

# Biomolecular structure (including protein structure)

CS/CME/BioE/Biophys/BMI 279

Sept. 26 and Oct. 1, 2024

Ron Dror

- Please raise your hand (or comment through Panopto) if you have questions, and especially if you're confused and would like clarification!
  - Please state your name
- Tutorial on Terminal and Python
  - Friday 10 am by Zoom (link on course web page)
  - You can also view the recording afterwards
  - Recommended if you haven't used Python and terminal (Mac, Linux) before

# Outline

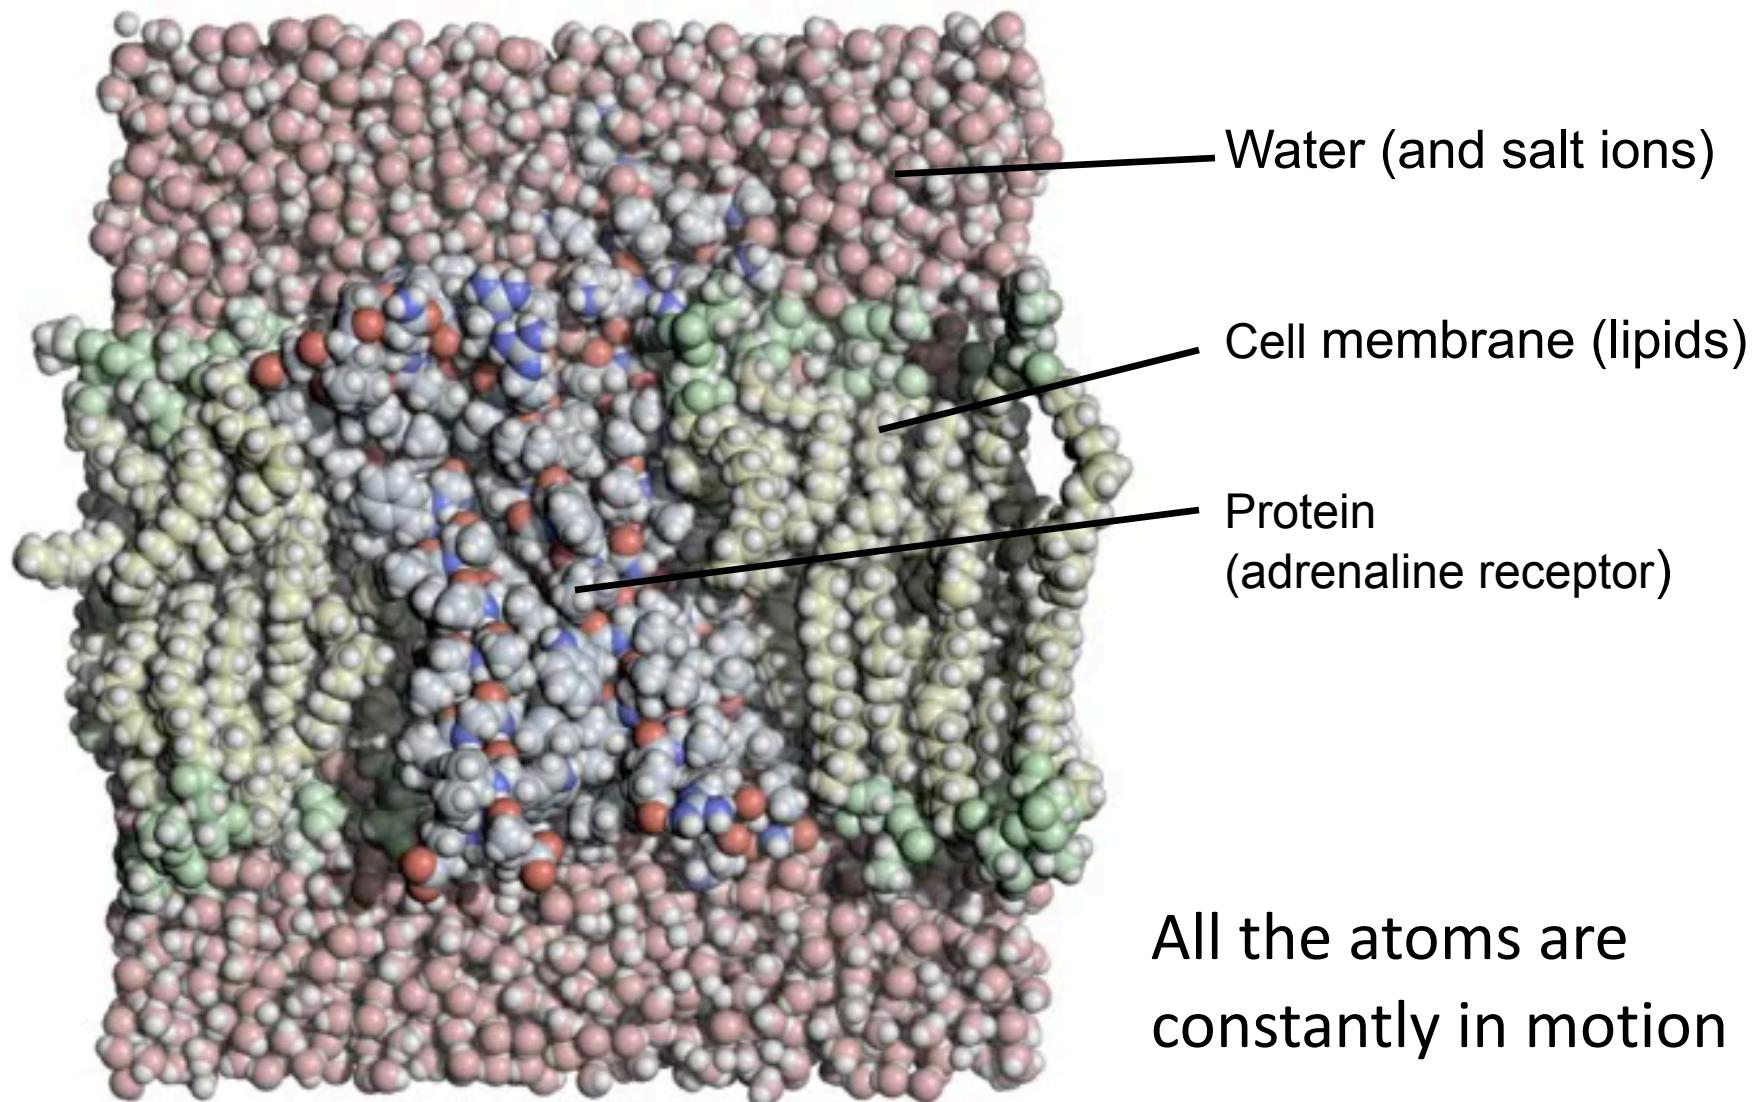

Note: I'll discuss proteins first, as an example.

These concepts apply to other biomolecules as well.

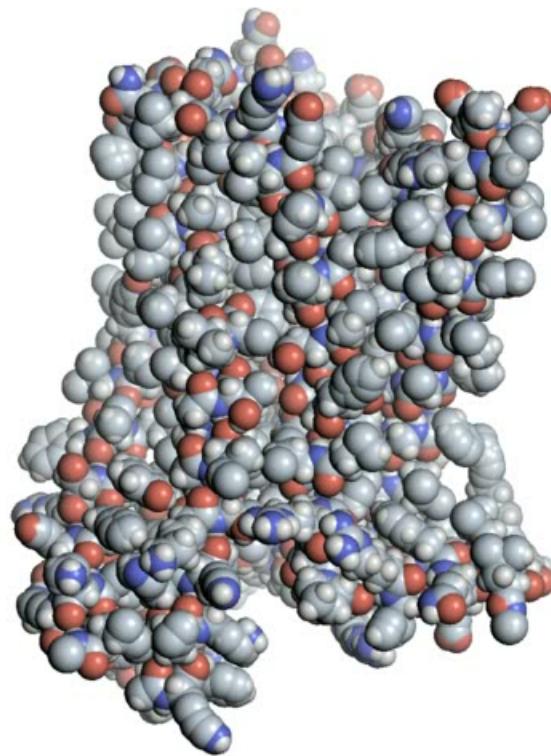

- Visualizing biomolecules (e.g., proteins)
- The Protein Data Bank (PDB)
- Chemical (2D) structure of proteins
- What determines the 3D structure of a protein?  
