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>None implemented. This means no non-Advanced SIMD saturate instructions are implemented.</td>
</tr>
<tr>
<td>0001</td>
<td>Adds the QADD, QDADD, QDSUB, and QSUB instructions, and the Q bit in the PSRs.</td>
</tr>
</tbody>
</table>

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**Accessing the ID_ISAR3**

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c2, 3</td>
<td>000</td>
<td>011</td>
<td>0000</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.84   ID_ISAR4, Instruction Set Attribute Register 4

The ID_ISAR4 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_ISAR4 is architecturally mapped to AArch64 System register ID_ISAR4_EL1.

**Attributes**

ID_ISAR4 is a 32-bit register.

**Field descriptions**

The ID_ISAR4 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 28 27 24 23 20 19 16 15 12 11 8 7 4 3 0</td>
<td>SWP_frac  PSR_M  Barrier  SMC  Writeback  WithShifts  Unpriv  SynchPrim_frac</td>
</tr>
</tbody>
</table>

**SWP_frac, bits [31:28]**

Indicates support for the memory system locking the bus for SWP or SWPB instructions. Defined values are:

- **0000**: SWP or SWPB instructions not implemented.
- **0001**: SWP or SWPB implemented but only in a uniprocessor context. SWP and SWPB do not guarantee whether memory accesses from other masters can come between the load memory access and the store memory access of the SWP or SWPB.

All other values are reserved. This field is valid only if the ID_ISAR0.Swap_intras field is 0000. In ARMv8-A the only permitted value is 0000.

**PSR_M, bits [27:24]**

Indicates the implemented M profile instructions to modify the PSRs. Defined values are:

- **0000**: None implemented.
- **0001**: Adds the M profile forms of the CPS, MRS, and MSR instructions.

All other values are reserved. In ARMv8-A the only permitted value is 0000.

**SynchPrim_frac, bits [23:20]**

Used in conjunction with ID_ISAR3.SynchPrim to indicate the implemented Synchronization Primitive instructions. Possible values are:

- **0000**: If SynchPrim = 0000, no Synchronization Primitives implemented. If SynchPrim = 0001, adds the LDREX and STREX instructions. If SynchPrim = 0010, also adds the CLREX, LDREXB, LDREXH, STREXB, STREXH, LDREXD, and STREXD instructions.
0011 If SynchPrim == 0001, adds the LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

In ARMv8-A the only permitted value is 0000.

Barrier, bits [19:16]
Indicates the implemented Barrier instructions in the A32 and T32 instruction sets. Defined values are:
0000 None implemented. Barrier operations are provided only as System instructions in the (coproc==1111) encoding space.
0001 Adds the DMB, DSB, and ISB barrier instructions.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

SMC, bits [15:12]
Indicates the implemented SMC instructions. Defined values are:
0000 None implemented.
0001 Adds the SMC instruction.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

Writeback, bits [11:8]
Indicates the support for Writeback addressing modes. Defined values are:
0000 Basic support. Only the LDM, STM, PUSH, POP, SRS, and RFE instructions support writeback addressing modes. These instructions support all of their writeback addressing modes.
0001 Adds support for all of the writeback addressing modes.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

WithShifts, bits [7:4]
Indicates the support for instructions with shifts. Defined values are:
0000 Nonzero shifts supported only in MOV and shift instructions.
0001 Adds support for shifts of loads and stores over the range LSL 0-3.
0011 As for 0001, and adds support for other constant shift options, both on load/store and other instructions.
0100 As for 0011, and adds support for register-controlled shift options.

All other values are reserved.
In ARMv8-A the only permitted value is 0100.

Unpriv, bits [3:0]
Indicates the implemented unprivileged instructions. Defined values are:
0000 None implemented. No T variant instructions are implemented.
0001 Adds the LDRBT, LDRT, STRBT, and STRT instructions.
0010 As for 0001, and adds the LDRH, LDRT, LDRSBT, LDRSHT, and STRHT instructions.

All other values are reserved.
In ARMv8-A the only permitted value is 0010.
Accessing the ID_ISAR4

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c2, 4</td>
<td>000</td>
<td>100</td>
<td>0000</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>

</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
### ID_ISAR5, Instruction Set Attribute Register 5

The ID_ISAR5 characteristics are:

**Purpose**

- Provides information about the instruction sets implemented by the PE in AArch32 state.
- Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR4.
- For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

- There is one instance of this register that is used in both Secure and Non-secure states.
- AArch32 System register ID_ISAR5 is architecturally mapped to AArch64 System register ID_ISAR5_EL1.

**Attributes**

- ID_ISAR5 is a 32-bit register.

**Field descriptions**

The ID_ISAR5 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:28]</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>

<tr>
<td>[3:0]</td>
<td>SEVL</td>
<td></td>
</tr>
</tbody>
</table>

#### Bits [31:28]

Reserved, RES0.

#### RDM, bits [27:24]

*In ARMv8.2 and ARMv8.1*

- Indicates whether the VQRDMLAH and VQRDMLSH instructions are implemented in AArch32 state. Defined values are:
  - 0000: No VQRDMLAH and VQRDMLSH instructions implemented.
  - 0001: VQRDMLAH and VQRDMLSH instructions implemented.
- All other values are reserved.
- In ARMv8.0 the only permitted value is 0000.
- From ARMv8.1 the only permitted value is 0001. This feature is identified by the name ARMv8.1-SIMD.

*In ARMv8.0.*

Reserved, RES0.

#### Bits [23:20]

Reserved, RES0.

#### CRC32, bits [19:16]

- Indicates whether the CRC32 instructions are implemented in AArch32 state.
  - 0000: No CRC32 instructions implemented.
- All other values are reserved.
In ARMv8.0 the permitted values are 0000 and 0001. From ARMv8.1 the only permitted value is 0001.

**SHA2, bits [15:12]**
Indicates whether the SHA2 instructions are implemented in AArch32 state.

- **0000**: No SHA2 instructions implemented.
- **0001**: SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

**SHA1, bits [11:8]**
Indicates whether the SHA1 instructions are implemented in AArch32 state.

- **0000**: No SHA1 instructions implemented.
- **0001**: SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

**AES, bits [7:4]**
Indicates whether the AES instructions are implemented in AArch32 state.

- **0000**: No AES instructions implemented.
- **0001**: AESE, AESD, AESMC, and AESIMC implemented.
- **0010**: As for 0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0010.

**SEVL, bits [3:0]**
Indicates whether the SEVL instruction is implemented in AArch32 state.

- **0000**: SEVL is implemented as a NOP.
- **0001**: SEVL is implemented as Send Event Local.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

**Accessing the ID_ISAR5**
This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>

</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) &&(HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.86   **ID_MMFR0, Memory Model Feature Register 0**

The ID_MMFR0 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_MMFR0 is architecturally mapped to AArch64 System register ID_MMFR0_EL1.

**Attributes**

ID_MMFR0 is a 32-bit register.

**Field descriptions**

The ID_MMFR0 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bit Positions</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnerShr</td>
<td>31 28</td>
</tr>
<tr>
<td>FCSE</td>
<td>27 24</td>
</tr>
<tr>
<td>AuxReg</td>
<td>23 20</td>
</tr>
<tr>
<td>TCM</td>
<td>19 16</td>
</tr>
<tr>
<td>ShareLvl</td>
<td>15 12</td>
</tr>
<tr>
<td>OuterShr</td>
<td>11 8</td>
</tr>
<tr>
<td>PMSA</td>
<td>7 4</td>
</tr>
<tr>
<td>VMSA</td>
<td>3 0</td>
</tr>
</tbody>
</table>

**InnerShr, bits [31:28]**

Innermost Shareability. Indicates the innermost shareability domain implemented. Defined values are:

0000  Implemented as Non-cacheable.
0001  Implemented with hardware coherency support.
1111  Shareability ignored.

All other values are reserved.

In ARMv8 the permitted values are 0000, 0001, and 1111.

This field is valid only if the implementation supports two levels of shareability, as indicated by ID_MMFR0.ShareLvl having the value 0001.

When ID_MMFR0.ShareLvl is zero, this field is UNK.

**FCSE, bits [27:24]**

Indicates whether the implementation includes the FCSE. Defined values are:

0000  Not supported.
0001  Support for FCSE.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

**AuxReg, bits [23:20]**

Auxiliary Registers. Indicates support for Auxiliary registers. Defined values are:

0000  None supported.
0001  Support for Auxiliary Control Register only.
### G6-5009

**ID033117**
Non-Confidential

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0010</td>
<td>Support for Auxiliary Fault Status Registers (AIFSR and ADFSR) and Auxiliary Control Register. All other values are reserved. In ARMv8 the only permitted value is 0010.</td>
</tr>
</tbody>
</table>

**Note**
Accesses to unimplemented Auxiliary registers are UNDEFINED.

#### TCM, bits [19:16]
Indicates support for TCMs and associated DMAs. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Not supported.</td>
</tr>
<tr>
<td>0001</td>
<td>Support is IMPLEMENTATION DEFINED. ARMv7 requires this setting.</td>
</tr>
<tr>
<td>0010</td>
<td>Support for TCM only, ARMv6 implementation.</td>
</tr>
<tr>
<td>0011</td>
<td>Support for TCM and DMA, ARMv6 implementation.</td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

#### ShareLvl, bits [15:12]
Shareability Levels. Indicates the number of shareability levels implemented. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>One level of shareability implemented.</td>
</tr>
<tr>
<td>0001</td>
<td>Two levels of shareability implemented.</td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8 the only permitted value is 0001.

#### OuterShr, bits [11:8]
Outermost Shareability. Indicates the outermost shareability domain implemented. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Implemented as Non-cacheable.</td>
</tr>
<tr>
<td>0001</td>
<td>Implemented with hardware coherency support.</td>
</tr>
<tr>
<td>1111</td>
<td>Shareability ignored.</td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8 the permitted values are 0000, 0001, and 1111.

#### PMSA, bits [7:4]
Indicates support for a PMSA. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Not supported.</td>
</tr>
<tr>
<td>0001</td>
<td>Support for IMPLEMENTATION DEFINED PMSA.</td>
</tr>
<tr>
<td>0010</td>
<td>Support for PMSAv6, with a Cache Type Register implemented.</td>
</tr>
<tr>
<td>0011</td>
<td>Support for PMSAv7, with support for memory subsections. ARMv7-R profile.</td>
</tr>
</tbody>
</table>

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

#### VMSA, bits [3:0]
Indicates support for a VMSA. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Not supported.</td>
</tr>
<tr>
<td>0001</td>
<td>Support for IMPLEMENTATION DEFINED VMSA.</td>
</tr>
<tr>
<td>0010</td>
<td>Support for VMSAv6, with Cache and TLB Type Registers implemented.</td>
</tr>
</tbody>
</table>
0011  Support for VMSAv7, with support for remapping and the Access flag. ARMv7-A profile.
0100  As for 0011, and adds support for the PXN bit in the Short-descriptor translation table format descriptors.
0101  As for 0100, and adds support for the Long-descriptor translation table format. All other values are reserved.
In ARMv8-A the only permitted value is 0101.

Accessing the ID_MMFR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c1, 4</td>
<td>000</td>
<td>100</td>
<td>0000</td>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.87 ID_MMFR1, Memory Model Feature Register 1

The ID_MMFR1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0, ID_MMFR2, ID_MMFR3, and ID_MMFR4.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_MMFR1 is architecturally mapped to AArch64 System register ID_MMFR1_EL1.

**Attributes**

ID_MMFR1 is a 32-bit register.

**Field descriptions**

The ID_MMFR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>

</table>

**BPred, bits [31:28]**

Branch Predictor. Indicates branch predictor management requirements. Defined values are:

- **0000**: No branch predictor, or no MMU present. Implies a fixed MPU configuration.
- **0001**: Branch predictor requires flushing on:
  - Enabling or disabling a stage of address translation.
  - Writing new data to instruction locations.
  - Writing new mappings to the translation tables.
  - Changes to the TTBR0, TTBR1, or TTBCR registers.
  - Changes to the ContextID or ASID, or to the FCSE ProcessID if this is supported.
- **0010**: Branch predictor requires flushing on:
  - Enabling or disabling a stage of address translation.
  - Writing new data to instruction locations.
  - Writing new mappings to the translation tables.
  - Any change to the TTBR0, TTBR1, or TTBCR registers without a change to the corresponding ContextID or ASID, or FCSE ProcessID if this is supported.
- **0011**: Branch predictor requires flushing only on writing new data to instruction locations.
- **0100**: For execution correctness, branch predictor requires no flushing at any time.

All other values are reserved.

In ARMv8-A the permitted values are **0010**, **0011**, or **0100**. For values other than **0000** and **0100** the ARM Architecture Reference Manual, or the product documentation, might give more information about the required maintenance.
L1TstCln, bits [27:24]

Level 1 cache Test and Clean. Indicates the supported Level 1 data cache test and clean operations, for Harvard or unified cache implementations. Defined values are:

0000  None supported.
0001  Supported Level 1 data cache test and clean operations are:
  •  Test and clean data cache.
0010  As for 0001, and adds:
  •  Test, clean, and invalidate data cache.

All other values are reserved.
In ARMv8-A the only permitted value is 0000.

L1Uni, bits [23:20]

Level 1 Unified cache. Indicates the supported entire Level 1 cache maintenance operations for a unified cache implementation. Defined values are:

0000  None supported.
0001  Supported entire Level 1 cache operations are:
  •  Invalidate cache, including branch predictor if appropriate.
  •  Invalidate branch predictor, if appropriate.
0010  As for 0001, and adds:
  •  Clean cache, using a recursive model that uses the cache dirty status bit.
  •  Clean and invalidate cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.
In ARMv8-A the only permitted value is 0000.

L1Hvd, bits [19:16]

Level 1 Harvard cache. Indicates the supported entire Level 1 cache maintenance operations for a Harvard cache implementation. Defined values are:

0000  None supported.
0001  Supported entire Level 1 cache operations are:
  •  Invalidate instruction cache, including branch predictor if appropriate.
  •  Invalidate branch predictor, if appropriate.
0010  As for 0001, and adds:
  •  Invalidate data cache.
  •  Invalidate data cache and instruction cache, including branch predictor if appropriate.
0011  As for 0010, and adds:
  •  Clean data cache, using a recursive model that uses the cache dirty status bit.
  •  Clean and invalidate data cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.
In ARMv8-A the only permitted value is 0000.

L1UniSW, bits [15:12]

Level 1 Unified cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a unified cache implementation. Defined values are:

0000  None supported.
Supported Level 1 unified cache line maintenance operations by set/way are:
- Clean cache line by set/way.

As for 0001, and adds:
- Clean and invalidate cache line by set/way.

As for 0010, and adds:
- Invalidate cache line by set/way.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

**L1HvdSW, bits [11:8]**

Level 1 Harvard cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a Harvard cache implementation. Defined values are:
- 000 None supported.
- 001 Supported Level 1 Harvard cache line maintenance operations by set/way are:
  - Clean data cache line by set/way.
  - Clean and invalidate data cache line by set/way.
- 0010 As for 0001, and adds:
  - Invalidate data cache line by set/way.
- 0011 As for 0010, and adds:
  - Invalidate instruction cache line by set/way.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

**L1UniVA, bits [7:4]**

Level 1 Unified cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a unified cache implementation. Defined values are:
- 000 None supported.
- 001 Supported Level 1 unified cache line maintenance operations by VA are:
  - Clean cache line by VA.
  - Invalidate cache line by VA.
  - Clean and invalidate cache line by VA.
- 0010 As for 0001, and adds:
  - Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

**L1HvdVA, bits [3:0]**

Level 1 Harvard cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a Harvard cache implementation. Defined values are:
- 000 None supported.
- 001 Supported Level 1 Harvard cache line maintenance operations by VA are:
  - Clean data cache line by VA.
  - Invalidate data cache line by VA.
  - Clean and invalidate data cache line by VA.
  - Clean instruction cache line by VA.
- 0010 As for 0001, and adds:
  - Invalidate branch predictor by VA, if branch predictor is implemented.
All other values are reserved.
In ARMv8-A the only permitted value is \(0000\).

**Accessing the ID_MMFR1**

This register can be read using MRC with the following syntax:

\[ \text{MRC} \ <\text{syntax}> \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, (&lt;Rt&gt;), c0, c1, 5</td>
<td>000</td>
<td>101</td>
<td>0000</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>E2H</th>
<th>TGE</th>
<th>NS</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>x</td>
<td>0</td>
<td>1</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
<td>1</td>
<td>-</td>
<td>n/a</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and \((\text{SCR\_EL3.NS} == 1) \&\& (\text{HCR\_EL2.E2H} == 0)\):
  - If \(\text{HCR\_EL2.TID3} == 1\), Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If \(\text{HSTR\_EL2.T0} == 1\), Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and \((\text{SCR\_EL3.NS} == 1) \&\& (\text{HCR\_EL2.E2H} == 1) \&\& (\text{HCR\_EL2.TGE} == 0)\):
  - If \(\text{HCR\_EL2.TID3} == 1\), Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If \(\text{HSTR\_EL2.T0} == 1\), Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and \(\text{SCR\_EL3.NS} == 1\):
  - If \(\text{HCR.TID3} == 1\), Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If \(\text{HSTR.T0} == 1\), Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.88   ID_MMFR2, Memory Model Feature Register 2

The ID_MMFR2 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0, ID_MMFR1, ID_MMFR3, and ID_MMFR4.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_MMFR2 is architecturally mapped to AArch64 System register ID_MMFR2_EL1.

**Attributes**

ID_MMFR2 is a 32-bit register.

**Field descriptions**

The ID_MMFR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value 1</th>
<th>Value 2</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>

<tr>
<td>3-0</td>
<td>L1HvdFG</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**HWAccFlg, bits [31:28]**

Hardware Access Flag. In earlier versions of the ARM Architecture, this field indicates support for a Hardware Access flag, as part of the VMSAv7 implementation. Defined values are:

- 0000 Not supported.
- 0001 Support for VMSAv7 Access flag, updated in hardware.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

**WFIStall, bits [27:24]**

Wait For Interrupt Stall. Indicates the support for Wait For Interrupt (WFI) stalling. Defined values are:

- 0000 Not supported.
- 0001 Support for WFI stalling.

All other values are reserved.

In ARMv8 the permitted values are 0000 and 0001.

**MemBarr, bits [23:20]**

Memory Barrier. Indicates the supported memory barrier System instructions in the (coproc==1111) encoding space:

- 0000 None supported.
- 0001 Supported memory barrier System instructions are:
  - Data Synchronization Barrier (DSB).
- 0010 As for 0001, and adds:
  - Instruction Synchronization Barrier (ISB).
• Data Memory Barrier (DMB).
All other values are reserved.
In ARMv8 the only permitted value is 0010.
ARM deprecates the use of these operations. ID_ISAR4.Barrier_intrs indicates the level of support for the preferred barrier instructions.

**UniTLB, bits [19:16]**
Unified TLB. Indicates the supported TLB maintenance operations, for a unified TLB implementation. Defined values are:
- 0000 Not supported.
- 0001 Supported unified TLB maintenance operations are:
  • Invalidate all entries in the TLB.
  • Invalidate TLB entry by VA.
- 0010 As for 0001, and adds:
  • Invalidate TLB entry by ASID match.
- 0011 As for 0010, and adds:
  • Invalidate instruction TLB and data TLB entries by VA All ASID. This is a shared unified TLB operation.
- 0100 As for 0011, and adds:
  • Invalidate Hyp mode unified TLB entry by VA.
  • Invalidate entire Non-secure PL1&0 unified TLB.
  • Invalidate entire Hyp mode unified TLB.
- 0101 As for 0100, and adds the following operations: TLBIMVALHIS, TLBIMVALHIS, TLBIMVAAL, TLBIMVAAAL, TLBIMVAALH.
- 0110 As for 0101, and adds the following operations: TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, TLBIIPAS2L.
All other values are reserved.
In ARMv8-A the only permitted value is 0110.

**HvdTLB, bits [15:12]**
If the Unified TLB field (UniTLB, bits [19:16]) is not 0000, then the meaning of this field is IMPLEMENTATION DEFINED. ARM deprecates the use of this field by software.

**L1HvdRng, bits [11:8]**
Level 1 Harvard cache Range. Indicates the supported Level 1 cache maintenance range operations, for a Harvard cache implementation. Defined values are:
- 0000 Not supported.
- 0001 Supported Level 1 Harvard cache maintenance range operations are:
  • Invalidate data cache range by VA.
  • Invalidate instruction cache range by VA.
  • Clean data cache range by VA.
  • Clean and invalidate data cache range by VA.
All other values are reserved.
In ARMv8 the only permitted value is 0000.
L1HvdBG, bits [7:4]
Level 1 Harvard cache Background fetch. Indicates the supported Level 1 cache background fetch operations, for a Harvard cache implementation. When supported, background fetch operations are non-blocking operations. Defined values are:
- 0000 Not supported.
- 0001 Supported Level 1 Harvard cache background fetch operations are:
  - Fetch instruction cache range by VA.
  - Fetch data cache range by VA.
All other values are reserved.
In ARMv8 the only permitted value is 0000.

L1HvdFG, bits [3:0]
Level 1 Harvard cache Foreground fetch. Indicates the supported Level 1 cache foreground fetch operations, for a Harvard cache implementation. When supported, foreground fetch operations are blocking operations. Defined values are:
- 0000 Not supported.
- 0001 Supported Level 1 Harvard cache foreground fetch operations are:
  - Fetch instruction cache range by VA.
  - Fetch data cache range by VA.
All other values are reserved.
In ARMv8 the only permitted value is 0000.

Accessing the ID_MMFR2
This register can be read using MRC with the following syntax:
MRC <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c1, 6</td>
<td>000</td>
<td>110</td>
<td>0000</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility
The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.89   ID_MMFR3, Memory Model Feature Register 3

The ID_MMFR3 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0, ID_MMFR1, ID_MMFR2, and ID_MMFR4.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_MMFR3 is architecturally mapped to AArch64 System register ID_MMFR3_EL1.

Attributes

ID_MMFR3 is a 32-bit register.

Field descriptions

The ID_MMFR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit No.</th>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>Supersec</td>
<td>Supersections. On a VMSA implementation, indicates whether Supersections are supported. Defined values are: 0000 Supersections supported. 1111 Supersections not supported. All other values are reserved. In ARMv8-A the permitted values are 0000 and 1111.</td>
</tr>
<tr>
<td>27-24</td>
<td>CMemSz</td>
<td>Cached Memory Size. Indicates the physical memory size supported by the caches. Defined values are: 0000 4GB, corresponding to a 32-bit physical address range. 0001 64GB, corresponding to a 36-bit physical address range. 0010 1TB or more, corresponding to a 40-bit or larger physical address range. All other values are reserved. In ARMv8-A the permitted values are 0000, 0001, and 0010.</td>
</tr>
<tr>
<td>23-20</td>
<td>CohWalk</td>
<td>Coherent Walk. Indicates whether Translation table updates require a clean to the point of unification. Defined values are: 0000 Updates to the translation tables require a clean to the point of unification to ensure visibility by subsequent translation table walks. 0001 Updates to the translation tables do not require a clean to the point of unification to ensure visibility by subsequent translation table walks.</td>
</tr>
<tr>
<td>19-16</td>
<td>PAN</td>
<td>MaintBcst</td>
</tr>
<tr>
<td>15-12</td>
<td></td>
<td>BPMaint</td>
</tr>
<tr>
<td>11-8</td>
<td></td>
<td>CMaintSW</td>
</tr>
<tr>
<td>7-4</td>
<td></td>
<td>CMaintVA</td>
</tr>
<tr>
<td>3-0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

**PAN, bits [19:16]**

*In ARMv8.2 and ARMv8.1*

Privileged Access Never. Indicates support for the PAN bit in CPSR, SPSR, and DSPSR in AArch32. Defined values are:

- 0000 PAN not supported.
- 0001 PAN supported.
- 0010 PAN supported and ATS1CPRP and ATS1CPWP instructions supported.

All other values are reserved.
In ARMv8.0 the only permitted value is 0000.
In ARMv8.1 the only permitted value is 0001. This feature is identified by the name ARMv8.1-PAN.
From ARMv8.2, the only permitted value is 0010. This feature is identified by the name ARMv8.2-ATS1E1.

*In ARMv8.0.*

Reserved, RES0.

**MaintBest, bits [15:12]**

Maintenance Broadcast. Indicates whether Cache, TLB, and branch predictor operations are broadcast. Defined values are:

- 0000 Cache, TLB, and branch predictor operations only affect local structures.
- 0001 Cache and branch predictor operations affect structures according to shareability and defined behavior of instructions. TLB operations only affect local structures.
- 0010 Cache, TLB, and branch predictor operations affect structures according to shareability and defined behavior of instructions.

All other values are reserved.
In ARMv8-A the only permitted value is 0010.

**BPMaint, bits [11:8]**

Branch Predictor Maintenance. Indicates the supported branch predictor maintenance operations in an implementation with hierarchical cache maintenance operations. Defined values are:

- 0000 None supported.
- 0001 Supported branch predictor maintenance operations are:
  - Invalidate all branch predictors.
- 0010 As for 0001, and adds:
  - Invalidate branch predictors by VA.

All other values are reserved.
In ARMv8-A the only permitted value is 0010.

**CMaintSW, bits [7:4]**

Cache Maintenance by Set/Way. Indicates the supported cache maintenance operations by set/way, in an implementation with hierarchical caches. Defined values are:

- 0000 None supported.
- 0001 Supported hierarchical cache maintenance instructions by set/way are:
  - Invalidate data cache by set/way.
  - Clean data cache by set/way.
  - Clean and invalidate data cache by set/way.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.
In a unified cache implementation, the data cache maintenance operations apply to the unified caches.

**CMaintVA, bits [3:0]**
Cache Maintenance by Virtual Address. Indicates the supported cache maintenance operations by VA, in an implementation with hierarchical caches. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>None supported.</td>
</tr>
<tr>
<td>0001</td>
<td>Supported hierarchical cache maintenance operations by VA are:</td>
</tr>
<tr>
<td></td>
<td>- Invalidate data cache by VA.</td>
</tr>
<tr>
<td></td>
<td>- Clean data cache by VA.</td>
</tr>
<tr>
<td></td>
<td>- Clean and invalidate data cache by VA.</td>
</tr>
<tr>
<td></td>
<td>- Invalidate instruction cache by VA.</td>
</tr>
<tr>
<td></td>
<td>- Invalidate all instruction cache entries.</td>
</tr>
</tbody>
</table>

All other values are reserved.
In ARMv8-A the only permitted value is 0001.
In a unified cache implementation, data cache maintenance operations apply to the unified caches, and the instruction cache maintenance instructions are not implemented.

**Accessing the ID_MMFR3**
This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c1, 7</td>
<td>000</td>
<td>111</td>
<td>0000</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**
The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>

</table>

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

* When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
— If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  — If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  — If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.90  ID_MMFR4, Memory Model Feature Register 4

The ID_MMFR4 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0, ID_MMFR1, ID_MMFR2, and ID_MMFR3.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_MMFR4 is architecturally mapped to AArch64 System register ID_MMFR4_EL1.

In an implementation that does not include ACTLR2 and HACTLR2 this register is RAZ.

**Attributes**

ID_MMFR4 is a 32-bit register.

**Field descriptions**

The ID_MMFR4 bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>

<td></td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RAZ.

**LSM, bits [23:20]**

*In ARMv8.2*

Indicates support for LSMAOE and nTLSMD bits in HSCTLR and SCTLR. Defined values are:

- 0000  LSMAOE and nTLSMD bits not supported.
- 0001  LSMAOE and nTLSMD bits supported.

All other values are reserved.

In ARMv8.0 and ARMv8.1 the only permitted value is 0000.

From ARMv8.2, the permitted values are 0000 and 0001. This feature is identified by the name ARMv8.2-LSMAOC.

*In ARMv8.1 and ARMv8.0.*

Reserved, RAZ.

**HPDS, bits [19:16]**

*In ARMv8.2*

Hierarchical permission disables bits in translation tables. Defined values are:

- 0000  Disabling of hierarchical controls not supported.
- 0001  Supports disabling of hierarchical controls using the TTBCR2.HPD0, TTBCR2.HPD1, and HTCR.HPD bits.
0010  Supports disabling of hierarchical controls using the TTBCR2.HPD0, TTBCR2.HPD1, and HTCR.HPD bits, and hardware allocation of bits[62:59] of the last level page table descriptor for IMPLEMENTATION DEFINED use.

All other values are reserved.
In ARMv8.0 and ARMv8.1 the only permitted value is 0000.
From ARMv8.2, the permitted values are 0000, 0001 and 0010. This feature is identified by the name ARMv8.2-AA32HPD.

--- Note ---
The encoding 0000 implies that the encoding for TTBCR2 is unallocated.

In ARMv8.1 and ARMv8.0.
Reserved, RAZ.

CnP, bits [15:12]

In ARMv8.2
Common not Private translations. Defined values are:
0000  Common not Private translations not supported.
0001  Common not Private translations supported.
All other values are reserved.
In ARMv8.0 and ARMv8.1 the only permitted value is 0000.
From ARMv8.2, the only permitted value is 0001. This feature is identified by the name ARMv8.2-TTCNP.

In ARMv8.1 and ARMv8.0.
Reserved, RAZ.

XNX, bits [11:8]

In ARMv8.2
Support for execute never control distinction at stage 2 bit. Defined values are:
0000  Distinction between EL0 and EL1 execute permission at stage 2 not supported.
0001  Distinction between EL0 and EL1 execute permission at stage 2 supported.
All other values are reserved.
In ARMv8.0 and ARMv8.1 the only permitted value is 0000.
From ARMv8.2, the only permitted value is 0001. This feature is identified by the name ARMv8.2-TTS2UXN.

In ARMv8.1 and ARMv8.0.
Reserved, RAZ.

AC2, bits [7:4]
Indicates the extension of the ACTLR and HACTLR registers using ACTLR2 and HACTLR2. Defined values are:
0000  ACTLR2 and HACTLR2 are not implemented.
0001  ACTLR2 and HACTLR2 are implemented.
All other values are reserved.
In ARMv8.0 and ARMv8.1 the permitted values are 0000 and 0001.
From ARMv8.2, the only permitted value is 0001.
SpecSEI, bits [3:0]

Describes whether the PE can generate SError interrupt exceptions from speculative reads of memory, including speculative instruction fetches. The defined values of this field are:

0000  The PE never generates an SError interrupt due to an external abort on a speculative read.
0001  The PE might generate an SError interrupt due to an external abort on a speculative read.

All other values are reserved.

When the RAS Extension is not implemented, this field is RAZ.

Accessing the ID_MMFR4

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c2, 6</td>
<td>000</td>
<td>110</td>
<td>0000</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>-</td>
</tr>
<tr>
<td>x 0 1</td>
<td>-</td>
</tr>
<tr>
<td>x 1 1</td>
<td>-</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- If EL2 is using AArch32 and HCR.TID3==1, then:
  - If this register is not RAZ/WI then Non-secure EL1 read accesses to this register are trapped to Hyp mode.
  - Otherwise, it is IMPLEMENTATION DEFINED whether Non-secure EL1 read accesses to this register are trapped to Hyp mode.

- If EL2 is using AArch64 and HCR_EL2.TID3==1, then:
  - If this register is not RAZ/WI then Non-secure EL1 read accesses to this register are trapped to EL2.
  - Otherwise, it is IMPLEMENTATION DEFINED whether Non-secure EL1 read accesses to this register are trapped to EL2.

- If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
G6.2.91 ID_PFR0, Processor Feature Register 0

The ID_PFR0 characteristics are:

Purpose

Gives top-level information about the instruction sets supported by the PE in AArch32 state.

Must be interpreted with ID_PFR1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_PFR0 is architecturally mapped to AArch64 System register ID_PFR0_EL1.

Attributes

ID_PFR0 is a 32-bit register.

Field descriptions

The ID_PFR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAS</td>
<td>RES0</td>
<td>State3</td>
<td>State2</td>
<td>State1</td>
<td>State0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

RAS, bits [31:28]

RAS Extension version. The defined values of this field are:

- 0000: No RAS Extension.
- 0001: Version 1 of the RAS Extension present.

All other values are reserved.

Bits [27:16]

Reserved, RES0.

State3, bits [15:12]

T32EE instruction set support. Defined values are:

- 0000: Not implemented.
- 0001: T32EE instruction set implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

State2, bits [11:8]

Jazelle extension support. Defined values are:

- 0000: Not implemented.
- 0001: Jazelle extension implemented, without clearing of JOSCR.CV on exception entry.
- 0010: Jazelle extension implemented, with clearing of JOSCR.CV on exception entry.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.
State1, bits [7:4]

T32 instruction set support. Defined values are:

0000  T32 instruction set not implemented.
0001  T32 encodings before the introduction of Thumb-2 technology implemented:
  • All instructions are 16-bit.
  • A BL or BLX is a pair of 16-bit instructions.
  • 32-bit instructions other than BL and BLX cannot be encoded.
0011  T32 encodings after the introduction of Thumb-2 technology implemented, for all
       16-bit and 32-bit T32 basic instructions.

All other values are reserved.
In ARMv8-A the only permitted value is 0011.

State0, bits [3:0]

A32 instruction set support. Defined values are:

0000  A32 instruction set not implemented.
0001  A32 instruction set implemented.
0011  All other values are reserved.
In ARMv8-A the only permitted value is 0011.

Accessing the ID_PFR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
ID_PFR1, Processor Feature Register 1

The ID_PFR1 characteristics are:

**Purpose**

Gives information about the AArch32 programmers' model.

Must be interpreted with ID_PFR0.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_PFR1 is architecturally mapped to AArch64 System register ID_PFR1_EL1.

**Attributes**

ID_PFR1 is a 32-bit register.

**Field descriptions**

The ID_PFR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>GIC</td>
<td>Virt_frac</td>
<td>Sec_frac</td>
<td>GenTimer</td>
<td></td>
<td>MProgMod</td>
<td></td>
<td>Security</td>
<td></td>
<td>ProgMod</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Virtualization</td>
<td></td>
</tr>
</tbody>
</table>

**GIC, bits [31:28]**

System register GIC CPU interface. Defined values are:

0000 No System register interface to the GIC CPU interface is supported.

0001 System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.

All other values are reserved.

**Virt_frac, bits [27:24]**

Virtualization fractional field. When the Virtualization field is 0000, determines the support for features from the ARMv7 Virtualization Extensions. Defined values are:

0000 No features from the ARMv7 Virtualization Extensions are implemented.

0001 The following features of the ARMv7 Virtualization Extensions are implemented:

- The SCR.SIF bit, if EL3 is implemented.
- The modifications to the SCR.AW and SCR.FW bits described in the Virtualization Extensions, if EL3 is implemented.
- The MSR (Banked register) and MRS (Banked register) instructions.
- The ERET instruction.

All other values are reserved.

In ARMv8-A the permitted values are:

- 0000 when EL2 is implemented.
- 0001 when EL2 is not implemented.

This field is only valid when the value of ID_PFR1.Virtualization is 0, otherwise it holds the value 0000.
**Note**

The ID_ISAR registers do not identify whether the instructions added by the ARMv7 Virtualization Extensions are implemented.

---

### Sec_frac, bits [23:20]

Security fractional field. When the Security field is 0000, determines the support for features from the ARMv7 Security Extensions. Defined values are:

- 0000: No features from the ARMv7 Security Extensions are implemented.
- 0001: The following features from the ARMv7 Security Extensions are implemented:
  - The VBAR register.
  - The TTBCR.PD0 and TTBCR.PD1 bits.
- 0010: As for 0001, plus the ability to access Secure or Non-secure physical memory is supported.

All other values are reserved.

In ARMv8-A the permitted values are:
- 0000 when EL3 is implemented.
- 0001 or 0010 when EL3 is not implemented.

This field is only valid when the value of ID_PFR1.Security is 0; otherwise, it holds the value 0000.

---

### GenTimer, bits [19:16]

Generic Timer support. Defined values are:

- 0000: Not implemented.
- 0001: Generic Timer implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

---

### Virtualization, bits [15:12]

Virtualization support. Defined values are:

- 0000: EL2, Hyp mode, and the HVC instruction not implemented.
- 0001: EL2, Hyp mode, the HVC instruction, and all the features described by Virt_frac == 0001 implemented.

All other values are reserved.

In ARMv8-A the permitted values are:
- 0000 when EL2 is not implemented.
- 0001 when EL2 is implemented.

In an implementation that includes EL2, if EL2 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0001.

**Note**

The ID_ISARs do not identify whether the HVC instruction is implemented.

---

### MProgMod, bits [11:8]

M profile programmers' model support. Defined values are:

- 0000: Not supported.
- 0010: Support for two-stack programmers' model.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.
Security, bits [7:4]

Security support. Defined values are:

- **0000** EL3, Monitor mode, and the SMC instruction not implemented.
- **0001** EL3, Monitor mode, the SMC instruction, and all the features described by Sec_frac == 0001 implemented.
- **0010** As for 0001, and adds the ability to set the NSACR.RFR bit. Not permitted in ARMv8 as the NSACR.RFR bit is RES0.

All other values are reserved.

In ARMv8-A the permitted values are:
- **0000** when EL3 is not implemented.
- **0001** when EL3 is implemented.

In an implementation that includes EL3, if EL3 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0001.

ProgMod, bits [3:0]

Support for the standard programmers' model for ARMv4 and later. Model must support User, FIQ, IRQ, Supervisor, Abort, Undefined, and System modes. Defined values are:

- **0000** Not supported.
- **0001** Supported.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

**Accessing the ID_PFR1**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c1, l</td>
<td>000</td>
<td>001</td>
<td>0000</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.93 IFAR, Instruction Fault Address Register

The IFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception.

**Configurations**

AArch32 System register IFAR(NS) is architecturally mapped to AArch64 System register FAR_EL1[63:32].

AArch32 System register IFAR(S) is architecturally mapped to AArch32 System register HIFAR when EL2 is implemented.

AArch32 System register IFAR(S) is architecturally mapped to AArch64 System register FAR_EL2[63:32] when EL2 is implemented.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

IFAR is a 32-bit register.

**Field descriptions**

The IFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>VA of faulting address of synchronous Prefetch Abort exception</td>
</tr>
</tbody>
</table>

**Accessing the IFAR**

This register can be read using MRC with the following syntax:

\[
\text{MRC <syntax>}
\]

This register can be written using MCR with the following syntax:

\[
\text{MCR <syntax>}
\]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c6, c0, 2</td>
<td>000</td>
<td>010</td>
<td>0110</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>

</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T6==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.94  IFSR, Instruction Fault Status Register

The IFSR characteristics are:

Purpose

Holds status information about the last instruction fault.

Configurations

AArch32 System register IFSR is architecturally mapped to AArch64 System register IFSR32_EL2.

The current translation table format determines which format of the register is used.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

IFSR is a 32-bit register.

Field descriptions

The IFSR bit assignments are:

When TTBCR.EAE==0:

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0    IFAR is valid.
1    IFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.

Bit [11]

Reserved, RES0.
FS[4], bit [10]

See FS[3:0], bits [3:0] for description of the FS field.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.
1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:4]

Reserved, RES0.

FS[3:0], bits [3:0]

Fault status bits. Interpreted with bit [10]. Possible values of FS[4:0] are:

- 00001 PC alignment fault
- 00010 Debug exception
- 00011 Access flag fault, level 1
- 00101 Translation fault, level 1
- 00110 Access flag fault, level 2
- 00111 Translation fault, level 2
- 01000 Synchronous external abort, not on translation table walk
- 01001 Domain fault, level 1
- 01011 Domain fault, level 2
- 01100 Synchronous external abort, on translation table walk, level 1
- 01101 Permission fault, level 1
- 01110 Synchronous external abort, on translation table walk, level 2
- 01111 Permission fault, level 2
- 10000 TLB conflict abort
- 10100 IMPLEMENTATION DEFINED fault (Lockdown fault)
- 11001 Synchronous parity or ECC error on memory access, not on translation table walk
- 11100 Synchronous parity or ECC error on translation table walk, level 1
- 11110 Synchronous parity or ECC error on translation table walk, level 2

All other values are reserved.

When the RAS Extension is implemented, 11001, 11100, and 11110 are reserved.

For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Short-descriptor translation table lookup on page G4-4669.

When TTBCR.EAE==1:

```
  31  17  16  15  13  12  11  10  9  8  6  5  0
  RES0 | RES0 | RES0 | STATUS
FnV   | LPAE  | RES0 | Ext
```
Bits [31:17]
Reserved, RES0.

FnV, bit [16]
FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0 IFAR is valid.
- 1 IFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.

Bits [15:13]
Reserved, RES0.

ExT, bit [12]
External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0.

For aborts other than external aborts this bit always returns 0.

Bits [11:10]
Reserved, RES0.

LPAE, bit [9]
On taking a Data Abort exception, this bit is set as follows:

- 0 Using the Short-descriptor translation table formats.
- 1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]
Reserved, RES0.

STATUS, bits [5:0]
Fault status bits. Possible values of this field are:

- 000000 Address size fault in TTBR0 or TTBR1
- 000001 Address size fault, level 1
- 000010 Address size fault, level 2
- 000011 Address size fault, level 3
- 000101 Translation fault, level 1
- 000110 Translation fault, level 2
- 000111 Translation fault, level 3
- 001001 Access flag fault, level 1
- 001010 Access flag fault, level 2
- 001011 Access flag fault, level 3
- 001101 Permission fault, level 1
- 001110 Permission fault, level 2
- 001111 Permission fault, level 3
- 010000 Synchronous external abort, not on translation table walk
- 010101 Synchronous external abort, on translation table walk, level 1
G6 AArch32 System Register Descriptions
G6.2 General system control registers

010110  Synchronous external abort, on translation table walk, level 2
010111  Synchronous external abort, on translation table walk, level 3
011000  Synchronous parity or ECC error on memory access, not on translation table walk
011101  Synchronous parity or ECC error on memory access on translation table walk, level 1
011110  Synchronous parity or ECC error on memory access on translation table walk, level 2
011111  Synchronous parity or ECC error on memory access on translation table walk, level 3
100001  PC alignment fault
100010  Debug exception
110000  TLB conflict abort

All other values are reserved.

When the RAS Extension is implemented, 011000, 011101, 011110, and 011111 are reserved.

For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Long-descriptor translation table lookup on page G4-4671.

Accessing the IFSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c5, c0, 1</td>
<td>000</td>
<td>001</td>
<td>0101</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
<td>EL1 EL2 EL3</td>
<td>IFSR</td>

</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  — If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  — If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  — If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  — If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  — If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  — If HSTR.T5==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.95 ISR, Interrupt Status Register

The ISR characteristics are:

**Purpose**

Shows whether any IRQ, FIQ, or external abort is pending. In an implementation that includes EL2, when the register is accessed from Non-secure EL1, a pending interrupt might be a physical interrupt or a virtual interrupt, and the architecture does not provide any mechanism that software executing at Non-secure EL1 can use to determine whether a pending interrupt is physical or virtual. For all other accesses, any indicated interrupt must be a physical interrupt.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ISR is architecturally mapped to AArch64 System register ISR_EL1.

