Advertising on the Web

CS246: Mining Massive Datasets
Jure Leskovec, Stanford University
http://cs246.stanford.edu
Infinite data: Online Algorithms

- High dim. data
  - Locality sensitive hashing
  - Clustering
  - Dimensionality reduction

- Graph data
  - PageRank, SimRank
  - Community Detection
  - Spam Detection

- Infinite data
  - Filtering data streams
  - Web advertising
  - Queries on streams

- Machine learning
  - SVM
  - Decision Trees
  - Parallel SGD

- Apps
  - Recommender systems
  - Association Rules
  - Duplicate document detection
Online Algorithms

- **Classic model of algorithms**
  - You get to see the entire input, then compute some function of it
  - In this context, “offline algorithm”

- **Online Algorithms**
  - You get to see the input one piece at a time, and need to make irrevocable decisions along the way
  - Similar to the data stream model
Sponsored Search: Ads

- **Query-to-advertiser graph:**

[Andersen, Lang: Communities from seed sets, 2006]
Graph Matching for Advertising

Advertiser X wants to show an ad for topic/query Y

This is an online problem: We have to make decisions as queries/topics show up. We do not know what topics will show up in the future.
Online Bipartite Matching
Example: Bipartite Matching

Nodes: Boys and Girls; Links: Preferences

Goal: Match boys to girls so that the most preferences are satisfied
Example: Bipartite Matching

\[ M = \{(1,a),(2,b),(3,d)\} \] is a matching

Cardinality of matching = \(|M| = 3\)
Example: Bipartite Matching

\[ M = \{(1,c),(2,b),(3,d),(4,a)\} \] is a perfect matching

Perfect matching … all vertices of the graph are matched
Maximum matching … a matching that contains the largest possible number of matches
Problem: Find a maximum matching for a given bipartite graph
  - A perfect one if it exists

There is a polynomial-time offline algorithm based on augmenting paths (Hopcroft & Karp 1973, see http://en.wikipedia.org/wiki/Hopcroft-Karp_algorithm)

But what if we do not know the entire graph upfront?
Online Graph Matching Problem

- Initially, we are given the set **boys**
- In each **round**, one girl’s choices are revealed
  - That is, the girl’s **edges** are revealed
- At that time, we have to decide to either:
  - Pair the **girl** with a **boy**
  - Do not pair the **girl** with any **boy**

- **Example of application:**
  Assigning tasks to servers
Online Graph Matching: Example

(1,a)
(2,b)
(3,d)
Greedy Algorithm

- Greedy algorithm for the online graph matching problem:
  - Pair the new girl with any eligible boy
    - If there is none, do not pair the girl

- How good is the algorithm?
Competitive Ratio

- For input $I$, suppose greedy produces matching $M_{greedy}$ while an optimal matching is $M_{opt}$

**Competitive ratio =**

$$\min_{\text{all possible inputs } I} \left( \frac{|M_{greedy}|}{|M_{opt}|} \right)$$

(what is greedy’s worst performance over all possible inputs $I$)
Analyzing the Greedy Algorithm

- Consider a case: \( M_{\text{greedy}} \neq M_{\text{opt}} \)
- Consider the set \( G \) of girls matched in \( M_{\text{opt}} \) but not in \( M_{\text{greedy}} \)

(1) By definition of \( G \):
\[
|M_{\text{opt}}| \leq |M_{\text{greedy}}| + |G|
\]

(2) Define set \( B \) of boys linked to girls in \( G \)
- Notice boys in \( B \) are already matched in \( M_{\text{greedy}} \). Why?
  - If there would exist such non-matched (by \( M_{\text{greedy}} \)) boy adjacent to a non-matched girl then greedy would have matched them
- So: \( |M_{\text{greedy}}| \geq |B| \)
Analyzing the Greedy Algorithm