Physics underlying biomolecular structure
  - Basic interactions
  - Complex interactions
- Protein structure: a more detailed view
- Structures of other biomolecules

# Visualizing biomolecules (e.g., proteins)

# Protein surrounded by other molecules

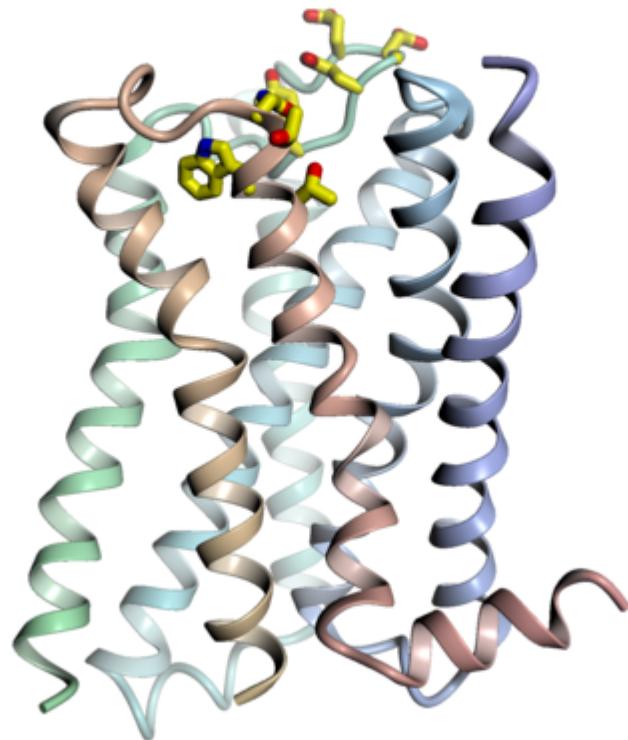

# Protein only, static structure

Adrenaline receptor

# Further simplified representation

Adrenaline receptor

# Key take-aways from these visualizations

- Protein and surrounding atoms fill space (close-packed).
- Simplified visual representations help you figure out what's going on.
- All of these atoms are constantly moving around, and the protein's shape keeps changing.
  - When we talk about “the” 3D structure of a protein, we really mean an *average* structure. Even that average depends on the experimental conditions (e.g., which other molecules are bound to the protein)