**Attributes**

ISR is a 32-bit register.

**Field descriptions**

The ISR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:9</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>8</td>
<td>Asynchronous external abort pending bit:</td>
</tr>
<tr>
<td></td>
<td>0: No pending asynchronous external abort.</td>
</tr>
<tr>
<td></td>
<td>1: An asynchronous external abort is pending.</td>
</tr>
<tr>
<td>7</td>
<td>IRQ pending bit. Indicates whether an IRQ interrupt is pending:</td>
</tr>
<tr>
<td></td>
<td>0: No pending IRQ.</td>
</tr>
<tr>
<td></td>
<td>1: An IRQ interrupt is pending.</td>
</tr>
<tr>
<td>6</td>
<td>FIQ pending bit. Indicates whether an FIQ interrupt is pending.</td>
</tr>
<tr>
<td></td>
<td>0: No pending FIQ.</td>
</tr>
<tr>
<td></td>
<td>1: An FIQ interrupt is pending.</td>
</tr>
<tr>
<td>5:0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Accessing the ISR**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c12, c1, 0</td>
<td>000</td>
<td>000</td>
<td>1100</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T12==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T12==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T12==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.96   ITLBIALL, Instruction TLB Invalidate All

The ITLBIALL characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from instruction TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

**Configurations**

There are no configuration notes.

**Attributes**

ITLBIALL is a 32-bit System instruction.

**Field descriptions**

ITLBIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the ITLBIALL instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;R&gt;, c8, c5, 0</td>
<td>000</td>
<td>000</td>
<td>1000</td>
<td>1111</td>
<td>0101</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>WO</td>
</tr>
<tr>
<td>NS</td>
<td>-</td>
</tr>
<tr>
<td>EL0</td>
<td>-</td>
</tr>
<tr>
<td>EL1</td>
<td>WO</td>
</tr>
<tr>
<td>EL2</td>
<td>n/a</td>
</tr>
</tbody>
</table>
When \texttt{HCR.FB} is 1, at Non-secure EL1 this instruction executes as a \texttt{TLBIALLIS} operating on instruction TLBs only.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see \textit{Synchronous exception prioritization for exceptions taken to AArch32 state} on page G1-4344 for exceptions taken to AArch32 state and \textit{Synchronous exception prioritization for exceptions taken to AArch64} on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (\texttt{SCR.EL3.NS} == 1) && (\texttt{HCR.EL2.E2H} == 0):
  - If \texttt{HCR.EL2.TTLB}==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If \texttt{HSTR.EL2.T8}==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (\texttt{SCR.EL3.NS} == 1) && (\texttt{HCR.EL2.E2H} == 1) && (\texttt{HCR.EL2.TGE} == 0):
  - If \texttt{HCR.EL2.TTLB}==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If \texttt{HSTR.EL2.T8}==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and \texttt{SCR.EL3.NS} == 1:
  - If \texttt{HCR.TTLB}==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If \texttt{HSTR.T8}==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.97 ITLBIASID, Instruction TLB Invalidate by ASID match

The ITLBIASID characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from instruction TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

**Configurations**

There are no configuration notes.

**Attributes**

ITLBIASID is a 32-bit System instruction.

**Field descriptions**

The ITLBIASID input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>8</td>
<td>ASID</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

**Executing the ITLBIASID instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```
This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c5, 2</td>
<td>000</td>
<td>010</td>
<td>1000</td>
<td>1111</td>
<td>0101</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a TLBIASIDIS operating on instruction TLBs only.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.98  **ITLBIMVA, Instruction TLB Invalidate by VA**

The ITLBIMVA characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from instruction TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

**Configurations**

There are no configuration notes.

**Attributes**

ITLBIMVA is a 32-bit System instruction.

**Field descriptions**

The ITLBIMVA input value bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>24</th>
<th>23</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.
Executing the ITLBIMVA instruction

This instruction is executed using MCR with the following syntax:

\[ \text{MCR} \ <\text{syntax}> \]

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c5, 1</td>
<td>000</td>
<td>001</td>
<td>1000</td>
<td>1111</td>
<td>0101</td>
</tr>
</tbody>
</table>

Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a TLBIMVAIS operating on instruction TLBs only.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.99 JIDR, Jazelle ID Register

The JIDR characteristics are:

**Purpose**

A Jazelle register, which identified the Jazelle architecture version.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

JIDR is a 32-bit register.

**Field descriptions**

The JIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RAZ.</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

RAZ.

**Accessing the JIDR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 7, &lt;Rt&gt;, c0, c0, 0</td>
<td>111</td>
<td>000</td>
<td>0000</td>
<td>1110</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
<tr>
<td>NS</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
<tr>
<td></td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

For accesses from EL0 it is IMPLEMENTATION DEFINED whether the register is RO or UNDEFINED.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID0==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID0==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID0==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
G6.2.100 JMCR, Jazelle Main Configuration Register

The JMCR characteristics are:

Purpose

A Jazelle register, which provides control of the Jazelle extension.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

JMCR is a 32-bit register.

Field descriptions

The JMCR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ/WI</td>
</tr>
</tbody>
</table>

Accessing the JMCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 7, &lt;Rt&gt;, c2, c0, 0</td>
<td>111</td>
<td>000</td>
<td>0010</td>
<td>1110</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
<td>NS</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>x</td>
<td>x</td>
<td>θ</td>
<td>IMPLEMENTATION DEFINED</td>
<td>RW</td>
<td>n/a</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
<td>1</td>
<td>IMPLEMENTATION DEFINED</td>
<td>RW</td>
<td>RW</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
<td>1</td>
<td>IMPLEMENTATION DEFINED</td>
<td>n/a</td>
<td>RW</td>
</tr>
</tbody>
</table>

For accesses from EL0 it is IMPLEMENTATION DEFINED whether the register is RW or UNDEFINED.
G6.2.101  JOSCR, Jazelle OS Control Register

The JOSCR characteristics are:

**Purpose**

A Jazelle register, which provides operating system control of the Jazelle Extension.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

JOSCR is a 32-bit register.

**Field descriptions**

The JOSCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td>RAZ/WI</td>
</tr>
</tbody>
</table>

**Accessing the JOSCR**

This register can be read using MRC with the following syntax:

```mrc <syntax>```

This register can be written using MCR with the following syntax:

```mcr <syntax>```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 7, &lt;Rt&gt;, c1, c0, 0</td>
<td>111</td>
<td>000</td>
<td>0001</td>
<td>1110</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>EL1</td>
</tr>
<tr>
<td>NS</td>
<td>EL2</td>
</tr>
<tr>
<td></td>
<td>EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>IMPLEMENTATION DEFINED RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>IMPLEMENTATION DEFINED RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>IMPLEMENTATION DEFINED n/a RW RW</td>
</tr>
</tbody>
</table>

For accesses from EL0 it is IMPLEMENTATION DEFINED whether the register is RW or UNDEFINED.
G6.2.102   MAIR0, Memory Attribute Indirection Register 0

The MAIR0 characteristics are:

Purpose

Along with MAIR1, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations.

AttrIndx[2] indicates the MAIR register to be used:

- When AttrIndx[2] is 0, MAIR0 is used.
- When AttrIndx[2] is 1, MAIR1 is used.

Configurations

AArch32 System register MAIR0 is architecturally mapped to AArch64 System register MAIR_EL1[31:0].

MAIR0 and PRRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in PRRR.
- When it is set to 1, the register is as described in MAIR0.

When EL3 is using AArch32, write access to MAIR0(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MAIR0 is a 32-bit register.

Field descriptions

The MAIR0 bit assignments are:

When TTBCR.EAE==1:

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>16 15</th>
<th>8 7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr3</td>
<td>Attr2</td>
<td>Attr1</td>
<td>Attr0</td>
<td></td>
</tr>
</tbody>
</table>

Attr<n>, bits [8n+7:8n], for n = 0 to 3

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>00RW, RW not 0</td>
<td>Normal memory, Outer Write-Through Transient</td>
</tr>
<tr>
<td>0100</td>
<td>Normal memory, Outer Non-cacheable</td>
</tr>
</tbody>
</table>
R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.
The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>01RW, RW not 00</td>
<td>Normal memory, Outer Write-Back Transient</td>
</tr>
<tr>
<td>10RW</td>
<td>Normal memory, Outer Write-Through Non-transient</td>
</tr>
<tr>
<td>11RW</td>
<td>Normal memory, Outer Write-Back Non-transient</td>
</tr>
</tbody>
</table>

The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device-nGnRNRE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>00RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>1000</td>
<td>Device-nGRE memory</td>
<td>Normal memory, Inner Write-Through Non-transient (RW=00)</td>
</tr>
<tr>
<td>10RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>1100</td>
<td>Device-GRE memory</td>
<td>Normal memory, Inner Write-Back Non-transient (RW=00)</td>
</tr>
<tr>
<td>11RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.
The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

### Accessing the MAIR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1 opc2 CRn coproc CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c10, c2, 0</td>
<td>000 000 1010 1111 0010</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H</td>
<td>TGE</td>
<td>NS</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to MAIR0_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.103 MAIR1, Memory Attribute Indirection Register 1

The MAIR1 characteristics are:

**Purpose**

Along with MAIR0, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations.

AttrIndx[2] indicates the MAIR register to be used:

- When AttrIndx[2] is 0, MAIR0 is used.
- When AttrIndx[2] is 1, MAIR1 is used.

**Configurations**

AArch32 System register MAIR1 is architecturally mapped to AArch64 System register MAIR_EL1[63:32].

MAIR1 and NMRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in NMRR.
- When it is set to 1, the register is as described in MAIR1.

When EL3 is using AArch32, write access to MAIR1(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MAIR1 is a 32-bit register.

**Field descriptions**

The MAIR1 bit assignments are:

*When TTBCR.EAE==1:*

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr7</td>
<td>Attr6</td>
<td>Attr5</td>
<td>Attr4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Attr<n>, bits [8(n-4)+7:8(n-4)], for n = 4 to 7

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>00RW, RW not 00</td>
<td>Normal memory, Outer Write-Through Transient</td>
</tr>
<tr>
<td>0100</td>
<td>Normal memory, Outer Non-cacheable</td>
</tr>
</tbody>
</table>
### Accessing the MAIR1

This register can be read using MRC with the following syntax:

**MRC <syntax>**

This register can be written using MCR with the following syntax:

**MCR <syntax>**

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c10, c2, 1</td>
<td>000</td>
<td>001</td>
<td>1010</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>00RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>01RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>1000</td>
<td>Device-nGRE memory</td>
<td>Normal memory, Inner Write-Through Non-transient (RW=00)</td>
</tr>
<tr>
<td>10RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>1100</td>
<td>Device-GRE memory</td>
<td>Normal memory, Inner Write-Back Non-transient (RW=00)</td>
</tr>
<tr>
<td>11RW, RW not 00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
<td></td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x x 0</td>
<td>n/a n/a RW</td>
<td>MAIR1_s</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x 0 1</td>
<td>RW RW RW</td>
<td>MAIR1_ns</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x 1 1</td>
<td>n/a RW RW</td>
<td>MAIR1_ns</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x x 0</td>
<td>RW n/a n/a</td>
<td>MAIR1 ns</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 0 1</td>
<td>RW RW n/a</td>
<td>MAIR1</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 1 1</td>
<td>n/a RW n/a</td>
<td>MAIR1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x x 0</td>
<td>RW n/a n/a</td>
<td>MAIR1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 0 1</td>
<td>RW RW n/a</td>
<td>MAIR1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 1 1</td>
<td>n/a RW n/a</td>
<td>MAIR1</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to MAIR1_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
### G6.2.104 MIDR, Main ID Register

The MIDR characteristics are:

**Purpose**

Provides identification information for the PE, including an implementer code for the device and a device ID number.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register MIDR is architecturally mapped to AArch64 System register MIDR_EL1.

AArch32 System register MIDR is architecturally mapped to External register MIDR_EL1.

Some fields of the MIDR are IMPLEMENTATION DEFINED. For details of the values of these fields for a particular ARMv8 implementation, and any implementation-specific significance of these values, see the product documentation.

**Attributes**

MIDR is a 32-bit register.

**Field descriptions**

The MIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Purpose</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:24</td>
<td>Implementer code</td>
<td>0x41</td>

<td>Implementer code</td>
<td>0x4D</td>
<td>Qualcomm Inc.</td>
</tr>
<tr>
<td>31:24</td>
<td>Implementer code</td>
<td>0x4E</td>
<td>Marvell International Ltd.</td>
</tr>
<tr>
<td>31:24</td>
<td>Implementer code</td>
<td>0x4F</td>
<td>Intel Corporation</td>
</tr>
</tbody>
</table>

### Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>ASCII representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x41</td>
<td>A</td>
<td>ARM Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>B</td>
<td>Broadcom Corporation</td>
</tr>
<tr>

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

**Variant, bits [23:20]**

An *IMPLEMENTATION DEFINED* variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

**Architecture, bits [19:16]**

The permitted values of this field are:

- 0001 ARMv4
- 0010 ARMv4T
- 0011 ARMv5 (obsolete)
- 0100 ARMv5T
- 0101 ARMv5TE
- 0110 ARMv5TEJ
- 0111 ARMv6
- 1111 Architectural features are individually identified in the ID_* registers, see *Identification registers, functional group* on page G4-4727.

All other values are reserved.

**PartNum, bits [15:4]**

An *IMPLEMENTATION DEFINED* primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

**Revision, bits [3:0]**

An *IMPLEMENTATION DEFINED* revision number for the device.

### Accessing the MIDR

This register can be read using MRC with the following syntax:

```c
MRC <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c0, 0</td>
<td>000 000 0000 1111 0000</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.105 MPIDR, Multiprocessor Affinity Register

The MPIDR characteristics are:

**Purpose**

In a multiprocessor system, provides an additional PE identification mechanism for scheduling purposes.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register MPIDR is architecturally mapped to AArch64 System register MPIDR_EL1.

The assigned value of the MPIDR.\{Aff2, Aff1, Aff0\} or MPIDR_EL1.\{Aff3, Aff2, Aff1, Aff0\} set of fields of each PE must be unique within the system as a whole.

In a uniprocessor system ARM recommends that each Aff<\text{n}> field of this register returns a value of 0.

**Attributes**

MPIDR is a 32-bit register.

**Field descriptions**

The MPIDR bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>30</th>
<th>29</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td></td>
<td></td>
<td>U</td>
<td>RES0</td>
<td>Aff2</td>
<td>Aff1</td>
<td>Aff0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>MT</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**M, bit [31]**

Indicates whether this implementation includes the functionality introduced by the ARMv7 Multiprocessing Extensions. The possible values of this bit are:

0: This implementation does not include the ARMv7 Multiprocessing Extensions functionality.
1: This implementation includes the ARMv7 Multiprocessing Extensions functionality.

In ARMv8 this bit is RES1.

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

0: Processor is part of a multiprocessor system.
1: Processor is part of a uniprocessor system.

**Bits [29:25]**

Reserved, RES0.

**MT, bit [24]**

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. The possible values of this bit are:

0: Performance of PEs at the lowest affinity level is largely independent.
1: Performance of PEs at the lowest affinity level is very interdependent.
Aff2, bits [23:16]  
Affinity level 2. The least significant affinity level field, for this PE in the system.

Aff1, bits [15:8]  
Affinity level 1. The intermediate affinity level field, for this PE in the system.

Aff0, bits [7:0]  
Affinity level 0. The most significant affinity level field, for this PE in the system.

Accessing the MPIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c0, 5</td>
<td>000</td>
<td>101</td>
<td>0000</td>
<td>1111</td>
<td>000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RO n/a RO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RO RO RO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RO RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.106  MVBAR, Monitor Vector Base Address Register

The MVBAR characteristics are:

**Purpose**

When EL3 is implemented and can use AArch32, holds the vector base address for any exception that is taken to Monitor mode.

Secure software must program the MVBAR with the required initial value as part of the PE boot sequence.

**Configurations**

This register is only accessible in Secure state.

It is IMPLEMENTATION DEFINED whether MVBAR[0] has a fixed value and ignored writes, or takes the last value written to it.

Write access to MVBAR is disabled when the CP15SDISABLE signal is asserted HIGH.

On a reset into EL3 using AArch32, the reset value of MVBAR is an IMPLEMENTATION DEFINED choice between:

- MVBAR[31:5] = an IMPLEMENTATION DEFINED value, which might be UNKNOWN.
- MVBAR[4:1] = RES0.
- MVBAR[0] = 0.

And:

- MVBAR[31:1] = an IMPLEMENTATION DEFINED value that is bits[31:1] of the AArch32 reset address.
- MVBAR[0] = 1.

**Attributes**

MVBAR is a 32-bit register.

**Field descriptions**

The MVBAR bit assignments are:

**When programmed with a vector base address:**

<table>
<thead>
<tr>
<th>31</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector Base Address</td>
<td>Reserved</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:5]**

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

**Reserved, bits [4:0]**

Reserved, see Configurations.

**Accessing the MVBAR**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c12, c0, 1</td>
<td>000</td>
<td>001</td>
<td>1100</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to MVBAR is **undefined** when the CP15SDISABLE signal is asserted **HIGH**.

If EL3 is implemented and is using AArch64, any read or write to MVBAR from Secure EL1 using AArch32 is trapped as an exception to EL3.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T12==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.107   MVFR0, Media and VFP Feature Register 0

The MVFR0 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR1 and MVFR2.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register MVFR0 is architecturally mapped to AArch64 System register MVFR0_EL1.

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

**Attributes**

MVFR0 is a 32-bit register.

**Field descriptions**

The MVFR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Field names</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 28 27 24 23 20 19 16 15 12 11 8 7 4 3 0</td>
<td>FPRound</td>
</tr>
</tbody>
</table>

**FPRound**, bits [31:28]

Floating-Point Rounding modes. Indicates whether the floating-point implementation provides support for rounding modes. Defined values are:

- **0000**: Not implemented, or only Round to Nearest mode supported, except that Round towards Zero mode is supported for VCVT instructions that always use that rounding mode regardless of the FPSCR setting.
- **0001**: All rounding modes supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

**FPShVec**, bits [27:24]

Short Vectors. Indicates whether the floating-point implementation provides support for the use of short vectors. Defined values are:

- **0000**: Short vectors not supported.
- **0001**: Short vector operation supported.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

**FPSqrt**, bits [23:20]

Square Root. Indicates whether the floating-point implementation provides support for the ARMv6 VFP square root operations. Defined values are:

- **0000**: Not supported in hardware.
- **0001**: Supported.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

The VSQRT.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VSQRT.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

**FPDivide, bits [19:16]**
Indicates whether the floating-point implementation provides support for VFP divide operations. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Not supported in hardware.</td>
</tr>
<tr>
<td>0001</td>
<td>Supported.</td>
</tr>
</tbody>
</table>

All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

The VDIV.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VDIV.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

**FPTrap, bits [15:12]**
Floating Point Exception Trapping. Indicates whether the floating-point implementation provides support for exception trapping. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Not supported.</td>
</tr>
<tr>
<td>0001</td>
<td>Supported.</td>
</tr>
</tbody>
</table>

All other values are reserved.
A value of 0001 indicates that, when the corresponding trap is enabled, a floating-point exception generates an exception.

**FPDP, bits [11:8]**
Double Precision. Indicates whether the floating-point implementation provides support for double-precision operations. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Not supported in hardware.</td>
</tr>
<tr>
<td>0001</td>
<td>Supported, VFPv2.</td>
</tr>
<tr>
<td>0010</td>
<td>Supported, VFPv3, VFPv4, or ARMv8. VFPv3 and ARMv8 add an instruction to load a double-precision floating-point constant, and conversions between double-precision and fixed-point values.</td>
</tr>
</tbody>
</table>

All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0010.

A value of 0b0001 or 0b0010 indicates support for all VFP double-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F64 is only available if the Square root field is 0001.
- VDIV.F64 is only available if the Divide field is 0001.
- Conversion between double-precision and single-precision is only available if the single-precision field is nonzero.

**FPSP, bits [7:4]**
Single Precision. Indicates whether the floating-point implementation provides support for single-precision operations. Defined values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>Not supported in hardware.</td>
</tr>
<tr>
<td>0001</td>
<td>Supported, VFPv2.</td>
</tr>
<tr>
<td>0010</td>
<td>Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a single-precision floating-point constant, and conversions between single-precision and fixed-point values.</td>
</tr>
</tbody>
</table>
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0010.
A value of 0b0001 or 0b0010 indicates support for all VFP single-precision instructions in the
supported version of VFP, except that, in addition to this field being nonzero:
• VSQRT.F32 is only available if the Square root field is 0001.
• VDIV.F32 is only available if the Divide field is 0001.
• Conversion between double-precision and single-precision is only available if the
double-precision field is nonzero.

SIMDReg, bits [3:0]
Advanced SIMD registers. Indicates whether the Advanced SIMD and floating-point
implementation provides support for the Advanced SIMD and floating-point register bank. Defined
values are:
0000 The implementation has no Advanced SIMD and floating-point support.
0001 The implementation includes floating-point support with 16 x 64-bit registers.
0010 The implementation includes Advanced SIMD and floating-point support with 32 x
64-bit registers.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0010.

Accessing the MVFR0
This register can be read using VMRS with the following syntax:
VMRS <Rt>, <spec_reg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;spec_reg&gt;</th>
<th>reg</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVFR0</td>
<td>0111</td>
</tr>
</tbody>
</table>

Accessibility
The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td></td>
</tr>

</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CPACR.cp10==00, read accesses to this register from PL1 are UNDEFINED.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CPTR_EL2.TFP==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CPTR_EL2.FPEN==00, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If CPTR_EL2.FPEN==10, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCPTR.TCP10==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HCPTR.TCP10==1, Non-secure read accesses to this register from EL2 are UNDEFINED.
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If NSACR.cp10==0, Non-secure read accesses to this register from EL1 and EL2 are UNDEFINED.

- When EL3 is implemented and is using AArch64:
  - If CPTR_EL3.TFP==1, read accesses to this register from EL1 and EL2 are trapped to EL3.
### G6.2.108 MVFR1, Media and VFP Feature Register 1

The MVFR1 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR0 and MVFR2.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register MVFR1 is architecturally mapped to AArch64 System register MVFR1_EL1.

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

**Attributes**

MVFR1 is a 32-bit register.

**Field descriptions**

The MVFR1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>SIMDFMAC</td>
</tr>
<tr>
<td>27-24</td>
<td>FPHP</td>
</tr>
<tr>
<td>23-19</td>
<td>SIMDHP</td>
</tr>
<tr>
<td>18-15</td>
<td>SIMDSP</td>
</tr>
<tr>
<td>14-11</td>
<td>SIMDInt</td>
</tr>
<tr>
<td>10-7</td>
<td>SIMDLS</td>
</tr>
<tr>
<td>6</td>
<td>FPDNaN</td>
</tr>
<tr>
<td>5</td>
<td>FPfZ</td>
</tr>
</tbody>
</table>

**SIMDFMAC, bits [31:28]**

Advanced SIMD Fused Multiply-Accumulate. Indicates whether the Advanced SIMD implementation provides fused multiply accumulate instructions. Defined values are:

- **0000**  Not implemented.
- **0001**  Implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

The Advanced SIMD and floating-point implementations must provide the same level of support for these instructions.

**FPHP, bits [27:24]**

Floating Point Half Precision. Indicates the level of half-precision floating-point support. Defined values are:

- **0000**  Not supported.
- **0001**  Floating-point half-precision conversion instructions are supported for conversion between single-precision and half-precision.
- **0010**  Floating-point half-precision conversion instructions are supported for conversion between single-precision and half-precision and between double-precision and half-precision.
- **0011**  As for 0010, and also includes support for half-precision floating-point arithmetic.

All other values are reserved.
The permitted values are:
- 0000 in an implementation without floating-point support.
- 0010 in an implementation with floating-point support, that does not include the ARMv8.2-FP16 extension.
- 0011 in an implementation with floating-point support, that includes the ARMv8.2-FP16 extension.

SIMDHP, bits [23:20]
Advanced SIMD Half Precision. Indicates the level of half-precision floating-point support. Defined values are:
- 0000 Not supported.
- 0001 SIMD half-precision conversion instructions are supported for conversion between single-precision and half-precision.
- 0010 As for 0010, and also includes support for half-precision floating-point arithmetic.

All other values are reserved.

The permitted values are:
- 0000 in an implementation without SIMD floating-point support.
- 0001 in an implementation with SIMD floating-point support, that does not include the ARMv8.2-FP16 extension.
- 0010 in an implementation with SIMD floating-point support, that includes the ARMv8.2-FP16 extension.

SIMDSP, bits [19:16]
Advanced SIMD Single Precision. Indicates whether the Advanced SIMD and floating-point implementation provides single-precision floating-point instructions. Defined values are:
- 0000 Not implemented.
- 0001 Implemented. This value is permitted only if the SIMDInt field is 0001.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

SIMDInt, bits [15:12]
Advanced SIMD Integer. Indicates whether the Advanced SIMD and floating-point implementation provides integer instructions. Defined values are:
- 0000 Not implemented.
- 0001 Implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

SIMDLS, bits [11:8]
Advanced SIMD Load/Store. Indicates whether the Advanced SIMD and floating-point implementation provides load/store instructions. Defined values are:
- 0000 Not implemented.
- 0001 Implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

FPDNaN, bits [7:4]
Default NaN mode. Indicates whether the floating-point implementation provides support only for the Default NaN mode. Defined values are:
- 0000 Not implemented, or hardware supports only the Default NaN mode.
Hardware supports propagation of NaN values.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

FPFtZ, bits [3:0]
Flush to Zero mode. Indicates whether the floating-point implementation provides support only for
the Flush-to-Zero mode of operation. Defined values are:
0000  Not implemented, or hardware supports only the Flush-to-Zero mode of operation.
0001  Hardware supports full denormalized number arithmetic.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

Accessing the MVFR1
This register can be read using VMRS with the following syntax:
VMRS <rt>, <spec_reg>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;spec_reg&gt;</th>
<th>reg</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVFR1</td>
<td>0110</td>
</tr>
</tbody>
</table>

Accessibility
The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>TGE</td>
<td>- RO n/a RO</td>
</tr>
<tr>

<tr>
<td></td>
<td>- n/a RO RO</td>
</tr>
</tbody>
</table>

Traps and Enables
For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for
exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous
exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.
Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CPACR.cp10==00, read accesses to this register from PL1 are UNDEFINED.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CPTR_EL2.TFP==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) &&
  (HCR_EL2.TGE == 0):
  - If CPTR_EL2.FPEN==00, Non-secure read accesses to this register from EL1 are trapped to EL2.
— If CPTR_EL2.FPEN==10, Non-secure read accesses to this register from EL1 are trapped to EL2.
— If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HCPTR.TCP10==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  — If HCPTR.TCP10==1, Non-secure read accesses to this register from EL2 are UNDEFINED.
  — If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

• When EL3 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If NSACR.cp10==0, Non-secure read accesses to this register from EL1 and EL2 are UNDEFINED.

• When EL3 is implemented and is using AArch64:
  — If CPTR_EL3.TFP==1, read accesses to this register from EL1 and EL2 are trapped to EL3.
G6.2.109 MVFR2, Media and VFP Feature Register 2

The MVFR2 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR0 and MVFR1.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register MVFR2 is architecturally mapped to AArch64 System register MVFR2_EL1.

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

**Attributes**

MVFR2 is a 32-bit register.

**Field descriptions**

The MVFR2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>FPMisc</td>
<td>SIMDMisc</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**FPMisc, bits [7:4]**

Indicates whether the floating-point implementation provides support for miscellaneous VFP features.

- 0000 Not implemented, or no support for miscellaneous features.
- 0001 Support for Floating-point selection.
- 0010 As 0001, and Floating-point Conversion to Integer with Directed Rounding modes.
- 0011 As 0010, and Floating-point Round to Integer Floating-point.
- 0100 As 0011, and Floating-point MaxNum and MinNum.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0100.

**SIMDMisc, bits [3:0]**

Indicates whether the Advanced SIMD implementation provides support for miscellaneous Advanced SIMD features.

- 0000 Not implemented, or no support for miscellaneous features.
- 0001 Floating-point Conversion to Integer with Directed Rounding modes.
- 0010 As 0001, and Floating-point Round to Integer Floating-point.
- 0011 As 0010, and Floating-point MaxNum and MinNum.

All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0011.

### Accessing the MVFR2

This register can be read using VMRS with the following syntax:

```
VMRS <Rt>, <spec_reg>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;spec_reg&gt;</th>
<th>reg</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVFR2</td>
<td>0101</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RO</td>
</tr>
<tr>
<td>NS</td>
<td>n/a</td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CPACR.cp10==00, read accesses to this register from PL1 are UNDEFINED.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CPTR_EL2.TFP==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CPTR_EL2.FPEN==00, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If CPTR_EL2.FPEN==10, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCPTR.TCP10==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HCPTR.TCP10==0, Non-secure read accesses to this register from EL2 are UNDEFINED.
  - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If NSACR.cp10==1, Non-secure read accesses to this register from EL1 and EL2 are UNDEFINED.
• When EL3 is implemented and is using AArch64:
  — If CPTR_EL3.TFP==1, read accesses to this register from EL1 and EL2 are trapped to EL3.
**G6.2.110 NMRR, Normal Memory Remap Register**

The NMRR characteristics are:

**Purpose**

Provides additional mapping controls for memory regions that are mapped as Normal memory by their entry in the PRRR.

Used in conjunction with the PRRR.

**Configurations**

AArch32 System register NMRR is architecturally mapped to AArch64 System register MAIR_EL1[63:32].

MAIR1 and NMRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in NMRR.
- When it is set to 1, the register is as described in MAIR1.

When EL3 is using AArch32, write access to NMRR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

NMRR is a 32-bit register.

**Field descriptions**

The NMRR bit assignments are:

*When TTBCR.EAE==0:*

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>OR7  OR6  OR5  OR4  OR3  OR2  OR1  OR0  IR7  IR6  IR5  IR4  IR3  IR2  IR1  IR0</td>
</tr>
</tbody>
</table>

**OR<n>, bits [2n+17:2n+16], for n = 0 to 7**

Outer Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

- 00: Region is Non-cacheable.
- 01: Region is Write-Back, Write-Allocate.
- 10: Region is Write-Through, no Write-Allocate.
- 11: Region is Write-Back, no Write-Allocate.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

**IR<n>, bits [2n+1:2n], for n = 0 to 7**

Inner Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

- 00: Region is Non-cacheable.
- 01: Region is Write-Back, Write-Allocate.
10 Region is Write-Through, no Write-Allocate.
11 Region is Write-Back, no Write-Allocate.

The meaning of the field with \( n = 6 \) is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination \( \{ \text{TEX}[0] = 1, \text{C} = 1, \text{B} = 0 \} \) is IMPLEMENTATION DEFINED.

Accessing the NMRR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
</table>
p15, 0, <Rt>, c10, c2, 1 | 000  | 001  | 1010  | 1111  | 0010 |

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H</td>
<td>TGE</td>
<td>NS</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to NMRR_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
— If HCR_EL2.TVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
— If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  — If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  — If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  — If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  — If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.111 NSACR, Non-Secure Access Control Register

The NSACR characteristics are:

**Purpose**

When EL3 is implemented and can use AArch32, defines the Non-secure access permissions to Trace, Advanced SIMD and floating-point functionality. Also includes IMPLEMENTATION DEFINED bits that can define Non-secure access permissions for IMPLEMENTATION DEFINED functionality.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

--- Note ---

In AArch64 state, the NSACR controls are replaced by controls in CPTR_EL3.

Some or all RW fields of this register have defined reset values. These apply whenever the register is accessible. This means they apply when the PE resets into EL3 using AArch32.

**Attributes**

NSACR is a 32-bit register.

**Field descriptions**

The NSACR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>21-20</td>
<td>RES0</td>
</tr>
<tr>

</tr>
<tr>
<td>2</td>
<td>RES0</td>
</tr>
<tr>
<td>1</td>
<td>RES0</td>
</tr>
<tr>
<td>0</td>
<td>RES0</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64 then:

- Any read of the NSACR from Non-secure EL2 or Non-secure EL1 returns a value of 0x00000C00.
- Any read or write to NSACR from Secure EL1 is trapped as an exception to EL3.

If EL3 is not implemented, then any read of the NSACR from EL2 or EL1 returns a value of 0x00000C00.

**Bits [31:21]**

Reserved, RES0.

**NSTRCDIS, bit [20]**

Disables Non-secure System register accesses to all implemented trace registers.

- 0: This control has no effect on:
  - System register access to implemented trace registers.
  - The behavior of CPACR.TRCDIS and HCPTR.TTA.
- 1: Non-secure System register accesses to all implemented trace registers are disabled, meaning:
  - CPACR.TRCDIS behaves as RAO/WI in Non-secure state, regardless of its actual value.
  - HCPTR.TTA behaves as RAO/WI, regardless of its actual value.
The implementation of this field must correspond to the implementation of the `CPACR.TRCDIS` field:

- If `CPACR.TRCDIS` is RAZ/WI, this field is RAZ/WI.
- If `CPACR.TRCDIS` is RW, this field is RW.

**Note**

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are **UNDEFINED**.
- The architecture does not provide Non-secure access controls on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bit [19]

Reserved, RES0.

**IMPLEMENTATION DEFINED, bits [18:16]**

IMPLEMENTATION DEFINED.

**NSASEDIS, bit [15]**

Disables Non-secure access to the Advanced SIMD functionality.

0  This control has no effect on:
   - Non-secure access to Advanced SIMD functionality.
   - The behavior of `CPACR.ASEDIS` and `HCPTR.TASE`.

1  Non-secure access to the Advanced SIMD functionality is disabled, meaning:
   - `CPACR.ASEDIS` behaves as RAO/WI in Non-secure state, regardless of its actual value.
   - `HCPTR.TASE` behaves as RAO/WI, regardless of its actual value.

The implementation of this field must correspond to the implementation of the `CPACR.ASEDIS` field:

- If `CPACR.ASEDIS` is RES0, this field is RES0. If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.
- If `CPACR.ASEDIS` is RAZ/WI, this field is RAZ/WI.
- If `CPACR.ASEDIS` is RW, this field is RW.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [14:12]

Reserved, RES0.

**cp11, bit [11]**

The value of this field is ignored. If this field is programmed with a different value to the cp10 field then this field is **UNKNOWN** on a direct read of the NSACR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally **UNKNOWN**.
cp10, bit [10]

Enable Non-secure access to the Advanced SIMD and floating-point features. Possible values of the fields are:

0  
Advanced SIMD and floating-point features can be accessed only from Secure state. 
Any attempt to access this functionality from Non-secure state is UNDEFINED. 
When the PE is in Non-secure state:
  •  The CPACR.{cp11, cp10} fields ignore writes and read as 0b00, access denied.  
  •  The HCPTR.{TCP11, TCP10} fields behave as RAO/WI, regardless of their actual values.

1  
Advanced SIMD and floating-point features can be accessed from both Security states.

If Non-secure access to the Advanced SIMD and floating-point functionality is enabled, the CPACR must be checked to determine the level of access that is permitted.

The Advanced SIMD and floating-point features controlled by these fields are:
  •  Execution of any floating-point or Advanced SIMD instruction.  
  •  Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.  
  •  Any access to the FPSCR, FPSID, MVFR0, MVFR1, MVFR2, or FPEXC System registers.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [9:0]

Reserved, RES0.

Accessing the NSACR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

EL3     | RW              |
If EL3 is implemented and is using AArch64, any read from or write to NSACR from Secure EL1 is trapped as an exception to EL3.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.112   PAR, Physical Address Register

The PAR characteristics are:

**Purpose**

Returns the output address (OA) from an address translation instruction that executed successfully, or fault information if the instruction did not execute successfully.

**Configurations**

AArch32 System register PAR is architecturally mapped to AArch64 System register PAR_EL1. The PAR returns a 32-bit value:

- When the PE is not in Hyp mode and is using the Short-descriptor translation table format.
- When the PE is in Hyp mode and executes an ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, or ATS12NSOUW instruction when the value of HCR.VM is 0 and the value of TTBCR.EAE is 0. In these cases, PAR[63:32] is RES0.

Otherwise, the PAR returns a 64-bit value. This means it returns a 64-bit value in the following cases:

- When using the Long-descriptor translation table format.
- If the stage 1 address translation is disabled and TTBCR.EAE is set to 1.
- In an implementation that includes EL2, for the result of an ATS1Cxx instruction performed from Hyp mode.

For PL1&0 stage 1 translations, TTBCR.EAE selects the translation table format.

**Attributes**

PAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits[31:0] and do not modify bits[63:32].

The Configurations section specifies the cases where each PAR format is used.

**Field descriptions**

The PAR bit assignments are:

**For all register layouts:**

F, bit [0]

Indicates whether the instruction performed a successful address translation.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Address translation completed successfully.</td>
</tr>
<tr>
<td>1</td>
<td>Address translation aborted.</td>
</tr>
</tbody>
</table>
When the instruction returned a 32-bit value to the PAR, PAR.F==0:

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

On a successful conversion, the PAR can return a value that indicates the resulting attributes, rather than the values that appear in the translation table descriptors. More precisely:

- Memory attribute fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the translation table descriptors. This applies to the NOS, SH, Inner, and Outer fields.
- See the NS bit description for constraints on the value it returns.

PA, bits [31:12]
Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[31:12].

LPAE, bit [11]
When updating the PAR with the result of the translation operation, this bit is set as follows:
0 Short-descriptor translation table format used. This means the PAR returned a 32-bit value.

NOS, bit [10]
Not Outer Shareable. When the returned value of PAR.SH is 1, indicates the Shareability attribute for the physical memory region:
0 Memory region is Outer Shareable.
1 Memory region is Inner Shareable.
When the returned value of PAR.SH is 0 the value returned to this field is UNKNOWN.
The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

NS, bit [9]
Non-secure. The NS attribute for a translation table entry from a Secure translation regime.
For a result from a Secure translation regime, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.
For a result from a Non-secure translation regime, this bit is UNKNOWN.

IMP DEF, bit [8]
IMPLEMENTATION DEFINED.
SH, bit [7]

Shareability. Indicates whether the physical memory region is Non-shareable:

0   Memory is Non-shareable.
1   Memory is shareable, and PAR.NOS indicates whether the region is Outer Shareable or Inner Shareable.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

Inner[2:0], bits [6:4]

Inner cacheability attribute for the region. Permitted values are:

000   Non-cacheable.
001   Device-nGnRnE.
011   Device-nGnRE.
101   Write-Back, Write-Allocate.
110   Write-Through.
111   Write-Back, no Write-Allocate.

The values 010 and 100 are reserved.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

Outer[1:0], bits [3:2]

Outer cacheability attribute for the region. Permitted values are:

00   Non-cacheable.
01   Write-Back, Write-Allocate.
10   Write-Through, no Write-Allocate.
11   Write-Back, no Write-Allocate.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

SS, bit [1]

Supersection. Used to indicate if the result is a Supersection:

0   Result is not a Supersection. PAR[31:12] contains OA[31:12].
1   Result is a Supersection, and:
   •   PAR[31:24] contains OA[31:24].
   •   PAR[15:12] contains 0b0000.

If an implementation supports less than 40 bits of physical address, the bits in the PAR field that correspond to physical address bits that are not implemented are UNKNOWN.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

0   Address translation completed successfully.
When the instruction returned a 32-bit value to the PAR, PAR.F==1:

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

**IMP DEF, bits [31:16]**

IMPLEMENTATION DEFINED.

**Bits [15:12]**

Reserved, RES0.

**LPAE, bit [11]**

When updating the PAR with the result of the translation operation, this bit is set as follows:

0    Short-descriptor translation table format used. This means the PAR returned a 32-bit value.

**Bits [10:7]**

Reserved, RES0.

**FS, bits [6:1]**

Fault status bits. Bits [12,10,3:0] from the DFSR, indicating the source of the abort.

**F, bit [0]**

Indicates whether the instruction performed a successful address translation.

1    Address translation aborted.

When the instruction returned a 64-bit value to the PAR, PAR.F==0:

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

On a successful conversion, the PAR can return a value that indicates the resulting attributes, rather than the values that appear in the translation table descriptors. More precisely:

- Memory attribute fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the translation table descriptors. This applies to the ATTR and SH fields.
· See the NS bit description for constraints on the value it returns.

**ATTR, bits [63:56]**

Memory attributes for the returned output address. This field uses the same encoding as the Attr<n> fields in MAIR0 and MAIR1.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

**Bits [55:40]**

Reserved, RES0.

**PA, bits [39:12]**

Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[39:12].

**LPAE, bit [11]**

When updating the PAR with the result of the translation operation, this bit is set as follows:

1 Long-descriptor translation table format used. This means the PAR returned a 64-bit value.

**IMP DEF, bit [10]**

IMPLEMENTATION DEFINED.

**NS, bit [9]**

Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

For a result from a Secure translation regime, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

**SH, bits [8:7]**

Shareability attribute, for the returned output address. Permitted values are:

00 Non-shareable.
10 Outer Shareable.
11 Inner Shareable.

The value 01 is reserved.

--- Note ---

This field returns the value 10 for:

· Any type of Device memory.
· Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

**Bits [6:1]**

Reserved, RES0.

**F, bit [0]**

Indicates whether the instruction performed a successful address translation.

0 Address translation completed successfully.
When the instruction returned a 64-bit value to the PAR, \( \text{PAR.F} = 1 \):

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

**IMP DEF, bits [63:56]**
IMPLEMENTATION DEFINED.

**IMP DEF, bits [55:52]**
IMPLEMENTATION DEFINED.

**IMP DEF, bits [51:48]**
IMPLEMENTATION DEFINED.

**Bits [47:12]**
Reserved, RES0.

**LPAE, bit [11]**
When updating the PAR with the result of the translation operation, this bit is set as follows:
1 Long-descriptor translation table format used. This means the PAR returned a 64-bit value.

**Bit [10]**
Reserved, RES0.

**FSTAGE, bit [9]**
Indicates the translation stage at which the translation aborted:
0 Translation aborted because of a fault in the stage 1 translation.
1 Translation aborted because of a fault in the stage 2 translation.

**S2WLK, bit [8]**
If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

**Bit [7]**
Reserved, RES0.

**FST, bits [6:1]**
Fault status field. Values are as in the DFSR.STATUS and IFSR.STATUS fields when using the Long-descriptor translation table format.

**F, bit [0]**
Indicates whether the instruction performed a successful address translation:
1 Address translation aborted.
**Accessing the PAR**

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T7==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T7==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T7==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.113  PRRR, Primary Region Remap Register

The PRRR characteristics are:

**Purpose**

Controls the top level mapping of the TEX[0], C, and B memory region attributes.

**Configurations**

AArch32 System register PRRR is architecturally mapped to AArch64 System register MAIR_EL1[31:0].

MAIR0 and PRRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in PRRR.
- When it is set to 1, the register is as described in MAIR0.

