Lecture 5

Randomized algorithms
and QuickSort

**INEFFECTIVE Sorts**

```
DEFINE HALFHEARTEDMERGESORT(list):
  IF LENGTH(list) < 2:
    RETURN list
  PIVOT = INT((LENGTH(list) / 2))
  A = HALFHEARTEDMERGESORT(list[:PIVOT])
  B = HALFHEARTEDMERGESORT(list[PIVOT:])
  // UMMMM
  RETURN [A, B] // HERE. SORRY.

DEFINE FASTBOGOSORT(list):
  // AN OPTIMIZED BOGOSORT
  // RUNS IN O(N LOG N)
  FOR N FROM 1 TO LOG(LENGTH(list)):
    SHUFFLE(list)
    IF ISORTED(list):
      RETURN list
  RETURN "KERNEL PAGE FAULT (ERROR CODE: 2)"

DEFINE JOBINTERVIEWQUICKSORT(list):
  OK SO YOU CHOOSE A PIVOT
  THEN DIVIDE THE LIST IN HALF
  FOR EACH HALF:
    CHECK TO SEE IF IT'S SORTED
    NO, WAIT, IT DOESN'T MATTER
    COMPARE EACH ELEMENT TO THE PIVOT
    THE BIGGER ONES GO IN A NEW LIST
    THE EQUAL ONES GO INTO, UH
    THE SECOND LIST FROM BEFORE
    HANG ON, LET ME NAME THE LISTS
    THIS IS LIST A
    THE NEW ONE IS LIST B
    PUT THE BIG ONES INTO LIST B
    NOW TAKE THE SECOND LIST
    CALL IT LIST, UH, A2.
    WHICH ONE WAS THE PIVOT IN?
    SCRAPE ALL THAT
    IT JUST RECURSIVELY CALLS ITSELF
    UNTIL BOTH LISTS ARE EMPTY
    RIGHT?
    NOT EMPTY, BUT YOU KNOW WHAT I MEAN
    AM I ALLOWED TO USE THE STANDARD LIBRARIES?

DEFINE PANICSORT(list):
  IF ISORTED(list):
    RETURN list
  FOR N FROM 1 TO 10000:
    PIVOT = RANDOM(0, LENGTH(list))
    LIST = LIST[:PIVOT] + LIST[PIVOT:]
    IF ISORTED(list):
      RETURN list
    IF ISORTED(list):
      RETURN list
    IF ISORTED(list):
      // THIS CAN'T BE HAPPENING
      RETURN list
    IF ISORTED(list):
      // COME ON COME ON
      RETURN list
    // OH JEEZ
    // I'M GONNA BE IN SO MUCH TROUBLE
    LIST = [ ]
    SYSTEM("SHUTDOWN -H +5")
    SYSTEM("RM -RF /")
    SYSTEM("RM -RF ~/*")
    SYSTEM("RM -RF /")
    SYSTEM("RD /S /Q C:\*") // PORTABILITY
    RETURN [1, 2, 3, 4, 5]
```
Announcements

• HW2 Due Wednesday!
• Add/Drop deadline is Friday!
  • We will release grades for HW1 well before then so you have some more data.
• CS161A (ACE) materials are available for everyone on the course website!
  • Thanks Stephan!
• HW Party this week will be in BISHOP (not Gates)
• Is anyone missing a red Stanford hoodie?
  • Left at Michelle’s section last week
  • It’s in my office (Gates 168), shoot me an email to find a time to pick it up (marykw@stanford)
More announcements

• When submitting HW:
  • If working in a group, and you want to submit together, please tag your group-mates!
  • If you re-submit, you need to re-tag all your group members.
  • If working in a group and you want to submit similar but separate PSETs, please list your group-mates at the top of the assignment.
More announcements
A few notes from feedback

• The laser pointer doesn’t show up on the videos
  • Sorry! Better now?

• Office hours are crazy!
  • We are sorry and we are working on it! In the meantime, consider:
    • HW party (there were way fewer people in Week 2)
    • Section
    • OH earlier in the HW cycle

• The lectures sometimes skip over some details...where can we get those details?
  • Check out the textbook! There’s a reading assignment for every lecture posted on the webpage!