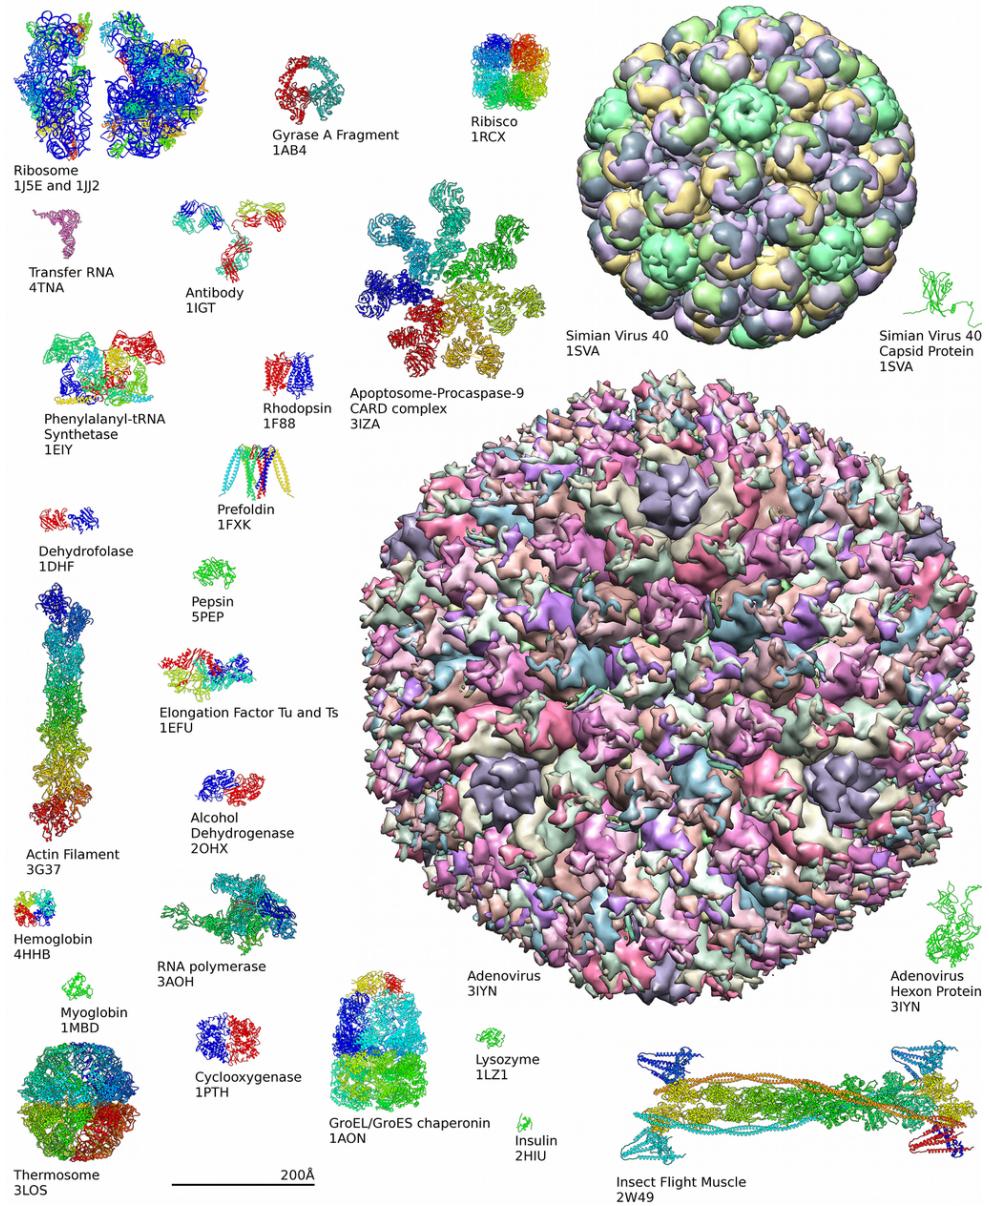

conditions also include temperature and acidity

**A Structural View of Biology**

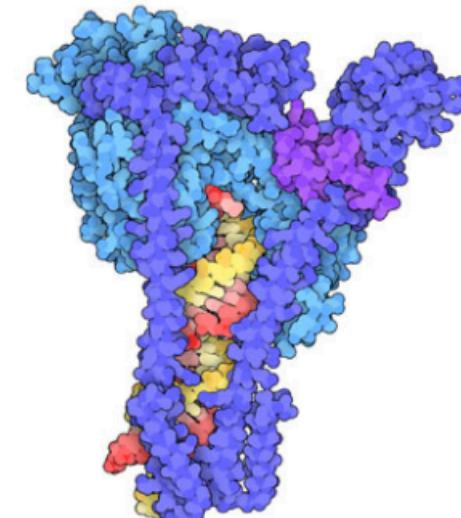

This resource is powered by the Protein Data Bank archive-information about the 3D shapes of proteins, nucleic acids, and complex assemblies that helps students and researchers understand all aspects of biomedicine and agriculture, from protein synthesis to health and disease.

As a member of the wwPDB, the RCSB PDB curates and annotates PDB data. The RCSB PDB builds upon the data by creating tools and resources for research and education in molecular biology, structural biology, computational biology, and beyond.

# The Protein Data Bank (PDB)

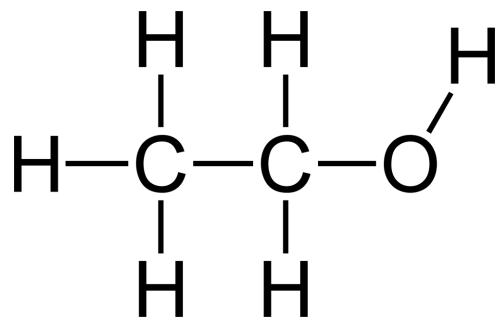

- <https://www.rcsb.org/>
- A collection of essentially all published, experimentally determined structures of biomacromolecules (e.g., proteins, DNA, RNA)
- Currently ~225,000 structures.
- Each identified by 4-character code (e.g., 6YYT)
- Browse the PDB and look at some structures.  
Options:
  - 3D view in applet on PDB web pages
  - PyMOL: fetch 6YYT