When EL3 is using AArch32, write access to PRRR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PRRR is a 32-bit register.

**Field descriptions**

The PRRR bit assignments are:

*When TTBCR.EAE==0:*

```plaintext
    31 30 29 28 27 26 25 24 23  20 19 18 17 16 15 14 13 12 11  10  9  8  7  6  5  4  3  2  1  0

RES0    TR7   TR6   TR5   TR4   TR3   TR2   TR1   TR0

NOS7    NOS6    NOS5    NOS4    NOS3    NOS2    NOS1    NOS0

NS1    NS0    DS1    DS0
```

**NOS<n>, bit [n+24], for n = 0 to 7**

Not Outer Shareable. NOS<n> is the Outer Shareable property for memory attributes n, if the region is mapped as Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, and the appropriate PRRR.{NS0, NS1} field identifies the region as shareable. n is the value of the concatenation of the {TEX[0], C, B} bits from the translation table descriptor. The possible values of each NOS<n> field other than NOS6 are:

- 0 Memory region is Outer Shareable.
- 1 Memory region is Inner Shareable.
The value of this bit is ignored if the region is:
- Device memory
- Normal memory that is at least one of:
  - Inner Non-cacheable, Outer Non-cacheable.
  - Identified by the appropriate PRRR.\{NS0, NS1\} field as Non-shareable.

The meaning of the NOS6 field is IMPLEMENTATION DEFINED.

Bits [23:20]

Reserved, RES0.

NS1, bit [19]

Mapping of S = 1 attribute for Normal memory regions. This field is used in determining the Shareability of a memory region that is mapped to Normal memory and both:
- Is not Inner Non-cacheable, Outer Non-cacheable.
- Has the S bit in the translation table descriptor set to 1.

The possible values of this bit are:
0  Region is Non-shareable.
1  Region is shareable. The value of the appropriate PRRR.NOS<\n> field determines whether the region is Inner Shareable or Outer Shareable.

NS0, bit [18]

Mapping of S = 0 attribute for Normal memory regions. This field is used in determining the Shareability of a memory region that is mapped to Normal memory and both:
- Is not Inner Non-cacheable, Outer Non-cacheable.
- Has the S bit in the translation table descriptor set to 0.

The possible values of this bit are:
0  Region is Non-shareable.
1  Region is shareable. The value of the appropriate PRRR.NOS<\n> field determines whether the region is Inner Shareable or Outer Shareable.

DS1, bit [17]

Mapping of S = 1 attribute for Device memory. In ARMv8, all types of Device memory are Outer Shareable, and therefore this bit is RES1.

DS0, bit [16]

Mapping of S = 0 attribute for Device memory. In ARMv8, all types of Device memory are Outer Shareable, and therefore this bit is RES1.

TR<\n>, bits [2n+1:2n], for n = 0 to 7

TR<\n> is the primary TEx mapping for memory attributes n, and defines the mapped memory type for a region with attributes n. n is the value of the concatenation of the \{TEX[0], C, B\} bits from the translation table descriptor. The possible values for each field other than TR6 are:
00  Device-nGnRnE memory
01  Device-nGnRE memory
10  Normal memory

The value 11 is reserved. The effect of programming a field to 11 is CONSTRAINED UNPREDICTABLE, see Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.

The meaning of the TR6 field is IMPLEMENTATION DEFINED.
Accessing the PRRR

This register can be read using MRC with the following syntax:

\[ \text{MRC } \text{<syntax>} \]

This register can be written using MCR with the following syntax:

\[ \text{MCR } \text{<syntax>} \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c10, c2, 0</td>
<td>000</td>
<td>000</td>
<td>1010</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL3 is not implemented.</td>
<td>x x 0</td>
<td>- RW n/a n/a</td>
<td>PRRR</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 0 1</td>
<td>- RW RW n/a</td>
<td>PRRR</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 1 1</td>
<td>- n/a RW n/a</td>
<td>PRRR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x x 0</td>
<td>- RW n/a n/a</td>
<td>PRRR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 0 1</td>
<td>- RW RW n/a</td>
<td>PRRR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 1 1</td>
<td>- n/a RW n/a</td>
<td>PRRR</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x x 0</td>
<td>- n/a n/a RW</td>
<td>PRRR_s</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x 0 1</td>
<td>- RW RW RW</td>
<td>PRRR_ns</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x 1 1</td>
<td>- n/a RW RW</td>
<td>PRRR_ns</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to PRRR_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
— If \( HCR\_EL2\_TRVM == 1 \), Non-secure read accesses to this register from EL1 are trapped to EL2.
— If \( HSTR\_EL2\_T10 == 1 \), Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR\_EL3\_NS == 1:
  — If \( HCR\_TVM == 1 \), Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  — If \( HCR\_TRVM == 1 \), Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  — If \( HSTR\_T10 == 1 \), Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.114 REVIDR, Revision ID Register

The REVIDR characteristics are:

**Purpose**

Provides implementation-specific minor revision information.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register REVIDR is architecturally mapped to AArch64 System register REVIDR_EL1.

If REVIDR has the same value as MIDR, then its contents have no significance.

**Attributes**

REVIDR is a 32-bit register.

**Field descriptions**

The REVIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

**Accessing the REVIDR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>

<td>- n/a RO RO</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on* page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID1==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.115   **RMR, Reset Management Register**

The RMR characteristics are:

**Purpose**

If EL1 or EL3 is the highest implemented Exception level and this register is implemented:

- A write to the register at the highest implemented Exception level can request a Warm reset.
- If the highest implemented Exception level can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register RMR is architecturally mapped to AArch64 System register RMR_EL1 when EL1 is highest implemented Exception level.

AArch32 System register RMR is architecturally mapped to AArch64 System register RMR_EL3 when EL3 is implemented.

Only implemented if EL1 or EL3 is the highest implemented Exception level. In this case:

- If the highest implemented Exception level can use AArch32 and AArch64 then this register must be implemented.
- If the highest implemented Exception level cannot use AArch64 then it is IMPLEMENTATION DEFINED whether the register is implemented.

See the field descriptions for the reset values. These apply whenever the register is implemented.

**Attributes**

RMR is a 32-bit register.

**Field descriptions**

The RMR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>RMR, bit [1] Reset Request</td>
</tr>
<tr>
<td></td>
<td>AArch64, bit [0] Determines AArch32/AArch64-execution-state-on-Warm-reset</td>
</tr>
</tbody>
</table>

**Bits [31:2]**

Reserved, RES0.

**RR, bit [1]**

Reset Request. Setting this bit to 1 requests a Warm reset.

This field resets to 0 on a Warm or Cold reset.

**AA64, bit [0]**

When the highest implemented Exception level can use AArch64, determines which Execution state the PE boots into after a Warm reset:

- 0 AArch32.
- 1 AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If the highest implemented Exception level cannot use AArch64 this bit is RAZ/WI.
When implemented as a RW field, this field resets to 0 on a Cold reset.

Accessing the RMR

This register can be read using MRC with the following syntax:

\[ \text{MRC } <\text{syntax}> \]

This register can be written using MCR with the following syntax:

\[ \text{MCR } <\text{syntax}> \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>(&lt;\text{syntax}&gt;)</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>(p15, 0, &lt;Rt&gt;, c12, c0, 2)</td>
<td>000</td>
<td>010</td>
<td>1100</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>(E2H)</td>
<td>(TGE)</td>
</tr>
<tr>
<td>EL1 is the highest implemented Exception level.</td>
<td>(x)</td>
<td>(x)</td>
</tr>
<tr>
<td>EL2 is the highest implemented Exception level.</td>
<td>(x)</td>
<td>(0)</td>
</tr>
<tr>
<td>EL3 is the highest implemented Exception level.</td>
<td>(x)</td>
<td>(1)</td>
</tr>
<tr>
<td>EL3 is the highest implemented Exception level.</td>
<td>(x)</td>
<td>(x)</td>
</tr>
<tr>
<td>EL3 is the highest implemented Exception level.</td>
<td>(x)</td>
<td>(0)</td>
</tr>
<tr>
<td>EL3 is the highest implemented Exception level.</td>
<td>(x)</td>
<td>(1)</td>
</tr>
</tbody>
</table>

The encoding for this register is UNDEFINED:

- If the RMR is not implemented.
- At all Exception levels other than the highest implemented Exception level.

When EL3 is implemented, ARM deprecates accessing this register from any PE mode other than Monitor mode.
G6.2.116 RVBAR, Reset Vector Base Address Register

The RVBAR characteristics are:

**Purpose**

If EL3 is not implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch32 state.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

This register is only implemented if the highest Exception level implemented is capable of using AArch32, and is not EL3.

**Attributes**

RVBAR is a 32-bit register.

**Field descriptions**

The RVBAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reset Address[31:1]</td>
</tr>
<tr>
<td>30</td>
<td>Reserved, RES1</td>
</tr>
</tbody>
</table>

**Accessing the RVBAR**

This register can be read using MRC with the following syntax:

**MRC <syntax>**

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c12, c0, l</td>
<td>000</td>
<td>001</td>
<td>1100</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>EL1 is the highest implemented Exception level.</td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>EL2 is the highest implemented Exception level.</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL2 is the highest implemented Exception level.</td>
<td>x</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is the highest implemented Exception level.</td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>EL3 is the highest implemented Exception level.</td>
<td>x</td>
<td>0</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T12==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
### SCR, Secure Configuration Register

The SCR characteristics are:

**Purpose**

When EL3 is implemented and can use AArch32, defines the configuration of the current Security state. It specifies:

- The Security state, either Secure or Non-secure.
- What mode the PE branches to if an IRQ, FIQ, or External Abort occurs.
- Whether the CPSR.F or CPSR.A bits can be modified when SCR.NS==1.

**Configurations**

This register is only accessible in Secure state.

AArch32 System register SCR can be mapped to AArch64 System register SCR_EL3, but this is not architecturally mandated.

Some or all RW fields of this register have defined reset values. These apply whenever the register is accessible. This means they apply when the PE resets into EL3 using AArch32.

**Attributes**

SCR is a 32-bit register.

**Field descriptions**

The SCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>30-16</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>15</td>
<td>TERR</td>
</tr>
<tr>
<td>14-0</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**Bits [31:16]**

Reserved, RES0.

**TERR, bit [15]**

Trap Error record accesses. If the RAS Extension is implemented, the possible values of this bit are:

- 0: Do not trap accesses to record registers from EL1 and EL2 to EL3.
- 1: Accesses to the ER* registers from EL1 and EL2 generate a Trap exception to EL3.

This bit resets to 0 on Warm reset.

When the RAS Extension is not implemented, this field is RES0.
Bit [14]

Reserved, RES0.

TWE, bit [13]

Traps WFE instructions to Monitor mode.

0  This control does not cause any instructions to be trapped.
1  Any attempt to execute a WFE instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state and the attempted execution does not generate an exception that is taken to EL1 or EL2 by SCTLR.nTWE or HCR.TWE.

Any exception that is taken to EL1 or to EL2 has priority over this trap.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

When this register has an architecturally-defined reset value, this field resets to 0.

TWI, bit [12]

Traps WFI instructions to Monitor mode.

0  This control does not cause any instructions to be trapped.
1  Any attempt to execute a WFI instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state and the attempted execution does not generate an exception that is taken to EL1 or EL2 by SCTLR.nTWI or HCR.TWI.

Any exception that is taken to EL1 or to EL2 has priority over this trap.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [11:10]

Reserved, RES0.

SIF, bit [9]

Secure instruction fetch. When the PE is in Secure state, this bit disables instruction fetch from Non-secure memory. The possible values for this bit are:

0  Secure state instruction fetches from Non-secure memory are permitted.
1  Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.
HCE, bit [8]

Hypervisor Call instruction enable. Enables EL2 and Non-secure EL1 execution of HVC instructions.

0  HVC instructions are:
    • UNDEFINED at Non-secure EL1. The Undefined Instruction exception is taken from PL1 to PL1.
    • UNPREDICTABLE at EL2. Behavior is one of the following:
      — The instruction is UNDEFINED.
      — The instruction executes as a NOP.

1  HVC instructions are enabled at EL2 and Non-secure EL1.

Note

HVC instructions are always UNDEFINED at EL0 and in Secure state.

If EL2 is not implemented, this bit is RES0 and HVC is UNDEFINED.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

SCD, bit [7]

Secure Monitor Call disable. Disables SMC instructions.

0  SMC instructions are enabled.

1  In Non-secure state, SMC instructions are UNDEFINED. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.
   In Secure state, behavior is one of the following:
    • The instruction is UNDEFINED.
    • The instruction executes as a NOP.

Note

SMC instructions are always UNDEFINED at PL0.

When this register has an architecturally-defined reset value, this field resets to 0.

nET, bit [6]

Not Early Termination. This bit disables early termination. The possible values of this bit are:

0  Early termination permitted. Execution time of data operations can depend on the data values.

1  Disable early termination. The number of cycles required for data operations is forced to be independent of the data values.

This IMPLEMENTATION DEFINED mechanism can disable data dependent timing optimizations from multiplies and data operations. It can provide system support against information leakage that might be exploited by timing correlation types of attack.

On implementations that do not support early termination or do not support disabling early termination, this bit is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

AW, bit [5]

When the value of SCR.EA is 1 and the value of HCR.AMO is 0, this bit controls whether CPSR.A masks an external abort taken from Non-secure state, and the possible values of this bit are:

0  External aborts taken from Non-secure state are not masked by CPSR.A, and are taken to EL3.

1  External aborts taken from Secure state are masked by CPSR.A.
External aborts taken from either Security state are masked by CPSR.A. When CPSR.A is 0, the abort is taken to EL3.

When SCR.EA is 0 or HCR.AMO is 1, this bit has no effect.

When this register has an architecturally-defined reset value, this field resets to 0.

FW, bit [4]

When the value of SCR.FIQ is 1 and the value of HCR.FMO is 0, this bit controls whether CPSR.F masks an FIQ interrupt taken from Non-secure state, and the possible values of this bit are:

0  An FIQ taken from Non-secure state is not masked by CPSR.F, and is taken to EL3.  
   An FIQ taken from Secure state is masked by CPSR.F.
1  An FIQ taken from either Security state is masked by CPSR.F. When CPSR.F is 0, the FIQ is taken to EL3.

When SCR.FIQ is 0 or HCR.FMO is 1, this bit has no effect.

When this register has an architecturally-defined reset value, this field resets to 0.

EA, bit [3]

External Abort handler. This bit controls which mode takes external aborts. The possible values of this bit are:

0  External aborts taken to Abort mode.
1  External aborts taken to Monitor mode.

When this register has an architecturally-defined reset value, this field resets to 0.

FIQ, bit [2]

FIQ handler. This bit controls which mode takes FIQ exceptions. The possible values of this bit are:

0  FIQs taken to FIQ mode.
1  FIQs taken to Monitor mode.

When this register has an architecturally-defined reset value, this field resets to 0.

IRQ, bit [1]

IRQ handler. This bit controls which mode takes IRQ exceptions. The possible values of this bit are:

0  IRQs taken to IRQ mode.
1  IRQs taken to Monitor mode.

When this register has an architecturally-defined reset value, this field resets to 0.

NS, bit [0]

Non-secure bit. Except when the PE is in Monitor mode, this bit determines the Security state of the PE:

0  PE is in Secure state.
1  PE is in Non-secure state.

If the HCR.TGE bit is set, an attempt to change from a Secure PL1 mode to a Non-secure EL1 mode by changing the SCR.NS bit from 0 to 1 results in the SCR.NS bit remaining as 0.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c1, c1, 0</td>
<td>000</td>
<td>000</td>
<td>0001</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, any read or write to SCR from Secure EL1 using AArch32 is trapped as an exception to EL3.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.118 SCTRL, System Control Register

The SCTRL characteristics are:

**Purpose**

Provides the top level control of the system, including its memory system.

**Configurations**

AArch32 System register SCTRL is architecturally mapped to AArch64 System register SCTRL_EL1.

When EL3 is using AArch32, write access to SCTRL(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

Some bits in the register are read-only. These bits relate to non-configurable features of an implementation, and are provided for compatibility with previous versions of the architecture.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SCTRL is a 32-bit register.

**Field descriptions**

The SCTRL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>30</td>

---

G6-5106 Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved. Non-Confidential
When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED choice between:

- 0.
- A value determined by an input configuration signal.

**AFE, bit [29]**

Access Flag Enable. When using the Short-descriptor translation table format for the PL1&0 translation regime, this bit enables use of the AP[0] bit in the translation descriptors as the Access flag, and restricts access permissions in the translation descriptors to the simplified model. The possible values of this bit are:

- 0 In the translation table descriptors, AP[0] is an access permissions bit. The full range of access permissions is supported. No Access flag is implemented.
- 1 In the translation table descriptors, AP[0] is the Access flag. Only the simplified model for access permissions is supported.

When using the Long-descriptor translation table format, the VMSA behaves as if this bit is set to 1, regardless of the value of this bit.

The AFE bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

**TRE, bit [28]**

TEX remap enable. This bit enables remapping of the TEX[2:1] bits in the PL1&0 translation regime for use as two translation table bits that can be managed by the operating system. Enabling this remapping also changes the scheme used to describe the memory region attributes in the VMSA. The possible values of this bit are:

- 0 TEX remap disabled. TEX[2:0] are used, with the C and B bits, to describe the memory region attributes.
- 1 TEX remap enabled. TEX[2:1] are reassigned for use as bits managed by the operating system. The TEX[0], C, and B bits are used to describe the memory region attributes, with the MMU remap registers.

When the value of TTBCR.EAE is 1, this bit is RES1.

The TRE bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

**Bits [27:26]**

Reserved, RES0.

**EE, bit [25]**

The value of the PSTATE.E bit on branch to an exception vector or coming out of reset, and the endianness of stage 1 translation table walks in the PL1&0 translation regime.

The possible values of this bit are:

- 0 Little-endian. PSTATE.E is cleared to 0 on taking an exception or coming out of reset. Stage 1 translation table walks in the PL1&0 translation regime are little-endian.
- 1 Big-endian. PSTATE.E is cleared to 0 on taking an exception or coming out of reset. Stage 1 translation table walks in the PL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support for data accesses at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support for data accesses at Exception Levels higher than EL0, this bit is RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to an IMPLEMENTATION DEFINED choice between:

- 0.
- A value determined by an input configuration signal.
Bit [24]
Reserved, RES0.

SPAN, bit [23]

*In ARMv8.2 and ARMv8.1*

Set Privileged Access Never, on taking an exception to EL1 from either Secure or Non-secure state, or to EL3 from Secure state when EL3 is using AArch32.

0  CPSR.PAN is set to 1 in the following situations:
   •  In Non-secure state, on taking an exception to EL1.
   •  In Secure state, when EL3 is using AArch64, on taking an exception to EL1.
   •  In Secure state, when EL3 is using AArch32, on taking an exception to EL3.

1  The value of CPSR.PAN is left unchanged on taking an exception.

*In ARMv8.0.*

Reserved, RES1.

Bit [22]
Reserved, RES1.

Bit [21]
Reserved, RES0.

UWXN, bit [20]

Unprivileged write permission implies PL1 XN (Execute-never). This bit can force all memory regions that are writable at PL0 to be treated as XN for accesses from software executing at PL1. The possible values of this bit are:

0  This control has no effect on memory access permissions.

1  Any region that is writable at PL0 forced to XN for accesses from software executing at PL1.

The UWXN bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the PL1&0 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

0  This control has no effect on memory access permissions.

1  Any region that is writable in the PL1&0 translation regime is forced to XN for accesses from software executing at PL1 or PL0.

The WXN bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

nTWE, bit [18]

Traps EL0 execution of WFE instructions to Undefined mode.

0  Any attempt to execute a WFE instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

1  This control does not cause any instructions to be trapped.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.
--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 1.

Bit [17]

Reserved, RES0.

nTWI, bit [16]

Traps EL0 execution of WFI instructions to Undefined mode.

0 Any attempt to execute a WFI instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

1 This control does not cause any instructions to be trapped.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 1.

Bits [15:14]

Reserved, RES0.

V, bit [13]

Vectors bit. This bit selects the base address of the exception vectors for exceptions taken to a PE mode other than Monitor mode or Hyp mode:

0 Normal exception vectors. Base address is held in VBAR.

1 High exception vectors (Hivec), base address 0xFFFF0000. This base address cannot be remapped.

When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED choice between:

• 0.

• A value determined by an input configuration signal.

I, bit [12]

Instruction access Cacheability control, for accesses at EL1 and EL0:

0 All instruction access to Normal memory from PL1 and PL0 are Non-cacheable for all levels of instruction and unified cache.
   If the value of SCTLR.M is 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

1 All instruction access to Normal memory from PL1 and PL0 can be cached at all levels of instruction and unified cache.
   If the value of SCTLR.M is 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.
Instruction accesses to Normal memory from Non-secure EL1 and Non-secure EL0 are Cacheable regardless of the value of the SCTLR.I bit if either:

- EL2 is using AArch32 and the value of HCR.DC is 1.
- EL2 is using AArch64 and the value of HCR_EL2.DC is 1.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [11]
Reserved, RES1.

Bits [10:9]
Reserved, RES0.

SED, bit [8]
SETEND instruction disable. Disables SETEND instructions at PL0 and PL1.
0 SETEND instruction execution is enabled at PL0 and PL1.
1 SETEND instructions are UNDEFINED at PL0 and PL1.

If the implementation does not support mixed-endian operation at any Exception level, this bit is RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

ITD, bit [7]
IT Disable. Disables some uses of IT instructions at PL1 and PL0.
0 All IT instruction functionality is enabled at PL1 and PL0.
1 Any attempt at PL1 or PL0 to execute any of the following is UNDEFINED:
   • All encodings of the IT instruction with hw1[3:0]=1000.
   • All encodings of the subsequent instruction with the following values for hw1:
     11xxxxxxxxxxxx
     All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
     1011xxxxxxxxxx
     All instructions in Miscellaneous 16-bit instructions on page F3-2883.
     10100xxxxxxxx
     ADD Rd, PC, #imm
     01001xxxxxxxx
     LDR Rd, [PC, #imm]
     01001xxxxxxxx
     ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
     010001xx1xxxx
     ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn.

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:
   • A 16-bit instruction, that can only be followed by another 16-bit instruction.
   • The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.
An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information see Changes to an ITD control by an instruction in an IT block on page E1-2738.

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAZ/WI.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**UNK, bit [6]**

Writes to this bit are IGNORED. Reads of this bit return an UNKNOWN value.

**CP15BEN, bit [5]**

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==1111) encoding space from PL1 and PL0:

- 0: PL0 and PL1 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is UNDEFINED.
- 1: PL0 and PL1 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is enabled.

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAO/WI.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 1.

**LSMAOE, bit [4]**

*In ARMv8.2*

Load Multiple and Store Multiple Atomicity and Ordering Enable. When the OPTIONAL feature ARMv8.2-LSMAOC is implemented, defined values are:

- 0: For all memory accesses at EL1 or EL0, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.
- 1: The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 is as defined for ARMv8.0.

This bit is permitted to be cached in a TLB.

If this bit is not implemented, it is RES1.

When this register has an architecturally-defined reset value, this field resets to 1.

*In ARMv8.1 and ARMv8.0.*

Reserved, RES1.

**nTLSMD, bit [3]**

*In ARMv8.2*

No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory. When the OPTIONAL feature ARMv8.2-LSMAOC is implemented, defined values are:

- 0: All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.
- 1: All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.

This bit is permitted to be cached in a TLB.

If this bit is not implemented, it is RES1.
When this register has an architecturally-defined reset value, this field resets to 1.

In ARMv8.1 and ARMv8.0.

Reserved, RES1.

C, bit [2]

Cacheability control, for data accesses at EL1 and EL0:
0    All data access to Normal memory from PL1 and PL0, and all accesses to the PL1&0 stage 1 translation tables, are Non-cacheable for all levels of data and unified cache.
1    All data access to Normal memory from PL1 and PL0, and all accesses to the PL1&0 stage 1 translation tables, can be cached at all levels of data and unified cache.

The PE ignores SCLTR.C for Non-secure state and data accesses to Normal memory from EL1 and EL0 are Cacheable if either:
- EL2 is using AArch32 and the value of HCR.DC is 1.
- EL2 is using AArch64 and the value of HCR_EL2.DC is 1.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at PL1 and PL0:
0    Alignment fault checking disabled when executing at PL1 or PL0.
      Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.
1    Alignment fault checking enabled when executing at PL1 or PL0.
      All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception. Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

When this register has an architecturally-defined reset value, this field resets to 0.

M, bit [0]

MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:
0    EL1 and EL0 stage 1 address translation disabled.
      See the SCTLR.I field for the behavior of instruction accesses to Normal memory.
1    EL1 and EL0 stage 1 address translation enabled.

In the Non-secure state the PE behaves as if the value of the SCTLR.M field is 0 for all purposes other than returning the value of a direct read of the field if either:
- EL2 is using AArch32 and the value of HCR.{DC, TGE} is not {0, 0}.
- EL2 is using AArch64 and the value of HCR_EL2.{DC, TGE} is not {0, 0}.

When this register has an architecturally-defined reset value, this field resets to 0.

**Accessing the SCTLR**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c1, c0, 0</td>
<td>000</td>
<td>000</td>
<td>0001</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H</td>
<td>TGE</td>
<td>NS</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to SCTL_R_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.119   SPSR, Saved Program Status Register

The SPSR characteristics are:

Purpose
Holds the saved process state for the current mode.

Configurations
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes
SPSR is a 32-bit register.

Field descriptions
The SPSR bit assignments are:

<table>

</tbody>
</table>

- **N, bit [31]**
  - Set to the value of CPSR.N on taking an exception to the current mode, and copied to CPSR.N on executing an exception return operation in the current mode.

- **Z, bit [30]**
  - Set to the value of CPSR.Z on taking an exception to the current mode, and copied to CPSR.Z on executing an exception return operation in the current mode.

- **C, bit [29]**
  - Set to the value of CPSR.C on taking an exception to the current mode, and copied to CPSR.C on executing an exception return operation in the current mode.

- **V, bit [28]**
  - Set to the value of CPSR.V on taking an exception to the current mode, and copied to CPSR.V on executing an exception return operation in the current mode.

- **Q, bit [27]**
  - Set to the value of CPSR.Q on taking an exception to the current mode, and copied to CPSR.Q on executing an exception return operation in the current mode.

- **IT[1:0], bits [26:25]**
  - IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

- **J, bit [24]**
  - RES0.
  - In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.
Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to the current mode, and copied to CPSR.PAN on executing an exception return operation in the current mode.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

- 0: Little-endian operation
- 1: Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

- 0: Exception not masked.
- 1: Exception masked.
### I, bit [7]

IRQ mask bit. The possible values of this bit are:

- **0**: Exception not masked.
- **1**: Exception masked.

### F, bit [6]

FIQ mask bit. The possible values of this bit are:

- **0**: Exception not masked.
- **1**: Exception masked.

### T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- **0**: Taken from A32 state.
- **1**: Taken from T32 state.

### M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

- **1**: Exception taken from AArch32.

### M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved.
G6.2.120  **SPSR_abt, Saved Program Status Register (Abort mode)**

The SPSR_abt characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Abort mode.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register SPSR_abt is architecturally mapped to AArch64 System register SPSR_abt.

**Attributes**

SPSR_abt is a 32-bit register.

**Field descriptions**

The SPSR_abt bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td><strong>N</strong>, bit [31] Set to the value of CPSR.N on taking an exception to Abort mode, and copied to CPSR.N on executing an exception return operation in Abort mode.</td>
</tr>
<tr>
<td>30</td>
<td><strong>Z</strong>, bit [30] Set to the value of CPSR.Z on taking an exception to Abort mode, and copied to CPSR.Z on executing an exception return operation in Abort mode.</td>
</tr>
<tr>
<td>29</td>
<td><strong>C</strong>, bit [29] Set to the value of CPSR.C on taking an exception to Abort mode, and copied to CPSR.C on executing an exception return operation in Abort mode.</td>
</tr>
<tr>
<td>28</td>
<td><strong>V</strong>, bit [28] Set to the value of CPSR.V on taking an exception to Abort mode, and copied to CPSR.V on executing an exception return operation in Abort mode.</td>
</tr>
<tr>
<td>27</td>
<td><strong>Q</strong>, bit [27] Set to the value of CPSR.Q on taking an exception to Abort mode, and copied to CPSR.Q on executing an exception return operation in Abort mode.</td>
</tr>
<tr>
<td>26</td>
<td><strong>IT[1:0]</strong>, bits [26:25] IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.</td>
</tr>
</tbody>
</table>
In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]
Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1
When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to Abort mode, and copied to CPSR.PAN on executing an exception return operation in Abort mode.
When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0
Reserved, RES0.

Bit [21]
Reserved, RES0.

IL, bit [20]
Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]
IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.
• IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
• IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.
The IT field is 0b00000000 when no IT block is active.

E, bit [9]
Endianness state bit. Controls the load and store endianness for data accesses:
0 Little-endian operation
1 Big-endian operation.
Instruction fetches ignore this bit.
When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.
If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.
Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]
SError interrupt mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0  Exception not masked.
1  Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0  Taken from A32 state.
1  Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1  Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained Unpredictable, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6117.

**Accessing the SPSR_abt**

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;banked_reg&gt;</th>
<th>R</th>
<th>M</th>
<th>M1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPSR_abt</td>
<td>1</td>
<td>1</td>
<td>0100</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>-</td>
</tr>
<tr>
<td>x 0 1</td>
<td>-</td>
</tr>
<tr>
<td>x 1 1</td>
<td>-</td>
</tr>
</tbody>
</table>

Using MRS (banked register) and MSR (banked register) instructions, at PL1 this register is only accessible from PE modes other than Abort mode. In Abort mode, it is accessible as the current SPSR.
G6.2.121  SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to FIQ mode.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register SPSR_fiq is architecturally mapped to AArch64 System register SPSR_fiq.

**Attributes**

SPSR_fiq is a 32-bit register.

**Field descriptions**

The SPSR_fiq bit assignments are:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 16 15 10 9 8 7 6 5 4 3 0
N  Z  C  V  Q  J  IL  GE  IT[7:2]  E  A  I  F  T  M[3:0]
```

- **N**, bit [31]
  
  Set to the value of CPSR.N on taking an exception to FIQ mode, and copied to CPSR.N on executing an exception return operation in FIQ mode.

- **Z**, bit [30]
  
  Set to the value of CPSR.Z on taking an exception to FIQ mode, and copied to CPSR.Z on executing an exception return operation in FIQ mode.

- **C**, bit [29]
  
  Set to the value of CPSR.C on taking an exception to FIQ mode, and copied to CPSR.C on executing an exception return operation in FIQ mode.

- **V**, bit [28]
  
  Set to the value of CPSR.V on taking an exception to FIQ mode, and copied to CPSR.V on executing an exception return operation in FIQ mode.

- **Q**, bit [27]
  
  Set to the value of CPSR.Q on taking an exception to FIQ mode, and copied to CPSR.Q on executing an exception return operation in FIQ mode.

- **IT[1:0]**, bits [26:25]
  
  IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

- **J**, bit [24]
  
  RES0.
In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

**Bit [23]**
Reserved, RES0.

**PAN, bit [22]**

*In ARMv8.2 and ARMv8.1*
When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to FIQ mode, and copied to CPSR.PAN on executing an exception return operation in FIQ mode.
When ARMv8.1-PAN is not implemented, this bit is RES0.

*In ARMv8.0*
Reserved, RES0.

**Bit [21]**
Reserved, RES0.

**IL, bit [20]**
Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**
Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**
IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.
- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**
Endianness state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation
1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

**A, bit [8]**
SError interrupt mask bit. The possible values of this bit are:

0 Exception not masked.
1 Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0 Taken from A32 state.
1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>User</td>
</tr>
<tr>
<td>0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0110</td>
<td>Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)</td>
</tr>
<tr>
<td>0111</td>
<td>Abort</td>
</tr>
<tr>
<td>1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>1111</td>
<td>System</td>
</tr>
</tbody>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.

Accessing the SPSR_fiq

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;banked_reg&gt;</th>
<th>R</th>
<th>M</th>
<th>M1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPSR_fiq</td>
<td>1</td>
<td>0</td>
<td>1110</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>0 0 0</td>
<td>RW n/a RW</td>
</tr>
<tr>
<td>0 1 0</td>
<td>RW RW RW</td>
</tr>
<tr>
<td>1 1 1</td>
<td>n/a RW RW</td>
</tr>
</tbody>
</table>

Using MRS (banked register) and MSR (banked register) instructions, at PL1 this register is only accessible from PE modes other than FIQ mode. In FIQ mode, it is accessible as the current SPSR.
G6.2.122   SPSR_hyp, Saved Program Status Register (Hyp mode)

The SPSR_hyp characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Hyp mode.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states. AArch32 System register SPSR_hyp is architecturally mapped to AArch64 System register SPSR_EL2.

**Attributes**

SPSR_hyp is a 32-bit register.

**Field descriptions**

The SPSR_hyp bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>

</tr>
</tbody>
</table>

**N, bit [31]**

Set to the value of CPSR.N on taking an exception to Hyp mode, and copied to CPSR.N on executing an exception return operation in Hyp mode.

**Z, bit [30]**

Set to the value of CPSR.Z on taking an exception to Hyp mode, and copied to CPSR.Z on executing an exception return operation in Hyp mode.

**C, bit [29]**

Set to the value of CPSR.C on taking an exception to Hyp mode, and copied to CPSR.C on executing an exception return operation in Hyp mode.

**V, bit [28]**

Set to the value of CPSR.V on taking an exception to Hyp mode, and copied to CPSR.V on executing an exception return operation in Hyp mode.

**Q, bit [27]**

Set to the value of CPSR.Q on taking an exception to Hyp mode, and copied to CPSR.Q on executing an exception return operation in Hyp mode.

**IT[1:0], bits [26:25]**

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

**J, bit [24]**

RES0.
In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

**Bit [23]**

Reserved, RES0.

**PAN, bit [22]**

*In ARMv8.2 and ARMv8.1*

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to Hyp mode, and copied to CPSR.PAN on executing an exception return operation in Hyp mode. When ARMv8.1-PAN is not implemented, this bit is RES0.

*In ARMv8.0*

Reserved, RES0.

**Bit [21]**

Reserved, RES0.

**IL, bit [20]**

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.

- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is \(0b00000000\) when no IT block is active.

**E, bit [9]**

Endianness state bit. Controls the load and store endianness for data accesses:

- \(0\) Little-endian operation
- \(1\) Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

**A, bit [8]**

SError interrupt mask bit. The possible values of this bit are:

- \(0\) Exception not masked.
- \(1\) Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0 Taken from A32 state.
1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0111</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b1011</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1010</td>
<td>Hyp</td>
</tr>
<tr>
<td>0b1111</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSERVED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.

Accessing the SPSR_hyp

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;banked_reg&gt;</th>
<th>R</th>
<th>M</th>
<th>M1</th>

</tbody>
</table>

Using MRS (banked register) and MSR (banked register) instructions, this register is only accessible from Monitor mode. In Hyp mode, this register is accessible as the current SPSR.
G6.2.123   SPSR_irq, Saved Program Status Register (IRQ mode)

The SPSR_irq characteristics are:

Purpose

Holds the saved process state when an exception is taken to IRQ mode.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register SPSR_irq is architecturally mapped to AArch64 System register SPSR_irq.

Attributes

SPSR_irq is a 32-bit register.

Field descriptions

The SPSR_irq bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| N  | Z  | C  | V  | Q  | J  | IL | GE | IT[7:2] | E | A | I | F | T | M[3:0] |
| IT[1:0] | RES0 | PAN | RES0 |

N, bit [31]

Set to the value of CPSR.N on taking an exception to IRQ mode, and copied to CPSR.N on executing an exception return operation in IRQ mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to IRQ mode, and copied to CPSR.Z on executing an exception return operation in IRQ mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to IRQ mode, and copied to CPSR.C on executing an exception return operation in IRQ mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to IRQ mode, and copied to CPSR.V on executing an exception return operation in IRQ mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to IRQ mode, and copied to CPSR.Q on executing an exception return operation in IRQ mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.
In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]
Reserved, RES0.

PAN, bit [22]

**In ARMv8.2 and ARMv8.1**

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to IRQ mode, and copied to CPSR.PAN on executing an exception return operation in IRQ mode.

When ARMv8.1-PAN is not implemented, this bit is RES0.

**In ARMv8.0**
Reserved, RES0.

Bit [21]
Reserved, RES0.

IL, bit [20]
Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]
Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- **IT[7:5]** holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- **IT[4:0]** encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is \texttt{0b00000000} when no IT block is active.

E, bit [9]
Endianness state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]
SError interrupt mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:

0    Exception not masked.
1    Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0    Exception not masked.
1    Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0    Taken from A32 state.
1    Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1    Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>User</td>
</tr>
<tr>
<td>0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0110</td>
<td>Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)</td>
</tr>
<tr>
<td>0111</td>
<td>Abort</td>
</tr>
<tr>
<td>1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is constrained unpredictable, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.

Accessing the SPSR_irq

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;banked_reg&gt;</th>
<th>R</th>
<th>M</th>
<th>M1</th>
</tr>
</thead>
<tbody>
<tr>

Using MRS (banked register) and MSR (banked register) instructions, at PL1 this register is only accessible from PE modes other than IRQ mode. In IRQ mode, it is accessible as the current SPSR.
G6.2.124  SPSR_mon, Saved Program Status Register (Monitor mode)

The SPSR_mon characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Monitor mode.

**Configurations**

This register is only accessible in Secure state.

AArch32 System register SPSR_mon can be mapped to AArch64 System register SPSR_EL3, but this is not architecturally mandated.

**Attributes**

SPSR_mon is a 32-bit register.

**Field descriptions**

The SPSR_mon bit assignments are:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 16 15 10 9 8 7 6 5 4 3 0 |
|------------------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| N Z C V Q J IL GE IT[7:2] E A I F T M[3:0] |

- **N, bit [31]**
  
  Set to the value of CPSR.N on taking an exception to Monitor mode, and copied to CPSR.N on executing an exception return operation in Monitor mode.

- **Z, bit [30]**
  
  Set to the value of CPSR.Z on taking an exception to Monitor mode, and copied to CPSR.Z on executing an exception return operation in Monitor mode.

- **C, bit [29]**
  
  Set to the value of CPSR.C on taking an exception to Monitor mode, and copied to CPSR.C on executing an exception return operation in Monitor mode.

- **V, bit [28]**
  
  Set to the value of CPSR.V on taking an exception to Monitor mode, and copied to CPSR.V on executing an exception return operation in Monitor mode.

- **Q, bit [27]**
  
  Set to the value of CPSR.Q on taking an exception to Monitor mode, and copied to CPSR.Q on executing an exception return operation in Monitor mode.

- **IT[1:0], bits [26:25]**
  
  IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

- **J, bit [24]**
  
  RES0.
In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

**Bit [23]**
Reserved, RES0.

**PAN, bit [22]**

*In ARMv8.2 and ARMv8.1*
When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to Monitor mode, and copied to CPSR.PAN on executing an exception return operation in Monitor mode.
When ARMv8.1-PAN is not implemented, this bit is RES0.

*In ARMv8.0*
Reserved, RES0.

**Bit [21]**
Reserved, RES0.

**IL, bit [20]**
Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**
Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**
IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.
- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is \(0b00000000\) when no IT block is active.

**E, bit [9]**
Endianness state bit. Controls the load and store endianness for data accesses:
- 0 Little-endian operation
- 1 Big-endian operation.
Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.
If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.
Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

**A, bit [8]**
Serror interrupt mask bit. The possible values of this bit are:
- 0 Exception not masked.
- 1 Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:

0    Exception not masked.
1    Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0    Exception not masked.
1    Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0    Taken from A32 state.
1    Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1    Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>

</tbody>
</table>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.

Accessing the SPSR_mon

This register can be read using MRS (banked register) with the following syntax:

\[
\text{MRS } \langle \text{Rd}\rangle, \langle \text{banked_reg}\rangle
\]

This register can be written using MSR (banked register) with the following syntax:

\[
\text{MSR } \langle \text{banked_reg}\rangle, \langle \text{Rd}\rangle
\]
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;banked_reg&gt;</th>
<th>R</th>
<th>M</th>
<th>M1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPSR_mon</td>
<td>1</td>
<td>1</td>
<td>1100</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Using MRS (banked register) and MSR (banked register) instructions, this register is only accessible from EL3 modes other than Monitor mode. In Monitor mode, it is accessible as the current SPSR.
G6.2.125   SPSR_svc, Saved Program Status Register (Supervisor mode)

The SPSR_svc characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Supervisor mode.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register SPSR_svc is architecturally mapped to AArch64 System register SPSR_EL1.

**Attributes**

SPSR_svc is a 32-bit register.

**Field descriptions**

The SPSR_svc bit assignments are:

```
   31 30 29 28 27 26 25 24 23 22 21 20 19 16 15 10 9 8 7 6 5 4 3 0
   N  Z  C  V  Q  J  IL  GE  IT[7:2]  E  A  I  F  T  M[3:0]
   IT[1:0] RES0
   PAN RES0
```

**N, bit [31]**

Set to the value of CPSR.N on taking an exception to Supervisor mode, and copied to CPSR.N on executing an exception return operation in Supervisor mode.

**Z, bit [30]**

Set to the value of CPSR.Z on taking an exception to Supervisor mode, and copied to CPSR.Z on executing an exception return operation in Supervisor mode.

**C, bit [29]**

Set to the value of CPSR.C on taking an exception to Supervisor mode, and copied to CPSR.C on executing an exception return operation in Supervisor mode.

**V, bit [28]**

Set to the value of CPSR.V on taking an exception to Supervisor mode, and copied to CPSR.V on executing an exception return operation in Supervisor mode.

**Q, bit [27]**

Set to the value of CPSR.Q on taking an exception to Supervisor mode, and copied to CPSR.Q on executing an exception return operation in Supervisor mode.

**IT[1:0], bits [26:25]**

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

**J, bit [24]**

RES0.
In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

**Bit [23]**

Reserved, RES0.

**PAN, bit [22]**

*In ARMv8.2 and ARMv8.1*

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to Supervisor mode, and copied to CPSR.PAN on executing an exception return operation in Supervisor mode.

When ARMv8.1-PAN is not implemented, this bit is RES0.

*In ARMv8.0*

Reserved, RES0.

**Bit [21]**

Reserved, RES0.

**IL, bit [20]**

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is \(0b00000000\) when no IT block is active.

**E, bit [9]**

Endianness state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

**A, bit [8]**

SError interrupt mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:
- 0: Exception not masked.
- 1: Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
- 0: Exception not masked.
- 1: Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
- 0: Taken from A32 state.
- 1: Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:
- 1: Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>User</td>
</tr>
<tr>
<td>0b0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0b0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0b0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0b0110</td>
<td>Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)</td>
</tr>
<tr>
<td>0b0111</td>
<td>Abort</td>
</tr>
<tr>
<td>0b1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>0b1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is constrained unpredictable, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.

Accessing the SPSR_svc

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;banked_reg&gt;</th>
<th>R</th>
<th>M</th>
<th>M1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPSR_svc</td>
<td>1</td>
<td>1</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Using MRS (banked register) and MSR (banked register) instructions, at PL1 this register is only accessible from PE modes other than Supervisor mode. In Supervisor mode, it is accessible as the current SPSR.
G6.2.126 SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

**Purpose**
Holds the saved process state when an exception is taken to Undefined mode.

**Configurations**
There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register SPSR_und is architecturally mapped to AArch64 System register SPSR_und.

**Attributes**
SPSR_und is a 32-bit register.

**Field descriptions**
The SPSR_und bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>[31]</td>
<td>Set to the value of CPSR.N on taking an exception to Undefined mode, and copied to CPSR.N on executing an exception return operation in Undefined mode.</td>
</tr>
<tr>
<td>Z</td>
<td>[30]</td>
<td>Set to the value of CPSR.Z on taking an exception to Undefined mode, and copied to CPSR.Z on executing an exception return operation in Undefined mode.</td>
</tr>
<tr>
<td>C</td>
<td>[29]</td>
<td>Set to the value of CPSR.C on taking an exception to Undefined mode, and copied to CPSR.C on executing an exception return operation in Undefined mode.</td>
</tr>
<tr>
<td>V</td>
<td>[28]</td>
<td>Set to the value of CPSR.V on taking an exception to Undefined mode, and copied to CPSR.V on executing an exception return operation in Undefined mode.</td>
</tr>
<tr>
<td>Q</td>
<td>[27]</td>
<td>Set to the value of CPSR.Q on taking an exception to Undefined mode, and copied to CPSR.Q on executing an exception return operation in Undefined mode.</td>
</tr>
<tr>
<td>IT[1:0], bits [26:25]</td>
<td>IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.</td>
<td></td>
</tr>
<tr>
<td>J</td>
<td>[24]</td>
<td>RES0.</td>
</tr>
</tbody>
</table>
In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state.
ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

**Bit [23]**
Reserved, RES0.

**PAN, bit [22]**

*In ARMv8.2 and ARMv8.1*
When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to Undefined mode, and copied to CPSR.PAN on executing an exception return operation in Undefined mode.
When ARMv8.1-PAN is not implemented, this bit is RES0.

*In ARMv8.0*
Reserved, RES0.

**Bit [21]**
Reserved, RES0.

**IL, bit [20]**
Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

**GE, bits [19:16]**
Greater than or Equal flags, for parallel addition and subtraction.

**IT[7:2], bits [15:10]**
IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.
- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.
The IT field is 0b00000000 when no IT block is active.

**E, bit [9]**
Endianness state bit. Controls the load and store endianness for data accesses:
- 0 Little-endian operation
- 1 Big-endian operation.
Instruction fetches ignore this bit.
When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.
If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.
If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.
Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

**A, bit [8]**
SAbort interrupt mask bit. The possible values of this bit are:
- 0 Exception not masked.
- 1 Exception masked.
I, bit [7]

IRQ mask bit. The possible values of this bit are:
0   Exception not masked.
1   Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:
0   Exception not masked.
1   Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:
0   Taken from A32 state.
1   Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:
1   Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>User</td>
</tr>
<tr>
<td>0001</td>
<td>FIQ</td>
</tr>
<tr>
<td>0010</td>
<td>IRQ</td>
</tr>
<tr>
<td>0011</td>
<td>Supervisor</td>
</tr>
<tr>
<td>0110</td>
<td>Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)</td>
</tr>
<tr>
<td>0111</td>
<td>Abort</td>
</tr>
<tr>
<td>1011</td>
<td>Undefined</td>
</tr>
<tr>
<td>1111</td>
<td>System</td>
</tr>
</tbody>
</table>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.

Accessing the SPSR_und

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;banked_reg&gt;</th>
<th>R</th>
<th>M</th>
<th>M1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPSR_und</td>
<td>1</td>
<td>1</td>
<td>0110</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
</tbody>
</table>

Using MRS (banked register) and MSR (banked register) instructions, at PL1 this register is only accessible from PE modes other than Undefined mode. In Undefined mode, it is accessible as the current SPSR.
G6.2.127  TCMTR, TCM Type Register

The TCMTR characteristics are:

**Purpose**

Provides information about the implementation of the TCM.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

TCMTR is a 32-bit register.

**Field descriptions**

The TCMTR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

**Accessing the TCMTR**

This register can be read using MRC with the following syntax:

\[ \text{MRC} \text{ <syntax>} \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c0, 2</td>
<td>000</td>
<td>010</td>
<td>0000</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RO n/a RO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RO RO RO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RO RO</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID1==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.128 TLBIALL, TLB Invalidate All

The TLBIALL characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this instruction.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALL is a 32-bit System instruction.

**Field descriptions**

TLBIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBIALL instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c7, 0</td>
<td>000</td>
<td>000</td>
<td>1000</td>
<td>1111</td>
<td>0111</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>WO</td>
</tr>
<tr>
<td>NS</td>
<td></td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a TLBIALLIS.
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.129 TLBIALLH, TLB Invalidate All, Hyp mode

The TLBIALLH characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for the Non-secure EL2 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBIALLH is a 32-bit System instruction.

Field descriptions

TLBIALLH ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBIALLH instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c8, c7, 0</td>
<td>100</td>
<td>000</td>
<td>1000</td>
<td>1111</td>
<td>0111</td>
</tr>
</tbody>
</table>

Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS EL0 EL1 EL2 EL3</td>
<td></td>
</tr>
<tr>
<td>x x 0 - - n/a WO</td>
<td></td>
</tr>
<tr>
<td>x 0 1 - - WO WO</td>
<td></td>
</tr>
<tr>
<td>x 1 1 - n/a WO WO</td>
<td></td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.
**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.130 TLBIALLHIS, TLB Invalidate All, Hyp mode, Inner Shareable

The TLBIALLHIS characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for the Non-secure EL2 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instruction.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALLHIS is a 32-bit System instruction.

**Field descriptions**

TLBIALLHIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBIALLHIS instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c8, c3, 0</td>
<td>100</td>
<td>000</td>
<td>1000</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>-</td>
</tr>
<tr>
<td>NS</td>
<td>-</td>
</tr>
<tr>
<td>E2H</td>
<td>0</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0)$:
  - If $HSTR\_EL2.T8==1$, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and $(SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0)$:
  - If $HSTR\_EL2.T8==1$, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and $SCR\_EL3.NS == 1$:
  - If $HSTR.T8==1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.131 TLBIALLIS, TLB Invalidate All, Inner Shareable

The TLBIALLIS characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBIALLIS is a 32-bit System instruction.

Field descriptions

TLBIALLIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBIALLIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c3, 0</td>
<td>000</td>
<td>000</td>
<td>1000</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>WO</td>
</tr>
<tr>
<td>NS</td>
<td>WO</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.132 TLBIALLNSNH, TLB Invalidate All, Non-Secure Non-Hyp

The TLBIALLNSNH characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for stage 1 or stage 2 of the Non-secure PL1&0 translation regime, regardless of the associated VMID.

The invalidation only applies to the PE that executes this instruction.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALLNSNH is a 32-bit System instruction.

**Field descriptions**

TLBIALLNSNH ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBIALLNSNH instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c8, c7, 4</td>
<td>100</td>
<td>100</td>
<td>1000</td>
<td>1111</td>
<td>0111</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- - n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- - WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONstrained UNpredictable, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.133 TLBIALLNSNHIS, TLB Invalidate All, Non-Secure Non-Hyp, Inner Shareable

The TLBIALLNSNHIS characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for stage 1 or stage 2 of the Non-secure PL1&0 translation regime, regardless of the associated VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instruction.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIALLNSNHIS is a 32-bit System instruction.

**Field descriptions**

TLBIALLNSNHIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBIALLNSNHIS instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c8, c3, 4</td>
<td>100</td>
<td>100</td>
<td>1000</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- - n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- - WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.134 TLBIASID, TLB Invalidate by ASID match

The TLBIASID characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIASID is a 32-bit System instruction.

**Field descriptions**

The TLBIASID input value bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

**Executing the TLBIASID instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c7, 2</td>
<td>000</td>
<td>010</td>
<td>1000</td>
<td>1111</td>
<td>0111</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td></td>
</tr>
<tr>
<td>NS</td>
<td></td>
</tr>
</tbody>
</table>

| x   | x   | 0   | -   | WO  | n/a | WO  |
| x   | 0   | 1   | -   | WO  | WO  | WO  |
| x   | 1   | 1   | -   | n/a | WO  | WO  |

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a TLBIASIDIS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.135  TLBIASIDIS, TLB Invalidate by ASID match, Inner Shareable

The TLBIASIDIS characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instruction.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIASIDIS is a 32-bit System instruction.

**Field descriptions**

The TLBIASIDIS input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td>ASID</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

**Executing the TLBIASIDIS instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>
This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c3, 2</td>
<td>000</td>
<td>010</td>
<td>1000</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

### Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.136  TLBIIPAS2, TLB Invalidate by Intermediate Physical Address, Stage 2

The TLBIIPAS2 characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this instruction.

**Configurations**

--- **Note** ---

This System instruction is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIIPAS2 is a 32-bit System instruction.

**Field descriptions**

The TLBIIPAS2 input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:28]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
</table>

**Executing the TLBIIPAS2 instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c8, c4, 1</td>
<td>100</td>
<td>001</td>
<td>1000</td>
<td>1111</td>
<td>0100</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is UNDEFINED.

If SCR.NS is 0, this instruction is a NOP.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.137 TLBIIPAS2IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Inner Shareable

The TLBIIPAS2IS characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instruction.

**Configurations**

--- Note ---

This System instruction is not implemented in architecture versions before ARMv8.

---

**Attributes**

TLBIIPAS2IS is a 32-bit System instruction.

**Field descriptions**

The TLBIIPAS2IS input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>27-0</td>
<td>IPA[39:12]</td>
</tr>
</tbody>
</table>

**Executing the TLBIIPAS2IS instruction**

This instruction is executed using MCR with the following syntax:

\[
\text{MCR } \text{<syntax>}\]

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c8, c0, 1</td>
<td>100</td>
<td>001</td>
<td>1000</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is UNDEFINED.

If SCR.NS is 0, this instruction is a NOP.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.138  TLBIIPAS2L, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level

The TLBIIPAS2L characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this instruction.

Configurations

Note

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2L is a 32-bit System instruction.

Field descriptions

The TLBIIPAS2L input value bit assignments are:

| Bits [31:28] | Reserved, RES0. |

Executing the TLBIIPAS2L instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c8, c4, 5</td>
<td>100</td>
<td>101</td>
<td>1000</td>
<td>1111</td>
<td>0100</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is UNDEFINED.

If SCR.NS is 0, this instruction is a NOP.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.139 TLBIIPAS2LIS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, Inner Shareable

The TLBIIPAS2LIS characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

**Configurations**

--- Note ---

This System instruction is not implemented in architecture versions before ARMv8.

--- Attributes ---

TLBIIPAS2LIS is a 32-bit System instruction.

**Field descriptions**

The TLBIIPAS2LIS input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>28</td>
<td>Reserved</td>
</tr>
<tr>
<td>27</td>
<td>IPA[39:12]</td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**IPA[39:12], bits [27:0]**

Bits[39:12] of the intermediate physical address to match.

**Executing the TLBIIPAS2LIS instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c8, c0, 5</td>
<td>100</td>
<td>101</td>
<td>1000</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- - n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- - WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is **UNDEFINED**.

If SCR.NS is 0, this instruction is a **NOP**.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is **CONSTRAINED UNPREDICTABLE**, and one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction is treated as a **NOP**.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.140  TLBIMVA, TLB Invalidate by VA

The TLBIMVA characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIMVA is a 32-bit System instruction.

**Field descriptions**

The TLBIMVA input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>VA</td>
</tr>
<tr>
<td>12</td>
<td>RES0</td>
</tr>
<tr>
<td>8</td>
<td>ASID</td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.
Executing the TLBIMVA instruction

This instruction is executed using MCR with the following syntax:

\[ \text{MCR} \ <\text{syntax}> \]

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c7, 1</td>
<td>000</td>
<td>001</td>
<td>1000</td>
<td>1111</td>
<td>0111</td>
</tr>
</tbody>
</table>

Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a TLBIMVAIS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.141  TLBIMVAA, TLB Invalidate by VA, All ASID

The TLBIMVAA characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified address.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIMVAA is a 32-bit System instruction.

**Field descriptions**

The TLBIMVAA input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12 11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

**Executing the TLBIMVAA instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c7, 3</td>
<td>000</td>
<td>011</td>
<td>1000</td>
<td>1111</td>
<td>0111</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>-</td>
</tr>
<tr>
<td>x 0 1</td>
<td>-</td>
</tr>
<tr>
<td>x 1 1</td>
<td>-</td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a **TLBIMVAAIS**.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.142 TLBIMVAAIS, TLB Invalidate by VA, All ASID, Inner Shareable

The TLBIMVAAIS characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified address.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIMVAAIS is a 32-bit System instruction.

**Field descriptions**

The TLBIMVAAIS input value bit assignments are:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>VA</td>
<td>12</td>
<td>11</td>
</tr>
<tr>
<td></td>
<td>RES0</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

**Bits [11:0]**

Reserved, RES0.

**Executing the TLBIMVAAIS instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c3, 3</td>
<td>000</td>
<td>011</td>
<td>1000</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.143  TLBIMVAAL, TLB Invalidate by VA, All ASID, Last level

The TLBIMVAAL characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified address.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

Note

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVAAL is a 32-bit System instruction.

Field descriptions

The TLBIMVAAL input value bit assignments are:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>12</td>
<td>11</td>
<td>0</td>
</tr>
<tr>
<td>VA</td>
<td></td>
<td></td>
<td>RES0</td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Executing the TLBIMVAAL instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c7, 7</td>
<td>000</td>
<td>111</td>
<td>1000</td>
<td>1111</td>
<td>0111</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a TLBIMVAALIS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.144 TLBIMVAALIS, TLB Invalidate by VA, All ASID, Last level, Inner Shareable

The TLBIMVAALIS characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified address.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

**Configurations**

---

**Note**

This System instruction is not implemented in architecture versions before ARMv8.

---

**Attributes**

TLBIMVAALIS is a 32-bit System instruction.

**Field descriptions**

The TLBIMVAALIS input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Bit 12</th>
<th>Bit 11</th>
<th>Bit 10</th>
<th>Bit 9</th>
<th>Bit 8</th>
<th>Bit 7</th>
<th>Bit 6</th>
<th>Bit 5</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

**Bits [11:0]**

Reserved, RES0.

**Executing the TLBIMVAALIS instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```
This syntax uses the following encoding in the System instruction encoding space:

```
<syntax>  opc1  opc2  CRn  coproc  CRm
p15, 0, <Rt>, c8, c3, 7  000  111  1000  1111  0011
```

### Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- **When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):**
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- **When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):**
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- **When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:**
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.145  TLBIMVAH, TLB Invalidate by VA, Hyp mode

The TLBIMVAH characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are
from any level of the translation table walk that would be required for the Non-secure EL2
translation regime and used to translate the specified address.
The invalidation only applies to the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBIMVAH is a 32-bit System instruction.

Field descriptions

The TLBIMVAH input value bit assignments are:

<table>
<thead>
<tr>
<th>VA</th>
<th>RES0</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>12</td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected
by this operation.

Bits [11:0]

Reserved, RES0.

Executing the TLBIMVAH instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c8, c7, 1</td>
<td>100</td>
<td>001</td>
<td>1000</td>
<td>1111</td>
<td>0111</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is **UNDEFINED**.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is **CONSTRAINED UNPREDICTABLE**, and one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction is treated as a **NOP**.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.146 TLBIMVAHIS, TLB Invalidate by VA, Hyp mode, Inner Shareable

The TLBIMVAHIS characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are
from any level of the translation table walk that would be required for the Non-secure EL2
translation regime and used to translate the specified address.
The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that
executes this instructions.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIMVAHIS is a 32-bit System instruction.

**Field descriptions**

The TLBIMVAHIS input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected
by this operation.

**Bits [11:0]**

Reserved, RES0.

**Executing the TLBIMVAHIS instruction**

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;R&gt;, c8, c3, 1</td>
<td>100</td>
<td>001</td>
<td>1000</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is **UNDEFINED**.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is **CONSTRAINED UNPREDICTABLE**, and one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction is treated as a **NOP**.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.147 TLBIMVAIS, TLB Invalidate by VA, Inner Shareable

The TLBIMVAIS characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instruction.

**Configurations**

There are no configuration notes.

**Attributes**

TLBIMVAIS is a 32-bit System instruction.

**Field descriptions**

The TLBIMVAIS input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.
Executing the TLBIMVAIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c3, 1</td>
<td>000</td>
<td>001</td>
<td>1000</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>WO</td>
</tr>
<tr>
<td>NS</td>
<td></td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.148 TLBIMVAL, TLB Invalidate by VA, Last level

The TLBIMVAL characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

**Configurations**

This System instruction is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVAL is a 32-bit System instruction.

**Field descriptions**

The TLBIMVAL input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

**Executing the TLBIMVAL instruction**

This instruction is executed using MCR with the following syntax:

VA  
\[
\begin{array}{c}
\text{31} \\
\text{12} \\
\text{11} \\
\text{8}  \\
\text{7}  \\
\text{0}
\end{array}
\]

RES0  
\[
\begin{array}{c}
\text{31} \\
\text{12} \\
\text{11} \\
\text{8}  \\
\text{7}  \\
\text{0}
\end{array}
\]

ASID
MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c7, 5</td>
<td>000</td>
<td>101</td>
<td>1000</td>
<td>1111</td>
<td>0111</td>
</tr>
</tbody>
</table>

**Accessibility**

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>-</td>
</tr>
<tr>
<td>x 0 1</td>
<td>-</td>
</tr>
<tr>
<td>x 1 1</td>
<td>-</td>
</tr>
</tbody>
</table>

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a TLBIMVALIS.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.149 TLBIMVALH, TLB Invalidate by VA, Last level, Hyp mode

The TLBIMVALH characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from the final level of the translation table walk that would be required for the Non-secure EL2 translation regime and used to translate the specified address.

The invalidation only applies to the PE that executes this instruction.

**Configurations**

This System instruction is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVALH is a 32-bit System instruction.

**Field descriptions**

The TLBIMVALH input value bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>VA</td>
</tr>
<tr>
<td>12</td>
<td>RES0</td>
</tr>
<tr>
<td>11</td>
<td>11 0</td>
</tr>
</tbody>
</table>
```

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:0]

Reserved, RES0.

**Executing the TLBIMVALH instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

```
<syntax>   opc1  opc2  CRn  coproc  CRM
p15, 4, <Rt>, c8, c7, 5   100  101  1000  1111  0111
```
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.150 TLBIMVALHIS, TLB Invalidate by VA, Last level, Hyp mode, Inner Shareable

The TLBIMVALHIS characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from the final level of the translation table walk that would be required for the Non-secure EL2 translation regime and used to translate the specified address. The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

**Configurations**

This System instruction is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVALHIS is a 32-bit System instruction.

**Field descriptions**

The TLBIMVALHIS input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Bit 12–11</th>
<th>Bit 10</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:0]**

Reserved, RES0.

**Executing the TLBIMVALHIS instruction**

This instruction is executed using MCR with the following syntax:

```
MCR <syntax>
```

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;R&gt;, c8, c3, 5</td>
<td>100</td>
<td>101</td>
<td>1000</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>
Accessibility

The instruction is executable as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.151 TLBIMVALID, TLB Invalidate by VA, Last level, Inner Shareable

The TLBIMVALID characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instruction.

**Configurations**

This System instruction is not implemented in architecture versions before ARMv8.

**Attributes**

TLBIMVALID is a 32-bit System instruction.

**Field descriptions**

The TLBIMVALID input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>VA</td>
</tr>
<tr>
<td>12:11</td>
<td>RES0</td>
</tr>
<tr>
<td>8:7</td>
<td>ASID</td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.
Executing the TLBIMVALIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c8, c3, 5</td>
<td>000</td>
<td>101</td>
<td>1000</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

Accessibility

The instruction is executable as follows:

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
  - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
G6.2.152 TLBTR, TLB Type Register

The TLBTR characteristics are:

**Purpose**

Provides information about the TLB implementation. The register must define whether the implementation provides separate instruction and data TLBs, or a unified TLB. Normally, the IMPLEMENTATION DEFINED information in this register includes the number of lockable entries in the TLB.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

TLBTR is a 32-bit register.

**Field descriptions**

The TLBTR bit assignments are:

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td>bits [31:1]</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
<tr>
<td>nU</td>
<td>bit [0]</td>
<td>Not Unified TLB. Indicates whether the implementation has a unified TLB:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: Unified TLB. 1: Separate Instruction and Data TLBs.</td>
</tr>
</tbody>
</table>

**Accessing the TLBTR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c0, c0, 3</td>
<td>000</td>
<td>011</td>
<td>0000</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RO</td>
</tr>
<tr>
<td>NS</td>
<td></td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TID1==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
G6.2.153  TPIDRPRW, PL1 Software Thread ID Register

The TPIDRPRW characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is not visible to software executing at EL0, for OS management purposes. The PE makes no use of this register.

Configurations

AArch32 System register TPIDRPRW is architecturally mapped to AArch64 System register TPIDR_EL1[31:0].

The PE never updates this register. This means the register is always UNKNOWN on reset.

Attributes

TPIDRPRW is a 32-bit register.

Field descriptions

The TPIDRPRW bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thread ID</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDRPRW

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c13, c0, 4</td>
<td>000</td>
<td>100</td>
<td>1101</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H</td>
<td>TGE</td>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T13==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.154  TPIDRURO, PL0 Read-Only Software Thread ID Register

The TPIDRURO characteristics are:

**Purpose**

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

The PE makes no use of this register.

**Configurations**

AArch32 System register TPIDRURO is architecturally mapped to AArch64 System register TPIDRRO_EL0[31:0].

The PE never updates this register. This means the register is always UNKNOWN on reset.

**Attributes**

TPIDRURO is a 32-bit register.

**Field descriptions**

The TPIDRURO bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Thread ID</td>
</tr>
</tbody>
</table>

**Accessing the TPIDRURO**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c13, c0, 3</td>
<td>000</td>
<td>011</td>
<td>1101</td>
<td>1111</td>
<td>000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>RO n/a n/a RW</td>
<td>TPI DRURO_s</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>RO n/a n/a n/a</td>
<td>TPI DRURO ns</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>RO n/a n/a n/a</td>
<td>TPI DRURO ns</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x</td>
<td>RO n/a n/a n/a</td>
<td>TPI DRURO</td>
</tr>
<tr>

<td>RO n/a n/a n/a</td>
<td>TPI DRURO</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>RO n/a n/a n/a</td>
<td>TPI DRURO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
G6.2.155 TPIDRURW, PL0 Read/Write Software Thread ID Register

The TPIDRURW characteristics are:

**Purpose**

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

**Configurations**

AArch32 System register TPIDRURW is architecturally mapped to AArch64 System register TPIDR_EL0[31:0].

The PE never updates this register. This means the register is always UNKNOWN on reset.

**Attributes**

TPIDRURW is a 32-bit register.

**Field descriptions**

The TPIDRURW bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>Thread ID. Thread identifying information stored by software running at this Exception level.</td>
</tr>
</tbody>
</table>

**Accessing the TPIDRURW**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>

</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
G6.2.156 TTBCR, Translation Table Base Control Register

The TTBCR characteristics are:

**Purpose**

The control register for stage 1 of the PL1&0 translation regime. Its controls include:

- Where the VA range is split between addresses translated using TTBR0 and addresses translated using TTBR1.
- The translation table format used by this stage of translation.

In ARMv8.2, when the value of TTBCR.{EAE, T2E} is {1,1}, TTBCR is used with TTBCR2.

**Configurations**

AArch32 System register TTBCR is architecturally mapped to AArch64 System register TCR_EL1[31:0].

The current translation table format determines which format of the register is used.

When EL3 is using AArch32, write access to TTBCR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

Some RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 then:

- The EAE bit resets to 0 in both the Secure and the Non-secure instances of the register.
- Other reset values apply only to the Secure instance of the register.

**Attributes**

TTBCR is a 32-bit register.

**Field descriptions**

The TTBCR bit assignments are:

*For all register layouts:*

**EAE, bit [31]**

Extended Address Enable. The meanings of the possible values of this bit are:

- 0 Use the VMSA8-32 translation system with the Short-descriptor translation table format.
- 1 Use the VMSA8-32 translation system with the Long-descriptor translation table format.

*When TTBCR.EAE==0:*

![TTBCR Diagram](image)

**EAE, bit [31]**

Extended Address Enable. The meanings of the possible values of this bit are:

- 0 Use the VMSA8-32 translation system with the Short-descriptor translation table format.
When this register has an architecturally-defined reset value, this field resets to 0.

**Bits [30:6]**

Reserved, RES0.

**PD1, bit [5]**

Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1. The encoding of this bit is:

0  Perform translation table walks using TTBR1.
1  A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to 0.

**PD0, bit [4]**

Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss for an address that is translated using TTBR0. The encoding of this bit is:

0  Perform translation table walks using TTBR0.
1  A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to 0.

**Bit [3]**

Reserved, RES0.

**N, bits [2:0]**

Indicate the width of the base address held in TTBR0. In TTBR0, the base address field is bits[31:14-N]. The value of N also determines:

- Whether TTBR0 or TTBR1 is used as the base address for translation table walks.
- The size of the translation table pointed to by TTBR0.

N can take any value from 0 to 7, that is, from 0b000 to 0b111.

When N has its reset value of 0, the translation table base is compatible with ARMv5 and ARMv6.

When this register has an architecturally-defined reset value, this field resets to 0.

**When TTBCR.EAE==1:**

**EAE, bit [31]**

Extended Address Enable. The meanings of the possible values of this bit are:

1  Use the VMSAv8-32 translation system with the Long-descriptor translation table format.
When this register has an architecturally-defined reset value, this field resets to 0.

IMP DEF, bit [30]
IMPLEMENTATION DEFINED.
When this register has an architecturally-defined reset value, this field resets to 0.

SH1, bits [29:28]
Shareability attribute for memory associated with translation table walks using TTBR1. Defined values are:
00 Non-shareable
10 Outer Shareable
11 Inner Shareable
Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNpredictable, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.
When this register has an architecturally-defined reset value, this field resets to 0.

ORGN1, bits [27:26]
Outer cacheability attribute for memory associated with translation table walks using TTBR1.
00 Normal memory, Outer Non-cacheable
01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable
10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable
11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable
When this register has an architecturally-defined reset value, this field resets to 0.

IRGN1, bits [25:24]
Inner cacheability attribute for memory associated with translation table walks using TTBR1.
00 Normal memory, Inner Non-cacheable
01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable
10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable
11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable
When this register has an architecturally-defined reset value, this field resets to 0.

EPD1, bit [23]
Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1. The encoding of this bit is:
0 Perform translation table walks using TTBR1.
1 A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.
When this register has an architecturally-defined reset value, this field resets to 0.

A1, bit [22]
Selects whether TTBR0 or TTBR1 defines the ASID. The encoding of this bit is:
0 TTBR0.ASID defines the ASID.
1 TTBR1.ASID defines the ASID.
When this register has an architecturally-defined reset value, this field resets to 0.

Bits [21:19]
Reserved, RES0.
T1SZ, bits [18:16]

See *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4594* for how TTBCR,\{T1SZ, T0SZ\} determine the input address ranges and memory region sizes translated using TTBR0 and TTBR1.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [15:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0.

00  Non-shareable
10  Outer Shareable
11  Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries on page K1-6117*.

When this register has an architecturally-defined reset value, this field resets to 0.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0.

00  Normal memory, Outer Non-cacheable
01  Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable
10  Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable
11  Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable

When this register has an architecturally-defined reset value, this field resets to 0.

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0.

00  Normal memory, Inner Non-cacheable
01  Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable
10  Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable
11  Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable

When this register has an architecturally-defined reset value, this field resets to 0.

EPD0, bit [7]

Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0. The encoding of this bit is:

0  Perform translation table walks using TTBR0.
1  A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to 0.

T2E, bit [6]

In ARMv8.2

TTBCR2 Enable.

Defined values are:

0  TTBCR2 is disabled. The contents of TTBCR2 are treated as 0 for all purposes other than reading or writing the register.
TTBCR2 is enabled.

If TTBCR.EAE==0, then the behavior is as if the bit is 0.

This bit is res0 if ARMv8.2-AA32HPD is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, res0.

Bits [5:3]

Reserved, res0.

T0SZ, bits [2:0]

See Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4594 for how TTBCR.{T1SZ, T0SZ} determine the input address ranges and memory region sizes translated using TTBR0 and TTBR1.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the TTBCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c2, c0, 2</td>
<td>000</td>
<td>010</td>
<td>0010</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL3 is not implemented.</td>
<td>E2H x TGE x NS 0</td>
<td>EL0 - RW n/a n/a</td>
<td>TTBCR</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>E2H x 0 TGE 1</td>
<td>EL1 - RW RW n/a</td>
<td>TTBCR</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>E2H x 1 TGE 1</td>
<td>EL2 n/a RW n/a</td>
<td>TTBCR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>E2H x x NS 0</td>
<td>EL3 - RW n/a n/a</td>
<td>TTBCR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>E2H x 0 TGE 1</td>
<td>EL3 - RW RW n/a</td>
<td>TTBCR</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>E2H x 1 TGE 1</td>
<td>EL3 n/a RW n/a</td>
<td>TTBCR</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>E2H x 0 TGE 1</td>
<td>EL3 - RW RW RW</td>
<td>TTBCR_ns</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>E2H x 1 TGE 1</td>
<td>EL3 n/a RW RW</td>
<td>TTBCR_ns</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>E2H x x TGE 0</td>
<td>EL3 n/a n/a RW</td>
<td>TTBCR_s</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to TTBCR_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.157 TTBCR2, Translation Table Base Control Register 2

The TTBCR2 characteristics are:

**Purpose**

The second control register for stage 1 of the PL1&0 translation regime.

If ARMv8.2-AA32HPD is not implemented and ARMv8.2-TTPBHA is not implemented, then this register is not implemented and its encoding is unallocated. Otherwise:

- When the value of TTBCR.\{EAE, T2E\} is not \{1, 1\}, the contents of TTBCR2 are treated as zero for all purposes other than reading or writing the register.
- When the value of TTBCR.\{EAE, T2E\} is \{1, 1\}, TTBCR2 is used with TTBCR.

**Configurations**

AArch32 System register TTBCR2 is architecturally mapped to AArch64 System register TCR_EL1[63:32].

When EL3 is using AArch32, write access to TTBCR2(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.2.

**Attributes**

TTBCR2 is a 32-bit register.

**Field descriptions**

The TTBCR2 bit assignments are:

```
+----------------------------------+------------------+------------------+

```

**Bits [31:19]**

Reserved, RES0.

**HWU162, bit [18]**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table block or level 3 entry for pages pointed to by TTBR1 if TTBCR2.HPD1==1 and TTBCR.T2E==1.

Defined values are:

- 0: The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1: The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD1 value is 1.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.
HWU161, bit [17]
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1
translation table block or level 3 entry for pages pointed to by TTBR1 if TTBCR2.HPD1==1 and
TTBCR.T2E==1.
Defined values are:
0  The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware
    for an IMPLEMENTATION DEFINED purpose.
1  The stage 1 translation table entry block or level 3 bit can be interpreted by hardware
    for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD1 value is 1.
This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

HWU160, bit [16]
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1
translation table block or level 3 entry for pages pointed to by TTBR1 if TTBCR2.HPD1==1 and
TTBCR.T2E==1.
Defined values are:
0  The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware
    for an IMPLEMENTATION DEFINED purpose.
1  The stage 1 translation table entry block or level 3 bit can be interpreted by hardware
    for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD1 value is 1.
This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

HWU159, bit [15]
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1
translation table block or level 3 entry for pages pointed to by TTBR1 if TTBCR2.HPD1==1 and
TTBCR.T2E==1.
Defined values are:
0  The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware
    for an IMPLEMENTATION DEFINED purpose.
1  The stage 1 translation table entry block or level 3 bit can be interpreted by hardware
    for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD1 value is 1.
This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

HWU062, bit [14]
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1
translation table block or level 3 entry for pages pointed to by TTBR0 if TTBCR2.HPD0==1 and
TTBCR.T2E==1.
Defined values are:
0  The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware
    for an IMPLEMENTATION DEFINED purpose.
1  The stage 1 translation table entry block or level 3 bit can be interpreted by hardware
    for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD0 value is 1.
This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

HWU061, bit [13]
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1
translation table block or level 3 entry for pages pointed to by TTBR0 if TTBCR2.HPD0==1 and
TTBCR.T2E==1.
Defined values are:
0  The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware
    for an IMPLEMENTATION DEFINED purpose.
The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD0 value is 1.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

**HWU060, bit [12]**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table block or level 3 entry for pages pointed to by TTBR0 if TTBCR2.HPD0==1 and TTBCR.T2E==1.

Defined values are:

0  The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

1  The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD0 value is 1.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

**HWU059, bit [11]**

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table block or level 3 entry for pages pointed to by TTBR0 if TTBCR2.HPD0==1 and TTBCR.T2E==1.

Defined values are:

0  The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

1  The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD0 value is 1.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

**HPD1, bit [10]**

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the translation tables pointed to by TTBR1.

Defined values are:

0  Hierarchical permissions are enabled.

1  Hierarchical permissions are disabled if TTBCR.T2E == 1.

When disabled, the permissions are treated as if the bits are 0.

If TTBCR.T2E == 0, the hierarchical permissions are enabled.

This bit is RES0 if ARMv8.2-AA32HPD is not implemented.

**HPD0, bit [9]**

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the translation tables pointed to by TTBR0.

Defined values are:

0  Hierarchical permissions are enabled.

1  Hierarchical permissions are disabled if TTBCR.T2E == 1.

When disabled, the permissions are treated as if the bits are 0.

If TTBCR.T2E == 0, the hierarchical permissions are enabled.

This bit is RES0 if ARMv8.2-AA32HPD is not implemented.

**Bits [8:0]**

Reserved, RES0.
Accessing the TTBCR2

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c2, c0, 3</td>
<td>000</td>
<td>011</td>
<td>0010</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
<td>NS</td>
<td>EL0</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x 0 1</td>
<td>-</td>
<td>RW</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x 1 1</td>
<td>-</td>
<td>n/a</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x x 0</td>
<td>-</td>
<td>RW</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 0 1</td>
<td>-</td>
<td>RW</td>
</tr>
<tr>
<td>EL3 is not implemented.</td>
<td>x 1 1</td>
<td>-</td>
<td>n/a</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x x 0</td>
<td>-</td>
<td>RW</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 0 1</td>
<td>-</td>
<td>RW</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x 1 1</td>
<td>-</td>
<td>n/a</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x x 0</td>
<td>-</td>
<td>n/a</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to TTBCR2_s is undefined when the CP15SDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
— If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
— If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  — If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  — If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
**G6.2.158  TTBR0, Translation Table Base Register 0**

The TTBR0 characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the PL1&0 translation regime, and other information for this translation regime.

**Configurations**

AArch32 System register TTBR0 is architecturally mapped to AArch64 System register TTBR0_EL1.

- **TTBCR.EAE** determines which TTBR0 format is used:
  - **EAE==0** 32-bit format is used. TTBR0[63:32] are ignored.
  - **EAE==1** 64-bit format is used.

  When EL3 is using AArch32, write access to TTBR0(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

  Used in conjunction with the TTBCR. When the 64-bit TTBR0 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR0.

  RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TTBR0 is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

**Field descriptions**

The TTBR0 bit assignments are:

**When TTBCR.EAE==0:**

<table>
<thead>
<tr>
<th>31</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**TTB0, bits [31:7]**

Translation table base address, bits[31:x], where x is 14-(TTBCR.N). Register bits [x-1:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:7] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

**IRGN[0], bit [6]**

See the IRGN[1] description.
NOS, bit [5]
Not Outer Shareable. When the value of TTBR0.S is 1, indicates whether the memory associated with a translation table walk is Inner Shareable or Outer Shareable:
0  Memory is Outer Shareable.
1  Memory is Inner Shareable.
This bit is ignored when the value of TTBR0.S is 0.

RGN, bits [4:3]
Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:
00  Normal memory, Outer Non-cacheable.
01  Normal memory, Outer Write-Back Write-Allocate Cacheable.
10  Normal memory, Outer Write-Through Cacheable.
11  Normal memory, Outer Write-Back no Write-Allocate Cacheable.

IMP, bit [2]
The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

S, bit [1]
Shareable. Indicates whether the memory associated with the translation table walks is Non-shareable:
0  Memory is Non-shareable.
1  Memory is shareable. The TTBR0.NOS field indicates whether the memory is Inner Shareable or Outer Shareable.

IRGN[1], bit [0]
Inner region bits. IRGN[1:0] indicate the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:
00  Normal memory, Inner Non-cacheable.
01  Normal memory, Inner Write-Back Write-Allocate Cacheable.
10  Normal memory, Inner Write-Through Cacheable.
11  Normal memory, Inner Write-Back no Write-Allocate Cacheable.

Note
The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 without the Multiprocessing Extensions can run unmodified on an implementation that includes the functionality introduced by the ARMv7 Multiprocessing Extensions.

When TTBCR.EAE==1:

```
  63 56 55 48 47 1 0
RES0 ASID BADDR
```

CnP
Bits [63:56]

Reserved, RES0.

ASID, bits [55:48]

An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.

BADDR, bits [47:1]

Translation table base address, bits[47:x]. Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONstrained UNpredictable, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of TTBCR.T0SZ as follows:

- If TTBCR.T0SZ is 0 or 1, x = 5 - TTBCR.T0SZ.
- If TTBCR.T0SZ is greater than 1, x = 14 - TTBCR.T0SZ.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

CnP, bit [0]

In ARMv8.2

Common not Private. In an implementation that includes ARMv8.2-TTCNP, when TTBCR.EAE == 1, indicates whether each entry that is pointed to by TTBR0 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0.CnP is 1.

0

The translation table entries pointed to by this instance of TTBR0, for the current ASID, are permitted to differ from corresponding entries for this instance of TTBR0 for other PEs in the Inner Shareable domain. This is not affected by:

- The value of TTBR0.CnP on those other PEs.
- The value of TTBCR.EAE on those other PEs.
- The value of the current ASID or, for the Non-secure instance of TTBR0, the value of the current VMID.

1

The translation table entries pointed to by this instance of TTBR0 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0.CnP is 1 for this instance of TTBR0 and all of the following apply:

- The translation table entries are pointed to by this instance of TTBR0.
- The value of the applicable TTBCR.EAE field is 1.
- The ASID is the same as the current ASID.
- For the Non-secure instance of TTBR0, the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

--- Note ---

If the value of the TTBR0.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONstrained UNpredictable, see CONSTRAINED UNpredictable behaviors due to caching of control or data values on page K1-6101.

In an implementation that does not include ARMv8.2-TTCNP this field is RES0.
In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Accessing the TTBR0

This register can be read using MRC with the following syntax:

MRC <syntax>  

This register can be written using MCR with the following syntax:

MCR <syntax>  

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c2, c0, 0</td>
<td>000</td>
<td>000</td>
<td>0010</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>

This register can be read using MRRC with the following syntax:

MRRC <syntax>  

This register can be written using MCRR with the following syntax:

MCRR <syntax>  

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, &lt;Rt2&gt;, c2</td>
<td>0000</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H</td>
<td>TGE</td>
<td>NS</td>

<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch32.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to TTBR0_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  — If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  — If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  — If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  — If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  — If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  — If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
### G6.2.159 TTBR1, Translation Table Base Register 1

The TTBR1 characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the PL1&0 translation regime, and other information for this translation regime.

**Configurations**

AArch32 System register TTBR1 is architecturally mapped to AArch64 System register TTBR1_EL1.

TTBCR.EAE determines which TTBR1 format is used:

- EAE==0 32-bit format is used. TTBR1[63:32] are ignored.
- EAE==1 64-bit format is used.

Used in conjunction with the TTBCR. When the 64-bit TTBR1 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR1.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TTBR1 is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

**Field descriptions**

The TTBR1 bit assignments are:

*When TTBCR.EAE==0:*

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-7</td>
<td>TTB1</td>
<td>Translation table base address, bits[31:14]. Register bits [13:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:</td>
</tr>
<tr>
<td></td>
<td>RGN</td>
<td>See the RGN[1] description.</td>
</tr>
<tr>
<td></td>
<td>IMP</td>
<td>See the IMP[2] description.</td>
</tr>
<tr>
<td></td>
<td>NOS</td>
<td>See the NOS[3] description.</td>
</tr>
<tr>
<td>6</td>
<td>IRGN[0]</td>
<td>IRGN[0] bit [6] is read and modified.</td>
</tr>
</tbody>
</table>

**TTB1, bits [31:7]**

Translation table base address, bits[31:14]. Register bits [13:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [13:7] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

**IRGN[0], bit [6]**

See the IRGN[1] description.
NOS, bit [5]
Not Outer Shareable. When the value of TTBR1.S is 1, indicates whether the memory associated with a translation table walk is Inner Shareable or Outer Shareable:
0 Memory is Outer Shareable.
1 Memory is Inner Shareable.
This bit is ignored when the value of TTBR1.S is 0.

RGN, bits [4:3]
Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:
00 Normal memory, Outer Non-cacheable.
01 Normal memory, Outer Write-Back Write-Allocate Cacheable.
10 Normal memory, Outer Write-Through Cacheable.
11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

IMP, bit [2]
The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

S, bit [1]
Shareable. Indicates whether the memory associated with the translation table walks is Non-shareable:
0 Memory is Non-shareable.
1 Memory is shareable. The TTBR1.NOS field indicates whether the memory is Inner Shareable or Outer Shareable.

IRGN[1], bit [0]
Inner region bits. IRGN[1:0] indicate the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:
00 Normal memory, Inner Non-cacheable.
01 Normal memory, Inner Write-Back Write-Allocate Cacheable.
10 Normal memory, Inner Write-Through Cacheable.
11 Normal memory, Inner Write-Back no Write-Allocate Cacheable.

**Note**
The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 without the Multiprocessing Extensions can run unmodified on an implementation that includes the functionality introduced by the ARMv7 Multiprocessing Extensions.

*When TTBCE.3==1:*

```
63 56 55 48 47 1 0
RES0 ASID BADDR
```
Bits [63:56]

Reserved, RES0.

ASID, bits [55:48]

An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.

BADDR, bits [47:1]

Translation table base address, bits[47:x]. Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of TTBCR.T1SZ as follows:

- If TTBCR.T1SZ is 0 or 1, \( x = 5 - \text{TTBCR}.T1SZ \).
- If TTBCR.T1SZ is greater than 1, \( x = 14 - \text{TTBCR}.T1SZ \).