• Please keep sending us feedback!
  • Anonymous feedback form on website
  • High-resolution feedback (random sample)
  • Just post on Ed
Ed Heroes!
As of Sunday evening

Last time

- We saw a divide-and-conquer algorithm to solve the \textbf{Select} problem in time $O(n)$ in the worst-case.
- It all came down to picking the pivot...

![Graph showing different algorithms for selection with varying performance times]

We choose a pivot \textit{cleverly}.

We choose a pivot \textit{randomly}.
Randomized algorithms

• We make some random choices during the algorithm.
• We hope the algorithm works.
• We hope the algorithm is fast.

For today we will look at algorithms that always work and are probably fast.

e.g., \textbf{Select} with a random pivot is a randomized algorithm.
• Always works (aka, is correct).
• Probably fast.
Today

• How do we analyze randomized algorithms?
• A few randomized algorithms for sorting.
  • BogoSort
  • QuickSort

• BogoSort is a pedagogical tool.
• QuickSort is important to know. (in contrast with BogoSort...
How do we measure the runtime of a randomized algorithm?

**Scenario 1**
1. You publish your algorithm.
2. Bad guy picks the input.
3. You run your randomized algorithm.

**Scenario 2**
1. You publish your algorithm.
2. Bad guy picks the input.
3. Bad guy chooses the randomness (fixes the dice) and runs your algorithm.

- In **Scenario 1**, the running time is a **random variable**.
  - It makes sense to talk about **expected running time**.
- In **Scenario 2**, the running time is **not random**.
  - We call this the **worst-case running time** of the randomized algorithm.
Today

• How do we analyze randomized algorithms?
• A few randomized algorithms for sorting.
  • BogoSort
  • QuickSort

• **BogoSort** is a pedagogical tool.
• **QuickSort** is important to know. (in contrast with BogoSort...)
From your pre-lecture exercise:

**BogoSort**

- **BogoSort**(A)
  - **While** true:
    - Randomly permute A.
    - Check if A is sorted.
    - **If** A is sorted, **return** A.

- Let $X_i = \begin{cases} 1 & \text{if A is sorted after iteration } i \\ 0 & \text{otherwise} \end{cases}$

- $E[X_i] = \frac{1}{n!} \quad \text{There are } n! \text{ possible orderings, and only one of them is sorted.}$

- $E[\text{number of iterations until A is sorted}] = n!$  
  \[ \text{Follows from properties of geometric random variables! (c.f. CS109). Or see skipped slides.} \]
Solutions to pre-lecture exercise 1

1. Let $X$ be a random variable which is 1 with probability 1/100 and 0 with probability 99/100.
   a) $E[X] = 1/100$
   b) If $X_1, X_2, \ldots, X_n$ are iid copies of $X$, by linearity of expectation,
      $$E \left[ \sum_{i=1}^{n} X_i \right] = \sum_{i=1}^{n} E[X_i] = \frac{n}{100}$$
   c) Let $N$ be the index of the first 1. Then $E[N] = 100$.

To see part (c), either:

- You saw in CS109 that $N$ is a geometric random variable, and you know a formula for that.
- Suppose you do the first trial. If it comes up 1 (with probability 1/100), then $N=1$. Otherwise, you start again except you’ve already used one trial. Thus:

  $$E[N] = \frac{1}{100} \cdot 1 + \left(1 - \frac{1}{100}\right) \cdot (1 + E[N]) = 1 + \left(1 - \frac{1}{100}\right)E[N]$$

  Solving for $E[N]$ we see $E[N] = 100$.

- (There are other derivations too).
Solutions to pre-lecture exercise 2

2. Let $X_i$ be 1 iff A is sorted on iteration $i$.
   a) Okay. (There wasn’t actually a question for part (a)…) 
   b) $E[X_i] = 1/n!$ since there are $n!$ possible orderings of A and only one is sorted. (Suppose A has distinct entries). 
   c) Let N be the index of the first 1. Then $E[N] = n!$.

Part (c) is similar to part (c) in exercise 1:

- You saw in CS109 that N is a geometric random variable, and you know a formula for that. Or,
- Suppose you do the first trial. If it comes up 1 (with probability $1/n!$), then $N=1$. Otherwise, you start again except you’ve already used one trial. Thus:

\[
E[N] = \frac{1}{n!} \cdot 1 + \left(1 - \frac{1}{n!}\right) \cdot (1 + E[N]) = 1 + \left(1 - \frac{1}{n!}\right) E[N]
\]

Solving for $E[N]$ we see $E[N] = n!$

- (There are other derivations too).
From your pre-lecture exercise:

**BogoSort**

- **BogoSort**(A)
  - **While** true:
    - Randomly permute A.
    - Check if A is sorted.
    - **If** A is sorted, **return** A.