# Chemical (two-dimensional) structure of proteins

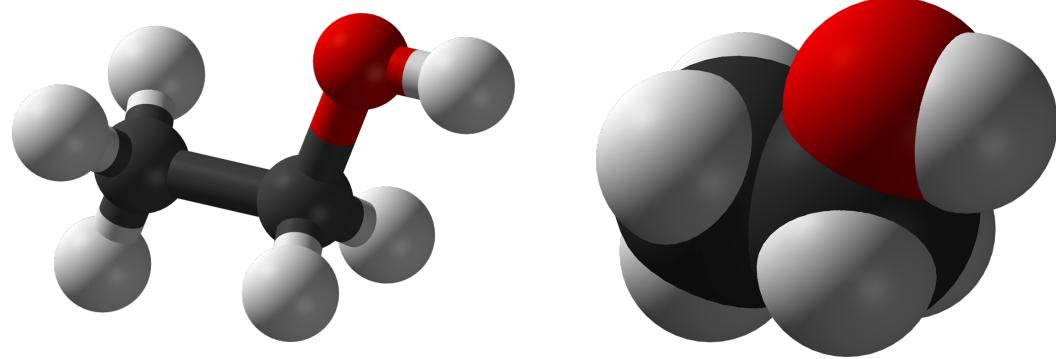

# Chemical (two-dimensional) structure vs. three-dimensional structure

- Chemical (two-dimensional) structure shows *covalent bonds* between atoms. Essentially a graph.
- Three-dimensional structure shows relative positions of atoms.

2D structure

3D structure

images from <https://en.wikipedia.org/wiki/Ethanol>

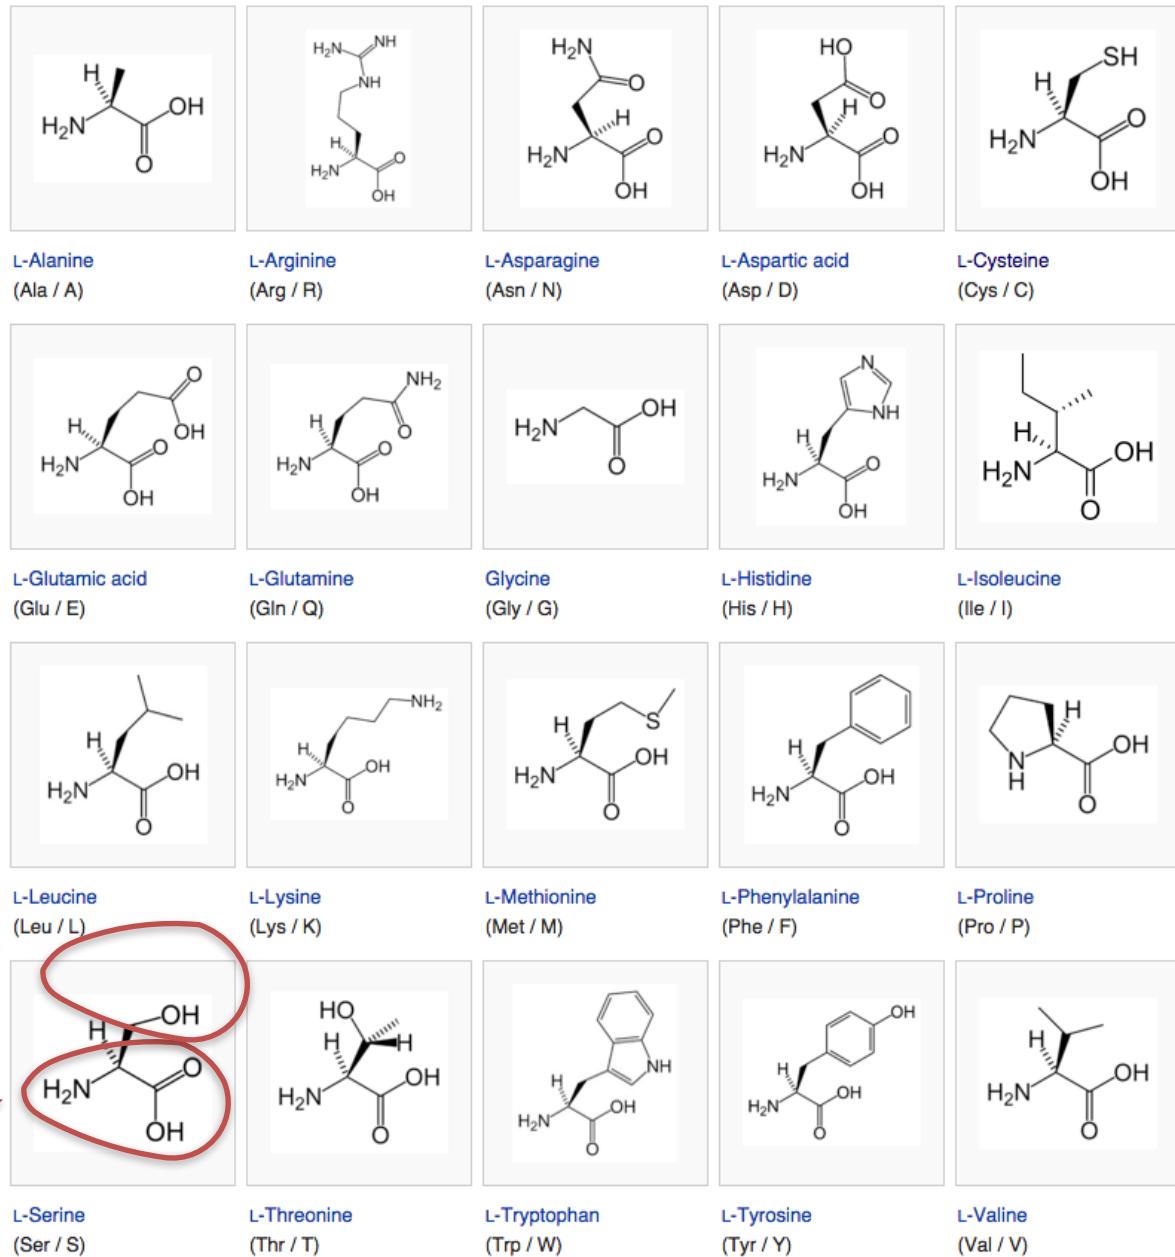

# Proteins are built from amino acids

- 20 “standard” amino acids
- Each has three-letter and one-letter abbreviations (e.g., Threonine = Thr = T; Tryptophan = Trp = W)