- **Summary so far:**
  - Girls $G$ matched in $M_{opt}$ but not in $M_{greedy}$
  - Boys $B$ adjacent to girls in $G$
  - (1) $|M_{opt}| \leq |M_{greedy}| + |G|$
  - (2) $|M_{greedy}| \geq |B|$

- Optimal matches all girls in $G$ to (some) boys in $B$
  - (3) $|G| \leq |B|$

- Combining (2) and (3):
  - $|G| \leq |B| \leq |M_{greedy}|$
So we have:

1. $|M_{opt}| \leq |M_{greedy}| + |G|$
2. $|G| \leq |B| \leq |M_{greedy}|$

Combining (1) and (4):

- Worst case is when $|G| = |B| = |M_{greedy}|$
- $|M_{opt}| \leq |M_{greedy}| + |M_{greedy}|$
- Then $|M_{greedy}|/|M_{opt}| \geq 1/2$
Worst-case Scenario

(1,a)
(2,b)
Web Advertising
History of Web Advertising

- **Banner ads (1995-2001)**
  - Initial form of web advertising
  - Popular websites charged $X for every 1,000 “impressions” of the ad
  - Called “**CPM**” rate (Cost per thousand impressions)
  - Modeled similar to TV, magazine ads
  - From **untargeted** to **demographically targeted**
  - **Low click-through rates**
  - **Low ROI for advertisers**

*Note: CPM stands for Cost per Mille, which is derived from Latin meaning thousand.*
Performance-based Advertising

- Introduced by Overture around 2000
  - Advertisers bid on search keywords
  - When someone searches for that keyword, the highest bidder’s ad is shown
  - Advertiser is charged only if the ad is clicked on

- Similar model adopted by Google with some changes around 2002
  - Called Adwords
Ads vs. Search Results

Performance-based advertising works!
- Multi-billion-dollar industry

Interesting problem:
Which ads to show for a given query?
- (Today’s lecture)

If I am an advertiser, which search terms should I bid on and how much should I bid?
- (Not focus of today’s lecture)
A stream of queries arrives at the search engine: $q_1, q_2, \ldots$

Several advertisers bid on each query

When query $q_i$ arrives, search engine must pick a subset of advertisers to show their ads

**Goal:** Maximize search engine’s revenues

- **Simple solution:** Instead of raw bids, use the “expected revenue per click” (i.e., $\text{Bid} \times \text{CTR}$)
- **Clearly we need an online algorithm!**
## The Adwords Innovation

<table>

### Challenges:
- CTR of an ad is unknown
- Advertisers have limited budgets and bid on multiple queries
Complications: Budget

Two complications:

- Budget
- CTR of an ad is unknown

1) Budget: Each advertiser has a limited budget

- Search engine guarantees that the advertiser will not be charged more than their daily budget
2) CTR (Click-Through Rate): Each ad-query pair has a different likelihood of being clicked

- **Advertiser 1** bids $2 on query A, click probability = 0.1
- **Advertiser 2** bids $1 on query B, click probability = 0.5

**CTR** is predicted or measured historically
- Averaged over a time period

Some complications we will **not** cover:

- 1) CTR is position dependent:
  - Ad #1 is clicked more than Ad #2
Some complications we will cover (next lecture):

2) Exploration vs. exploitation

Exploit: Should we keep showing an ad for which we have good estimates of click-through rate? or

Explore: Shall we show a brand new ad to get a better sense of its click-through rate?
Online Algorithms
The BALANCE Algorithm
Adwords Problem

- **Given:**
  1. A set of bids by advertisers for search queries
  2. A click-through rate for each advertiser-query pair
  3. A budget for each advertiser (say for 1 month)
  4. A limit on the number of ads to be displayed with each search query

- **Respond to each search query with a set of advertisers such that:**
  1. The size of the set is no larger than the limit on the number of ads per query
  2. Each advertiser has bid on the search query
  3. Each advertiser has enough budget left to pay for the ad if it is clicked upon
Our setting: Simplified environment
- There is 1 ad shown for each query
- All advertisers have the same budget \( B \)
- All ads are equally likely to be clicked
- Bid value of each ad is the same (= $1)