- Let $X_i = \begin{cases} 1 & \text{if A is sorted after iteration i} \\ 0 & \text{otherwise} \end{cases}$

- $E[X_i] = \frac{1}{n!}$
  - There are $n!$ possible orderings, and only one of them is sorted.

- $E[\text{number of iterations until A is sorted}] = n!$
  - Follows from properties of geometric random variables! (c.f. CS109). Or see skipped slides.

Assume A has distinct entries

Suppose that you can draw a random integer in \{1,\ldots,n\} in time $O(1)$. How would you randomly permute an array in-place in time $O(n)$?
Expected Running time of BogoSort

\[ E[\text{running time on a list of length } n] = E[\text{(number of iterations)} \cdot \text{(time per iteration)}] \]

\[ = \text{(time per iteration)} \cdot E[\text{number of iterations}] \]

\[ = O(n \cdot n!) \]

\[ = \text{REALLY REALLY BIG.} \]
Worst-case running time of BogoSort?

Think-Pair-Share Terrapins!
1 minute: think
1 minute: pair and share

- **BogoSort**(A)
  - **While** true:
    - Randomly permute A.
    - Check if A is sorted.
    - **If** A is sorted, **return** A.
Worst-case running time of BogoSort?

- **BogoSort**($A$)
  - **While** true:
    - Randomly permute $A$.
    - Check if $A$ is sorted.
    - **If** $A$ is sorted, **return** $A$. 

Think-Pair-Share Terrapins!

Infinite!
What have we learned?

• Expected running time:
  1. You publish your randomized algorithm.
  2. Bad guy picks an input.
  3. You get to roll the dice.

• Worst-case running time:
  1. You publish your randomized algorithm.
  2. Bad guy picks an input.
  3. Bad guy gets to “roll” the dice.

• Don’t use bogoSort.
Today

• How do we analyze randomized algorithms?
• A few randomized algorithms for sorting.
  • BogoSort
  • QuickSort

• BogoSort is a pedagogical tool.
• QuickSort is important to know. (in contrast with BogoSort...)
a better randomized algorithm: 

**QuickSort**

- Expected runtime $O(n \log(n))$.
- Worst-case runtime $O(n^2)$.
- In practice works great!
Quicksort

We want to sort this array.

First, pick a “pivot.”
Do it at random.

Next, partition the array into “bigger than 5” or “less than 5”

Arrange them like so:

L = array with things smaller than A[pivot]
R = array with things larger than A[pivot]

For the rest of the lecture, assume all elements of A are distinct.
PseudoPseudoCode for what we just saw

• QuickSort(A):
  • If len(A) <= 1:
    • return
  • Pick some \( x = A[i] \) at random. Call this the \textit{pivot}.
  • PARTITION the rest of A into:
    • L (less than \( x \)) and
    • R (greater than \( x \))
  • Replace A with \([L, x, R]\) (that is, rearrange A in this order)
  • QuickSort(L)
  • QuickSort(R)

Assume that all elements of A are distinct. How would you change this if that’s not the case?
Running time?

- \( T(n) = T(|L|) + T(|R|) + O(n) \)

- In an ideal world...
  - if the pivot splits the array exactly in half...
    \[
    T(n) = 2 \cdot T \left( \frac{n}{2} \right) + O(n)
    \]

- We’ve seen that a bunch:
  \[ T(n) = O(n \log(n)). \]
The expected running time of QuickSort is $O(n \log(n))$.

Proof:

- $E[|L|] = E[|R|] = \frac{n-1}{2}$.
  - The expected number of items on each side of the pivot is half of the things.
Aside

why is $E[|L|] = \frac{n-1}{2}$?

- $E[|L|] = E[|R|]$
  - by symmetry
- $E[|L| + |R|] = n - 1$
  - because $L$ and $R$ make up everything except the pivot.
- $E[|L|] + E[|R|] = n - 1$
  - By linearity of expectation
- $2E[|L|] = n - 1$
  - Plugging in the first bullet point.
- $E[|L|] = \frac{n-1}{2}$
  - Solving for $E[|L|]$. 