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

CnP, bit [0]

In ARMv8.2

Common not Private. In an implementation that includes ARMv8.2-TTCNP, when TTBCR.EAE ==1, indicates whether each entry that is pointed to by TTBR1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR1.CnP is 1.

0

The translation table entries pointed to by this instance of TTBR1, for the current ASID, are permitted to differ from corresponding entries for this instance of TTBR1 for other PEs in the Inner Shareable domain. This is not affected by:

- The value of TTBR1.CnP on those other PEs.
- The value of TTBCR.EAE on those other PEs.
- The value of the current ASID or, for the Non-secure instance of TTBR1, the value of the current VMID.

1

The translation table entries pointed to by this instance of TTBR1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR1.CnP is 1 for this instance of TTBR1 and all of the following apply:

- The translation table entries are pointed to by this instance of TTBR1.
- The value of the applicable TTBCR.EAE field is 1.
- The ASID is the same as the current ASID.
- For the Non-secure instance of TTBR1, the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

--- Note ---

If the value of the TTBR1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101.

In an implementation that does not include ARMv8.2-TTCNP this field is RES0.
In ARMv8.1 and ARMv8.0.

Reserved, RES0.

**Accessing the TTBR1**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c2, c0, l</td>
<td>000</td>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
  - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
  - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.160   VBAR, Vector Base Address Register

The VBAR characteristics are:

Purpose

When high exception vectors are not selected, holds the vector base address for exceptions that are
not taken to Monitor mode or to Hyp mode.

Software must program VBAR(NS) with the required initial value as part of the PE boot sequence.

Configurations

AArch32 System register VBAR is architecturally mapped to AArch64 System register

VBAR_EL1[31:0].

When EL3 is using AArch32, write access to VBAR(S) is disabled when the CP15SDISABLE
signal is asserted HIGH.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets
into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply
only to the Secure instance of the register. Otherwise, RW fields in this register reset to
architecturally UNKNOWN values.

Attributes

VBAR is a 32-bit register.

Field descriptions

The VBAR bit assignments are:

Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to
this Exception level. Bits[4:0] of an exception vector are the exception offset.

When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION
DEFINED value.

Bits [4:0]

Reserved, RES0.

Accessing the VBAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c12, c0, 0</td>
<td>000</td>
<td>000</td>
<td>1100</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H</td>
<td>TGE</td>
<td>NS</td>

<td>x</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>EL3 is using AArch64.</td>
<td>x</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

When EL3 is using AArch32, write access to VBAR_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T12==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.161 VMPIDR, Virtualization Multiprocessor ID Register

The VMPIDR characteristics are:

**Purpose**

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by Non-secure EL1 reads of MPIDR.

**Configurations**

AArch32 System register VMPIDR is architecturally mapped to AArch64 System register VMPIDR_EL2[31:0].

If EL2 is not implemented but EL3 is implemented, this register takes the value of the MPIDR.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VMPIDR is a 32-bit register.

**Field descriptions**

The VMPIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>U</td>
<td>RES0</td>
<td>Aff2</td>
<td>Aff1</td>
<td>Aff0</td>
<td>MT</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**M, bit [31]**

Indicates whether this implementation includes the functionality introduced by the ARMv7 Multiprocessing Extensions. The possible values of this bit are:

0   This implementation does not include the ARMv7 Multiprocessing Extensions functionality.
1   This implementation includes the ARMv7 Multiprocessing Extensions functionality.

In ARMv8 this bit is RES1.

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

0   Processor is part of a multiprocessor system.
1   Processor is part of a uniprocessor system.

When this register has an architecturally-defined reset value, this field resets to the value of MPIDR.U.

**Bits [29:25]**

Reserved, RES0.

**MT, bit [24]**

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. The possible values of this bit are:

0   Performance of PEs at the lowest affinity level is largely independent.
1   Performance of PEs at the lowest affinity level is very interdependent.
When this register has an architecturally-defined reset value, this field resets to the value of MPIDR.MT.

**Aff2, bits [23:16]**
Affinity level 2. The least significant affinity level field, for this PE in the system.
When this register has an architecturally-defined reset value, this field resets to the value of MPIDR.Aff2.

**Aff1, bits [15:8]**
Affinity level 1. The intermediate affinity level field, for this PE in the system.
When this register has an architecturally-defined reset value, this field resets to the value of MPIDR.Aff1.

**Aff0, bits [7:0]**
Affinity level 0. The most significant affinity level field, for this PE in the system.
When this register has an architecturally-defined reset value, this field resets to the value of MPIDR.Aff0.

**Accessing the VMPIDR**
This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>

</tr>
</tbody>
</table>

**Traps and Enables**
For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T0==1, Non-secure accesses to this register from EL1 are trapped to EL2.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T0==1, Non-secure accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HSTR.T0==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.162   VPIDR, Virtualization Processor ID Register

The VPIDR characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of MIDR.

Configurations

AArch32 System register VPIDR is architecturally mapped to AArch64 System register VPIDR_EL2.

If EL2 is not implemented but EL3 is implemented, this register takes the value of the MIDR.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VPIDR is a 32-bit register.

Field descriptions

The VPIDR bit assignments are:

<table>
<thead>
<tr>
<th>Implementer</th>
<th>Variant</th>
<th>PartNum</th>
<th>Revision</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 24 23 20 19 16 15 4 3 0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM.

Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>ASCII representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x41</td>
<td>A</td>
<td>ARM Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>B</td>
<td>Broadcom Corporation</td>
</tr>
<tr>
<td>0x43</td>
<td>C</td>
<td>Cavium Inc.</td>
</tr>
<tr>
<td>0x44</td>
<td>D</td>
<td>Digital Equipment Corporation</td>
</tr>
<tr>
<td>0x49</td>
<td>I</td>
<td>Infineon Technologies AG</td>
</tr>
<tr>
<td>0x4D</td>
<td>M</td>
<td>Motorola or Freescale Semiconductor Inc.</td>
</tr>
<tr>
<td>0x4E</td>
<td>N</td>
<td>NVIDIA Corporation</td>
</tr>
<tr>
<td>0x50</td>
<td>P</td>
<td>Applied Micro Circuits Corporation</td>
</tr>
<tr>
<td>0x51</td>
<td>Q</td>
<td>Qualcomm Inc.</td>
</tr>
<tr>
<td>0x56</td>
<td>V</td>
<td>Marvell International Ltd.</td>
</tr>
<tr>
<td>0x69</td>
<td>i</td>
<td>Intel Corporation</td>
</tr>
</tbody>
</table>
ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

When this register has an architecturally-defined reset value, this field resets to the value of MIDR.Implementer.

**Variant, bits [23:20]**

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

When this register has an architecturally-defined reset value, this field resets to the value of MIDR.Variant.

**Architecture, bits [19:16]**

The permitted values of this field are:

0001  ARMv4
0010  ARMv4T
0011  ARMv5 (obsolete)
0100  ARMv5T
0101  ARMv5TE
0110  ARMv5TEJ
0111  ARMv6
1111  Architectural features are individually identified in the ID_* registers, see Identification registers, functional group on page G4-4727.

All other values are reserved.

When this register has an architecturally-defined reset value, this field resets to the value of MIDR.Architecture.

**PartNum, bits [15:4]**

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

When this register has an architecturally-defined reset value, this field resets to the value of MIDR.PartNum.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the device.

When this register has an architecturally-defined reset value, this field resets to the value of MIDR.Revision.

### Accessing the VPIDR

This register can be read using MRC with the following syntax:

\[ \text{MRC <syntax>} \]

This register can be written using MCR with the following syntax:

\[ \text{MCR <syntax>} \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;R&gt;, c0, 0</td>
<td>100</td>
<td>000</td>
<td>0000</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>E2H</th>

<td>RW</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
<td>1</td>
<td>-</td>
<td>n/a</td>
<td>RW</td>
<td>RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T0==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T0==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T0==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.163 VTCR, Virtualization Translation Control Register

The VTCR characteristics are:

Purpose

The control register for stage 2 of the Non-secure PL1&0 translation regime.

--- Note ---

This stage of translation always uses the Long-descriptor translation table format.

Configurations

AArch32 System register VTCR is architecturally mapped to AArch64 System register VTCR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VTCR is a 32-bit register.

Field descriptions

The VTCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES1.</td>
</tr>
<tr>
<td>30:29</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>28</td>
<td>HWU62</td>
</tr>
<tr>
<td>27:24</td>
<td>SH0, SL0, S, TOSZ</td>
</tr>
</tbody>
</table>

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 2 translation table block or level 3 entry.

Defined values are:

0 The stage 2 translation table entry block or level 3 entry cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
1 The stage 2 translation table entry block or level 3 entry can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.
HWU61, bit [27]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 2 translation table block or level 3 entry.

Defined values are:

0  The stage 2 translation table entry block or level 3 entry cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
1  The stage 2 translation table entry block or level 3 entry can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

HWU60, bit [26]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 2 translation table block or level 3 entry.

Defined values are:

0  The stage 2 translation table entry block or level 3 entry cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
1  The stage 2 translation table entry block or level 3 entry can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

HWU59, bit [25]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 2 translation table block or level 3 entry.

Defined values are:

0  The stage 2 translation table entry block or level 3 entry cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
1  The stage 2 translation table entry block or level 3 entry can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

This bit is RES0 if ARMv8.2-TTPBHA is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Bits [24:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using VTTBR.

00  Non-shareable
10  Outer Shareable
11  Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.
ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using VTTBR.

- 00  Normal memory, Outer Non-cacheable
- 01  Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable
- 10  Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable
- 11  Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using VTTBR.

- 00  Normal memory, Inner Non-cacheable
- 01  Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable
- 10  Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable
- 11  Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable

SL0, bits [7:6]

Starting level for translation table walks using VTTBR.

- 00  Start at level 2
- 01  Start at level 1

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of T0SZ, then a stage 2 level 1 Translation fault is generated.

Bit [5]

Reserved, RES0.

S, bit [4]

Sign extension bit. This bit must be programmed to the value of T0SZ[3]. If it is not, then the behavior is CONSTRAINED UNPREDICTABLE and the stage 2 T0SZ value is treated as an UNKNOWN value, see Misprogramming VTCR.S on page K1-6114.

T0SZ, bits [3:0]

The size offset of the memory region addressed by VTTBR. The region size is $2^{(32-T0SZ)}$ bytes.

This field holds a four-bit signed integer value, meaning it supports values from -8 to 7.

--- Note ---

This is different from the other translation control registers, where TnSZ holds a three-bit unsigned integer, supporting values from 0 to 7.

---

If this field is programmed to a value that is not consistent with the programming of SL0 then a stage 2 level 1 Translation fault is generated.

Accessing the VTCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.2.164 VTTBR, Virtualization Translation Table Base Register

The VTTBR characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 2 of an address translation in the Non-secure PL1&0 translation regime, and other information for this translation regime.

**Configurations**

AArch32 System register VTTBR is architecturally mapped to AArch64 System register VTTBR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE reset into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VTTBR is a 64-bit register.

**Field descriptions**

The VTTBR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-56</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>55-48</td>
<td>VMID, bits</td>
</tr>
<tr>
<td>47-1</td>
<td>BADDR, bits</td>
</tr>
<tr>
<td></td>
<td>Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.</td>
</tr>
<tr>
<td></td>
<td>The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.</td>
</tr>
<tr>
<td></td>
<td>x is determined from the value of VTCR.SL0 and VTCR.T0SZ as follows:</td>
</tr>
<tr>
<td></td>
<td>If VTCR.SL0 is 00, meaning that lookup starts at level 2, then x is 14 - VTCR.T0SZ.</td>
</tr>
<tr>
<td></td>
<td>If VTCR.SL0 is 01, meaning that lookup starts at level 1, then x is 5 - VTCR.T0SZ.</td>
</tr>
<tr>
<td></td>
<td>If VTCR.SL0 is either 10 or 11 then a stage 2 level 1 Translation fault is generated. If bits[47:40] of the translation table base address are not zero, an Address size fault is generated. This field resets to a value that is architecturally UNKNOWN.</td>
</tr>
</tbody>
</table>

</tbody>
</table>
CnP, bit [0]

In ARMv8.2

Common not Private. In an implementation that includes ARMv8.2-TTCNP, indicates whether each entry that is pointed to by VTTBR is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VTTBR.CnP is 1.

0  The translation table entries pointed to by VTTBR are permitted to differ from the entries for VTTBR for other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.

1  The translation table entries pointed to by VTTBR are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of VTTBR.CnP is 1 and the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

——— Note ————

If the value of the VTTBR.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those VTTBRs do not point to the same translation table entries when the VMID value is the same as the current VMID, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101.

In an implementation that does not include ARMv8.2-TTCNP this field is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Accessing the VTTBR

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>coproc</th>
<th>CRm</th>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.3 Debug registers

This section lists the Debug System registers in AArch32 state, in alphabetic order.
G6.3.1 DBGAUTHSTATUS, Debug Authentication Status register

The DBGAUTHSTATUS characteristics are:

**Purpose**
Provides information about the state of the implementation defined authentication interface for debug.

**Configurations**
There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register DBGAUTHSTATUS is architecturally mapped to AArch64 System register DBGAUTHSTATUS_EL1.
AArch32 System register DBGAUTHSTATUS is architecturally mapped to External register DBGAUTHSTATUS_EL1.
This register is required in all implementations.

**Attributes**
DBGAUTHSTATUS is a 32-bit register.

**Field descriptions**
The DBGAUTHSTATUS bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>7-6</td>
<td>SNID, Secure non-invasive debug. Possible values of this field are:</td>
</tr>
<tr>
<td>00</td>
<td>Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.</td>
</tr>
<tr>
<td>10</td>
<td>Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.</td>
</tr>
<tr>
<td>11</td>
<td>Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.</td>
</tr>
<tr>
<td>5-4</td>
<td>SID, Secure invasive debug. Possible values of this field are:</td>
</tr>
<tr>
<td>00</td>
<td>Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.</td>
</tr>
<tr>
<td>10</td>
<td>Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.</td>
</tr>
<tr>
<td>11</td>
<td>Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.</td>
</tr>
<tr>
<td>3-2</td>
<td>NSNID, Non-secure non-invasive debug. Possible values of this field are:</td>
</tr>
<tr>
<td>00</td>
<td>Not implemented. EL3 is not implemented and the implemented Security state is Secure state.</td>
</tr>
</tbody>
</table>

...
10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

**NSID, bits [1:0]**

Non-secure invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

**Accessing the DBGAUTHSTATUS**

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c7, c14, 6</td>
<td>000</td>
<td>110</td>
<td>0111</td>
<td>1110</td>
<td>1110</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RO n/a RO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RO RO RO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RO RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, read accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.2 DBGBCR<n>, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n> characteristics are:

**Purpose**

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGBCR<n> is architecturally mapped to AArch64 System register DBGBCR<n>_EL1.

AArch32 System register DBGBCR<n> is architecturally mapped to External register DBGBCR<n>_EL1.

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGBCR<n> is a 32-bit register.

**Field descriptions**

The DBGBCR<n> bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bit assignments</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>24-23</td>
<td>BT, LBN, SSC</td>
</tr>
<tr>
<td>19-16</td>
<td>RES0, BAS</td>
</tr>
<tr>
<td>9</td>
<td>PMC, E</td>
</tr>
</tbody>
</table>

When the E field is zero, all the other fields in the register are ignored.

**Bits [31:24]**

Reserved, RES0.

**BT, bits [23:20]**

Breakpoint Type. Possible values are:

- 0000: Unlinked instruction address match.
- 0001: Linked instruction address match.
- 0010: Unlinked Context ID match.
- 0011: Linked Context ID match.
- 0100: Unlinked instruction address mismatch.
- 0101: Linked instruction address mismatch.
- 0110: Unlinked CONTEXTIDR_EL1 match (introduced in ARMv8.1).
- 0111: Linked CONTEXTIDR_EL1 match (introduced in ARMv8.1).
- 1000: Unlinked VMID match.
- 1001: Linked VMID match.
1010  Unlinked VMID and Context ID match.
1011  Linked VMID and Context ID match.
1100  Unlinked CONTEXTIDR_EL2 match (introduced in ARMv8.1).
1101  Linked CONTEXTIDR_EL2 match (introduced in ARMv8.1).
1110  Unlinked Full Context ID match (introduced in ARMv8.1).
1111  Linked Full Context ID match (introduced in ARMv8.1).

The field breaks down as follows:

- **BT[3:1]: Base type.**
  - 000  Match address. DBGBVR<\text{n}>. is the address of an instruction.
  - 001  Match Context ID. DBGBVR<\text{n}>.ContextID is a Context ID compared against CONTEXTIDR when ARMv8.1-VHE is not implemented, or not in a Host OS or a Host Application. When ARMv8.1-VHE is implemented, and in a Host OS or Host Application, the Context ID is compared against CONTEXTIDR_EL2.
  - 010  Mismatch address. DBGBVR<\text{n}>. is the address of an instruction to be stepped.
  - 011  Match CONTEXTIDR_EL1. DBGBVR<\text{n}>.ContextID is a Context ID compared against CONTEXTIDR.
  - 100  Match VMID. DBGBXVR<\text{n}>.VMID is a VMID compared against VTTBR.VMID.
  - 101  Match VMID and Context ID. DBGBVR<\text{n}>.ContextID is a Context ID compared against CONTEXTIDR, and DBGBXVR<\text{n}>.VMID is a VMID compared against VTTBR.VMID.
  - 110  Match CONTEXTIDR_EL2. DBGBXVR<\text{n}>.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.
  - 111  Match Full Context ID. DBGBVR<\text{n}>.ContextID is compared against CONTEXTIDR_EL1, and DBGBXVR<\text{n}>.ContextID2 is compared against CONTEXTIDR_EL2.

- **BT[0]: Enable linking.**

Constraints on breakpoint programming mean some values are reserved under certain conditions. For more information, see **Reserved DBGBCR<\text{n}>.BT values on page G2-4490.**

This field resets to a value that is architecturally UNKNOWN.

**LBN, bits [19:16]**

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of DBGBCR<\text{n}>.E is 0.

This field resets to a value that is architecturally UNKNOWN.

**SSC, bits [15:14]**

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint \text{n} is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the \{HMC, SSC, PMC\} fields. For more information, including the effect of programming the fields to a reserved set of values, see **Breakpoint usage constraints on page G2-4490.**

For more information on the operation of the SSC, HMC, and PMC fields, see **Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480.**

This field resets to a value that is architecturally UNKNOWN.
HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint \( n \) is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the \{HMC, SSC, PMC\} fields. For more information see the SSC, bits [15:14] description.

For more information on the operation of the SSC, HMC, and PMC fields, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-4480.

This field resets to a value that is architecturally UNKNOWN.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state.

The permitted values depend on the breakpoint type.

For Address match breakpoints, the permitted values are:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0011</td>
<td>DBGBVR(&lt;n&gt;)</td>
<td>Use for T32 instructions.</td>
</tr>
<tr>
<td>1100</td>
<td>DBGBVR(&lt;n&gt;+2)</td>
<td>Use for T32 instructions.</td>
</tr>
<tr>
<td>1111</td>
<td>DBGBVR(&lt;n&gt;)</td>
<td>Use for A32 instructions.</td>
</tr>
</tbody>
</table>

All other values are reserved. For more information, see *Reserved DBGBCR\(<n>\>.\{SSC, HMC, PMC\} values* on page G2-4491.

For more information on using the BAS field in Address Match breakpoints, see *Using the BAS field in Address Match breakpoints* on page G2-4483.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime, the permitted values are:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Step instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>-</td>
<td>Use for a match anywhere breakpoint.</td>
</tr>
<tr>
<td>0011</td>
<td>DBGBVR(&lt;n&gt;)</td>
<td>Use for stepping T32 instructions.</td>
</tr>
<tr>
<td>1100</td>
<td>DBGBVR(&lt;n&gt;+2)</td>
<td>Use for stepping T32 instructions.</td>
</tr>
<tr>
<td>1111</td>
<td>DBGBVR(&lt;n&gt;)</td>
<td>Use for stepping A32 instructions.</td>
</tr>
</tbody>
</table>

All other values are reserved. For more information, see *Reserved DBGBCR\(<n>\>.\{SSC, HMC, PMC\} values* on page G2-4491.

For more information on using the BAS field in address mismatch breakpoints, see *Using the BAS field in Address Match breakpoints* on page G2-4483.

For Context matching breakpoints, this field is RES1 and ignored.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [4:3]

Reserved, RES0.
PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480.

This field resets to a value that is architecturally UNKNOWN.

E, bit [0]

Enable breakpoint DBGBVR<n>. Possible values are:

0  Breakpoint disabled.
1  Breakpoint enabled.

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGBCR<n>

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, &lt;CRm&gt;, 5</td>
<td>000</td>
<td>101</td>
<td>0000</td>
<td>1110</td>
<td>n&lt;3:0&gt;</td>
</tr>
</tbody>
</table>

•  <CRm> is in the range c0 - c15.

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

•  Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state.

•  Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

•  Software Access debug event on page H3-5493 for accesses to this register taken to Debug state.
Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If $\text{EDSCR.TDA}==1$, $\text{DBGOSLRSR.OSLK}==0$, and halting is allowed, accesses to this register from EL1 and EL2 generate a Software Access debug event.

- When EL2 is implemented and is using AArch64 and $\text{SCR_EL3.NS} == 1$:
  - If $\text{MDCR_EL2.TDA}==1$, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and $\text{SCR_EL3.NS} == 1$:
  - If $\text{HDCR.TDA}==1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If $\text{MDCR_EL3.TDA}==1$, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.3  DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n> characteristics are:

**Purpose**

Holds a value for use in breakpoint matching, either the virtual address of an instruction or a context ID. Forms breakpoint n together with control register DBGBCR<n>. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGBVR<n> is architecturally mapped to AArch64 System register DBGBVR<n>_EL1[31:0].

AArch32 System register DBGBVR<n> is architecturally mapped to External register DBGBVR<n>_EL1[31:0].

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Note**

Writes to DBGBVR<n> do not modify DBGBVR<n>_EL1[63:32].

**Attributes**

How this register is interpreted depends on the value of DBGBCR<n>.BT.

- When DBGBCR<n>.BT is 0b0x0x, this register holds a virtual address.
- When DBGBCR<n>.BT is 0b001x, 0b101x, or 0b111x, this register holds a Context ID.

For other values of DBGBCR<n>.BT, this register is RES0.

Some breakpoints might not support Context ID comparison. For more information, see the description of the DBGDIDR.CTX_CMPs field.

**Field descriptions**

The DBGBVR<n> bit assignments are:

*When DBGBCR<n>.BT==0b0000:*

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA[31:2]</td>
<td>Bits[31:2] of the address value for comparison. This field resets to a value that is architecturally UNKNOWN.</td>
</tr>
<tr>
<td>RES0</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>
When DBGBCR<n>.BT==0b001x:

ContextID, bits [31:0]

Context ID value for comparison.

The value is compared against CONTEXTIDR in the following cases:

- The PE is in Secure state.
- EL2 is using AArch32.
- When ARMv8.1-VHE is not implemented.
- When ARMv8.1-VHE is implemented, EL2 is using AArch64, and HCR_EL2.E2H is 0.
- When ARMv8.1-VHE is implemented, EL2 is using AArch64, HCR_EL2.{E2H, TGE} is \{1, 0\}, and the PE is in Non-secure EL0 or EL1.

When ARMv8.1-VHE is implemented, EL2 is using AArch64, HCR_EL2.{E2H, TGE} is \{1, 1\} and the PE is in Non-secure EL0, the value is compared against CONTEXTIDR_EL2.

This field resets to a value that is architecturally UNKNOWN.

When DBGBCR<n>.BT==0b101x and EL2 implemented:

ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR.

This field resets to a value that is architecturally UNKNOWN.

When DBGBCR<n>.BT==0b111x and EL2 implemented:

ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL2.

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGBVR<n>

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, &lt;CRm&gt;, 4</td>
<td>000</td>
<td>100</td>
<td>0000</td>
<td>1110</td>
<td>n&lt;3:0&gt;</td>
</tr>
</tbody>
</table>

- `<CRm>` is in the range c0 - c15.

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see:

- Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state.
- Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.
- Software Access debug event on page H3-5493 for accesses to this register taken to Debug state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If EDSCR.TDA==1, DBGOSLSR.OSLK==0, and halting is allowed, accesses to this register from EL1 and EL2 generate a Software Access debug event.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.4  DBGBXVR<\(n\)>, Debug Breakpoint Extended Value Registers, \(n = 0 - 15\)

The DBGBXVR<\(n\)> characteristics are:

**Purpose**

Holds a value for use in breakpoint matching, to support VMID matching. Used in conjunction with a control register DBGBCR<\(n\)> and a value register DBGBVR<\(n\)>; where EL2 is implemented and breakpoint \(n\) supports Context matching.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGBXVR<\(n\)> is architecturally mapped to AArch64 System register DBGBVR<\(n\)>\_EL1[63:32].

AArch32 System register DBGBXVR<\(n\)> is architecturally mapped to External register DBGBVR<\(n\)>\_EL1[63:32].

**Note**

Writes to DBGBXVR<\(n\)> do not modify DBGBVR<\(n\)>\_EL1[31:0].

This register is unallocated in any of the following cases:

- Breakpoint \(n\) is not implemented.
- Breakpoint \(n\) does not support Context matching.
- EL2 is not implemented.

For more information, see the description of the DBGDIDR.CTX_CMPs field.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

How this register is interpreted depends on the value of DBGBCR<\(n\>).BT.

- When DBGBCR<\(n\>).BT is 0b10xx, this register holds a VMID.
- When DBGBCR<\(n\>).BT is 0b11xx, this register holds a Context ID.

For other values of DBGBCR<\(n\>).BT, this register is RES0.

**Field descriptions**

The DBGBXVR<\(n\)> bit assignments are:

**When DBGBCR<\(n\>).BT==0b10xx and EL2 implemented:**

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
<td>29</td>
<td>28</td>
<td>27</td>
</tr>
<tr>
<td>16</td>
<td>15</td>
<td>14</td>
<td>13</td>
<td>12</td>
</tr>
<tr>
<td>8</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
</tr>

</tbody>
</table>

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VMID[15:8]</td>
<td>VMID[7:0]</td>
</tr>
</tbody>
</table>

Reserved, RES0.

VMID[15:8], bits [15:8]

*In ARMv8.2 and ARMv8.1*

Extension to VMID[7:0]. See VMID[7:0] for more details.

This field resets to a value that is architecturally UNKNOWN.

*In ARMv8.0,*
Reserved, RES0.

**VMID[7:0], bits [7:0]**

VMID value for comparison.

The VMID is 8 bits in the following cases.
- EL2 is using AArch32.
- ARMv8.1-VMID16 is not implemented.

When ARMv8.1-VMID16 is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:
- The implementation has an 8-bit VMID.
- VTCR_EL2.VS has a value of 0.
- EL2 is using AArch32.

This field resets to a value that is architecturally UNKNOWN.

**When DBGBCR<n>.BT==0b11xx and EL2 implemented:**

<table>
<thead>
<tr>
<th>ContextID2</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

**ContextID2, bits [31:0]**

Context ID value for comparison against CONTEXTIDR_EL2.

This field resets to a value that is architecturally UNKNOWN.

**Accessing the DBGBXVR<n>**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c1, &lt;CRm&gt;, 1</td>
<td>000</td>
<td>001</td>
<td>0001</td>
<td>1110</td>
<td>n&lt;3:0&gt;</td>
</tr>
</tbody>
</table>

- <CRm> is in the range c0 - c15.
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state.

- *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state.

- *Software Access debug event* on page H3-5493 for accesses to this register taken to Debug state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If EDSCR.TDA==1, DBGOSLSR.OSLK==0, and halting is allowed, accesses to this register from EL1 and EL2 generate a Software Access debug event.

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.5 DBGCLAIMCLR, Debug Claim Tag Clear register

The DBGCLAIMCLR characteristics are:

**Purpose**

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0.

The architecture does not define any functionality for the CLAIM tag bits.

--- Note ---

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMSET register.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGCLAIMCLR is architecturally mapped to AArch64 System register DBGCLAIMCLR_EL1.

AArch32 System register DBGCLAIMCLR is architecturally mapped to External register DBGCLAIMCLR_EL1.

An implementation must include 8 CLAIM tag bits.

This register is in the Cold reset domain. See the CLAIM field description for the effect of a Cold reset on the value returned by this register. This register is not affected by a Warm reset.

**Attributes**

DBGCLAIMCLR is a 32-bit register.

**Field descriptions**

The DBGCLAIMCLR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:8]</th>
<th>RAZ/SBZ</th>
<th>CLAIM</th>
</tr>
</thead>
</table>

- **Bits [31:8]**
  - Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

- **CLAIM, bits [7:0]**
  - Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.
  - Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.
  - Writing 0 to one of these bits has no effect.
  - A cold reset clears the CLAIM tag bits to 0.

**Accessing the DBGCLAIMCLR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c7, c9, 6</td>
<td>000</td>
<td>110</td>
<td>0111</td>
<td>1110</td>
<td>1001</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>-</td>
</tr>
<tr>
<td>x 0 1</td>
<td>-</td>
</tr>
<tr>
<td>x 1 1</td>
<td>-</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.6  DBGCLAIMSET, Debug Claim Tag Set register

The DBGCLAIMSET characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.
The architecture does not define any functionality for the CLAIM tag bits.

--- Note ---
CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMCLR register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register DBGCLAIMSET is architecturally mapped to AArch64 System register DBGCLAIMSET_EL1.
AArch32 System register DBGCLAIMSET is architecturally mapped to External register DBGCLAIMSET_EL1.
An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMSET is a 32-bit register.

Field descriptions

The DBGCLAIMSET bit assignments are:

<table>
<thead>
<tr>
<th>Bit positions: 31:8</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ/SBZ</td>
<td></td>
</tr>
<tr>
<td>CLAIM</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Set CLAIM tag bits. RAO.
Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.
Writing 0 to one of these bits has no effect.
A cold reset clears the CLAIM tag bits to 0.

Accessing the DBGCLAIMSET

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c7, c8, 6</td>
<td>000</td>
<td>110</td>
<td>0111</td>
<td>1110</td>
<td>1000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RW</td>
</tr>
<tr>
<td>NS</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.7 DBGDCCINT, DCC Interrupt Enable Register

The DBGDCCINT characteristics are:

Purpose

Enables interrupt requests to be signaled based on the DCC status flags.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDCCINT is architecturally mapped to AArch64 System register MDCCINT_EL1.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGDCCINT is a 32-bit register.

Field descriptions

The DBGDCCINT bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>30</td>
<td>RX, bit [30]</td>
</tr>
<tr>
<td>29</td>
<td>TX, bit [29]</td>
</tr>
<tr>
<td>28-0</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

Bit [31]

Reserved, RES0.

RX, bit [30]

DCC interrupt request enable control for DTRRX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

0  No interrupt request generated by DTRRX.
1  Interrupt request will be generated on RXfull == 1.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

When this register has an architecturally-defined reset value, this field resets to 0.

TX, bit [29]

DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

0  No interrupt request generated by DTRTX.
1  Interrupt request will be generated on TXfull == 0.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [28:0]

Reserved, RES0.
Accessing the DBGDCCINT

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>

<td>000</td>
<td>000</td>
<td>0000</td>
<td>1110</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>-</td>
</tr>
<tr>
<td>x 0 1</td>
<td>-</td>
</tr>
<tr>
<td>x 1 1</td>
<td>-</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.8  DBGDEVID, Debug Device ID register 0

The DBGDEVID characteristics are:

Purpose

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.
This register is required in all implementations.

Attributes

DBGDEVID is a 32-bit register.

Field descriptions

The DBGDEVID bit assignments are:

<table>
<thead>
<tr>
<th>Bit Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDMask</td>
<td>Indicates the level of support for the Context ID matching breakpoint masking capability. Permitted values of this field are:</td>
</tr>
<tr>
<td>AuxRegs</td>
<td>Indicates support for Auxiliary registers. Permitted values for this field are:</td>
</tr>
<tr>
<td>DoubleLock</td>
<td>Indicates the presence of the DBGOSDLR, OS Double Lock Register. Permitted values of this field are:</td>
</tr>
<tr>
<td>VirtExtns</td>
<td>Indicates whether EL2 is implemented. Permitted values of this field are:</td>
</tr>
</tbody>
</table>

CIDMask, bits [31:28]

Indicates the level of support for the Context ID matching breakpoint masking capability. Permitted values of this field are:
- 0000  Context ID masking is not implemented.
- 0001  Context ID masking is implemented.
All other values are reserved. The value of this for ARMv8 is 0000.

AuxRegs, bits [27:24]

Indicates support for Auxiliary registers. Permitted values for this field are:
- 0000  None supported.
- 0001  Support for External Debug Auxiliary Control Register, EDACR.
All other values are reserved.

DoubleLock, bits [23:20]

Indicates the presence of the DBGOSDLR, OS Double Lock Register. Permitted values of this field are:
- 0000  The DBGOSDLR is not present.
- 0001  The DBGOSDLR is present.
All other values are reserved. The value of this for ARMv8 is 0001.

VirtExtns, bits [19:16]

Indicates whether EL2 is implemented. Permitted values of this field are:
- 0000  EL2 is not implemented.
- 0001  EL2 is implemented.
All other values are reserved.
VectorCatch, bits [15:12]
Definitions the form of Vector Catch exception implemented. Permitted values of this field are:
0000  Address matching Vector Catch exception implemented.
0001  Exception matching Vector Catch exception implemented.
All other values are reserved.

BPAddrMask, bits [11:8]
Indicates the level of support for the instruction address matching breakpoint masking capability. Permitted values of this field are:
0000  Breakpoint address masking might be implemented. If not implemented, DBGBCR\(<n>\)[28:24] is RAZ/WI.
0001  Breakpoint address masking is implemented.
1111  Breakpoint address masking is not implemented. DBGBCR\(<n>\)[28:24] is RES0.
All other values are reserved. The value of this for ARMv8 is 1111.

WPAddrMask, bits [7:4]
Indicates the level of support for the data address matching watchpoint masking capability. Permitted values of this field are:
0000  Watchpoint address masking might be implemented. If not implemented, DBGWCR\(<n>\).MASK (Address mask) is RAZ/WI.
0001  Watchpoint address masking is implemented.
1111  Watchpoint address masking is not implemented. DBGWCR\(<n>\).MASK (Address mask) is RES0.
All other values are reserved. The value of this for ARMv8 is 0001.

PCSample, bits [3:0]
Indicates the level of PC Sample-based Profiling support using external debug registers. Permitted values of this field are:
0000  Architecture-defined form of PC Sample-based Profiling not implemented using external debug registers.
0010  Only EDPCSR and EDCIDSR are implemented. This option is only permitted if EL3 and EL2 are not implemented.
0011  EDPCSR, EDCIDSR, and EDVIDSR are implemented.
All other values are reserved.
From ARMv8.2 onwards, the only permitted value is 0b0000. The architecture defines the functionality in a different set of registers, see PMDEVID.

Accessing the DBGDEVID
This register can be read using MRC with the following syntax:
MRC<syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c7, c2, 7</td>
<td>000</td>
<td>111</td>
<td>0111</td>
<td>1110</td>
<td>0010</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TE</td>
</tr>
<tr>
<td></td>
<td>NS</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RO n/a RO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RO RO RO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RO RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3_NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3_NS == 1:
  - If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, read accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.9  DBGDEVID1, Debug Device ID register 1

The DBGDEVID1 characteristics are:

Purpose

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.
This register is required in all implementations.

Attributes

DBGDEVID1 is a 32-bit register.

Field descriptions

The DBGDEVID1 bit assignments are:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>4</td>
<td>3</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>PCSROffset</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:4]

Reserved, RES0.

PCSROffset, bits [3:0]

This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in ARMv8 are:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>EDPCSR not implemented.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0010</td>
<td>EDPCSR implemented. Samples have no offset applied and do not sample the instruction set state in AArch32 state.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note

In ARMv7, a PCSROffset value of 0000 has an alternative meaning that EDPCSR is implemented and returns values that have an offset applied and indicate the Instruction set state. This implementation option is not permitted in ARMv8.

From ARMv8.2 onwards, the only permitted value is 0b0000. The architecture defines the functionality in a different set of registers, see PMDEVID.

Accessing the DBGDEVID1

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;R&gt;, c7, c1, 7</td>
<td>000</td>
<td>111</td>
<td>0111</td>
<td>1110</td>
<td>0001</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, read accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.10  DBGDEVID2, Debug Device ID register 2

The DBGDEVID2 characteristics are:

**Purpose**

Reserved for future descriptions of features of the debug implementation.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

**Attributes**

DBGDEVID2 is a 32-bit register.

**Field descriptions**

The DBGDEVID2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Accessing the DBGDEVID2**

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c7, c0, 7</td>
<td>000</td>
<td>111</td>
<td>0111</td>
<td>1110</td>
<td>0000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, read accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.11 DBGDIDR, Debug ID Register

The DBGDIDR characteristics are:

Purpose

Specifies which version of the Debug architecture is implemented, and some features of the debug implementation.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

Attributes

DBGDIDR is a 32-bit register.

Field descriptions

The DBGDIDR bit assignments are:

<table>
<thead>

</tbody>
</table>

WRPs, bits [31:28]

The number of watchpoints implemented, minus 1.

Permitted values of this field are from 0b0001 for 2 implemented watchpoints, to 0b1111 for 16 implemented watchpoints.

The value of 0b0000 is reserved.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.WRPs.

BRPs, bits [27:24]

The number of breakpoints implemented, minus 1.

Permitted values of this field are from 0b0001 for 2 implemented breakpoint, to 0b1111 for 16 implemented breakpoints.

The value of 0b0000 is reserved.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.BRPs.

CTX_CMPs, bits [23:20]

The number of breakpoints that can be used for Context matching, minus 1.

Permitted values of this field are from 0b0000 for 1 Context matching breakpoint, to 0b1111 for 16 Context matching breakpoints.

The Context matching breakpoints must be the highest addressed breakpoints. For example, if six breakpoints are implemented and two are Context matching breakpoints, they must be breakpoints 4 and 5.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.CTX_CMPs.
Version, bits [19:16]

The Debug architecture version. Defined values are:
0001 ARMv6, v6 Debug architecture.
0010 ARMv6, v6.1 Debug architecture.
0011 ARMv7, v7 Debug architecture, with baseline CP14 registers implemented.
0100 ARMv7, v7 Debug architecture, with all CP14 registers implemented.
0101 ARMv7, v7.1 Debug architecture.
0110 ARMv8, v8 Debug architecture.
0111 ARMv8.1, v8 Debug architecture, with Virtualization Host Extensions.
1000 ARMv8.2, v8.2 Debug architecture.

All other values are reserved.

• In an ARMv8.0 implementation, the only permitted value is 0110.
• In an ARMv8.1 implementation that includes ARMv8.1-VHE, the only permitted value is 0111.
• In an ARMv8.1 implementation that does not include ARMv8.1-VHE, the permitted values are 0110 and 0111.
• In an ARMv8.2 implementation, the only permitted value is 1000.

Bit [15]
Reserved, RES1.

nSUHD_imp, bit [14]

In ARMv7-A, was Secure User Halting Debug not implemented.
The value of this bit must match the value of the SE_imp bit.

Bit [13]
Reserved, RES0.

SE_imp, bit [12]

EL3 implemented. The meanings of the values of this bit are:
0 EL3 not implemented.
1 EL3 implemented.
The value of this bit must match the value of the nSUHD_imp bit.

Bits [11:0]

Reserved, RES0.

Accessing the DBGDIDR

This register can be read using MRC with the following syntax:
MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;R&gt;, c0, c0, 0</td>
<td>000</td>
<td>000</td>
<td>0000</td>
<td>1110</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>RO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>RO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>RO</td>
</tr>
</tbody>
</table>

ARM deprecates any access to this register from EL0.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If DBGDSCRx.UDCCdis==1, read accesses to this register from EL0 are trapped to Undefined mode.
  - If MDSCR_EL1.TDCC==1, read accesses to this register from EL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.3.12 DBGDRAR, Debug ROM Address Register

The DBGDRAR characteristics are:

**Purpose**

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. ARMv8 deprecates any use of this register.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states. AArch32 System register DBGDRAR is architecturally mapped to AArch64 System register MDRAR_EL1. If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

**Attributes**

DBGDRAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, bits [31:0] are read.

**Field descriptions**

The DBGDRAR bit assignments are:

*When accessing as a 32-bit register:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>ROMADDR[31:12]</td>
<td></td>
</tr>
<tr>
<td>12</td>
<td>RES0</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>Valid</td>
<td></td>
</tr>
</tbody>
</table>

**ROMADDR[31:12], bits [31:12]**

Bits [31:12] of the ROM table physical address. Bits [11:0] of the address are zero. In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

**Bits [11:2]**

Reserved, RES0.

**Valid, bits [1:0]**

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

- **00**: ROM Table address is not valid. Software must ignore ROMADDR.
- **11**: ROM Table address is valid.

Other values are reserved.

*When accessing as a 64-bit register:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>RES0</td>
<td></td>
</tr>
<tr>
<td>48</td>
<td>ROMADDR[47:12]</td>
<td></td>
</tr>
<tr>
<td>47</td>
<td>RES0</td>
<td></td>
</tr>
<tr>
<td>12</td>
<td>Valid</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:48]**

Reserved, RES0.
ROMADDR[47:12], bits [47:12]

Bits[47:12] of the ROM table physical address.

If the physical address size in bits (PAsize) is less than 48 then the register bits corresponding to ROMADDR [47:PAsize] are RES0.

Bits [11:0] of the ROM table physical address are zero.

ARM strongly recommends that bits ROMADDR[(PAsize-1):32] are zero in any system that supports AArch32 at the highest implemented Exception level.

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:
00    ROM Table address is not valid. Software must ignore ROMADDR.
11    ROM Table address is valid.

Other values are reserved.

Accessing the DBGDRAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c1, c0, 0</td>
<td>000</td>
<td>000</td>
<td>0001</td>
<td>1110</td>
<td>000</td>
</tr>
</tbody>
</table>

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, &lt;Rt2&gt;, c1</td>
<td>0000</td>
<td>1110</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0  EL1  EL2  EL3</td>
</tr>
<tr>
<td>TGE</td>
<td>RO     RO    n/a  RO</td>
</tr>
<tr>
<td>NS</td>
<td>RO     RO    RO   RO</td>
</tr>
<tr>
<td>x</td>
<td>RO     n/a   RO   RO</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If DBGDSCR_ext.UDCCdis==1, read accesses to this register from EL0 are trapped to Undefined mode.
  - If MDCR_EL1.TDCC==1, read accesses to this register from EL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDRA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDRA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
G6.3.13 **DBGDSAR, Debug Self Address Register**

The DBGDSAR characteristics are:

**Purpose**

In earlier versions of the ARM Architecture, this register defines the offset from the base address defined in DBGDRAR of the physical base address of the debug registers for the PE. ARMv8 deprecates any use of this register.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

**Attributes**

DBGDSAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, bits [31:0] are read.