most common AAs that occur in your body

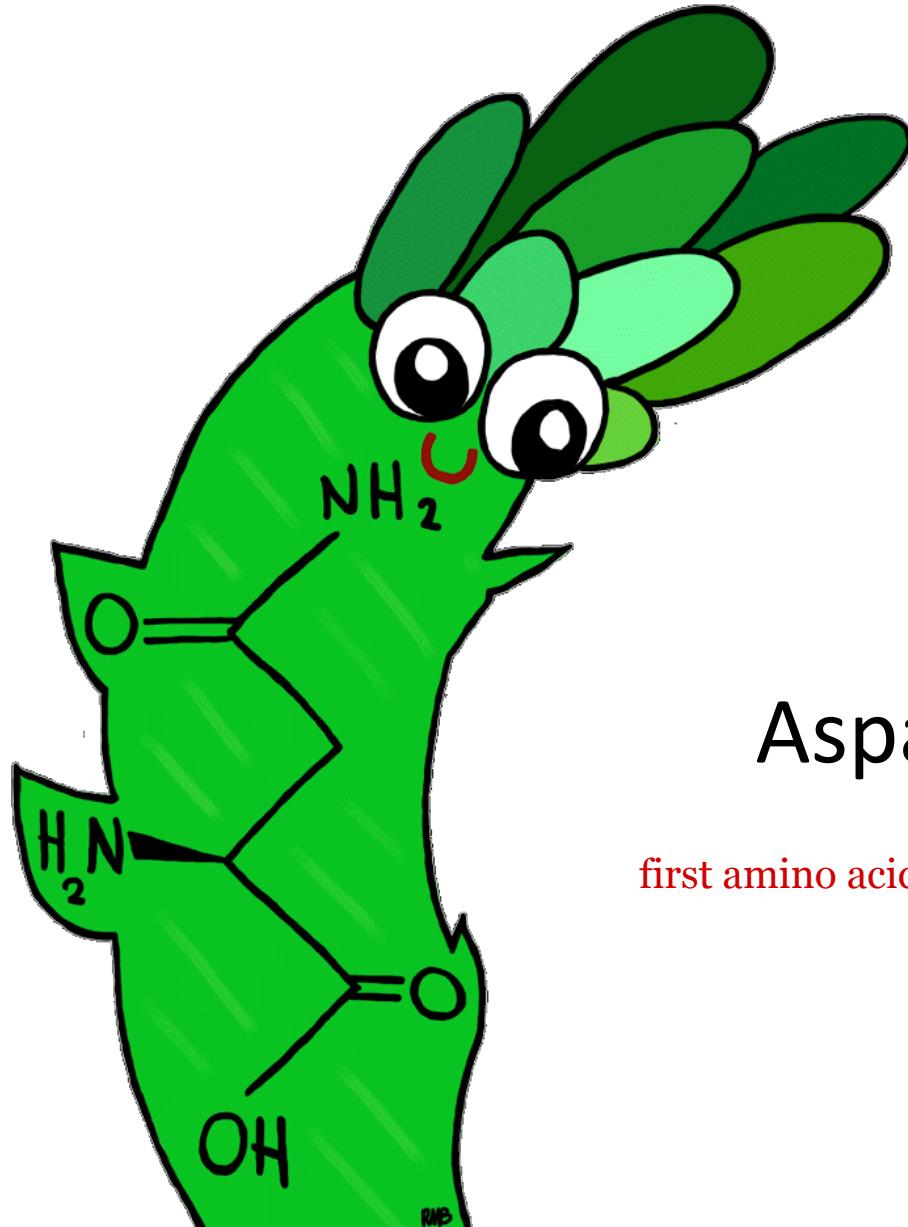

The “side chain” is different in each amino acid.

All amino acids have this part in common.

You don't need to memorize all the structures

[https://en.wikipedia.org/wiki/Proteinogenic\\_amino\\_acid](https://en.wikipedia.org/wiki/Proteinogenic_amino_acid)

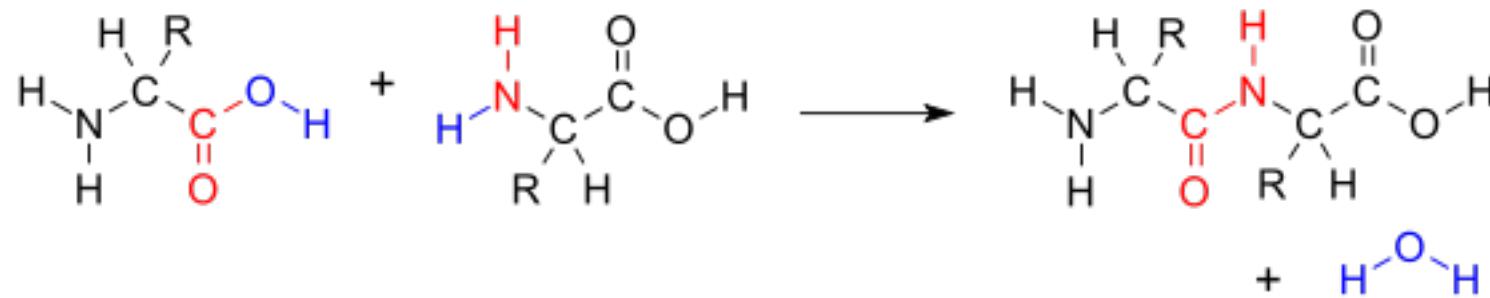

# Asparagine

first amino acid to be isolated (purified)