Remember, we are assuming all elements of $A$ are distinct.
The expected running time of QuickSort is \( O(n \log(n)) \).

Proof:

• \( E[|L|] = E[|R|] = \frac{n-1}{2} \).
  • The expected number of items on each side of the pivot is half of the things.

• If that occurs, the running time is \( T(n) = O(n \log(n)) \).
  • Since the relevant recurrence relation is \( T(n) = 2T\left(\frac{n-1}{2}\right) + O(n) \)

• Therefore, the expected running time is \( O(n \log(n)) \).

*Disclaimer: this proof is wrong.
Red flag

Sort(A):
- If len(A) <= 1:
  - return

Pick the pivot \( x \) to be either \( \text{max}(A) \) or \( \text{min}(A) \), randomly
- We can find the max and min in \( O(n) \) time

PARTITION the rest of A into:
- L (less than \( x \)) and
- R (greater than \( x \))

Replace A with \([L, x, R]\) (that is, rearrange A in this order)

Same recurrence relation:
\[
T(n) = T(|L|) + T(|R|) + O(n)
\]
- We still have \( E[|L|] = E[|R|] = \frac{n-1}{2} \)
- But now, one of \(|L|\) or \(|R|\) is always \( n-1 \).
- You check: Running time is \( \Theta(n^2) \), with probability 1.
The expected running time of SlowSort is $O(n \log(n))$.

Proof:

- $E[|L|] = E[|R|] = \frac{n-1}{2}$.
  - The expected number of items on each side of the pivot is half of the things.
- If that occurs, the running time is $T(n) = O(n \log(n))$.
  - Since the relevant recurrence relation is $T(n) = 2T\left(\frac{n-1}{2}\right) + O(n)$
- Therefore, the expected running time is $O(n \log(n))$.

*Disclaimer: this proof is wrong.
What’s wrong?

- \( E[|L|] = E[|R|] = \frac{n-1}{2}. \)
  - The expected number of items on each side of the pivot is half of the things.
- If that occurs, the running time is \( T(n) = O(n \log(n)) \).
  - Since the relevant recurrence relation is \( T(n) = 2T\left(\frac{n-1}{2}\right) + O(n) \)
  - Therefore, the expected running time is \( O(n \log(n)) \).

That’s not how expectations work!

- The running time in the “expected” situation is not the same as the expected running time.
- Sort of like how \( E[X^2] \) is not the same as \( (E[X])^2 \)
Instead

• We’ll have to think a little harder about how the algorithm works.

Next goal:

• Get the same conclusion, correctly!
Example of recursive calls

Pick 5 as a pivot

Partition on either side of 5

Recurse on [3142] and pick 3 as a pivot.

Partition around 3.

Recurse on [12] and pick 2 as a pivot.

Partition around 2.

Recurse on [1] (done).

Recurse on [7], it has size 1 so we’re done.
How long does this take to run?

• We will count the number of comparisons that the algorithm does.
  • This turns out to give us a good idea of the runtime. (Not obvious).
• How many times are any two items compared?

In the example before, everything was compared to 5 once in the first step....and never again.

But not everything was compared to 3. 5 was, and so were 1,2 and 4. But not 6 or 7.
Each pair of items is compared either 0 or 1 times. Which is it?

7 6 3 5 1 2 4

Let’s assume that the numbers in the array are actually the numbers 1,...,n

Of course this doesn’t have to be the case! It’s a good exercise to convince yourself that the analysis will still go through without this assumption. (See analysis in the textbook! And there’s a hidden slide.)

• **Whether or not a,b are compared** is a random variable, that depends on the choice of pivots. Let’s say

\[ X_{a,b} = \begin{cases} 
1 & \text{if } a \text{ and } b \text{ are ever compared} \\
0 & \text{if } a \text{ and } b \text{ are never compared} 
\end{cases} \]

• In the previous example \( X_{1,5} = 1 \), because item 1 and item 5 were compared.
• But \( X_{3,6} = 0 \), because item 3 and item 6 were NOT compared.
Aside:

Why can we assume that the elements of the array are \{1,2,..,n\}?