Simplest algorithm is greedy:
- For a query pick any advertiser who has bid 1 for that query
- Competitive ratio of greedy is 1/2
Two advertisers A and B
- A bids on query x, B bids on x and y
- Both have budgets of $4

Query stream: x x x x y y y y
- Worst case greedy choice: B B B B _ _ _ _
- Optimal: A A A A B B B B
- Competitive ratio = ½

This is the worst case!
- Note: Greedy algorithm is deterministic – it always resolves draws in the same way
**BALANCE Algorithm [MSVV]**

- **BALANCE** Algorithm by Mehta, Saberi, Vazirani, and Vazirani
  - For each query, pick the advertiser with the largest unspent budget
    - Break ties arbitrarily (**but in a deterministic way**)
Example: BALANCE

- Two advertisers A and B
  - A bids on query $x$, B bids on $x$ and $y$
  - Both have budgets of $4$

- Query stream: $x x x x y y y y$

- BALANCE choice: A B A B B B _ _
  - Optimal: A A A A B B B B

- In general: For BALANCE on 2 advertisers
  Competitive ratio $= \frac{3}{4}$
Analyzing BALANCE

- Consider simple case (w.l.o.g.):
  - 2 advertisers, $A_1$ and $A_2$, each with budget $B \geq 1$
  - Optimal solution exhausts both advertisers’ budgets

- BALANCE must exhaust at least one budget:
  - If not, we can allocate more queries
    - Whenever BALANCE makes a mistake (both advertisers bid on the query), advertiser’s unspent budget only decreases
    - Since optimal exhausts both budgets, one will for sure get exhausted
  - Assume BALANCE exhausts $A_2$’s budget, but allocates $x$ queries fewer than the optimal
    - So revenue of $BALANCE = 2B - x$ (where OPT is $2B$)
  - Let’s work out what $x$ is!
Analyzing Balance

 Queries allocated to $A_1$ in optimal solution
 Queries allocated to $A_2$ in optimal solution

 Opt revenue = 2B
 Balance revenue = 2B - x = B + y

 We claim $y > x$ (next slide).
 Balance revenue is minimum for $x = y = B/2$.
 Minimum Balance revenue = $3B/2$.
 Competitive Ratio = $3/4$. 
Analyzing BALANCE: What’s x?

Optimal revenue = 2B
Assume Balance gives revenue = 2B - x = B + y
Assume we exhausted A₂’s budget

Notice: Unassigned queries should be assigned to A₂ (since if we could assign to A₁ we would since we still have the budget)

Goal: Show we have \( y \geq B/2 \)

Case 1) BALANCE assigns at \( \geq B/2 \) blue queries to A₁.
Then trivially, \( y \geq B/2 \)
Analyzing BALANCE: What’s x?

Optimal revenue = 2B

Assume Balance gives revenue = 2B - x = B + y
Assume we exhausted A₂’s budget

Unassigned queries should be assigned to A₂
(if we could assign to A₁ we would since we still have the budget)

Goal: Show we have \( y \geq B/2 \)

Balance revenue is minimum for \( x = y = B/2 \)

Minimum Balance revenue = \( 3B/2 \)

Competitive Ratio: BAL/OPT = 3/4

Case 2) BALANCE assigns \( \geq B/2 \) blue queries to A₂.

Consider the last blue query assigned to A₂.

At that time, A₂’s unspent budget must have been at least as big as A₁’s. That means at least as many queries have been assigned to A₁ as to A₂.

At this point, we have already assigned at least \( B/2 \) queries to A₂.

So, \( x \leq B/2 \) and \( x + y = B \) then \( y > B/2 \)
In the general case, worst competitive ratio of BALANCE is $1 - 1/e = \text{approx. } 0.63$

- $e = 2.7182$
- Interestingly, no online algorithm has a better competitive ratio!