**Field descriptions**

The DBGDSAR bit assignments are:

**When accessing as a 32-bit register:**

<table>
<thead>
<tr>
<th>Offset, bits [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>This register value is RAZ.</td>
</tr>
</tbody>
</table>

**When accessing as a 64-bit register:**

<table>
<thead>
<tr>
<th>Offset, bits [63:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>This register value is RAZ.</td>
</tr>
</tbody>
</table>

**Accessing the DBGDSAR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c2, c0, 0</td>
<td>000</td>
<td>000</td>
<td>0010</td>
<td>1110</td>
<td>0000</td>
</tr>
</tbody>
</table>

This register can be read using MRRC with the following syntax:

MRRC <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, &lt;Rt2&gt;, c2</td>
<td>0000</td>
<td>1110</td>
<td>0010</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If `DBGDSCRext.UDCCdis==1`, read accesses to this register from EL0 are trapped to Undefined mode.
  - If `MDSCR_EL1.TDCC==1`, read accesses to this register from EL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
  - If `MDCR_EL2.TDRA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
  - If `HDCR.TDRA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If `MDCR_EL3.TDA==1`, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
### G6.3.14 DBGDSCRext, Debug Status and Control Register, External View

The DBGDSCRext characteristics are:

#### Purpose
Main control register for the debug implementation.

#### Configurations
There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDSCRext is architecturally mapped to AArch64 System register MDSCR_EL1.

This register is required in all implementations.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

#### Attributes
DBGDSCRext is a 32-bit register.

#### Field descriptions
The DBGDSCRext bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>30</td>
<td>RXfull, bit [30]</td>
</tr>
<tr>
<td>29</td>
<td>DTRRX full. Used for save/restore of EDSCR.RXfull.</td>
</tr>
<tr>
<td>28</td>
<td>When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.</td>
</tr>
<tr>
<td>27</td>
<td>When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW and holds the value of EDSCR.RXfull.</td>
</tr>
<tr>
<td>26</td>
<td>ARM deprecates use of this bit other than for save/restore. Use DBGDSCRint to access the DTRRX full status.</td>
</tr>
<tr>
<td>25</td>
<td>Reads and writes of this bit are indirect accesses to EDSCR.RXfull.</td>
</tr>
</tbody>
</table>
The architected behavior of this field determines the value it returns after a reset.

**TXfull, bit [29]**

DTRTX full. Used for save/restore of EDSCR.TXfull.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW and holds the value of EDSCR.TXfull.

ARM deprecates use of this bit other than for save/restore. Use DBGDSCRint to access the DTRTX full status.

Reads and writes of this bit are indirect accesses to EDSCR.TXfull.

The architected behavior of this field determines the value it returns after a reset.

**Bit [28]**

Reserved, RES0.

**RXO, bit [27]**

Used for save/restore of EDSCR.RXO.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW and holds the value of EDSCR.RXO.

Reads and writes of this bit are indirect accesses to EDSCR.RXO.

The architected behavior of this field determines the value it returns after a reset.

**TXU, bit [26]**

Used for save/restore of EDSCR.TXU.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW and holds the value of EDSCR.TXU.

Reads and writes of this bit are indirect accesses to EDSCR.TXU.

The architected behavior of this field determines the value it returns after a reset.

**Bits [25:24]**

Reserved, RES0.

**INTdis, bits [23:22]**

Used for save/restore of EDSCR.INTdis.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this field is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this field is RW and holds the value of EDSCR.INTdis.

Reads and writes of this field are indirect accesses to EDSCR.INTdis.

The architected behavior of this field determines the value it returns after a reset.

**TDA, bit [21]**

Used for save/restore of EDSCR.TDA.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW and holds the value of EDSCR.TDA.
Reads and writes of this bit are indirect accesses to `EDSCR.TDA`

The architected behavior of this field determines the value it returns after a reset.

**Bit [20]**

Reserved, RES0.

**SC2, bit [19]**

*In ARMv8.1*

Used for save/restore of `EDSCR.SC2`

When `DBGOSLSR.OSLK == 0` (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When `DBGOSLSR.OSLK == 1` (the OS lock is locked), this bit is RW and holds the value of `EDSCR.SC2`.

Reads and writes of this bit are indirect accesses to `EDSCR.SC2`.

If the PC Sample-based Profiling Extension is not implemented, then this field is RES0.

*In ARMv8.2 and ARMv8.0.*

Reserved, RES0.

**NS, bit [18]**

Non-secure status. Returns the inverse of `IsSecure()`.

This bit is RO.

ARM deprecates use of this field.

**SPNIDdis, bit [17]**

Secure privileged profiling disabled status bit. This bit is RO.

Permitted values are:

0  If EL3 is implemented, profiling allowed in Secure privileged modes.
1  If EL3 is implemented, profiling prohibited in Secure privileged modes.

This field is RES0 if EL3 is not implemented.

- This field is RES1 if either:
  - EL3 is using AArch64 and the Effective value of `SCR_EL3.NS` is 1.
  - EL3 is using AArch32 and the Effective value of `SCR.NS` is 1.

- Otherwise, the field is RES0 if any of the following applies, and RES1 otherwise:
  - ARMv8.2-Debug is not implemented and `ExternalSecureNoninvasiveDebugEnabled()` returns TRUE.
  - EL3 is using AArch32 and the value of `SDCR.SPME` is 1.
  - EL3 is using AArch64 and the value of `MDCR_EL3.SPME` is 1.

ARM deprecates use of this field.

**SPIDdis, bit [16]**

Secure privileged AArch32 invasive self-hosted debug disabled status bit. This bit is RO and depends on the value of `SDCR.SPD` and the pseudocode function `AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()`.

Permitted values are:

0  Self-hosted debug enabled in Secure privileged AArch32 modes.
1  Self-hosted debug disabled in Secure privileged AArch32 modes.

This bit reads as 1 if any of the following is true and reads as 0 otherwise:

- `SDCR.SPD` has the value 30.
- `SDCR.SPD` has the value 00 and `AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()` returns FALSE.

ARM deprecates use of this field.
MDBGen, bit [15]

Monitor debug events enable. Enable Breakpoint, Watchpoint, and Vector Catch exceptions.

0  Breakpoint, Watchpoint, and Vector Catch exceptions disabled.
1  Breakpoint, Watchpoint, and Vector Catch exceptions enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

HDE, bit [14]

Used for save/restore of EDSCR.HDE.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW and holds the value of EDSCR.HDE.

Reads and writes of this bit are indirect accesses to EDSCR.HDE.

The architected behavior of this field determines the value it returns after a reset.

Bit [13]

Reserved, RES0.

UDCCdis, bit [12]

Traps EL0 accesses to the DCC registers to Undefined mode.

0  This control does not cause any instructions to be trapped.
1  EL0 accesses to the DBGDSCRint, DBGDTRRXint, DBGDTRTXint, DBGDIDR, DBGDSAR, and DBGDRAR are trapped to Undefined mode.

——— Note ————

All accesses to these registers are trapped, including LDC and STC accesses to DBGDTRTXint and DBGDTRRXint, and MRRc accesses to DBGDSAR and DBGDRAR.

Traps of EL0 accesses to the DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of EDSCR.ERR.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW and holds the value of EDSCR.ERR.

Reads and writes of this bit are indirect accesses to EDSCR.ERR.

The architected behavior of this field determines the value it returns after a reset.

MOE, bits [5:2]

Method of Entry for debug exception. When a debug exception is taken to an Exception level using AArch32, this field is set to indicate the event that caused the exception:

0001  Breakpoint
0011  Software breakpoint (BKPT) instruction
0101  Vector catch
1010  Watchpoint

This field resets to a value that is architecturally UNKNOWN.
Bits [1:0]

Reserved, RES0.

Accessing the DBGDSCRxext

This register can be read using MRC with the following syntax:

\texttt{MRC <syntax>}

This register can be written using MCR with the following syntax:

\texttt{MCR <syntax>}

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, c2, 2</td>
<td>000</td>
<td>010</td>
<td>0000</td>
<td>1110</td>
<td>0010</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

Individual fields within this register might have restricted accessibility when \texttt{DBGOSLSR.OSLK == 0} (the OS lock is unlocked.) See the field descriptions for more detail.

Traps and Enables

For a description of the prioritization of any generated exceptions, see \textit{Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344} for exceptions taken to AArch32 state and \textit{Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827} for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If \texttt{MDCR_EL2.TDA==1}, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If \texttt{HDCR.TDA==1}, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  — If \texttt{MDCR_EL3.TDA==1}, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.15 DBGDSCRint, Debug Status and Control Register, Internal View

The DBGDSCRint characteristics are:

**Purpose**
Main control register for the debug implementation. This is an internal, read-only view.

**Configurations**
There is one instance of this register that is used in both Secure and Non-secure states.
This register is required in all implementations.
DBGDSCRint. {NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE} are UNKNOWN when the register is accessed at EL0. However, although these values are not accessible at EL0 by instructions that are neither UNPREDICTABLE nor return UNKNOWN values, it is permissible for an implementation to return the values of DBGDSCRext. {NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE} for these fields at EL0.
It is also permissible for an implementation to return the same values as defined for a read of DBGDSCRint at EL1 or above. (This is the case even if the implementation does not support AArch32 at EL1 or above.)

**Attributes**
DBGDSCRint is a 32-bit register.

**Field descriptions**
The DBGDSCRint bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>30</td>
<td>RXfull</td>

</tbody>
</table>

Reserved, RES0.

**Bit [30]**
DTRRX full. Read-only view of the equivalent bit in the EDSCR.

**Bit [29]**
DTRTX full. Read-only view of the equivalent bit in the EDSCR.

**Bits [28:19]**
Reserved, RES0.

**Bit [18]**
Non-secure status.
Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

**Bit [17]**
Secure privileged non-invasive debug disable.
Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

**SPIDdis, bit [16]**
Secure privileged invasive debug disable.
Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

**MDBGen, bit [15]**
Monitor debug events enable.
Read-only view of the equivalent bit in the DBGDSCRext.

**Bits [14:13]**
Reserved, RES0.

**UDCCdis, bit [12]**
User mode access to Debug Communications Channel disable.
Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

**Bits [11:6]**
Reserved, RES0.

**MOE, bits [5:2]**
Method of Entry for debug exception. When a debug exception is taken to an Exception level using AArch32, this field is set to indicate the event that caused the exception:

- 0001 Breakpoint
- 0011 Software breakpoint (BKPT) instruction
- 0101 Vector catch
- 1010 Watchpoint

Read-only view of the equivalent bit in the DBGDSCRext.

**Bits [1:0]**
Reserved, RES0.

**Accessing the DBGDSCRint**
This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, c1, 0</td>
<td>000</td>
<td>000</td>
<td>0000</td>
<td>1110</td>
<td>0001</td>
</tr>
</tbody>
</table>
**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>RO RO n/a RO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>RO RO RO RO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>RO n/a RO RO</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If DBGDSCRext.UDCC=1, read accesses to this register from EL0 are trapped to Undefined mode.
  - If MDSCR_EL1.TDCC==1, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
### G6.3.16 DBGDTRRXext, Debug OS Lock Data Transfer Register, Receive, External View

The DBGDTRRXext characteristics are:

**Purpose**

Used for save/restore of DBGDTRRXint. It is a component of the Debug Communications Channel.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDTRRXext is architecturally mapped to AArch64 System register OSDTRRX_EL1.

**Attributes**

DBGDTRRXext is a 32-bit register.

**Field descriptions**

The DBGDTRRXext bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:0]</td>
<td>Update DTRRX without side-effect.</td>
</tr>
</tbody>
</table>

Updates to this register update the value in DTRRX and do not change RXfull.

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

This field resets to a value that is architecturally UNKNOWN.

**Accessing the DBGDTRRXext**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

```
<syntax> opc1 opc2 CRn coproc CRm

p14, 0, <Rt>, c0, c0, 2 000 010 0000 1110 0000
```
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>-</td>
</tr>
<tr>
<td>x 0 1</td>
<td>-</td>
</tr>
<tr>
<td>x 1 1</td>
<td>-</td>
</tr>
</tbody>
</table>

ARM deprecates reads and writes of DBGDTRRXext through the System register interface when the OS lock is unlocked.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
**G6.3.17 DBGDTRRXint, Debug Data Transfer Register, Receive**

The DBGDTRRXint characteristics are:

**Purpose**

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. It is a component of the Debug Communications Channel.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDTRRXint is architecturally mapped to AArch64 System register DBGDTRRX_EL0.

AArch32 System register DBGDTRRXint is architecturally mapped to External register DBGDTRRX_EL0.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGDTRRXint is a 32-bit register.

**Field descriptions**

The DBGDTRRXint bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Update DTRRX</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Accessing the DBGDTRRXint

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, c5, 0</td>
<td>000</td>
<td>000</td>
<td>0000</td>
<td>1110</td>
<td>0101</td>
</tr>
</tbody>
</table>

Data can be stored to memory from this register using STC.
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RO</td>
</tr>
<tr>
<td>NS</td>
<td>RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules, in Non-debug state:

- In both security states, and not dependent on other bits:
  - If DBGDSCRext.UDCCdis==1, read accesses to this register from EL0 are trapped to Undefined mode.
  - If MDSCR_EL1.TDCC==1, read accesses to this register from EL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

Note

Read accesses to this register are not trapped in Debug state.
G6.3.18 DBGDTRTXext, Debug OS Lock Data Transfer Register, Transmit

The DBGDTRTXext characteristics are:

Purpose

Used for save/restore of DBGDTRTXint. It is a component of the Debug Communication Channel.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDTRTXext is architecturally mapped to AArch64 System register OSDTRTX_EL1.

Attributes

DBGDTRTXext is a 32-bit register.

Field descriptions

The DBGDTRTXext bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:0]</td>
<td>Return DTRTX without side-effect</td>
</tr>
</tbody>
</table>

Bits [31:0]

Return DTRTX without side-effect.

Reads of this register return the value in DTRTX and do not change TXfull.

 Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRTXext

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, c3, 2</td>
<td>000</td>
<td>010</td>
<td>0000</td>
<td>1110</td>
<td>0011</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

ARM deprecates reads and writes of DBGDTRTXext through the System register interface when the OS lock is unlocked.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.19 DBGDTRTXint, Debug Data Transfer Register, Transmit

The DBGDTRTXint characteristics are:

**Purpose**
Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. It is a component of the Debug Communication Channel.

**Configurations**
There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register DBGDTRTXint is architecturally mapped to AArch64 System register DBGDTRTX_EL0.
AArch32 System register DBGDTRTXint is architecturally mapped to External register DBGDTRTX_EL0.
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**
DBGDTRTXint is a 32-bit register.

**Field descriptions**
The DBGDTRTXint bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>Return DTRTX</td>
</tr>
</tbody>
</table>

If TXfull is set to 0, then writes of this register update the value in DTRTX and set TXfull to 1.
For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.
This field resets to a value that is architecturally UNKNOWN.

**Accessing the DBGDTRTXint**
This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, c5, 0</td>
<td>000</td>
<td>000</td>
<td>0000</td>
<td>1110</td>
<td>0101</td>
</tr>
</tbody>
</table>

Data can be loaded from memory into this register using LDC (immediate) and LDC (literal).
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>WO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules, in Non-debug state:

- In both security states, and not dependent on other bits:
  - If DBGDSCRex.udcdis==1, write accesses to this register from EL0 are trapped to Undefined mode.
  - If MDSCR_EL1.tdccc==1, write accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.tdca==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDRC.TDCA==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.tdca==1, write accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

——— Note ————

Write accesses to this register are not trapped in Debug state.
G6.3.20 DBGOSDLR, Debug OS Double Lock Register

The DBGOSDLR characteristics are:

**Purpose**
Locks out the external debug interface.

**Configurations**
There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSDLR is architecturally mapped to AArch64 System register OSDLR_EL1.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
DBGOSDLR is a 32-bit register.

**Field descriptions**
The DBGOSDLR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:1</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>0</td>
<td>DLK, OS Double Lock control bit. Possible values are:</td>
</tr>
<tr>
<td>0</td>
<td>OS Double Lock unlocked.</td>
</tr>
<tr>
<td>1</td>
<td>OS Double Lock locked, if DBGPRCR.CORENPDRO (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state. When this register has an architecturally-defined reset value, this field resets to 0.</td>
</tr>
</tbody>
</table>

**Accessing the DBGOSDLR**
This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c1, c3, 4</td>
<td>000</td>
<td>100</td>
<td>0001</td>
<td>1110</td>
<td>0011</td>
</tr>
</tbody>
</table>
Accessibility
The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

Traps and Enables
For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDOSA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.21   DBGOSECCR, Debug OS Lock Exception Catch Control Register

The DBGOSECCR characteristics are:

Purpose

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register DBGOSECCR is architecturally mapped to AArch64 System register OSECCR_EL1.
AArch32 System register DBGOSECCR is architecturally mapped to External register EDECCR.
If OSLSR.OSLK == 0 then DBGOSECCR returns an UNKNOWN value on reads and ignores writes.

Attributes

DBGOSECCR is a 32-bit register.

Field descriptions

The DBGOSECCR bit assignments are:

*When OSLSR.OSLK==1:*

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>EDECCR</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.
Reads or writes to this field are indirect accesses to EDECCR.

Accessing the DBGOSECCR

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, c6, 2</td>
<td>000</td>
<td>010</td>
<td>0000</td>
<td>1110</td>
<td>0110</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td></td>
</tr>
<tr>
<td>NS</td>
<td>-</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
**G6.3.22 DBGOSLAR, Debug OS Lock Access Register**

The DBGOSLAR characteristics are:

**Purpose**

Provides a lock for the debug registers. The OS lock also disables some Software debug events.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSLAR is architecturally mapped to AArch64 System register OSLAR_EL1.

AArch32 System register DBGOSLAR is architecturally mapped to External register OSLAR_EL1.

**Attributes**

DBGOSLAR is a 32-bit register.

**Field descriptions**

The DBGOSLAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>OS Lock Access</td>
</tr>
</tbody>
</table>

OS Lock Access. Writing the value 0xC5ACCE55 to the DBGOSLAR sets the OS lock to 1. Writing any other value sets the OS lock to 0.

Use DBGOSLSR.OSLK to check the current status of the lock.

**Accessing the DBGOSLAR**

This register can be written using MCR with the following syntax:

\[\text{MCR } \text{<syntax>}\]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c1, c0, 4</td>
<td>000</td>
<td>100</td>
<td>0001</td>
<td>1110</td>
<td>000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- WO n/a WO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- WO WO WO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a WO WO</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

• When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If MDCR_EL2.TDOSA==1, Non-secure write accesses to this register from EL1 are trapped to EL2 using AArch64.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCCR.TDOSA==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.

• When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TDOSA==1, write accesses to this register from EL1 and EL2 are trapped to EL3 using AArch64.
G6.3.23  DBGOSLSR, Debug OS Lock Status Register

The DBGOSLSR characteristics are:

**Purpose**

Provides status information for the OS lock.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSLSR is architecturally mapped to AArch64 System register OSLR_EL1.

The OS lock status is also visible in the external debug interface through EDPRSR.

This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Cold reset RW fields in this register reset to architecturally **UNKNOWN** values. The register is not affected by a Warm reset.

**Attributes**

DBGOSLSR is a 32-bit register.

**Field descriptions**

The DBGOSLSR bit assignments are:

```
+---------+---+---+---+---+
|  31     | 4 3 2 1 0 |
| RES0    | OSLM[0]   |
|         | OSLK      |
|         | nTT       |
|         | OSLM[1]   |
```

**Bits [31:4]**

Reserved, RES0.

**OSLM[1] , bit [3]**

See below for description of the OSLM field.

**nTT, bit [2]**

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

**OSLK, bit [1]**

OS Lock Status. The possible values are:

0  OS lock unlocked.

1  OS lock locked.

The OS lock is locked and unlocked by writing to the OS Lock Access Register.

When this register has an architecturally-defined reset value, this field resets to 1.
OSLM[0], bit [0]
OS lock model implemented. Identifies the form of OS save and restore mechanism implemented.
In ARMv8 these bits are as follows:
10 OS lock implemented. DBGOSRR not implemented.
All other values are reserved.

Accessing the DBGOSLSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c1, c1, 4</td>
<td>000</td>
<td>100</td>
<td>0001</td>
<td>1110</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>E2H</th>
<th>TGE</th>
<th>NS</th>
<th>EL0</th>
<th>EL1</th>
<th>EL2</th>
<th>EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>x</td>
<td>0</td>
<td>-</td>
<td>RO</td>
<td>n/a</td>
<td>RO</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
<td>1</td>
<td>-</td>
<td>RO</td>
<td>RO</td>
<td>RO</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
<td>1</td>
<td>-</td>
<td>n/a</td>
<td>RO</td>
<td>RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDOSA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDOSA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDOSA==1, read accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.24   DBGPRCR, Debug Power Control Register

The DBGPRCR characteristics are:

**Purpose**
Controls behavior of the PE on powerdown request.

**Configurations**
There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register DBGPRCR is architecturally mapped to AArch64 System register DBGPRCR_EL1.
Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register.
The other bits in these registers are not mapped to each other.
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**
DBGPRCR is a 32-bit register.

**Field descriptions**
The DBGPRCR bit assignments are:

31 1 0

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CORENPDRQ</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:1]**
Reserved, RES0.

**CORENPDRQ, bit [0]**
Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:
0 If the system responds to a powerdown request, it powers down Core power domain.
1 If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

Writes to this bit are permitted regardless of the state of the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request Core no powerdown regardless of whether invasive debug is permitted.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state.

**Accessing the DBGPRCR**
This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, cl, c4, 4</td>
<td>000</td>
<td>100</td>
<td>0001</td>
<td>1110</td>
<td>0100</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDOSA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
**G6.3.25  DBGVCR, Debug Vector Catch Register**

The DBGVCR characteristics are:

**Purpose**

Controls Vector Catch debug events.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGVCR is architecturally mapped to AArch64 System register DBGVCR32_EL2.

This register is required in all implementations.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGVCR is a 32-bit register.

**Field descriptions**

The DBGVCR bit assignments are:

*When EL3 implemented and using AArch32:*

Reserved, RES0.

**MF, bit [15]**
FIQ vector catch enable in Monitor mode.
The exception vector offset is 0x1C.
This field resets to a value that is architecturally UNKNOWN.

**MI, bit [14]**
IRQ vector catch enable in Monitor mode.
The exception vector offset is 0x18.
This field resets to a value that is architecturally UNKNOWN.

**Bit [13]**
Reserved, RES0.

**MD, bit [12]**
Data Abort vector catch enable in Monitor mode.
The exception vector offset is 0x10.
This field resets to a value that is architecturally UNKNOWN.

**MP, bit [11]**
Prefetch Abort vector catch enable in Monitor mode.
The exception vector offset is 0x0C.
This field resets to a value that is architecturally UNKNOWN.

**MS, bit [10]**
Secure Monitor Call (SMC) vector catch enable in Monitor mode.
The exception vector offset is 0x08.
This field resets to a value that is architecturally UNKNOWN.

**Bits [9:8]**
Reserved, RES0.
SF, bit [7]

FIQ vector catch enable in Secure state.
The exception vector offset is $0x1C$.
This field resets to a value that is architecturally UNKNOWN.

SI, bit [6]

IRQ vector catch enable in Secure state.
The exception vector offset is $0x18$.
This field resets to a value that is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.
The exception vector offset is $0x10$.
This field resets to a value that is architecturally UNKNOWN.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.
The exception vector offset is $0x0C$.
This field resets to a value that is architecturally UNKNOWN.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is $0x08$.
This field resets to a value that is architecturally UNKNOWN.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.
The exception vector offset is $0x04$.
This field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

When EL3 implemented and using AArch64:

![Diagram of AArch32 System Register](attachment:image.png)
NSF, bit [31]
FIQ vector catch enable in Non-secure state.
The exception vector offset is 0x1C.
This field resets to a value that is architecturally UNKNOWN.

NSI, bit [30]
IRQ vector catch enable in Non-secure state.
The exception vector offset is 0x18.
This field resets to a value that is architecturally UNKNOWN.

Bit [29]
Reserved, RES0.

NSD, bit [28]
Data Abort vector catch enable in Non-secure state.
The exception vector offset is 0x10.
This field resets to a value that is architecturally UNKNOWN.

NSP, bit [27]
Prefetch Abort vector catch enable in Non-secure state.
The exception vector offset is 0x0C.
This field resets to a value that is architecturally UNKNOWN.

NSS, bit [26]
Supervisor Call (SVC) vector catch enable in Non-secure state.
The exception vector offset is 0x08.
This field resets to a value that is architecturally UNKNOWN.

NSU, bit [25]
Undefined Instruction vector catch enable in Non-secure state.
The exception vector offset is 0x04.
This field resets to a value that is architecturally UNKNOWN.

Bits [24:8]
Reserved, RES0.

SF, bit [7]
FIQ vector catch enable in Secure state.
The exception vector offset is 0x1C.
This field resets to a value that is architecturally UNKNOWN.

SI, bit [6]
IRQ vector catch enable in Secure state.
The exception vector offset is 0x18.
This field resets to a value that is architecturally UNKNOWN.

Bit [5]
Reserved, RES0.

SD, bit [4]
Data Abort vector catch enable in Secure state.
The exception vector offset is 0x10.
This field resets to a value that is architecturally **UNKNOWN**.

**SP, bit [3]**

Prefetch Abort vector catch enable in Secure state.
The exception vector offset is 0x0c.
This field resets to a value that is architecturally **UNKNOWN**.

**SS, bit [2]**

Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is 0x08.
This field resets to a value that is architecturally **UNKNOWN**.

**SU, bit [1]**

Undefined Instruction vector catch enable in Secure state.
The exception vector offset is 0x04.
This field resets to a value that is architecturally **UNKNOWN**.

**Bit [0]**

Reserved, RES0.

**Bits [31:8]**

Reserved, RES0.

**F, bit [7]**

FIQ vector catch enable.
The exception vector offset is 0x1c.
This field resets to a value that is architecturally **UNKNOWN**.

**I, bit [6]**

IRQ vector catch enable.
The exception vector offset is 0x18.
This field resets to a value that is architecturally **UNKNOWN**.

**Bit [5]**

Reserved, RES0.

**D, bit [4]**

Data Abort vector catch enable.
The exception vector offset is 0x10.
This field resets to a value that is architecturally **UNKNOWN**.

**P, bit [3]**

Prefetch Abort vector catch enable.
The exception vector offset 0x0C.
This field resets to a value that is architecturally UNKNOWN.

**S, bit [2]**
Supervisor Call (SVC) vector catch enable.
The exception vector offset is 0x08.
This field resets to a value that is architecturally UNKNOWN.

**U, bit [1]**
Undefined Instruction vector catch enable.
The exception vector offset is 0x04.
This field resets to a value that is architecturally UNKNOWN.

**Bit [0]**
Reserved, RES0.

**Accessing the DBGVCR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, c7, 0</td>
</tr>
<tr>
<td>opc1</td>
</tr>
<tr>
<td>000</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td></td>
</tr>
<tr>
<td>NS</td>
<td></td>
</tr>
<tr>
<td></td>
<td>RW</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

• When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.26  DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n> characteristics are:

**Purpose**

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGWCR<n> is architecturally mapped to AArch64 System register DBGWCR<n>_EL1.

AArch32 System register DBGWCR<n> is architecturally mapped to External register DBGWCR<n>_EL1.

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGWCR<n> is a 32-bit register.

**Field descriptions**

The DBGWCR<n> bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>29</th>
<th>28</th>
<th>24</th>
<th>23</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>12</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td>MASK</td>
<td>RES0</td>
<td>LBN</td>
<td>SSC</td>
<td>BAS</td>
<td>LSC</td>
<td>PAC</td>
<td>E</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When the E field is zero, all the other fields in the register are ignored.

**Bits [31:29]**

Reserved, RES0.

**MASK, bits [28:24]**

Address mask. Only objects up to 2GB can be watched using a single mask.

- **0000**: No mask.
- **0001**: Reserved.
- **0010**: Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0x7FFFFFFF mask for address).

This field resets to a value that is architecturally UNKNOWN.
Bits [23:21]
Reserved, RES0.

WT, bit [20]
Watchpoint type. Possible values are:
0 Unlinked data address match.
1 Linked data address match.
This field resets to a value that is architecturally UNKNOWN.

LBN, bits [19:16]
Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.
This field resets to a value that is architecturally UNKNOWN.

SSC, bits [15:14]
Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.
For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-4499.
This field resets to a value that is architecturally UNKNOWN.

HMC, bit [13]
Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.
For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-4499.
This field resets to a value that is architecturally UNKNOWN.

BAS, bits [12:5]
Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n> is being watched.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxxxxxx1</td>
<td>Match byte at DBGWVR&lt;n&gt;</td>
</tr>
<tr>
<td>xxxxxxxl</td>
<td>Match byte at DBGWVR&lt;n&gt;+1</td>
</tr>
<tr>
<td>xxxxx1xx</td>
<td>Match byte at DBGWVR&lt;n&gt;+2</td>
</tr>
<tr>
<td>xxxxx1xxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+3</td>
</tr>
</tbody>
</table>

In cases where DBGWVR<n> addresses a double-word:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description, if DBGWVR&lt;n&gt;[2] == 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxx1xxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+4</td>
</tr>
<tr>
<td>xx1xxxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+5</td>
</tr>
<tr>
<td>x1xxxxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+6</td>
</tr>
<tr>
<td>lxxxxxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+7</td>
</tr>
</tbody>
</table>
If DBGWVR<\texttt{n}>[2] \(= 1\), only BAS[3:0] are used and BAS[7:4] are ignored. ARM deprecates setting DBGWVR<\texttt{n}>[2] \(= 1\).

The valid values for BAS are non-zero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See Reserved DBGWCR<\texttt{n}>, BAS values on page G2-4507.

This field resets to a value that is architecturally UNKNOWN.

**LSC, bits [4:3]**

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

- 01 Match instructions that load from a watchpointed address.
- 10 Match instructions that store to a watchpointed address.
- 11 Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

This field resets to a value that is architecturally UNKNOWN.

**PAC, bits [2:1]**

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint \(n\) is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-4499.

This field resets to a value that is architecturally UNKNOWN.

**E, bit [0]**

Enable watchpoint \(n\). Possible values are:

- 0 Watchpoint disabled.
- 1 Watchpoint enabled.

This field resets to a value that is architecturally UNKNOWN.

**Accessing the DBGWCR<\texttt{n}>**

This register can be read using MRC with the following syntax:

\[
\text{MRC} <\text{syntax}> 
\]

This register can be written using MCR with the following syntax:

\[
\text{MCR} <\text{syntax}> 
\]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, &lt;CRm&gt;, 7</td>
<td>000</td>
<td>111</td>
<td>0000</td>
<td>1110</td>
<td>(n&lt;3:0&gt;)</td>
</tr>
</tbody>
</table>

- \(<\text{CRm}>\) is in the range \(c0 - c15\).
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>- RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>- RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>- n/a RW RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state.

- *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state.

- *Software Access debug event on page H3-5493* for accesses to this register taken to Debug state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If EDSCR.TDA==1, DBGOSLSR.OSLK==0, and halting is allowed, accesses to this register from EL1 and EL2 generate a Software Access debug event.

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
DBGWFAR, Debug Watchpoint Fault Address Register

The DBGWFAR characteristics are:

Purpose

Previously returned information about the address of the instruction that accessed a watchpointed address. Is now deprecated and RES0.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

DBGWFAR is a 32-bit register.

Field descriptions

The DBGWFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

Bits [31:0]

Reserved, RES0.

Accessing the DBGWFAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, c6, 0</td>
<td>000</td>
<td>000</td>
<td>0000</td>
<td>1110</td>
<td>0110</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>

<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.28 DBGWVR<\(n\)>, Debug Watchpoint Value Registers, \(n = 0 - 15\)

The DBGWVR<\(n\)> characteristics are:

**Purpose**

Holds a data address value for use in watchpoint matching. Forms watchpoint \(n\) together with control register DBGWCR<\(n\)>.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGWVR<\(n\)> is architecturally mapped to AArch64 System register DBGWVR<\(n\)>._EL1[31:0].

AArch32 System register DBGWVR<\(n\)> is architecturally mapped to External register DBGWVR<\(n\)>._EL1[31:0].

If breakpoint \(n\) is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGWVR<\(n\)> is a 32-bit register.

**Field descriptions**

The DBGWVR<\(n\)> bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>VA</td>
</tr>
<tr>
<td>2-0</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**VA, bits [31:2]**

Bits[31:2] of the address value for comparison.

ARM deprecates setting DBGWVR<\(n\)>[2] == 1.

This field resets to a value that is architecturally UNKNOWN.

**Bits [1:0]**

Reserved, RES0.

**Accessing the DBGWVR<\(n\)>**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p14, 0, &lt;Rt&gt;, c0, &lt;CRm&gt;, 6</td>
<td>000</td>
<td>110</td>
<td>0000</td>
<td>1110</td>
<td>n&lt;3:0&gt;</td>
</tr>
</tbody>
</table>

- <CRm> is in the range c0 - c15.

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see:

- *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state.
- *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state.
- *Software Access debug event* on page H3-5493 for accesses to this register taken to Debug state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If ESCR.TDA==1, DBGOSLRS.OSLK==0, and halting is allowed, accesses to this register from EL1 and EL2 generate a Software Access debug event.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.3.29   DLR, Debug Link Register

The DLR characteristics are:

**Purpose**

In Debug state, holds the address to restart from.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states. AArch32 System register DLR is architecturally mapped to AArch64 System register DLR_EL0[31:0].

**Attributes**

DLR is a 32-bit register.

**Field descriptions**

The DLR bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:0</td>
<td>Restart address</td>
</tr>
</tbody>
</table>

**Accessing the DLR**

This register can be read using MRC with the following syntax:

\[ \text{MRC } \text{<syntax>} \]

This register can be written using MCR with the following syntax:

\[ \text{MCR } \text{<syntax>} \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>\text{&lt;syntax&gt;}</th>
<th>\text{opc1}</th>
<th>\text{opc2}</th>
<th>\text{CRn}</th>
<th>\text{coproc}</th>
<th>\text{CRm}</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 3, &lt;Rt&gt;, c4, c5, 1</td>
<td>011</td>
<td>001</td>
<td>0100</td>
<td>1111</td>
<td>0101</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL</td>

<tr>
<td>0</td>
<td>n/a</td>
</tr>
<tr>
<td>1</td>
<td>RW</td>
</tr>
<tr>
<td>1</td>
<td>n/a</td>
</tr>
</tbody>
</table>

...
Access to this register is from Debug state only. During normal execution this register is unallocated.
G6.3.30 DSPSR, Debug Saved Program Status Register

The DSPSR characteristics are:

**Purpose**

Holds the saved process state on entry to Debug state.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DSPSR is architecturally mapped to AArch64 System register DSPSR_EL0.

**Attributes**

DSPSR is a 32-bit register.

**Field descriptions**

The DSPSR bit assignments are:

*When entering Debug state from AArch32 and exiting Debug state to AArch32:*

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>10</th>
<th>9</th>
<th>8</th>

<td>M[3:0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>IT[1:0]</td>
<td>RES0</td>
<td>PAN</td>
<td>M[4]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **N**, bit [31]
  
  Set to the value of CPSR.N on entering Debug state, and copied to CPSR.N on exiting Debug state.

- **Z**, bit [30]
  
  Set to the value of CPSR.Z on entering Debug state, and copied to CPSR.Z on exiting Debug state.

- **C**, bit [29]
  
  Set to the value of CPSR.C on entering Debug state, and copied to CPSR.C on exiting Debug state.

- **V**, bit [28]
  
  Set to the value of CPSR.V on entering Debug state, and copied to CPSR.V on exiting Debug state.

- **Q**, bit [27]
  
  Set to the value of CPSR.Q on entering Debug state, and copied to CPSR.Q on exiting Debug state.

- **IT[1:0]**, bits [26:25]
  
  IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

- **J**, bit [24]
  
  RES0.

  In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

- **Bit [23]**
  
  Reserved, RES0.
PAN, bit [22]

*In ARMv8.2 and ARMv8.1*

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on entering Debug state, and copied to CPSR.PAN on exiting Debug state.

When ARMv8.1-PAN is not implemented, this bit is RES0.

*In ARMv8.0*

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of PSTATE.SS immediately before Debug state was entered.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation

1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SWithError interrupt mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.
F, bit [6]

FIQ mask bit. The possible values of this bit are:
0 Exception not masked.
1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:
0 Taken from A32 state.
1 Taken from T32 state.

M[4], bit [4]

Execution state that Debug state was entered from. Possible values of this bit are:
1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that Debug state was entered from. The possible values are:

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>User</td>
</tr>
<tr>
<td>0001</td>
<td>FIQ</td>

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-6117.

Accessing the DSPSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 3, &lt;Rt&gt;, c4, c5, 0</td>
<td>011</td>
<td>000</td>
<td>0100</td>
<td>1111</td>
<td>0101</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Access to this register is from Debug state only. During normal execution this register is unallocated.
G6.3.31  **HDCR, Hyp Debug Control Register**

The HDCR characteristics are:

**Purpose**

Controls the trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to functions provided by the debug and trace architectures and the Performance Monitors Extension.

**Configurations**

AArch32 System register HDCR is architecturally mapped to AArch64 System register **MDCR_EL2**.

If EL2 is not implemented, this register is RES0 from EL3.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally *UNKNOWN* values.

**Attributes**

HDCR is a 32-bit register.

**Field descriptions**

The HDCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>18</td>
<td>RES0</td>
</tr>
<tr>
<td>17</td>
<td>HPMD</td>
</tr>
<tr>
<td>16</td>
<td>HPMN</td>
</tr>
<tr>
<td>12</td>
<td>TPMCR</td>
</tr>
<tr>
<td>11</td>
<td>TPM</td>
</tr>
<tr>
<td>10</td>
<td>HPME</td>
</tr>
<tr>
<td>9</td>
<td>TDE</td>
</tr>
<tr>
<td>8</td>
<td>TDA</td>
</tr>
<tr>
<td>6</td>
<td>TDOSA</td>
</tr>
<tr>
<td>5</td>
<td>TDRA</td>
</tr>
</tbody>
</table>

**Bits [31:18]**

Reserved, RES0.

**HPMD, bit [17]**

*In ARMv8.2 and ARMv8.1*

Guest Performance Monitors Disable. This control prohibits event counting at EL2. Permitted values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Event counting allowed in Hyp mode.</td>
</tr>
<tr>
<td>1</td>
<td>Event counting prohibited in Hyp mode.</td>
</tr>
</tbody>
</table>

In an ARMv8.1 implementation, event counting is prohibited unless enabled by the `IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled()`.

This control applies only to:

- The event counters in the range \([0..(HPMN-1)]\).
- If `PMCR.DP` is set to 1, `PMCCNTR`.

The other event counters are unaffected. When `PMCR.DP` is set to 0, `PMCCNTR` is unaffected.

When this register has an architecturally-defined reset value, this field resets to 0.
In ARMv8.0.

Reserved, RES0.

Bits [16:12]

Reserved, RES0.

TDRA, bit [11]

Trap Debug ROM Address register access. Traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to Hyp mode.

0 This control does not cause any instructions to be trapped.

1 Non-secure EL0 and EL1 System register accesses to the DBGDRAR or DBGDSAR are trapped to Hyp mode, unless it is trapped by DBGDSCRext.UDCCdis.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to 0.

TDOSA, bit [10]

Trap debug OS-related register access. Traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode.

0 This control does not cause any instructions to be trapped.

1 Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.

The registers for which accesses are trapped are as follows:

- DBGOSLSR, DBGOSLAR, DBGOSDLR, and the DBGPRCR.
- Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

Note

These registers are not accessible at EL0.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to 0.

TDA, bit [9]

Trap debug access. Traps Non-secure EL0 and EL1 System register accesses to those debug System registers in the (coproc==1110) encoding space that are not trapped by either of the following:

- HDCR.TDRA.
- HDCR.TDOSA.

0 This control does not cause any instructions to be trapped.

1 Non-secure EL0 or EL1 System register accesses to the debug registers, other than the registers trapped by HDCR.TDRA and HDCR.TDOSA, are trapped to Hyp mode, unless it is trapped by DBGDSCRext.UDCCdis.

Traps of AArch32 accesses to DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to 0.

TDE, bit [8]

Trap Debug exceptions. The possible values of this bit are:

0 This control has no effect on the routing of debug exceptions, and has no effect on Non-secure accesses to debug registers.
In Non-secure state:

- Debug exceptions generated at EL1 or EL0 are routed to EL2.
- The HDCR. {TDRA, TDOSA, TDA} fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

When HCR.TGE == 1, the PE behaves as if the value of this field is 1 for all purposes other than returning the value of a direct read of the register.

When this register has an architecturally-defined reset value, this field resets to 0.

**HPME, bit [7]**

Hypervisor Performance Monitors Counters Enable. The possible values of this bit are:

0 Hyp mode Performance Monitors counters disabled.
1 Hyp mode Performance Monitors counters enabled.

When the value of this bit is 1, the Performance Monitors counters that are reserved for use from Hyp mode or Secure state are enabled. For more information see the description of the HPMN field.

If the Performance Monitors Extension is not implemented, this field is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

**TPM, bit [6]**

Trap Performance Monitors accesses. Traps Non-secure EL0 and EL1 accesses to all Performance Monitors registers to Hyp mode.

0 This control does not cause any instructions to be trapped.
1 Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.

--- **Note** ---

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

---

If the Performance Monitors Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**TPMCR, bit [5]**

Trap PMCR accesses. Traps Non-secure EL0 and EL1 accesses to the PMCR to Hyp mode.

0 This control does not cause any instructions to be trapped.
1 Non-secure EL0 and EL1 accesses to the PMCR are trapped to Hyp mode, unless it is trapped by PMUSERENR.EN.

--- **Note** ---

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

---

If the Performance Monitors Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**HPMN, bits [4:0]**

Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 modes, and from Non-secure EL0 modes if unprivileged access is enabled.

If the Performance Monitors Extension is not implemented, this field is RES0.
In Non-secure state, HPMN divides the Performance Monitors counters as follows. If software is accessing Performance Monitors counter \( n \) then, in Non-secure state:

- If \( n \) is in the range \( 0 \leq n < \text{HPMN} \), the counter is accessible from EL1 and EL2, and from EL0 if unprivileged access to the counters is enabled. PMCR.E enables the operation of counters in this range.
- If \( n \) is in the range \( \text{HPMN} \leq n < \text{PMCR.N} \), the counter is accessible only from EL2 and from Secure state. HDCR.HPME enables the operation of counters in this range.

If this field is set to 0, or to a value larger than PMCR.N, then the following constrained unpredictable behavior applies:

- The value returned by a direct read of HDCR.HPMN is unknown.
- Either:
  - An unknown number of counters are reserved for EL2 use. That is, the PE behaves as if HDCR.HPMN is set to an unknown non-zero value less than PMCR.N.
  - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to the value of PMCR.N.