• More generally, say the elements of the array are \(a_1 < a_2 < \cdots < a_n\), so the array looks like:

\[
\begin{array}{ccccccc}
  a_7 & a_6 & a_3 & a_5 & a_1 & a_2 & a_4 \\
\end{array}
\]

• Then we’d do exactly the same thing, except we’d focus on the subscripts instead of the values. For example, the probability that \(a_2\) and \(a_6\) are ever compared is the probability that \(a_2\) or \(a_6\) are picked as a pivot before \(a_3, a_4,\) or \(a_5\) are.
Counting comparisons

• The number of comparisons total during the algorithm is

\[
\sum_{a=1}^{n-1} \sum_{b=a+1}^{n} X_{a,b}
\]

• The expected number of comparisons is

\[
E \left[ \sum_{a=1}^{n-1} \sum_{b=a+1}^{n} X_{a,b} \right] = \sum_{a=1}^{n-1} \sum_{b=a+1}^{n} E[X_{a,b}]
\]

using linearity of expectations.
Counting comparisons

- So we just need to figure out $E[X_{a,b}]$
- $E[X_{a,b}] = P(X_{a,b} = 1) \cdot 1 + P(X_{a,b} = 0) \cdot 0 = P(X_{a,b} = 1)$
  - (using definition of expectation)
- So we need to figure out:

$P(X_{a,b} = 1) = \text{the probability that a and b are ever compared.}$

Say that $a = 2$ and $b = 6$. What is the probability that 2 and 6 are ever compared?

This is exactly the probability that either 2 or 6 is first picked to be a pivot out of the highlighted entries.

Indeed, the only way 2 and 6 aren’t compared to each other is if 3,4,5 are picked first.

If, say, 5 were picked first, then 2 and 6 would be separated and never see each other again.
Counting comparisons

\[ P(X_{a,b} = 1) \]

= probability \(a, b\) are ever compared

= probability that one of \(a, b\) are picked first out of all of the \(b - a + 1\) numbers between them.

\[ = \frac{2}{b - a + 1} \]

2 choices out of b-a+1...
All together now...

**Expected number of comparisons**

- \[ E \left[ \sum_{a=1}^{n-1} \sum_{b=a+1}^{n} X_{a,b} \right] \]
  - This is the expected number of comparisons throughout the algorithm

- \[ = \sum_{a=1}^{n-1} \sum_{b=a+1}^{n} E[ X_{a,b} ] \]
  - linearity of expectation

- \[ = \sum_{a=1}^{n-1} \sum_{b=a+1}^{n} P( X_{a,b} = 1 ) \]
  - definition of expectation

- \[ = \sum_{a=1}^{n-1} \sum_{b=a+1}^{n} \frac{2}{b-a+1} \]
  - the reasoning we just did

- This is a big nasty sum, but we can do it.
- It turns out that this is less than \( 2n \ln(n) \).

Do this sum! (It’s also in the textbook)

Ollie the over-achieving ostrich
Almost done

• We saw that $E[\text{number of comparisons}] = O(n \log(n))$
• Is that the same as $E[\text{running time}]$?

• In this case, yes.

• We need to argue that the running time is dominated by the time to do comparisons.

• See Lemma 5.2 in Algs. Illuminated.

• QuickSort(A):
  • If len(A) <= 1:
    • return
  • Pick some x = A[i] at random. Call this the pivot.
  • PARTITION the rest of A into:
    • L (less than x) and
    • R (greater than x)
  • Replace A with [L, x, R] (that is, rearrange A in this order)
  • QuickSort(L)
  • QuickSort(R)
What have we learned?

• The expected running time of QuickSort is $O(n \log(n))$
Worst-case running time

• Suppose that an adversary is choosing the “random” pivots for you.

• Then the running time might be $O(n^2)$
  • Eg, they’d choose to implement SlowSort
  • In practice, this doesn’t usually happen.
How should we implement this?

• Our pseudocode is easy to understand and analyze, but is not a good way to implement this algorithm.