# Proteins are chains of amino acids

- Amino acids link together through a chemical reaction (“condensation”)

"R" - generic representation of side chain

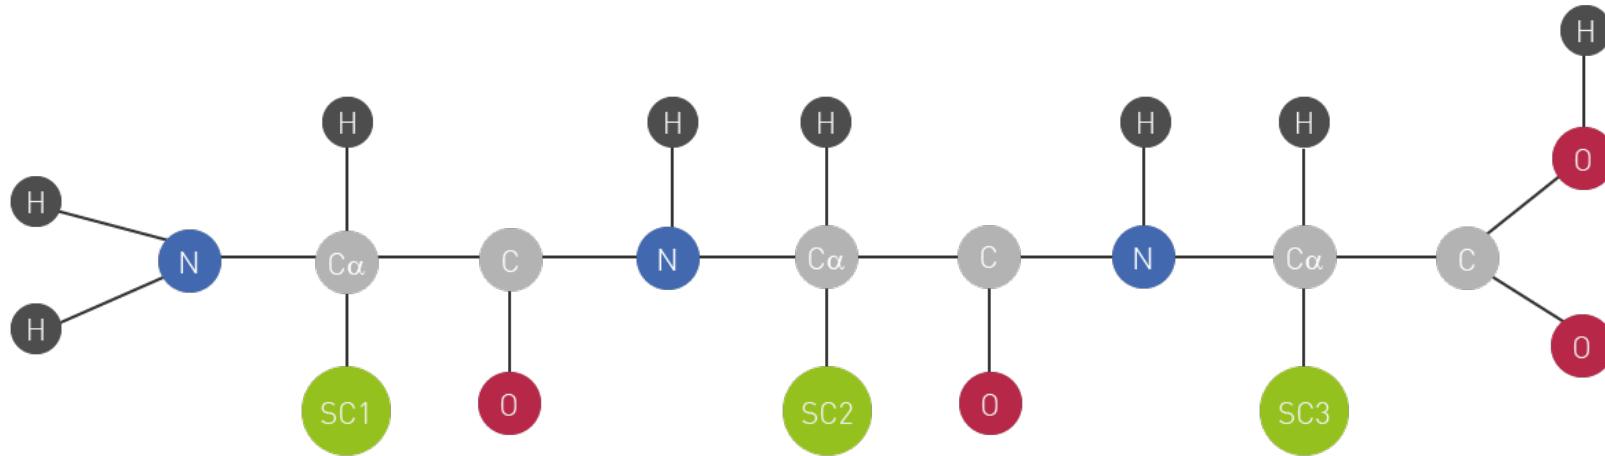

[http://en.wikipedia.org/wiki/Condensation\\_reaction](http://en.wikipedia.org/wiki/Condensation_reaction)

- Strictly speaking, elements of the chain are amino acid *residues*. They are usually just called “**residues**”
- The bonds linking these residues are “peptide bonds.” The chains are also called “polypeptides”

"polypeptide" usually refers to a shorter chain, "protein" usually refers to a longer chain

# Proteins have uniform backbones with differing side chains

Carbon alpha (C-alpha) is the carbon connected to the side chain

What determines the 3D structure of a protein?  
Physics underlying biomolecular structure

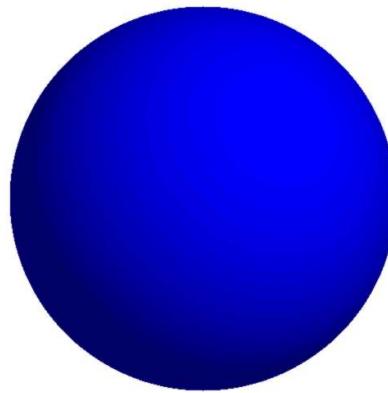

# Why do proteins have well-defined structure?

- The sequence of amino acids in a protein (usually) suffices to determine its structure.
- A chain of amino acids (usually) “folds” spontaneously into the protein’s preferred structure, known as the “native structure”
- Why?
  - Intuitively: some amino acid types prefer to be inside, some prefer to be outside, some pairs prefer to be near one another, etc.
  - To understand this better, examine forces acting between atoms

What determines the 3D structure of a protein?  
Physics underlying biomolecular structure