**Accessing the HDCR**

This register can be read using MRC with the following syntax:

**MRC \(<\text{syntax}>\)**

This register can be written using MCR with the following syntax:

**MCR \(<\text{syntax}>\)**

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>(&lt;\text{syntax}&gt;) \ p15, 4, (&lt;\text{Rt}&gt;), c1, c1, 1 \</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>100 001 0001 1111 0001</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>n/a</td>
</tr>
<tr>

</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TDA==1, accesses to this register from EL2 are trapped to EL3 using AArch64.
G6.3.32 SDCR, Secure Debug Control Register

The SDCR characteristics are:

**Purpose**
When EL3 is implemented and can use AArch32, controls debug and performance monitors functionality in Secure state.

**Configurations**
This register is only accessible in Secure state.
AArch32 System register SDCR can be mapped to AArch64 System register MDCR_EL3, but this is not architecturally mandated.
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
SDCR is a 32-bit register.

**Field descriptions**
The SDCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>22-20</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>19</td>
<td>SPD</td>
</tr>
<tr>
<td>18</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>17</td>
<td>Reserved, RES0</td>
</tr>
<tr>

<td>Reserved, RES0</td>
</tr>
<tr>
<td>0</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**EPMAD, bit [21]**
External debug interface Performance Monitors registers disable. This disables access to these registers by an external debugger:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Access to Performance Monitors registers from external debugger is permitted.</td>
</tr>
<tr>
<td>1</td>
<td>Access to Performance Monitors registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.</td>
</tr>
</tbody>
</table>

If the Performance Monitors Extension is not implemented or does not support external debug interface accesses this bit is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**EDAD, bit [20]**
External debug interface breakpoint and watchpoint register access disable. This disables access to these registers by an external debugger:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Access to breakpoint and watchpoint registers from external debugger is permitted.</td>
</tr>
</tbody>
</table>
Access to breakpoint and watchpoint registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [19:18]
Reserved, RES0.

SPME, bit [17]
Secure Performance Monitors enable. This allows event counting in Secure state:
0 Event counting prohibited in Secure state.
In an ARMv8.0 or ARMv8.1 implementation, event counting is prohibited unless ExternalSecureNoninvasiveDebugEnabled() is TRUE, meaning this control is overridden by the IMPLEMENTATION DEFINED authentication interface.
1 Event counting allowed in Secure state.
If the Performance Monitors Extension is not implemented, this field is RES0.
When this register has an architecturally-defined reset value, this field resets to 0.

Bit [16]
Reserved, RES0.

SPD, bits [15:14]
AArch32 Secure privileged debug. Enables or disables debug exceptions from Secure state, other than Breakpoint Instruction exceptions. Valid values for this field are:
00 Legacy mode. Debug exceptions from Secure EL1 are enabled by the authentication interface.
10 Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.
11 Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.
Other values are reserved, and have the CONSTRAINED UNPREDICTABLE behavior that they must have the same behavior as 0b00. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.
If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.
Otherwise, debug exceptions from Secure EL0 are enabled only if SDER32_EL3.SUIDEN == 1.
Ignored in Non-secure state. Debug exceptions from Breakpoint Instruction exceptions are always enabled.
When this register has an architecturally-defined reset value, this field resets to 0.

Bits [13:0]
Reserved, RES0.

Accessing the SDCR
This register can be read using MRC with the following syntax:
MRC <syntax>
This register can be written using MCR with the following syntax:
MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c1, c3, 1</td>
<td>000</td>
<td>001</td>
<td>0001</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If EL3 is implemented and is using AArch64, any read or write to SDCR from Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.3.33  SDER, Secure Debug Enable Register

The SDER characteristics are:

**Purpose**

Controls invasive and non-invasive debug in the Secure EL0 mode.

**Configurations**

This register is only accessible in Secure state.

AArch32 System register SDER is architecturally mapped to AArch64 System register SDER32_EL3.

If EL3 is not implemented and EL1 supports AArch32, SDER is implemented only if the implemented Security state is Secure state.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SDER is a 32-bit register.

**Field descriptions**

The SDER bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>

</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
G6.4 Performance Monitors registers

This section lists the Performance Monitors registers in AArch32.
G6.4.1 PMCCFILTR, Performance Monitors Cycle Count Filter Register

The PMCCFILTR characteristics are:

**Purpose**

Determines the modes in which the Cycle Counter, PMCCNTR, increments.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCCFILTR is architecturally mapped to AArch64 System register PMCCFILTR_EL0.

AArch32 System register PMCCFILTR is architecturally mapped to External register PMCCFILTR_EL0.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMCCFILTR is a 32-bit register.

**Field descriptions**

The PMCCFILTR bit assignments are:

```
       31 30 29 28 27 26  0
       P U          RES0
```

**P, bit [31]**

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

0  Count cycles in EL1.
1  Do not count cycles in EL1.

When this register has an architecturally-defined reset value, this field resets to 0.

**U, bit [30]**

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0  Count cycles in EL0.
1  Do not count cycles in EL0.

When this register has an architecturally-defined reset value, this field resets to 0.

**NSK, bit [29]**

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted. Otherwise, cycles in Non-secure EL1 are not counted.
When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**NSU, bit [28]**

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted. Otherwise, cycles in Non-secure EL0 are not counted.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**NSH, bit [27]**

Non-secure EL2 (Hyp mode) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0  Do not count cycles in EL2.
1  Count cycles in EL2.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

**Bits [26:0]**

Reserved, RES0.

**Accessing the PMCCFILTR**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p15, 0, &lt;Rt&gt;, c14, c15, 7</code></td>
<td>000</td>
<td>111</td>
<td>1110</td>
<td>1111</td>
<td>1111</td>
</tr>
</tbody>
</table>

PMCCFILTR can also be accessed by using `PMXEVTYPER` with `PMSELR.SEL` set to 0b11111.

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>RW RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>RW RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>RW n/a RW RW</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If $\text{PMUSERENR.\text{EN}}=0$, accesses to this register from EL0 are trapped to Undefined mode.
  - If $\text{PMUSERENR.\text{EL0.\text{EN}}}==0$, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and SCR.\_EL3.NS == 1:
  - If $\text{MDCR.\_EL2.TPM}==1$, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR.\_EL3.NS == 1:
  - If $\text{HDCR.TPM}==1$, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If $\text{MDCR.\_EL3.TPM}==1$, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.2 PMCCNTR, Performance Monitors Cycle Count Register

The PMCCNTR characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter on page D5-2139* for more information. PMCCFILTR determines the modes and states in which the PMCCNTR can increment.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCCNTR is architecturally mapped to AArch64 System register PMCCNTR_EL0.

AArch32 System register PMCCNTR is architecturally mapped to External register PMCCNTR_EL0.

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR continues to increment when clocks are stopped by WFI and WFE instructions.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCCNTR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

Field descriptions

The PMCCNTR bit assignments are:

*When accessing as a 32-bit register:*

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CCNT</td>
<td></td>
</tr>
</tbody>
</table>

**CCNT, bits [31:0]**

Cycle count. Depending on the values of PMCR.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR.C sets this field to 0.

*When accessing as a 64-bit register:*

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CCNT</td>
<td></td>
</tr>
</tbody>
</table>

"G6 AArch32 System Register Descriptions"

"G6.4 Performance Monitors registers"
CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR.C sets this field to 0.

Accessing the PMCCNTR

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

• In both security states, and not dependent on other bits:
  — If PMUSERENR.CR==0, and PMUSERENR.EN==0, read accesses to this register from EL0 are trapped to Undefined mode.
  — If PMUSERENR_EL0.CR==0, and PMUSERENR_EL0.EN==0, read accesses to this register from EL0 are trapped to EL1.
  — If PMUSERENR.EN==0, write accesses to this register from EL0 are trapped to Undefined mode.
  — If PMUSERENR_EL0.EN==0, write accesses to this register from EL0 are trapped to EL1.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  — If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

• When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.3 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

**Purpose**

Defines which common architectural and common microarchitectural feature events in the range 0x000 to 0x01F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCEID0 is architecturally mapped to AArch64 System register PMCEID0_EL0[31:0].

AArch32 System register PMCEID0 is architecturally mapped to External register PMCEID0[31:0].

**Attributes**

PMCEID0 is a 32-bit register.

**Field descriptions**

The PMCEID0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID[31:0]</td>
<td></td>
</tr>
</tbody>
</table>

**ID[31:0], bits [31:0]**

PMCEID0[n] maps to event n. For a list of event numbers and descriptions, see *Events, event numbers, and mnemonics on page D5-2152*.

For each bit:

0 The common event is not implemented.
1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

**Accessing the PMCEID0**

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c12, 6</td>
<td>000</td>
<td>110</td>
<td>1001</td>
<td>1111</td>
<td>1100</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, read accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T9==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TPM==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TPM==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  - If HSTR.T9==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TPM==1, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.4 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

**Purpose**

Defines which common architectural and common microarchitectural feature events in the range 0x020 to 0x03f are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCEID1 is architecturally mapped to AArch64 System register PMCEID1_EL0[31:0].

AArch32 System register PMCEID1 is architecturally mapped to External register PMCEID1[31:0].

**Attributes**

PMCEID1 is a 32-bit register.

**Field descriptions**

The PMCEID1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The common event is not implemented.</td>
</tr>
<tr>
<td>1</td>
<td>The common event is implemented.</td>
</tr>
</tbody>
</table>

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

**Accessing the PMCEID1**

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>

</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>RO RO n/a RO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>RO RO RO RO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>RO n/a RO RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

• In both security states, and not dependent on other bits:
  — If PMUSERENR.EN==0, read accesses to this register from EL0 are trapped to Undefined mode.
  — If PMUSERENR_EL0.EN==0, read accesses to this register from EL0 are trapped to EL1.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T9==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If MDCR_EL2.TPM==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCR.TPM==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  — If HSTR.T9==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

• When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TPM==1, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.5   PMCEID2, Performance Monitors Common Event Identification register 2

The PMCEID2 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range
0x4000 to 0x401F are implemented. If a particular bit is set to 1, then the event for that bit is
implemented.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register PMCEID2 is architecturally mapped to AArch64 System register
PMCEID0_EL0[63:32].
AArch32 System register PMCEID2 is architecturally mapped to External register
PMCEID2[63:32].
This register is introduced in ARMv8.1.

Attributes

PMCEID2 is a 32-bit register.

Field descriptions

The PMCEID2 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
<td>The common event is not implemented.</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>The common event is implemented.</td>
</tr>
</tbody>
</table>

For each bit:

- 0: The common event is not implemented.
- 1: The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in
future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning
that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID2

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c14, 4</td>
<td>000</td>
<td>100</td>
<td>1001</td>
<td>1111</td>
<td>1110</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x</td>
<td>RO RO n/a RO</td>
</tr>
<tr>
<td>x</td>
<td>RO RO RO RO</td>
</tr>
<tr>
<td>1</td>
<td>RO n/a RO RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, read accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, read accesses to this register from EL0 are trapped to EL1.
G6.4.6  PMCEID3, Performance Monitors Common Event Identification register 3

The PMCEID3 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x4020 to 0x403F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCEID3 is architecturally mapped to AArch64 System register PMCEID1_EL0[63:32].

AArch32 System register PMCEID3 is architecturally mapped to External register PMCEID3[63:32].

This register is introduced in ARMv8.1.

Attributes

PMCEID3 is a 32-bit register.

Field descriptions

The PMCEID3 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
<th>ID[16447:16416]</th>
</tr>
</thead>
</table>

ID[16447:16416], bits [31:0]

PMCEID3[31:0] maps to common events 0x4020 to 0x403F. For a list of event numbers and descriptions, see Events, event numbers, and mnemonics on page D5-2152.

For each bit:

0 The common event is not implemented.
1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID3

This register can be read using MRC with the following syntax:

\[
\text{MRC <syntax>}
\]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, c9, c14, 5</td>
<td>000</td>
<td>101</td>
<td>1001</td>
<td>1111</td>
<td>1110</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>RO</td>
</tr>
<tr>
<td>x 0 1</td>
<td>RO</td>
</tr>
<tr>
<td>x 1 1</td>
<td>RO</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, read accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, read accesses to this register from EL0 are trapped to EL1.
G6.4.7 PMCNTENCLR, Performance Monitors Count Enable Clear register

The PMCNTENCLR characteristics are:

**Purpose**

Disables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR< Ensemble>. Reading this register shows which counters are enabled.

PMCNTENCLR is used in conjunction with the PMCNTENSET register.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCNTENCLR is architecturally mapped to AArch64 System register PMCNTENCLR_EL0.

AArch32 System register PMCNTENCLR is architecturally mapped to External register PMCNTENCLR_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMCNTENCLR is a 32-bit register.

**Field descriptions**

The PMCNTENCLR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>PMCCNTR disable bit. Disables the cycle counter register. Possible values are:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>0: When read, means the cycle counter is disabled. When written, has no effect.</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1: When read, means the cycle counter is enabled. When written, disables the cycle counter.</td>
<td>1</td>
</tr>
<tr>
<td>30-n</td>
<td>Event counter disable bit for PMEVCNTR&lt; Ensemble&gt;.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64 or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Possible values of each bit are:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>0: When read, means that PMEVCNTR&lt; Ensemble&gt; is disabled. When written, has no effect.</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1: When read, means that PMEVCNTR&lt; Ensemble&gt; is enabled. When written, disables PMEVCNTR&lt; Ensemble&gt;.</td>
<td>1</td>
</tr>
</tbody>
</table>

**Accessing the PMCNTENCLR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c12, 2</td>
<td>000</td>
<td>010</td>
<td>1001</td>
<td>1111</td>
<td>1100</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HSCR.HPMN or MDCR_EL2.HPMN can change the behavior of accesses to PMCINTENCLR. See the description of the $P<n>$ bit.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.8  PMCNTENSET, Performance Monitors Count Enable Set register

The PMCNTENSET characteristics are:

**Purpose**

Enables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<\(n\)>. Reading this register shows which counters are enabled.

PMCNTENSET is used in conjunction with the PMCNTENCLR register.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCNTENSET is architecturally mapped to AArch64 System register PMCNTENSET_EL0.

AArch32 System register PMCNTENSET is architecturally mapped to External register PMCNTENSET_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMCNTENSET is a 32-bit register.

**Field descriptions**

The PMCNTENSET bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>C</td>
<td>PMCCNTR enable bit. Enables the cycle counter register. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: When read, means the cycle counter is disabled. When written, has no effect.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: When read, means the cycle counter is enabled. When written, enables the cycle counter.</td>
</tr>
</tbody>
</table>
| 30-0| P<\(n\)>, bit [n] | Event counter enable bit for PMEVCNTR<\(n\)>.
|     |                | Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN, if EL2 is using AArch64 or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N. |
|     |                | Possible values of each bit are: |
|     |                | 0: When read, means that PMEVCNTR<\(n\)> is disabled. When written, has no effect. |
|     |                | 1: When read, means that PMEVCNTR<\(n\)> event counter is enabled. When written, enables PMEVCNTR<\(n\)>.

**Accessing the PMCNTENSET**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c12, 1</td>
<td>000</td>
<td>001</td>
<td>1001</td>
<td>1111</td>
<td>1100</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RW</td>
</tr>
<tr>
<td>NS</td>
<td>RW</td>
</tr>
</tbody>
</table>

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMCNTENSET. See the description of the P<n> bit.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-4344 for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 state](#) on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, accesses to this register from EL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  - If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.9   PMCR, Performance Monitors Control Register

The PMCR characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register PMCR is architecturally mapped to AArch64 System register PMCR_EL0.
AArch32 System register PMCR[6:0] is architecturally mapped to External register PMCR_EL0[6:0].
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCR is a 32-bit register.

Field descriptions

The PMCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Name</th>
<th>Value in Bit</th>
<th>Description</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-24</td>
<td>IMP</td>
<td>31 24</td>
<td>Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.</td>
<td>The implementer codes are allocated by ARM. Values have the same interpretation as bits [31:24] of the MIDR.</td>
</tr>
<tr>
<td>23-16</td>
<td>IDCODE</td>
<td>23 16</td>
<td>Identification code. This field is RO with an IMPLEMENTATION DEFINED value.</td>
<td>Each implementer must maintain a list of identification codes that is specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.</td>
</tr>
<tr>
<td>15-11</td>
<td>N</td>
<td>15 11</td>
<td>Number of event counters. A RO field that indicates the number counters implemented. A value of 0b00000 in this field indicates that only the Cycle Count Register PMCCNTR is implemented.</td>
<td>The value of this field is the number of event counters implemented. This value is in the range of 0b000000, in which case only the PMCCNTR is implemented, to 0b111111, which indicates that the PMCCNTR and 31 event counters are implemented. In an implementation that includes EL2, reads of this field from Non-secure EL1 and Non-secure EL0 return the value of HDCR.HPMN if EL2 is using AArch32, or the value of MDCR_EL2.HPMN if EL2 is using AArch64.</td>
</tr>
<tr>
<td>10-7</td>
<td>RES0</td>
<td>10 7</td>
<td>Reserved, RES0.</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
LC, bit [6]

Long cycle counter enable. Determines which PMCCNTR bit generates an overflow recorded by PMOVSR[31].

0 Cycle counter overflow on increment that changes PMCCNTR[31] from 1 to 0.
1 Cycle counter overflow on increment that changes PMCCNTR[63] from 1 to 0.

ARM deprecates use of PMCR.LC = 0.

This field resets to a value that is architecturally UNKNOWN.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

0 PMCCNTR, if enabled, counts when event counting is prohibited.
1 PMCCNTR does not count when event counting is prohibited.

Counting events is never prohibited in Non-secure state. However, there are some restrictions on counting events in Secure state. For more information about the interaction between the Performance Monitors and EL3, see Interaction with EL3 on page D5-2145

When EL3 is not implemented, this field is RES0:
- When ARMv8.1-PMU is not implemented.
- When ARMv8.1-PMU is implemented, only if EL2 is not implemented.

Otherwise this field is RW.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

0 Do not export events.
1 Export events where not prohibited.

This field enables the exporting of events over an event bus to another device, for example to an OPTIONAL trace macrocell. If the implementation does not include such an event bus then this field is RAZ/WI, otherwise it is an RW field.

In an implementation that includes an event bus, no events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

D, bit [3]

Clock divider. The possible values of this bit are:

0 When enabled, PMCCNTR counts every clock cycle.
1 When enabled, PMCCNTR counts once every 64 clock cycles.

This bit is RW.

If PMCR.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of PMCR.D = 1.

When this register has an architecturally-defined reset value, this field resets to 0.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

0 No action.
1 Reset PMCCNTR to zero.
This bit is always RAZ.

Resetting PMCCNTR does not clear the PMCCNTR overflow bit to 0.

**P, bit [1]**

Event counter reset. This bit is WO. The effects of writing to this bit are:

0 No action.

1 Reset all event counters accessible in the current EL, not including PMCCNTR, to zero.

This bit is always RAZ.

In Non-secure EL0 and EL1, if EL2 is implemented, a write of 1 to this bit does not reset event counters that HDCR.HPMN or MDCR_EL2.HPMN reserves for EL2 use.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Resetting the event counters does not clear any overflow bits to 0.

**E, bit [0]**

Enable. The possible values of this bit are:

0 All counters that are accessible at Non-secure EL1, including PMCCNTR, are disabled.

1 All counters that are accessible at Non-secure EL1 are enabled by PMCNTENSET.

This bit is RW.

If EL2 is implemented, this bit does not affect the operation of event counters that HDCR.HPMN or MDCR_EL2.HPMN reserves for EL2 use.

When this register has an architecturally-defined reset value, this field resets to 0.

### Accessing the PMCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c12, 0</td>
<td>000</td>
<td>000</td>
<td>1001</td>
<td>1111</td>
<td>1100</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, accesses to this register from EL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
  - If MDCR_EL2.TPMCR==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  - If HDCR.TPMCR==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  - If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.10  PMEVCNTR<n>, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n> characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMEVCNTR<n> is architecturally mapped to AArch64 System register PMEVCNTR<n>_EL0.

AArch32 System register PMEVCNTR<n> is architecturally mapped to External register PMEVCNTR<n>_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVCNTR<n> is a 32-bit register.

Field descriptions

The PMEVCNTR<n> bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Event counter n</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td>n</td>
</tr>
</tbody>
</table>

Accessing the PMEVCNTR<n>

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, &lt;CRm&gt;, &lt;opc2&gt;</td>
<td>000</td>
<td>n2:0</td>
<td>1110</td>
<td>1111</td>
<td>10:n4:3</td>
</tr>
</tbody>
</table>

•  <opc2> is in the range 0 - 7.
•  <CRm> is in the range c8 - c11.

PMEVCNTR<n> can also be accessed by using PMXEVNCNTR with PMSELR.SEL set to the value of <n>.
### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RW</td>
</tr>
<tr>
<td>NS</td>
<td>x</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RW</td>
</tr>
<tr>
<td>NS</td>
<td>x</td>
</tr>
</tbody>
</table>

If \(<n>\) is greater than or equal to the number of accessible counters, reads and writes of PMEVCNTR\(<n>\) are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- **Accesses to the register are UNDEFINED.**
- **Accesses to the register behave as RAZ/WI.**
- **Accesses to the register execute as a **NOP**.**
- **In Non-secure state, for an access from PL1 or a permitted access from PL0,** if PMSELR.SEL, or PMSELR_EL0.SEL if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

**Note**

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.* Subject to the prioritization rules:

- **In both security states, and not dependent on other bits:**
  - If PMUSERENR.EN==0, and PMUSERENR.ER==0, read accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR.EN==0, write accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, and PMUSERENR_EL0.ER==0, read accesses to this register from EL0 are trapped to EL1.
  - If PMUSERENR_EL0.EN==0, write accesses to this register from EL0 are trapped to EL1.
- **When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:**
  - If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
• When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.11 PMEVTYPER<n>, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n> characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMEVTYPER<n> is architecturally mapped to AArch64 System register PMEVTYPER<n>_EL0.

AArch32 System register PMEVTYPER<n> is architecturally mapped to External register PMEVTYPER<n>_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVTYPER<n> is a 32-bit register.

Field descriptions

The PMEVTYPER<n> bit assignments are:

```
31 30 29 28 27 26 25 24 16 15 10 9 0
P  U  RES0  evtCount[15:10]  evtCount[9:0]
NSK  NSU  NSH  RES0  MT
```

P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

0  Count events in EL1.
1  Do not count events in EL1.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0  Count events in EL0.
1  Do not count events in EL0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.
NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted. Otherwise, events in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure EL2 (Hyp mode) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count events in EL2.
1 Count events in EL2.

Bit [26]

Reserved, RES0.

MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

0 Count events only on controlling PE.
1 Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

--- Note ---

• An implementation is described as multi-threaded when the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, the value of MPIDR_EL1.MT, when read at the highest implemented Exception level, is 1.
• Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.

Bits [24:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

_in ARMv8.2 and ARMv8.1_ Extension to evtCount[9:0]. See evtCount[9:0] for more details.

_in ARMv8.0._ Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>. Software must program this field with an event that is supported by the PE being programmed.

There are three ranges of event numbers:

• Event numbers in the range 0x000 to 0x03F are common architectural and microarchitectural events.
• Event numbers in the range 0x040 to 0x0BF are ARM recommended common architectural and microarchitectural events.
• Event numbers in the range 0x0C0 to 0x3FF are IMPLEMENTATION DEFINED events.
If `evtCount` is programmed to an event that is reserved or not supported by the PE, the behavior depends on the event type:

- For the range `0x000` to `0x03F`, no events are counted, and the value returned by a direct or external read of the `evtCount` field is the value written to the field.
- For IMPLEMENTATION DEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the `evtCount` field is UNKNOWN.

**Note**

UNPREDICTABLE means the event must not expose privileged information.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on `evtCount` is the value written.

### Accessing the PMEVTYPER<\(n\)>

This register can be read using MRC with the following syntax:

\[ \text{MRC <syntax>} \]

This register can be written using MCR with the following syntax:

\[ \text{MCR <syntax>} \]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, &lt;CRm&gt;, &lt;opc2&gt;</td>
<td>000</td>
<td>(n&lt;2:0&gt;)</td>
<td>1110</td>
<td>1111</td>
<td>11: (n&lt;4:3&gt;)</td>
</tr>
</tbody>
</table>

- `<opc2>` is in the range 0 - 7.
- `<CRm>` is in the range c12 - c15.

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

This register is accessible at EL0 when `PMUSERENR.EN` is set to 1.

`PMEVTYPER<\(n\)>` can also be accessed by using `PMXEVTPR` with `PMSELR.SEL` set to n.

If `<\(n\)>` is greater or equal to the number of accessible counters, reads and writes of `PMEVTYPER<\(n\)>` are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
• In Non-secure state, for an access from PL1 or a permitted access from PL0, if PMSELR.SEL, or
PMSELR_EL0.SEL if EL1 is using AArch64, is greater than or equal to the number of accessible counters
but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from
PL0 are permitted when:
  — EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  — EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note
In an implementation that includes EL2, in Non-secure state at EL0 and EL1:
• If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
• If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.
Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables
For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for
exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous
exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.
Subject to the prioritization rules:
• In both security states, and not dependent on other bits:
  — If PMUSERENR.EN==0, accesses to this register from EL0 are trapped to Undefined mode.
  — If PMUSERENR_EL0.EN==0, accesses to this register from EL0 are trapped to EL1.
• When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
• When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
### G6.4.12 PMINTENCLR, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR characteristics are:

**Purpose**

Disables the generation of interrupt requests on overflows from the Cycle Count Register, `PMCCNTR`, and the event counters `PMEVCNTR<n>`. Reading the register shows which overflow interrupt requests are enabled. PMINTENCLR is used in conjunction with the PMINTENSET register.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register `PMINTENCLR` is architecturally mapped to AArch64 System register `PMINTENCLR_EL1`.

AArch32 System register `PMINTENCLR` is architecturally mapped to External register `PMINTENCLR_EL1`.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMINTENCLR is a 32-bit register.

**Field descriptions**

The PMINTENCLR bit assignments are:

<table>
<thead>
<tr>
<th>Bit No.</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>C, bit [31]</td>
</tr>
<tr>
<td>30 32</td>
<td>P&lt;n&gt;, bit [n]</td>
</tr>
</tbody>
</table>

**C, bit [31]**

`PMCCNTR` overflow interrupt request disable bit. Possible values are:

- 0: When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1: When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

**P<n>, bit [n], for n = 0 to 30**

Event counter overflow interrupt request disable bit for `PMEVCNTR<n>`.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in `HDCR.HPMN`. Otherwise, N is the value in `PMCR.N`.

Bits [30:N] are RAZ/WI. Possible values are:

- 0: When read, means that the `PMEVCNTR<n>` event counter interrupt request is disabled. When written, has no effect.
- 1: When read, means that the `PMEVCNTR<n>` event counter interrupt request is enabled. When written, disables the `PMEVCNTR<n>` interrupt request.

**Accessing the PMINTENCLR**

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```
This register can be written using MCR with the following syntax:

\[
\text{MCR <syntax>}
\]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c14, 2</td>
<td>000</td>
<td>010</td>
<td>1001</td>
<td>1111</td>
<td>1110</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>RW RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>RW RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>RW n/a RW RW</td>
</tr>
</tbody>
</table>

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of `HDCR.HPMN` can change the behavior of accesses to `PMINTENCLR`. See the description of the `P<n>` bit.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:  
  - If `HSTR_EL2.T9==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
  - If `MDCR_EL2.TPM==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:  
  - If `HSTR_EL2.T9==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
  - If `HDCR.TPM==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
  - If `HSTR.T9==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If `MDCR_EL3.TPM==1`, accesses to this register from EL1 and EL2 are trapped to EL3.
G6.4.13 PMINTENSET, Performance Monitors Interrupt Enable Set register

The PMINTENSET characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<\textless n\textgreater>. Reading the register shows which overflow interrupt requests are enabled.

PMINTENSET is used in conjunction with the PMINTENCLR register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMINTENSET is architecturally mapped to AArch64 System register PMINTENSET_EL1.

AArch32 System register PMINTENSET is architecturally mapped to External register PMINTENSET_EL1.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMINTENSET is a 32-bit register.

Field descriptions

The PMINTENSET bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;\textless n\textgreater&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

C, bit [31]

PMCCNTR overflow interrupt request enable bit. Possible values are:

0  When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

1  When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

P<\textless n\textgreater>, bit [n], for n = 0 to 30

Event counter overflow interrupt request enable bit for PMEVCNTR<\textless n\textgreater>.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Bits [30:N] are RAZ/WI.

Possible values are:

0  When read, means that the PMEVCNTR<\textless n\textgreater> event counter interrupt request is disabled. When written, has no effect.

1  When read, means that the PMEVCNTR<\textless n\textgreater> event counter interrupt request is enabled. When written, enables the PMEVCNTR<\textless n\textgreater> interrupt request.

Accessing the PMINTENSET

This register can be read using MRC with the following syntax:

MRC <syntax>
This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c14, 1</td>
<td>000</td>
<td>001</td>
<td>1001</td>
<td>1111</td>
<td>1110</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>RW RW n/a RW</td>
</tr>
<tr>
<td>x 0 1</td>
<td>RW RW RW RW</td>
</tr>
<tr>
<td>x 1 1</td>
<td>RW n/a RW RW</td>
</tr>
</tbody>
</table>

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMINTENSET. See the description of the P<\texttt{<n>}> bit.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state*. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T9==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TPM==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
  - If HSTR.T9==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TPM==1, accesses to this register from EL1 and EL2 are trapped to EL3.
PMOVSR, Performance Monitors Overflow Flag Status Register

The PMOVSR characteristics are:

**Purpose**
Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<n>. Writing to this register clears these bits.

**Configurations**
There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register PMOVSR is architecturally mapped to AArch64 System register PMOVSCLR_EL0.
AArch32 System register PMOVSR is architecturally mapped to External register PMOVSCLR_EL0.
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
PMOVSR is a 32-bit register.

**Field descriptions**
The PMOVSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>C</td>
<td>PMCCNTR overflow bit. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: When read, means the cycle counter has not overflowed. When written, has no effect.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.</td>
</tr>
<tr>
<td></td>
<td>P&lt;n&gt;, bit [n]</td>
<td>Event counter overflow clear bit for PMEVCNTR&lt;n&gt;.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64 or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Possible values of each bit are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: When read, means that PMEVCNTR&lt;n&gt; has not overflowed. When written, has no effect.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: When read, means that PMEVCNTR&lt;n&gt; has overflowed. When written, clears the PMEVCNTR&lt;n&gt; overflow bit to 0.</td>
</tr>
</tbody>
</table>

**Accessing the PMOVSR**
This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:
MCR `<syntax>`

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th><code>&lt;syntax&gt;</code></th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, <code>&lt;Rt&gt;</code>, c9, c12, 3</td>
<td>000</td>
<td>011</td>
<td>1001</td>
<td>1111</td>
<td>1100</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDSCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  - If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.15  PMOVSSET, Performance Monitors Overflow Flag Status Set register

The PMOVSSET characteristics are:

**Purpose**

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<\n>.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMOVSSET is architecturally mapped to AArch64 System register PMOVSSET_EL0.

AArch32 System register PMOVSSET is architecturally mapped to External register PMOVSSET_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMOVSSET is a 32-bit register.

**Field descriptions**

The PMOVSSET bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C, bit [31]</td>
<td>PMCCNTR overflow bit. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>0  When read, means the cycle counter has not overflowed. When written, has no effect.</td>
</tr>
<tr>
<td></td>
<td>1  When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.</td>
</tr>
</tbody>
</table>
| P<n>, bit [n], for n = 0 to 30 | Event counter overflow set bit for PMEVCNTR<\n>.
|                | Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64 or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N. Possible values are: |
|                | 0  When read, means that PMEVCNTR<\n> has not overflowed. When written, has no effect. |
|                | 1  When read, means that PMEVCNTR<\n> has overflowed. When written, sets the PMEVCNTR<\n> overflow bit to 1. |

**Accessing the PMOVSSET**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c14, 3</td>
<td>000</td>

</tbody>
</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, accesses to this register from EL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  - If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.16 PMSELR, Performance Monitors Event Counter Selection Register

The PMSELR characteristics are:

**Purpose**

Selects the current event counter PMEVCNTR<\(n\)> or the cycle counter, CCNT.

PMSELR is used in conjunction with PMXEVTYPER to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with PMXEVCNTR, to determine the value of a selected event counter.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMSELR is architecturally mapped to AArch64 System register PMSELR_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMSELR is a 32-bit register.

**Field descriptions**

The PMSELR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SEL</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:5]**

Reserved, RES0.

**SEL, bits [4:0]**

Selects event counter, PMEVCNTR<\(n\)> , where \(n\) is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPER or PMXEVCNTR occurs.

This field can take any value from 0 (\(0b00000\)) to (PMCR.N)-1, or 31 (\(0b11111\)).

When PMSELR.SEL is \(0b11111\) it selects the cycle counter and:

- A read of the PMXEVTYPER returns the value of PMCCFILTR.
- A write of the PMXEVTYPER writes to PMCCFILTR.
- A read or write of PMXEV CNTR has CONSTRAINED UNPREDICTABLE effects, that can be one of the following:
  - Access to PMXEV CNTR is UNDEFINED.
  - Access to PMXEV CNTR behaves as a NOP.
  - Access to PMXEV CNTR behaves as if the register is RAZ/WI.
  - Access to PMXEV CNTR behaves as if the PMSELR.SEL field contains an UNKNOWN value.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, the results of access to PMXEVTYPER or PMXEV CNTR are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Access to PMXEVTYPER or PMXEV CNTR is UNDEFINED.
• Access to PMXEVTYPER or PMXEVCNTR behaves as a NOP.
• Access to PMXEVTYPER or PMXEVCNTR behaves as if the register is RAZ/WI.
• Access to PMXEVTYPER or PMXEVCNTR behaves as if the PMSELR.SEL field contains an UNKNOWN value.
• Access to PMXEVTYPER or PMXEVCNTR behaves as if the PMSELR.SEL field contains 0b11111.

Direct reads of this field return an UNKNOWN value.

Accessing the PMSELR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c12, 5</td>
<td>000</td>
<td>101</td>
<td>1001</td>
<td>1111</td>
<td>1100</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RW</td>

</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

• In both security states, and not dependent on other bits:
  — If PMUSERENR.EN==0, and PMUSERENR.ER==0, accesses to this register from EL0 are trapped to Undefined mode.
  — If PMUSERENR_EL0.EN==0, and PMUSERENR_EL0.ER==0, accesses to this register from EL0 are trapped to EL1.

• When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  — If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

• When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.17  **PMSWINC, Performance Monitors Software Increment register**

The PMSWINC characteristics are:

**Purpose**

Increments a counter that is configured to count the Software increment event, event 0x00. For more information, see SW_INCR.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

- AArch32 System register PMSWINC is architecturally mapped to AArch64 System register PMSWINC_EL0.
- AArch32 System register PMSWINC is architecturally mapped to External register PMSWINC_EL0.

**Attributes**

PMSWINC is a 32-bit register.

**Field descriptions**

The PMSWINC bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>30</td>
<td>P&lt;n&gt;, bit [n], for n = 0 to 30</td>

</table>

### Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, and PMUSERENR.SW==0, write accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, and PMUSERENR_EL0.SW==0, write accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TPM==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
  - When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
    - If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
  - When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
    - If HDCR.TPM==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to Hyp mode.
    - If HSTR.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TPM==1, write accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
PMUSERENR, Performance Monitors User Enable Register

The PMUSERENR characteristics are:

**Purpose**

Enables or disables User mode access to the Performance Monitors.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMUSERENR is architecturally mapped to AArch64 System register PMUSERENR_EL0.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMUSERENR is a 32-bit register.

**Field descriptions**

The PMUSERENR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
| 3   | Event counter read trap control:  
|     | 0: EL0 reads of the PMXEVCNTR and PMEVCNTR, and EL0 read/write access to the PMSELR, are trapped to Undefined mode if PMUSERENR.EN is also 0.  
|     | 1: This control does not cause any instructions to be trapped.  
|     | When this register has an architecturally-defined reset value, this field resets to 0. |
| 2   | Cycle counter read trap control:  
|     | 0: EL0 reads of the PMCCNTR are trapped to Undefined mode if PMUSERENR.EN is also 0.  
|     | 1: This control does not cause any instructions to be trapped.  
|     | When this register has an architecturally-defined reset value, this field resets to 0. |
| 1   | Software increment write trap control:  
|     | 0: EL0 writes to the PMSWINC are trapped to Undefined mode if PMUSERENR.EN is also 0.  
| 0   | EN  
|     | SW  
|     | CR  
|     | ER  

Bits [31:4]

Reserved, RES0.

ER, bit [3]

Event counter read trap control:

0: EL0 reads of the PMXEVCNTR and PMEVCNTR, and EL0 read/write access to the PMSELR, are trapped to Undefined mode if PMUSERENR.EN is also 0.

1: This control does not cause any instructions to be trapped.

When this register has an architecturally-defined reset value, this field resets to 0.

CR, bit [2]

Cycle counter read trap control:

0: EL0 reads of the PMCCNTR are trapped to Undefined mode if PMUSERENR.EN is also 0.

1: This control does not cause any instructions to be trapped.

When this register has an architecturally-defined reset value, this field resets to 0.

SW, bit [1]

Software increment write trap control:

0: EL0 writes to the PMSWINC are trapped to Undefined mode if PMUSERENR.EN is also 0.
This control does not cause any instructions to be trapped.

When this register has an architecturally-defined reset value, this field resets to 0.

EN, bit [0]
Traps EL0 accesses to the Performance Monitors registers to Undefined mode:
0 EL0 accesses to the Performance Monitors registers are trapped to Undefined mode, unless enabled by one of PMUSERENR.{ER, CR, SW}.
1 This control does not cause any instructions to be trapped. Software can access all PMU registers at EL0.

Note
• The PMUSERENR is register is always RO at EL0 and not trapped by this bit.
• EL0 cannot read or write PMINTENSE and PMINTENCLR.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the PMUSERENR
This register can be read using MRC with the following syntax:
MRC <syntax>
This register can be written using MCR with the following syntax:
MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>

<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables
For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  — If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
• When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  — If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

• When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.19 PMXEV CNTR, Performance Monitors Selected Event Count Register

The PMXEV CNTR characteristics are:

**Purpose**

Reads or writes the value of the selected event counter, PMEVCNTR<\text{n}>. PMSELR.SEL determines which event counter is selected.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMXEV CNTR is architecturally mapped to AArch64 System register PMXEV CNTR_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMXEV CNTR is a 32-bit register.

**Field descriptions**

The PMXEV CNTR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMEVCNTR&lt;n&gt;</td>
<td>Value of the selected event counter, PMEVCNTR&lt;n&gt;, where n is the value stored in PMSELR.SEL.</td>
</tr>
</tbody>
</table>

**Accessing the PMXEV CNTR**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c13, 2</td>
<td>000</td>
<td>010</td>
<td>1001</td>
<td>1111</td>
<td>101</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RW</td>
</tr>
<tr>
<td>NS</td>
<td>x</td>
</tr>
<tr>
<td></td>
<td>x</td>
</tr>
<tr>
<td></td>
<td>x</td>
</tr>
</tbody>
</table>

If PMSELR_SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVCNTR are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if PMSELR_SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if PMSELR_SEL is 31.
- In Non-secure state, for an access from PL1 or a permitted access from PL0, if PMSELR_SEL, or PMSELR_EL0_SEL if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

---

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

---

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, and PMUSERENR.ER==0, read accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR.EN==0, write accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.ENV==0, and PMUSERENR_EL0.ER==0, read accesses to this register from EL0 are trapped to EL1.
  - If PMUSERENR_EL0.EN==0, write accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  - If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

- When EL3 is implemented and is using AArch64:
  - If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.4.20 PMXEVTYPER, Performance Monitors Selected Event Type Register

The PMXEVTYPER characteristics are:

**Purpose**

When PMSELR.SEL selects an event counter, this accesses a PMEVTYPER<\text{n}> register. When PMSELR.SEL selects the cycle counter, this accesses PMCCFILTR.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMXEVTYPER is architecturally mapped to AArch64 System register PMXEVTYPER_EL0.

When the value of PMSELR.SEL is 31, to select the cycle counter, RW fields in this register have defined reset values that apply only when the PE resets into an Exception level that is using AArch32. See PMCCFILTR for the reset values.

Otherwise, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN. This applies whenever PMSELR.SEL selects an event counter.

**Attributes**

PMXEVTYPER is a 32-bit register.

**Field descriptions**

The PMXEVTYPER bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Event type register or PMCCFILTR</th>
</tr>
</thead>
</table>

**Accessing the PMXEVTYPER**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c9, c13, 1</td>
<td>000</td>
<td>001</td>
<td>1001</td>
<td>1111</td>
<td>1101</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0</td>
</tr>
<tr>
<td>TGE</td>
<td>RW</td>
</tr>
<tr>
<td>NS</td>
<td>RW</td>
</tr>
</tbody>
</table>

If PMSELR_SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVTYPER are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if PMSELR_SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if PMSELR_SEL is 31.
- In Non-secure state, for an access from PL1 or a permitted access from PL0, if PMSELR_SEL, or PMSELR_EL0_SEL if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

--- Note ---

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If PMUSERENR.EN==0, accesses to this register from EL0 are trapped to Undefined mode.
  - If PMUSERENR_EL0.EN==0, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
• When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  — If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  — If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
  — If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

• When EL3 is implemented and is using AArch64:
  — If MDCR_EL3.TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
G6.5  Generic Timer registers

This section lists the Generic Timer registers in AArch32.
G6.5.1 CNTFRQ, Counter-timer Frequency register

The CNTFRQ characteristics are:

**Purpose**

This register is provided so that software can discover the frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTFRQ is architecturally mapped to AArch64 System register CNTFRQ_EL0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTFRQ is a 32-bit register.

**Field descriptions**

The CNTFRQ bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:0]</td>
<td>Clock frequency</td>
</tr>
</tbody>
</table>

Clock frequency. Indicates the system counter clock frequency, in Hz.

**Accessing the CNTFRQ**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c0, 0</td>
<td>000</td>
<td>000</td>
<td>1110</td>
<td>1111</td>
<td>0000</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL1 is the highest implemented Exception level.</td>
<td>E2H: x, TGE: x, NS: x</td>
<td>EL0: RO, EL1: RW, EL2: n/a, EL3: n/a</td>
</tr>
<tr>
<td>EL2 is the highest implemented Exception level.</td>
<td>E2H: x, TGE: 0, NS: 1</td>
<td>EL0: RO, EL1: RO, EL2: RW, EL3: n/a</td>
</tr>
<tr>
<td>EL2 is the highest implemented Exception level.</td>
<td>E2H: x, TGE: 1, NS: 1</td>
<td>EL0: RO, EL1: RO, EL2: RW, EL3: n/a</td>
</tr>
<tr>
<td>EL3 is the highest implemented Exception level.</td>
<td>E2H: x, TGE: x, NS: 0</td>
<td>EL0: RO, EL1: RO, EL2: RO, EL3: RW</td>
</tr>
<tr>
<td>EL3 is the highest implemented Exception level.</td>
<td>E2H: x, TGE: 0, NS: 1</td>
<td>EL0: RO, EL1: RO, EL2: RO, EL3: RW</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CNTKCTL_EL1.EL0PCTEN==0, and CNTKCTL_EL1.EL0VCTEN==0, read accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTL.PL0PCTEN==0, and CNTKCTL.PL0VCTEN==0, read accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CNTKCTL_EL1.EL0PCTEN==0, and CNTKCTL_EL1.EL0VCTEN==0, Non-secure read accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTL.PL0PCTEN==0, and CNTKCTL.PL0VCTEN==0, Non-secure read accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0PCTEN==0, and CNTHCTL_EL2.EL0VCTEN==0, Non-secure read accesses to this register from EL0 are trapped to EL2.
G6.5.2 CNTHCTL, Counter-timer Hyp Control register

The CNTHCTL characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 modes to the physical counter and the Non-secure EL1 physical timer.