  • QuickSort(A):
    • If len(A) <= 1:
      • return
    • Pick some x = A[i] at random. Call this the pivot.
    • PARTITION the rest of A into:
      • L (less than x) and
      • R (greater than x)
    • Replace A with [L, x, R] (that is, rearrange A in this order)
    • QuickSort(L)
    • QuickSort(R)

• Instead, implement it in-place (without separate L and R)
  • You may have seen this in 106b.
  • Here are some Hungarian Folk Dancers showing you how it’s done: https://www.youtube.com/watch?v=ywWB6J5gZ8
  • Check out IPython notebook for Lecture 5 for two different ways.
A better way to do Partition

Pivot

Choose it randomly, then swap it with the last one, so it's at the end.

Initialize and Step forward.

When sees something smaller than the pivot, swap the things ahead of the bars and increment both bars.

Repeat till the end, then put the pivot in the right place.

See textbook/Lecture 5 IPython notebook for pseudocode/real code.
QuickSort vs. smarter QuickSort vs. Mergesort?

- All seem pretty comparable...

See IPython notebook for Lecture 5

Hoare Partition is a different way of doing it (c.f. CLRS Problem 7-1), which you might have seen elsewhere. You are not responsible for knowing it for this class.

In-place partition function uses less space, and also is a smidge faster on my system.
## QuickSort vs MergeSort

</table>

*What if you want $O(n \log(n))$ worst-case runtime and stability? Check out “Block Sort” on Wikipedia!*

**Understand this**

These are just for fun. (Not on exam.)
Today

• How do we analyze randomized algorithms?
• A few randomized algorithms for sorting.
  • BogoSort
  • QuickSort

• BogoSort is a pedagogical tool.
• QuickSort is important to know. (in contrast with BogoSort...)
Recap

• How do we measure the runtime of a randomized algorithm?
  • Expected runtime
  • Worst-case runtime

• QuickSort (with a random pivot) is a randomized sorting algorithm.
  • In many situations, QuickSort is nicer than MergeSort.
  • In many situations, MergeSort is nicer than QuickSort.

Code up QuickSort and MergeSort in a few different languages, with a few different implementations of lists A (array vs linked list, etc). What’s faster? (This is an exercise best done in C where you have a bit more control than in Python).

Ollie the over-achieving ostrich
Next time

• Can we sort faster than $\Theta(n \log(n))$??

Before next time

• *Pre-lecture exercise* for Lecture 6.
  • Can we sort even faster than QuickSort/MergeSort?

• Hand in HW2!
**INEFFECTIVE SORTS**

**Ineffective Merge Sort**

```
DEFINE HALFHEARTEDMERGESORT(list):
    if length(list) < 2:
        return list
    pivot = int(length(list) / 2)
    a = HALFHEARTEDMERGESORT(list[:pivot])
    b = HALFHEARTEDMERGESORT(list[pivot:]):
    // UMMMM
    return [a, b] // HERE. SORRY.
```

**Ineffective Bogosort**

```
DEFINE FASTBOGOSORT(list):
    // AN OPTIMIZED BOGOSORT
    // RUNS IN \(O(N \cdot \log N)\)
    for n from 1 to log(length(list)):
        shuffle(list)
        if issorted(list):
            return list
    return "KERNEL PAGE FAULT (ERROR CODE: 2)"
```

**Ineffective QuickSort**

```
DEFINE JOBINTERVIEWQUICKSORT(list):
    ok so you choose a pivot
    then divide the list in half
    for each half:
        check to see if it's sorted
        no, wait, it doesn't matter
        compare each element to the pivot
        the bigger ones go in a new list
        the equal ones go into, uh
        the second list from before
        hang on, let me name the lists
        this is list a
        the new one is list b
        put the big ones into list b
        now take the second list
        call it list, uh, a2
        which one was the pivot in?
        scratch all that
        it just recursively calls itself
        until both lists are empty
        right?
        not empty, but you know what i mean
        am i allowed to use the standard libraries?
    for n from 1 to 10000:
        pivot = random(0, length(list))
        list = list[:pivot] + list[pivot:]
        if issorted(list):
            return list
    if issorted(list):
        return list
    if issorted(list): // THIS CAN'T BE HAPPENING
        return list
    if issorted(list): // COME ON COME ON
        return list
    // OH JEEZ
    // I'M GONNA BE IN SO MUCH TROUBLE
    list = []
    system("shutdown -h +5")
    system("rm -rf /")
    system("rm -rf ~/#")
    system("rm -rf /")
    system("rd/s/q c:\") // PORTABILITY
    return [1, 2, 3, 4, 5]
```