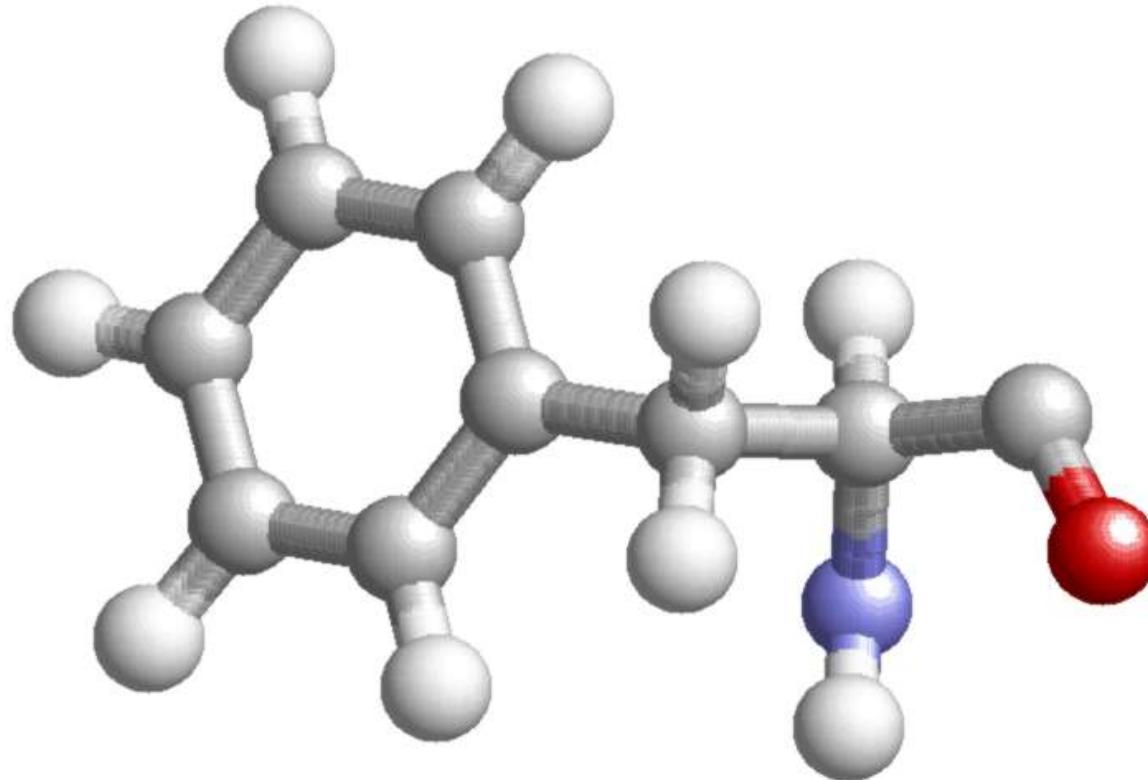

## Basic interactions

# Geometry of an atom

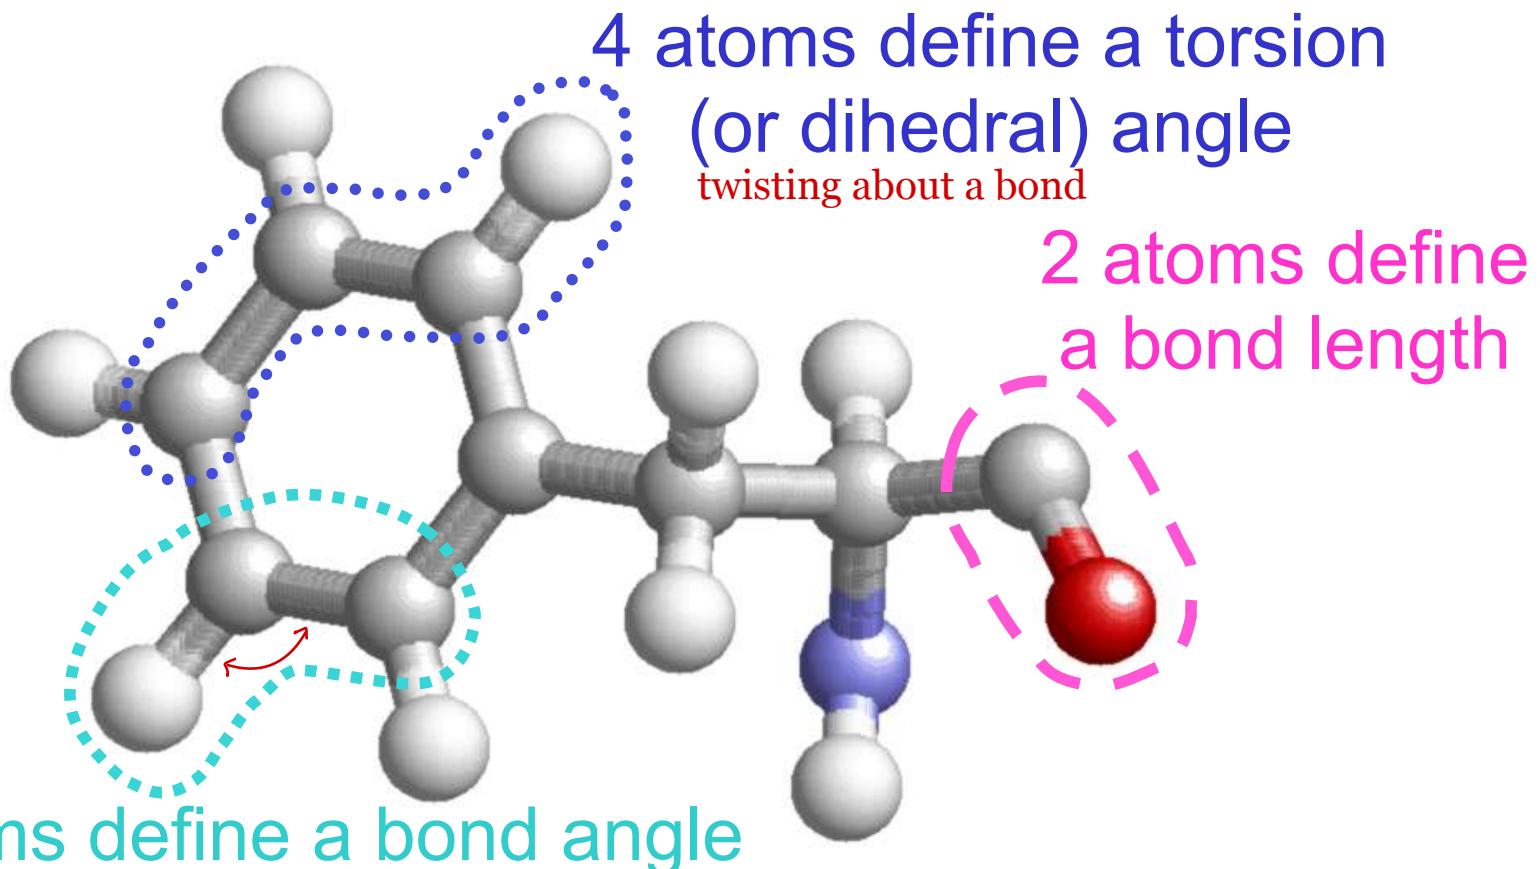

- To a first approximation (which suffices for the purposes of this course), we can think of an atom simply as a sphere.
- It occupies a position in space, specified by the  $(x, y, z)$  coordinates of its center, at a given point in time