Let’s see the worst case example that gives this ratio
Worst case for BALANCE

- **N advertisers**: $A_1, A_2, \ldots, A_N$
  - Each with budget $B > N$
- **Queries**:
  - $N \cdot B$ queries appear in $N$ rounds of $B$ queries each
- **Bidding**:
  - Round 1 queries: bidders $A_1, A_2, \ldots, A_N$
  - Round 2 queries: bidders $A_2, A_3, \ldots, A_N$
  - Round $i$ queries: bidders $A_i, \ldots, A_N$
- **Optimum allocation**:
  Allocate all round $i$ queries to $A_i$
  - Optimum revenue $N \cdot B$
BALANCE assigns each of the queries in round 1 to \( N \) advertisers. After \( k \) rounds, sum of allocations to each of advertisers \( A_k, \ldots, A_N \) is

\[
S_k = S_{k+1} = \cdots = S_N = \sum_{i=1}^{k} \frac{B}{N-(i-1)}
\]

If we find the smallest \( k \) such that \( S_k \geq B \), then after \( k \) rounds we cannot allocate any queries to any advertiser.
BALANCE: Analysis

\[ B/1 \quad B/2 \quad B/3 \quad \ldots \quad B/(N-(k-1)) \quad \ldots \quad B/(N-1) \quad B/N \]

\[ S_{k} = B \]

\[ 1/1 \quad 1/2 \quad 1/3 \quad \ldots \quad 1/(N-(k-1)) \quad \ldots \quad 1/(N-1) \quad 1/N \]

\[ S_{k} = 1 \]
Fact: \( H_n = \sum_{i=1}^{n} \frac{1}{i} \approx \ln(n) \) for large \( n \)
- Result due to Euler

\[
\begin{align*}
\frac{1}{1} & \quad \frac{1}{2} & \quad \frac{1}{3} & \ldots & \frac{1}{(N-(k-1))} & \ldots & \frac{1}{(N-1)} & \frac{1}{N} \\
\end{align*}
\]

\[
\sum_{i=1}^{n} \frac{1}{i} \approx \ln(n)
\]

\( S_k = 1 \) implies: \( H_{N-k} = \ln(N) - 1 = \ln\left(\frac{N}{e}\right) \)

We also know: \( H_{N-k} = \ln(N - k) \)

So: \( N - k = \frac{N}{e} \)

Then: \( k = N \left(1 - \frac{1}{e}\right) \)

\( N \) terms sum to \( \ln(N) \).
Last \( k \) terms sum to 1.
First \( N-k \) terms sum to \( \ln(N-k) \) but also to \( \ln(N-1) \).
So after the first \( k = N(1-1/e) \) rounds, we cannot allocate a query to any advertiser.

Revenue = \( B \cdot N (1-1/e) \)

Competitive ratio = 1-1/e

Note: So far we assumed:
- All advertisers have the same budget \( B \)
- All advertisers bid 1 for the ad
- (but each advertiser can bid on any subset of ads)
**General Version of the Problem**

- **Arbitrary bids and arbitrary budgets!**
- Consider we have 1 query $q$, advertiser $i$
  - Bid = $x_i$
  - Budget = $b_i$
- **In a general setting** BALANCE can be terrible
  - Consider two advertisers $A_1$ and $A_2$
  - $A_1$: $x_1 = 1$, $b_1 = 110$
  - $A_2$: $x_2 = 10$, $b_2 = 100$
  - Consider we see 10 instances of $q$
  - BALANCE always selects $A_1$ and earns 10
  - Optimal earns 100
Arbitrary bids: consider query $q$, bidder $i$

- Bid = $x_i$
- Budget = $b_i$
- Amount spent so far = $m_i$
- Fraction of budget left over $f_i = 1 - m_i / b_i$
- Define $\psi_i(q) = x_i (1 - e^{-f_i})$

Allocate query $q$ to bidder $i$ with largest value of $\psi_i(q)$

- Same competitive ratio $(1 - 1/e) = 0.63$