Configurations

AArch32 System register CNTHCTL is architecturally mapped to AArch64 System register CNTHCTL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHCTL is a 32-bit register.

Field descriptions

The CNTHCTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>24</td>
<td>EVNTI</td>
</tr>
<tr>
<td>23</td>
<td>EVNTDIR</td>
</tr>
<tr>
<td>22</td>
<td>EVNTEN</td>
</tr>
<tr>
<td>21</td>
<td>PL1PCEN</td>
</tr>
<tr>
<td>20</td>
<td>PL1PCTEN</td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the counter register CNTPCT is the trigger for the event stream generated from that counter, when that stream is enabled.

EVNTDIR, bit [3]

Controls which transition of the counter register CNTPCT trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

- 0: A 0 to 1 transition of the trigger bit triggers an event.
- 1: A 1 to 0 transition of the trigger bit triggers an event.

EVNTEN, bit [2]

Enables the generation of an event stream from the counter register CNTPCT:

- 0: Disables the event stream.
- 1: Enables the event stream.

PL1PCEN, bit [1]

Traps Non-secure EL0 and EL1 accesses to the physical timer registers to Hyp mode:

- 0: Non-secure EL0 and EL1 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are trapped to Hyp mode, unless the it is trapped by CNTKCTL.PLLPTEN.
This control does not cause any instructions to be trapped.
If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

**PL1PCTEN, bit [0]**

Traps Non-secure EL0 and EL1 accesses to the physical counter register to Hyp mode.

0  Non-secure EL0 and EL1 accesses to the CNTPCT are trapped to Hyp mode, unless it is trapped by CNTKCTL.PL0PCTEN.

1  This control does not cause any instructions to be trapped.
If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

### Accessing the CNTHCTL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, cl4, cl1, 0</td>
<td>100</td>
<td>000</td>
<td>1110</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>EL0 EL1 EL2 EL3</td>

G6.5.3 CNTHP_CTL, Counter-timer Hyp Physical Timer Control register

The CNTHP_CTL characteristics are:

**Purpose**

Control register for the Hyp mode physical timer.

**Configurations**

AArch32 System register CNTHP_CTL is architecturally mapped to AArch64 System register CNTHP_CTL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHP_CTL is a 32-bit register.

**Field descriptions**

The CNTHP_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>31:3</td>
<td>RESERVED.</td>
</tr>
<tr>
<td>3</td>
<td>ENABLE.</td>
</tr>
<tr>
<td>2</td>
<td>IMASK.</td>
</tr>
<tr>
<td>1</td>
<td>ISTATUS.</td>
</tr>
<tr>
<td>0</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

- 0: Timer condition is not met.
- 1: Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D6-2187 and *Operation of the TimerValue views of the timers* on page D6-2188.

This bit is read-only.

This field resets to a value that is architecturally UNKNOWN.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

- 0: Timer interrupt is not masked by the IMASK bit.
- 1: Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to a value that is architecturally UNKNOWN.
ENABLE, bit [0]

Enables the timer. Permitted values are:

- **0** Timer disabled.
- **1** Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from `CNTHP_TV AL` continues to count down.

--- Note

Disabling the output signal might be a power-saving option.

---

When this register has an architecturally-defined reset value, this field resets to 0.

### Accessing the CNTHP_CTL

This register can be read using MRC with the following syntax:

\[
\text{MRC <syntax>}
\]

This register can be written using MCR with the following syntax:

\[
\text{MCR <syntax>}
\]

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c14, c2, 1</td>
<td>100</td>
<td>001</td>
<td>1110</td>
<td>1111</td>
<td>0010</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 1</td>
<td>000</td>
<td>001</td>
<td>1110</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

### Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
<td>NS</td>
</tr>
<tr>
<td>p15, 4, &lt;Rt&gt;, c14, c2, 1</td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>p15, 4, &lt;Rt&gt;, c14, c2, 1</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>p15, 4, &lt;Rt&gt;, c14, c2, 1</td>
<td>x</td>
<td>1</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 1</td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

This table applies to all instructions that can access this register.
Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.
G6.5.4 CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register

The CNTHP_CVAL characteristics are:

**Purpose**

Holds the compare value for the Hyp mode physical timer.

**Configurations**

AArch32 System register CNTHP_CVAL is architecturally mapped to AArch64 System register CNTHP_CVAL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHP_CVAL is a 64-bit register.

**Field descriptions**

The CNTHP_CVAL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>CompareValue</td>
<td>Holds the EL2 physical timer CompareValue.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When CNTHP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CNTHP_CTL.ISTATUS is set to 1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If CNTHP_CTL.IMASK is 0, an interrupt is generated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When CNTHP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count.</td>
</tr>
</tbody>
</table>

**Accessing the CNTHP_CVAL**

This register can be read using MRRC with the following syntax:

```
MRRC <syntax>
```

This register can be written using MCRR with the following syntax:

```
MCRR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>opc1</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 6, &lt;Rt&gt;, &lt;Rt2&gt;, c14</td>
<td>0110</td>
<td>1111</td>
<td>1110</td>
</tr>
<tr>
<td>p15, 2, &lt;Rt&gt;, &lt;Rt2&gt;, c14</td>
<td>0010</td>
<td>1111</td>
<td>1110</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>E2H TGE</td>
<td>EL0 EL1 EL2 EL3</td>

<td>CNTP_CV AL CNTP_CV AL n/a n/a</td>
</tr>
<tr>
<td>p15, 2, &lt;Rt&gt;, &lt;Rt2&gt;, c14</td>
<td>1 1 1</td>
<td>RW n/a n/a n/a</td>
</tr>
</tbody>
</table>

This table applies to all instructions that can access this register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.
CNC T H P_TVAL, Counter-timer Hyp Physical Timer TimerValue register

The CNTHP_TVAL characteristics are:

**Purpose**

Holds the timer value for the Hyp mode physical timer.

**Configurations**

AArch32 System register CNTHP_TVAL is architecturally mapped to AArch64 System register CNTHP_TVAL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHP_TVAL is a 32-bit register.

**Field descriptions**

The CNTHP_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimerValue</td>
<td></td>
</tr>
</tbody>
</table>

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 physical timer.

On a read of this register:
- If CNTHP_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHP_CTL.ENABLE is 1, the value returned is (CNTHP_CVAL - CNTPCT).

On a write of this register, CNTHP_CVAL is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CNTHP_CVAL) is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:
- CNTHP_CTL.ISTATUS is set to 1.
- If CNTHP_CTL.IMASK is 0, an interrupt is generated.

When CNTHP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count, so the TimerValue view appears to continue to count down.

**Accessing the CNTHP_TVAL**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, c14, c2, 0</td>
<td>100</td>
<td>000</td>
<td>1110</td>
<td>1111</td>
<td>0010</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 0</td>
<td>000</td>
<td>000</td>
<td>1110</td>
<td>1111</td>
<td>0010</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
<td>NS</td>
</tr>
<tr>
<td>p15, 4, &lt;Rt&gt;, c14, c2, 0</td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>p15, 4, &lt;Rt&gt;, c14, c2, 0</td>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>p15, 4, &lt;Rt&gt;, c14, c2, 0</td>
<td>x</td>
<td>1</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 0</td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, 0</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

This table applies to all instructions that can access this register.

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state.

Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.
G6.5.6 CNTHV_CTL, Counter-timer Virtual Timer Control register (EL2)

The CNTHV_CTL characteristics are:

**Purpose**

Provides AArch32 access to the control register for the EL2 virtual timer.

--- Note ---

The EL2 virtual timer is implemented by ARMv8.1-VHE. It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of HCR_EL2.[E2H, TGE] is {1, 1}.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTHV_CTL is architecturally mapped to AArch64 System register CNTHV_CTL_EL2.

This register is introduced in ARMv8.1.

**Attributes**

CNTHV_CTL is a 32-bit register.

**Field descriptions**

The CNTHV_CTL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ENABLE</td>
<td>IMASK</td>
<td>ISTATUS</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Timer condition is not met.</td>
</tr>
<tr>
<td>1</td>
<td>Timer condition is met.</td>
</tr>
</tbody>
</table>

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D6-2187 and *Operation of the TimerValue views of the timers* on page D6-2188.

This bit is read-only.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Timer interrupt is not masked by the IMASK bit.</td>
</tr>
<tr>
<td>1</td>
<td>Timer interrupt is masked by the IMASK bit.</td>
</tr>
</tbody>
</table>
ENABLE, bit [0]

Enables the timer. Permitted values are:

0  Timer disabled.
1  Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHV_TV_AL continues to count down.

Note
Disabling the output signal might be a power-saving option.

Accessing the CNTHV_CTL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c3, 1</td>
<td>000</td>
<td>001</td>
<td>1110</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

This register is accessed using the encoding for CNTV_CTL.

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>

<td>RW</td>
</tr>
</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0VTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.
G6.5.7   CNTHV_CVAL, Counter-timer Virtual Timer CompareValue register (EL2)

The CNTHV_CVAL characteristics are:

**Purpose**

Provides AArch32 access to the compare value for the EL2 virtual timer.

--- Note ---

The EL2 virtual timer is implemented by ARMv8.1-VHE. It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTHV_CVAL is architecturally mapped to AArch64 System register CNTHV_CVAL_EL2.

This register is introduced in ARMv8.1.

**Attributes**

CNTHV_CVAL is a 64-bit register.

**Field descriptions**

The CNTHV_CVAL bit assignments are:

```
  63  0
CompareValue
```

**CompareValue, bits [63:0]**

Holds the EL2 virtual timer CompareValue.

When CNTHV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHV_CTL.ISTATUS is set to 1.
- If CNTHV_CTL.IMASK is 0, an interrupt is generated.

When CNTHV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count.

**Accessing the CNTHV_CVAL**

This register can be read using MRRC with the following syntax:

```
MRRC <syntax>
```

This register can be written using MCRR with the following syntax:

```
MCRR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>coproc</th>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0VTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.
G6.5.8  **CNTHV_TVAL, Counter-timer Virtual Timer TimerValue register (EL2)**

The CNTHV_TVAL characteristics are:

**Purpose**

Provides AArch32 access to the timer value for the EL2 virtual timer.

--- **Note** ---

The EL2 virtual timer is implemented by ARMv8.1-VHE. It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of HCR_EL2.{E2H, TGE} is {1, 1}.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTHV_TVAL is architecturally mapped to AArch64 System register CNTHV_TVAL_EL2.

This register is introduced in ARMv8.1.

**Attributes**

CNTHV_TVAL is a 32-bit register.

**Field descriptions**

The CNTHV_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimerValue</td>
<td></td>
</tr>
</tbody>
</table>

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 virtual timer.

On a read of this register:

- If CNTHV_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHV_CTL.ENABLE is 1, the value returned is (CNTHV_CVAL - CNTVCT).

On a write of this register, CNTHV_CVAL is set to (CNTVCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CNTHV_CVAL) is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTV_CTL.ISTATUS is set to 1.
- If CNTV_CTL.IMASK is 0, an interrupt is generated.

When CNTHV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down.

**Accessing the CNTHV_TVAL**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c3, 0</td>
<td>000</td>
<td>000</td>
<td>1110</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

This register is accessed using the encoding for CNTV_TVAL.

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>CNTV_TVAL</td>
</tr>
<tr>
<td>0 0 1</td>
<td>CNTV_TVAL</td>
</tr>
<tr>
<td>0 1 1</td>
<td>CNTV_TVAL</td>
</tr>
<tr>
<td>1 0 1</td>
<td>CNTV_TVAL</td>
</tr>
<tr>
<td>1 1 1</td>
<td>RW</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0VTEN == 0, Non-secure accesses to this register from EL0 are trapped to EL2.
G6.5.9 CNTKCTL, Counter-timer Kernel Control register

The CNTKCTL characteristics are:

**Purpose**
Controls the generation of an event stream from the virtual counter, and access from EL0 modes to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

**Configurations**
There is one instance of this register that is used in both Secure and Non-secure states.
AArch32 System register CNTKCTL is architecturally mapped to AArch64 System register CNTKCTL_EL1.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
CNTKCTL is a 32-bit register.

**Field descriptions**
The CNTKCTL bit assignments are:

![Field Diagram](image)

**Bits [31:10]**
Reserved, RES0.

**PL0PTEN, bit [9]**
Traps PL0 accesses to the physical timer registers to Undefined mode.
0   PL0 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL registers are trapped to Undefined mode.
1   This control does not cause any instructions to be trapped.

**PL0VTEN, bit [8]**
Traps PL0 accesses to the virtual timer registers to Undefined mode.
0   PL0 accesses to the CNTV_CTL, CNTV_CVAL, and CNTV_TVAL registers are trapped to Undefined mode.
1   This control does not cause any instructions to be trapped.

**EVNTI, bits [7:4]**
Selects which bit (0 to 15) of the counter register CNTVCT is the trigger for the event stream generated from that counter, when that stream is enabled.
EVNTDIR, bit [3]
Controls which transition of the counter register CNTVCT trigger bit, defined by EVNTI, generates an event when the event stream is enabled:
0 A 0 to 1 transition of the trigger bit triggers an event.
1 A 1 to 0 transition of the trigger bit triggers an event.

EVNTEN, bit [2]
Enables the generation of an event stream from the counter register CNTVCT:
0 Disables the event stream.
1 Enables the event stream.

PL0VCTEN, bit [1]
Traps PL0 accesses to the frequency register and virtual counter register to Undefined mode.
0 PL0 accesses to the CNTVCT are trapped to Undefined mode.
PL0 accesses to the CNTFRQ register are trapped to Undefined mode, if CNTKCTL.PL0PCTEN is also 0.
1 This control does not cause any instructions to be trapped.

PL0PCTEN, bit [0]
Traps PL0 accesses to the frequency register and physical counter register to Undefined mode.
0 PL0 accesses to the CNTPCT are trapped to Undefined mode.
PL0 accesses to the CNTFRQ register are trapped to Undefined mode, if CNTKCTL.PL0VCTEN is also 0.
1 This control does not cause any instructions to be trapped.

Accessing the CNTKCTL
This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c1, 0</td>
<td>000</td>
<td>000</td>
<td>1110</td>
<td>1111</td>
<td>0001</td>
</tr>
</tbody>
</table>

Accessibility
The register is accessible in software as follows:
G6.5.10 CNTP_CTL, Counter-timer Physical Timer Control register

The CNTP_CTL characteristics are:

**Purpose**

Control register for the EL1 physical timer.

**Configurations**

AArch32 System register CNTP_CTL is architecturally mapped to AArch64 System register CNTP_CTL_EL0.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTP_CTL is a 32-bit register.

**Field descriptions**

The CNTP_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:3</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>2</td>
<td>ISTATUS</td>
</tr>
<tr>
<td>1</td>
<td>IMASK</td>
</tr>
<tr>
<td>0</td>
<td>ENABLE</td>
</tr>
</tbody>
</table>

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

0 Timer condition is not met.
1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see Operation of the CompareValue views of the timers on page D6-2187 and Operation of the TimerValue views of the timers on page D6-2188.

This bit is read-only.

This field resets to a value that is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

0 Timer interrupt is not masked by the IMASK bit.
1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to a value that is architecturally UNKNOWN.
ENABLE, bit [0]

Enables the timer. Permitted values are:
0 Timer disabled.
1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TV AL continues to count down.

Note
Disabling the output signal might be a power-saving option.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the CNTP_CTL

This register can be read using MRC with the following syntax:
MRC <syntax>

This register can be written using MCR with the following syntax:
MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c2, l</td>
<td>000 001 1110 1111 0010</td>

</tbody>
</table>
Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CNTKCTL_EL1.EL0PTEN==0, accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTL.PL0PTEN==0, accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CNTHCTL_EL2.EL1PCEN==0, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If CNTHCTL_EL2.EL1PCEN==0, and CNTHCTL_EL1.EL0PTEN==1, Non-secure accesses to this register from EL0 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CNTHCTL_EL2.EL1PTEN==0, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If CNTHCTL_EL2.EL1PTEN==0, and CNTKCTL_EL1.EL0PTEN==1, Non-secure accesses to this register from EL0 are trapped to EL2.
  - If CNTKCTL_EL1.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTL.PL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If CNTHCTL.PL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
G6.5.11   CNTP_CVAL, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL characteristics are:

**Purpose**
Holds the compare value for the EL1 physical timer.

**Configurations**
AArch32 System register CNTP_CVAL is architecturally mapped to AArch64 System register CNTP_CVAL_EL0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
CNTP_CVAL is a 64-bit register.

**Field descriptions**
The CNTP_CVAL bit assignments are:

CompareValue, bits [63:0]
Holds the EL1 physical timer CompareValue.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTP_CTL.ISTATUS is set to 1.
- If CNTP_CTL.IMASK is 0, an interrupt is generated.

When CNTP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count.

**Accessing the CNTP_CVAL**
This register can be read using MRRC with the following syntax:
MRRC <syntax>

This register can be written using MCRR with the following syntax:
MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CNTKCT_EL1.EL0PTEN==0, accesses to this register from EL0 are trapped to EL1.
  - If CNTKCT.PL0PTEN==0, accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CNTHCTL_EL2.EL1PCEN==0, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If CNTHCTL_EL2.EL1PCEN==0, and CNTKCT_EL1.EL0PTEN==1, Non-secure accesses to this register from EL0 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CNTHCTL_EL2.EL1PTEN==0, Non-secure accesses to this register from EL1 are trapped to EL2.
  - If CNTHCTL_EL2.EL1PTEN==0, and CNTKCT_EL1.EL0PTEN==1, Non-secure accesses to this register from EL0 are trapped to EL2.
  - If CNTKCT_EL1.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL1.
  - If CNTKCT.PL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to Undefined mode.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  — If CNTHCTL_EL2.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.

• When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  — If CNTHCTL.PL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
G6.5.12 **CNTP_TVAL, Counter-timer Physical Timer TimerValue register**

The CNTP_TVAL characteristics are:

**Purpose**

Holds the timer value for the EL1 physical timer.

**Configurations**

AArch32 System register CNTP_TVAL is architecturally mapped to AArch64 System register CNTP_TVAL_EL0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTP_TVAL is a 32-bit register.

**Field descriptions**

The CNTP_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimerValue</td>
<td></td>
</tr>
</tbody>
</table>

**TimerValue, bits [31:0]**

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If CNTP_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTP_CTL.ENABLE is 1, the value returned is (CNTP_CV AL - CNTPCT).

On a write of this register, CNTP_CV AL is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CNTP_CV AL) is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTP_CTL.ISTATUS is set to 1.
- If CNTP_CTL.IMASK is 0, an interrupt is generated.

When CNTP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count, so the TimerValue view appears to continue to count down.

**Accessing the CNTP_TVAL**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

* When HCR_EL2.E2H == 0:
  * If CNTKCTL_EL1.ELOPTEN==0, accesses to this register from EL0 are trapped to EL1.
  * If CNTKCTL.PL0PTEN==0, accesses to this register from EL0 are trapped to Undefined mode.
* When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  * If CNTHCTL_EL2.EL1PCEN==0, Non-secure accesses to this register from EL1 are trapped to EL2.
  * If CNTHCTL_EL2.EL1PCEN==0, and CNTKCTL_EL1.ELOPTEN==1, Non-secure accesses to this register from EL0 are trapped to EL2.
* When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  * If CNTHCTL_EL2.EL1PTEN==0, Non-secure accesses to this register from EL1 are trapped to EL2.
  * If CNTHCTL_EL2.EL1PTEN==0, and CNTKCTL_EL1.ELOPTEN==1, Non-secure accesses to this register from EL0 are trapped to EL2.
  * If CNTKCTL_EL1.ELOPTEN==0, Non-secure accesses to this register from EL0 are trapped to Undefined mode.
* If CNTKCTL.PL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If CNTHCTL.PL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
G6.5.13 CNTPCT, Counter-timer Physical Count register

The CNTPCT characteristics are:

**Purpose**

Holds the 64-bit physical count value.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTPCT is architecturally mapped to AArch64 System register CNTPCT_EL0.

**Attributes**

CNTPCT is a 64-bit register.

**Field descriptions**

The CNTPCT bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Physical count value</th>
</tr>
</thead>
</table>

**Accessing the CNTPCT**

This register can be read using MRRC with the following syntax:

```
MRRC <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>coproc</th>
<th>CRm</th>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CNTKCTL_EL1.EL0PCTEN==0, read accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTL.PL0PCTEN==0, read accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CNTHCTL_EL2.EL1PCTEN==0, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If CNTHCTL_EL2.EL1PCTEN==0, and CNTKCTL_EL1.EL0PCTEN==1, Non-secure read accesses to this register from EL0 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CNTHCTL_EL2.EL1PCTEN==0, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If CNTHCTL_EL2.EL1PCTEN==0, and CNTKCTL_EL1.EL0PCTEN==1, Non-secure read accesses to this register from EL0 are trapped to EL2.
  - If CNTKCTL_EL1.EL0PCTEN==0, Non-secure read accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTL.PL0PCTEN==0, Non-secure read accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0PCTEN==0, Non-secure read accesses to this register from EL0 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
  - If CNTHCTL.PL1PCTEN==0, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
G6.5.14 CNTV_CTL, Counter-timer Virtual Timer Control register

The CNTV_CTL characteristics are:

**Purpose**

Control register for the virtual timer.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTV_CTL is architecturally mapped to AArch64 System register CNTV_CTL_EL0.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTV_CTL is a 32-bit register.

**Field descriptions**

The CNTV_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:3</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>2</td>
<td>ISTATUS</td>
</tr>
<tr>
<td>1</td>
<td>IMASK</td>
</tr>
<tr>
<td>0</td>
<td>ENABLE</td>
</tr>
</tbody>
</table>

- **ISTATUS, bit [2]**
  
  The status of the timer. This bit indicates whether the timer condition is met:
  
  0 Timer condition is not met.
  
  1 Timer condition is met.
  
  When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.
  
  When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.
  
  For more information see Operation of the CompareValue views of the timers on page D6-2187 and Operation of the TimerValue views of the timers on page D6-2188.
  
  This bit is read-only.
  
  This field resets to a value that is architecturally UNKNOWN.

- **IMASK, bit [1]**
  
  Timer interrupt mask bit. Permitted values are:
  
  0 Timer interrupt is not masked by the IMASK bit.
  
  1 Timer interrupt is masked by the IMASK bit.
  
  For more information, see the description of the ISTATUS bit.
  
  This field resets to a value that is architecturally UNKNOWN.
ENABLE, bit [0]

Enables the timer. Permitted values are:

0  Timer disabled.
1  Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TV continues to count down.

--- Note ---

Disabling the output signal might be a power-saving option.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the CNTV_CTL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th></th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c3, 1</td>
<td>000</td>
<td>001</td>
<td>1110</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0 EL1 EL2 EL3</td>
</tr>
<tr>
<td>x x 0</td>
<td>RW RW n/a RW</td>
</tr>
<tr>
<td>0 0 1</td>
<td>RW RW RW RW</td>
</tr>
<tr>
<td>0 1 1</td>
<td>RW n/a RW RW</td>
</tr>
<tr>
<td>1 0 1</td>
<td>RW RW n/a n/a</td>
</tr>
<tr>
<td>1 1 1</td>
<td>CNTHV_CTL n/a n/a n/a</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CNTKCTL_EL1.EL0VTEN==0, accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTL.PL0VTEN==0, accesses to this register from EL0 are trapped to Undefined mode.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) &&
  (HCR_EL2.TGE == 0):
  — If CNTKCTL_EL1.EL0VTEN==0, Non-secure accesses to this register from EL0 are trapped to EL1.
  — If CNTKCTL.PL0VTEN==0, Non-secure accesses to this register from EL0 are trapped to Undefined
  mode.
• When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) &&
  (HCR_EL2.TGE == 1):
  — If CNTHCTL_EL2.EL0VTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.
G6.5.15  CNTV_CVAL, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL characteristics are:

**Purpose**

Holds the compare value for the virtual timer.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTV_CVAL is architecturally mapped to AArch64 System register CNTV_CVAL_EL0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTV_CVAL is a 64-bit register.

**Field descriptions**

The CNTV_CVAL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:0</td>
<td>CompareValue</td>
</tr>
</tbody>
</table>

**CompareValue, bits [63:0]**

Holds the EL1 virtual timer CompareValue.

When CNTV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTV_CTL.ISTATUS is set to 1.
- If CNTV_CTL.IMASK is 0, an interrupt is generated.

When CNTV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count.

**Accessing the CNTV_CVAL**

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>opc1</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 3, &lt;Rt&gt;, &lt;Rt2&gt;, cl4</td>
<td>0011</td>
<td>1111</td>
<td>1110</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H TGE NS</td>
<td>EL0</td>
</tr>
<tr>
<td>x x 0</td>
<td>RW</td>
</tr>
<tr>
<td>0 0 1</td>
<td>RW</td>
</tr>
<tr>
<td>0 1 1</td>
<td>RW</td>
</tr>
<tr>
<td>1 0 1</td>
<td>RW</td>
</tr>
<tr>
<td>1 1 1</td>
<td>CNTHV_CVAL</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CNTKCTL_EL1.EL0VTEN==0, accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTL.PL0VTEN==0, accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CNTKCTL_EL1.EL0VTEN==0, Non-secure accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTL.PL0VTEN==0, Non-secure accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTHCTL_EL2.EL0VTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.
**G6.5.16 CNTV_TVAL, Counter-timer Virtual Timer TimerValue register**

The CNTV_TVAL characteristics are:

**Purpose**

Holds the timer value for the virtual timer.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTV_TVAL is architecturally mapped to AArch64 System register CNTV_TVAL_EL0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTV_TVAL is a 32-bit register.

**Field descriptions**

The CNTV_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimerValue</td>
<td></td>
</tr>
</tbody>
</table>

TimerValue, bits [31:0]

The TimerValue view of the virtual timer.

On a read of this register:

- If CNTV_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTV_CTL.ENABLE is 1, the value returned is (CNTV_CVAL - (CNTPCT - CNTP_CV AL)).

On a write of this register, CNTV_CVAL is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CNTP_CVAL) is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTV_CTL.ISTATUS is set to 1.
- If CNTV_CTL.IMASK is 0, an interrupt is generated.

When CNTV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down.

**Accessing the CNTV_TVAL**

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>
This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>opc2</th>
<th>CRn</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 0, &lt;Rt&gt;, c14, c3, 0</td>
<td>000</td>
<td>000</td>
<td>1110</td>
<td>1111</td>
<td>0011</td>
</tr>
</tbody>
</table>

**Accessibility**

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

**Traps and Enables**

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state*. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CNTKCTL_EL1.EL0VTEN == 0, accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTLP.L0VTEN == 0, accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CNTKCTL_EL1.EL0VTEN == 0, Non-secure accesses to this register from EL0 are trapped to EL1.
  - If CNTKCTLP.L0VTEN == 0, Non-secure accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTTHCTL_EL2.EL0VTEN == 0, Non-secure accesses to this register from EL0 are trapped to EL2.
G6.5.17 CNTVCT, Counter-timer Virtual Count register

The CNTVCT characteristics are:

**Purpose**

Holds the 64-bit virtual count value. The virtual count value is equal to the physical count value visible in CNTPCT minus the virtual offset visible in CNTVOFF.

**Configurations**

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTVCT is architecturally mapped to AArch64 System register CNTVCT_EL0.

The value of this register is the same as the value of CNTPCT in the following conditions:

- When EL2 is not implemented.
- When EL2 is implemented and is using AArch64, HCR_EL2.{E2H, TGE} is {1, 1}, and this register is read from Non-secure EL0.

**Attributes**

CNTVCT is a 64-bit register.

**Field descriptions**

The CNTVCT bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Virtual count value</td>
</tr>
</tbody>
</table>

**Bits [63:0]**

Virtual count value.

**Accessing the CNTVCT**

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 1, &lt;Rt&gt;, &lt;Rt2&gt;, c14</td>
<td>0001</td>
<td>1111</td>
<td>1110</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>

Traps and Enables

For a description of the prioritization of any generated exceptions, see Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344 for exceptions taken to AArch32 state and Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CNTKCTL.PL0VCTEN==0, read accesses to this register from EL0 are trapped to Undefined mode.
  - If CNTKCTL_EL1.PL0VCTEN==0, read accesses to this register from EL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CNTKCTL.PL0VCTEN==0, Non-secure read accesses to this register from EL0 are trapped to Undefined mode.
  - If CNTKCTL_EL1.PL0VCTEN==0, Non-secure read accesses to this register from EL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CNTKCTL_EL2.PL0VCTEN==0, Non-secure read accesses to this register from EL0 are trapped to EL2.
G6.5.18 CNTVOFF, Counter-timer Virtual Offset register

The CNTVOFF characteristics are:

**Purpose**
Holds the 64-bit virtual offset. This is the offset between the physical count value visible in CNTPCT and the virtual count value visible in CNTVCT.

**Configurations**
AArch32 System register CNTVOFF is architecturally mapped to AArch64 System register CNTVOFF_EL2.

If EL2 is not implemented, this register is RES0 from EL3 and the virtual counter uses a fixed virtual offset of zero.

--- Note ---
When EL2 is implemented and is using AArch64, if HCR_EL2.{E2H, TGE} is \{1, 1\}, the virtual counter uses a fixed virtual offset of zero when CNTVCT is read from Non-secure EL0.

When EL2 is implemented and can use AArch32, on a reset into an Exception level that is using AArch32 this register resets to an IMPLEMENTATION DEFINED value that might be UNKNOWN.

**Attributes**
CNTVOFF is a 64-bit register.

**Field descriptions**
The CNTVOFF bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual offset</th>
</tr>
</thead>
</table>

**Accessing the CNTVOFF**
This register can be read using MRRC with the following syntax:

```
MRRC <syntax>
```

This register can be written using MCRR with the following syntax:

```
MCRR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<table>
<thead>
<tr>
<th>&lt;syntax&gt;</th>
<th>opc1</th>
<th>coproc</th>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>p15, 4, &lt;Rt&gt;, &lt;Rt2&gt;, c14</td>
<td>0100</td>
<td>1111</td>
<td>1110</td>
</tr>
</tbody>
</table>
Accessibility

The register is accessible in software as follows:

<table>
<thead>
<tr>
<th>Control</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2H</td>
<td>TGE</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>x</td>
<td>0</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
</tr>
</tbody>
</table>
Part H
External Debug
Chapter H1
About External Debug

This chapter gives an overview of ARMv8 external debug, and specifies the required debug authentication. It contains the following sections:

- Introduction to external debug on page H1-5430.
- External debug on page H1-5431.
- Required debug authentication on page H1-5432.

Note
For information about self-hosted debug, see Chapter D2 AArch64 Self-hosted Debug and Chapter G2 AArch32 Self-hosted Debug.
H1.1  Introduction to external debug

ARMv8 supports both:

Self-hosted debug

The PE itself hosts a debugger. That is, developers developing software to run on the PE use debugger software running on the same PE.

External debug

The debugger is external to the PE. The debugging might be either on-chip, for example in a second PE, or off-chip, for example a JTAG debugger. External debug is particularly useful for:

• Hardware bring-up. That is, debugging during development when a system is first powered up and not all of the software functionality is available.

• PEs that are deeply embedded inside systems.

To support external debug, the ARM architecture defines required features that are called external debug features.

H1.1.1  Definition of a debugger in the context of external debug

When the description of external debug in this Part of the manual describes a debugger as controlling external debug this debugger might be a second on-chip PE or an off-chip device such as a JTAG debugger.
H1.2  **External debug**

Debug events allow an external debugger to halt the PE. ARMv8 provides the following debug events:

- **Halting Step debug events on page H3-5476**:  
  - The debugger can use this resource to make the PE step through code one line at a time.

- **Halt Instruction debug event on page H3-5486**:  
  - This might occur when software executes the Halting breakpoint instruction, **HLT**.

- **Exception Catch debug event on page H3-5487**:  
  - This can be programmed to occur on all entries to a given Exception level.

- **External Debug Request debug event on page H3-5490**:  
  - An embedded cross-trigger can signal this debug event.

- **OS Unlock Catch debug event on page H3-5491**:  
  - This might occur when the state of the OS Lock changes from locked to unlocked.

- **Reset Catch debug events on page H3-5492**:  
  - This might occur when the PE exits reset state.

- **Software Access debug event on page H3-5493**:  
  - This can be programmed to occur when software tries to access the Breakpoint Value registers, the Breakpoint Control registers, the Watchpoint value registers, or the Watchpoint Control registers. It caused a trap to Debug state.

Breakpoints and watchpoints can also halt the PE.

When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.

- The **Instruction Transfer Register**, ITR, passes instructions to the PE to execute in Debug state:  
  - The ITR contains a single register, EDITR, and associated flow-control flags.

- The **Debug Communications Channel**, DCC, passes data between the PE and the debugger:  
  - The DCC includes the data transfer registers, DTRRX and DTRTX, and associated flow-control flags.
  - Although the DCC is an essential part of Debug state operation, it can also be used in Non-debug state.

- The PE cannot service any interrupts in Debug state.

**Chapter H2 Debug State** describes Debug state in more detail.
H1.3 Required debug authentication

Any implementation must provide the debug authentication defined in this section, that controls:

- Whether the PE can halt.
- Whether non-invasive debug is permitted.
- Some legacy aspects of the AArch32 self-hosted debug model.

The pseudocode functions shown in Table H1-1, and the conditions that follow that table, define the architectural requirements for debug authentication.

### Table H1-1 Debug authentication functions

<table>
<thead>
<tr>
<th>Pseudocode function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ExternalSecureNoninvasiveDebugEnabled()</code></td>
<td>Returns TRUE if Secure non-invasive debug is enabled.</td>
</tr>
<tr>
<td><code>AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()</code></td>
<td>Returns TRUE if Secure invasive self-hosted debug is enabled in AArch32 state.</td>
</tr>
<tr>
<td><code>ExternalSecureInvasiveDebugEnabled()</code></td>
<td>Returns TRUE if Secure invasive debug is enabled.</td>
</tr>
<tr>
<td><code>ExternalNoninvasiveDebugEnabled()</code></td>
<td>Returns TRUE if Non-secure non-invasive debug is enabled.</td>
</tr>
<tr>
<td><code>ExternalInvasiveDebugEnabled()</code></td>
<td>Returns TRUE if Non-secure invasive debug is enabled.</td>
</tr>
</tbody>
</table>

The following conditions always apply:

- if `ExternalInvasiveDebugEnabled()` is FALSE then `ExternalSecureInvasiveDebugEnabled()` is FALSE.
- if `ExternalNoninvasiveDebugEnabled()` is FALSE then `ExternalSecureNoninvasiveDebugEnabled()` is FALSE.
- if `ExternalInvasiveDebugEnabled()` is TRUE then `ExternalNoninvasiveDebugEnabled()` is TRUE.
- if `ExternalSecureInvasiveDebugEnabled()` is TRUE then `ExternalSecureNoninvasiveDebugEnabled()` is TRUE.

ARM recommends the use of the interface described in Recommended authentication interface on page K2-6140 to provide this debug authentication. The pseudocode functions in Chapter J1 ARMv8 Pseudocode, that are linked to by the entries in the Pseudocode function column of Table H1-1, assume that this interface is implemented.
Chapter H2
Debug State

This chapter describes Debug state. It contains the following sections:

• About Debug state on page H2-5434.
• Halting the PE on debug events on page H2-5435.
• Entering Debug state on page H2-5442.
• Behavior in Debug state on page H2-5445.
• Exiting Debug state on page H2-5471.

——— Note ————
Table K11-1 on page K11-6282 disambiguates the general register references used in this chapter.
H2.1 About Debug state

In external debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The Instruction Transfer Register, ITR, passes instructions to the PE to execute in Debug state.
- The Debug Communications Channel, DCC, passes data between the PE and the debugger.

The PE cannot service any interrupts in Debug state.
H2.2 Halting the PE on debug events

For details of debug events, see Introduction to Halting debug events on page H3-5474 and Breakpoint and Watchpoint debug events on page H2-5436.

On a debug event, the PE must do one of the following:

• Enter Debug state.
• Pend the debug event.
• Generate a debug exception.
• Ignore the debug event.

This behavior depends on both:

• Whether halting is allowed by the current state of the debug authentication interface. See Halting allowed and halting prohibited.
• The type of debug event and the programming of the debug control registers.
  — See Halting debug events for all Halting debug events.
  — See Breakpoint and Watchpoint debug events on page H2-5436 for Breakpoint and Watchpoint debug events.

See also Other debug exceptions on page H2-5437.

This means that behavior can be CONSTRAINED UNPREDICTABLE if the conditions change. See Synchronization and Halting debug events on page H3-5494.

Summary of debug events and possible outcomes on page H3-5474 summarizes the possible outcomes of each type of debug event.

H2.2.1 Halting allowed and halting prohibited

Halting can be either allowed or prohibited:

• Halting is always prohibited in Debug state.
• Halting is always prohibited when DoubleLockStatus() == TRUE.
  — This means that OS Double Lock is locked.
• Halting is also controlled by the IMPLEMENTATION DEFINED authentication interface, and is prohibited when either:
  — The PE is in Non-secure state and ExternalInvasiveDebugEnabled() == FALSE.
  — The PE is in Secure state and ExternalSecureInvasiveDebugEnabled() == FALSE.

  — Note —
  See Appendix K2 Recommended External Debug Interface for more information on these functions.

• Otherwise, halting is allowed.

See

• Pseudocode description of Halting on debug events on page H2-5441
• Required debug authentication on page H1-5432.

H2.2.2 Halting debug events

The Halting debug events are described in Chapter H3 Halting Debug Events.
When a Halting debug event is generated, it causes entry to Debug state if all of:

- Halting is allowed. See *Halting allowed and halting prohibited* on page H2-5435.
- The Halting debug event is one of:
  - A Halt Instruction debug event and $\text{EDSCR.HDE} = 1$.
  - A Software Access debug event and $\text{OSLSR.EL1.OSLK} = 0$, meaning that the OS Lock is unlocked.
  - Neither a Halt Instruction debug event nor a Software Access debug event.

**Note**

- A Halt Instruction debug event is the only Halting debug event that relies on $\text{EDSCR.HDE} = 1$.
- Halting on Breakpoint and Watchpoint debug events is also controlled by $\text{EDSCR.HDE}$. See *Breakpoint and Watchpoint debug events*.
- $\text{EDSCR.HDE}$ can be written by software when the OS Lock is locked. Privileged code can use $\text{SDCR.TDOSA}$ and $\text{HDCR.TDOSA}$ to trap writes to these registers.

If a Halting debug event does not generate entry to Debug state because the conditions listed in this section do not hold, then:

- If the Halting debug event is a Halt Instruction debug event, the instruction that generated the Halting debug event is treated as UNDEFINED.
- If the Halting debug event is an Exception Catch debug event or a Software Access debug event, it is ignored.

In all other cases the Halting debug event is pended, see *Pending Halting debug events* on page H3-5494.

*Summary of actions from debug events* on page H2-5439 summarizes the possible outcome for each type of Debug event.

**Note**

Halting debug events never generate debug exceptions.

### H2.2.3 Breakpoint and Watchpoint debug events

A breakpoint or watchpoint generates an entry to Debug state if all of the following conditions hold:

- Halting debug is enabled, that is $\text{EDSCR.HDE} = 1$.
- Halting is allowed. See *Halting allowed and halting prohibited* on page H2-5435.
- The OS Lock is unlocked, that is $\text{OSLSR.OSLK} = 0$.

The Address Mismatch breakpoint type is reserved when all of these conditions are met.

$\text{MDSCR.EL1.MDE}$ or $\text{DBGDSCRext.MDBGen}$ is ignored when determining whether to enter Debug state. A breakpoint or watchpoint that generates entry to Debug state is a Breakpoint or Watchpoint debug event and does not generate a debug exception.

A breakpoint or watchpoint that does not generate an entry to Debug state either:

- Generates a Breakpoint or Watchpoint exception.
- Is ignored.

**Note**

$\text{EDSCR.HDE}$ is ignored when determining whether to generate a debug exception. The debug exception is suppressed only if the PE enters Debug state. This means that the use of Halting debug mode in Non-secure state does not affect the Exception model in Secure state.

See Chapter D2 *AArch64 Self-hosted Debug*, Chapter G2 *AArch32 Self-hosted Debug*, and the Note in *Other debug exceptions* on page H2-5437.
H2.2.4 Other debug exceptions

The following events never generate entry to Debug state:
- Breakpoint Instruction exceptions.
- Software Step exceptions.
- Vector Catch exceptions.

The behavior of these events is unchanged when Halting debug mode is enabled, that is when EDSCR.HDE == 1. This means that these events can do one of the following:
- They can generate a debug exception.
- They can be ignored.

For additional information, see Chapter D2 AArch64 Self-hosted Debug and Chapter G2 AArch32 Self-hosted Debug.

H2.2.5 Debug state entry and debug event prioritization

The following are synchronous debug events:
- Breakpoint debug event.
- Watchpoint debug event.
- Halting Step debug event.
- Halt Instruction debug event.
- Exception Catch debug event.
- Software Access debug event.
- Reset Catch debug event.

Each of these synchronous debug events are treated as a synchronous exception generated by an instruction, or by the taking of an exception or reset. That is, if halting is allowed, the synchronous debug event must be taken before any subsequent instructions are executed. Reset Catch debug events must be taken before the PE executes the instruction at the reset vector.

Note
- Reset Catch and Exception Catch debug events might be generated asynchronously, because they can result from an asynchronous exception. However, if halting is allowed after the reset or asynchronous exception has been processed, the Reset Catch or Exception Catch debug event is taken synchronously.
- The Halting Step debug event is generated by the instruction after the stepped instruction. Therefore, if the stepped instruction generates any other synchronous exceptions or debug events these are taken first.

If halting is prohibited then Halting Step debug events and Reset Catch debug events might be pended and taken asynchronously. OS Unlock Catch debug events are always pended and taken asynchronously. See Pending Halting debug events on page H3-5494.

The architecture does not define when asynchronous debug events are taken, and therefore the prioritization of asynchronous debug events is IMPLEMENTATION DEFINED. See Synchronization and Halting debug events on page H3-5494.

The following list shows how the synchronous debug events are prioritized, with -2 being the highest priority.

Note