# Geometry of a molecule

- A molecule is a set of atoms connected in a graph
- $(x, y, z)$  coordinates of every atom specify the molecule's geometry

# Geometry of a molecule

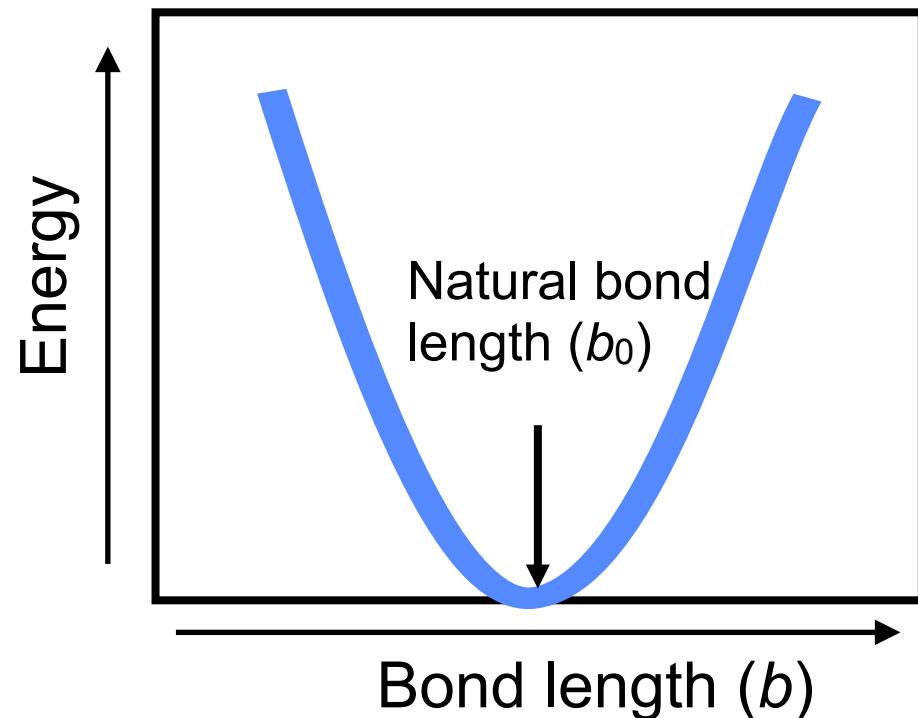

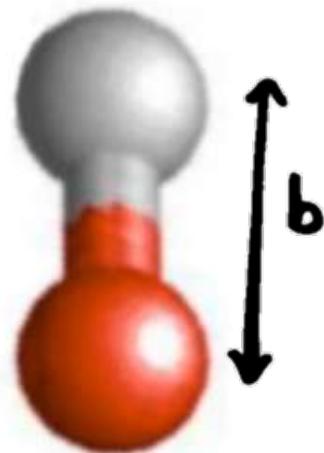

- Alternatively, we can specify the geometry of a molecule using bond lengths, bond angles, and torsion angles

# Forces between atoms

- We can approximate the total potential energy of a molecular system as a sum of individual contributions. Terms are additive.
  - Thus force on each atom is also a sum of individual contributions.
    - Remember: force is the derivative of energy.
    - Think of atoms as balls and forces as springs.
- Two types of forces:
  - Bonded forces: act between closely connected sets of atoms in the graph of covalent bonds
  - Non-bonded forces: act between all pairs of atoms

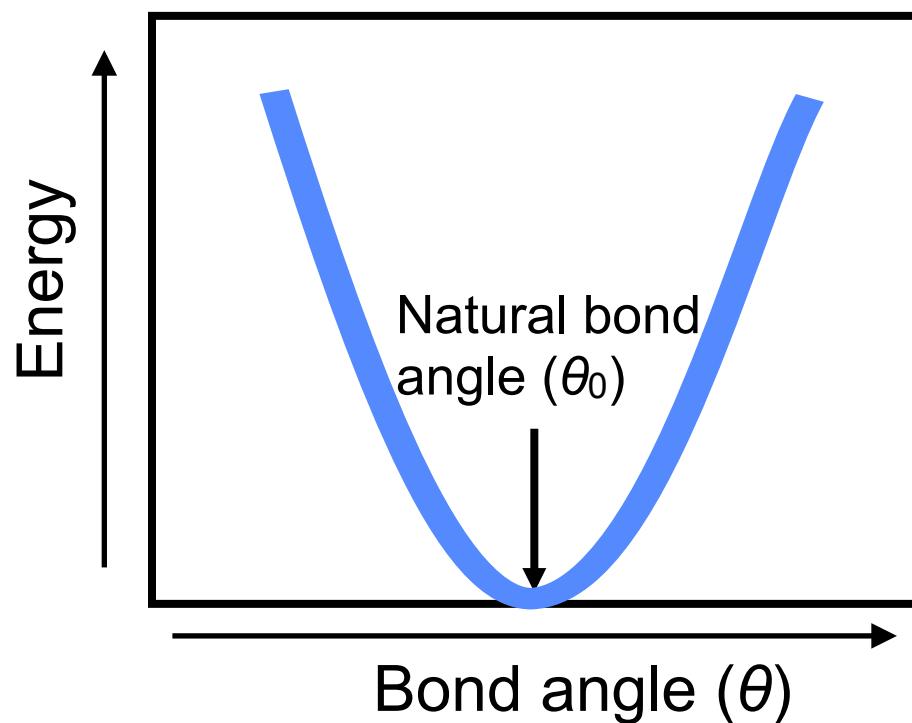

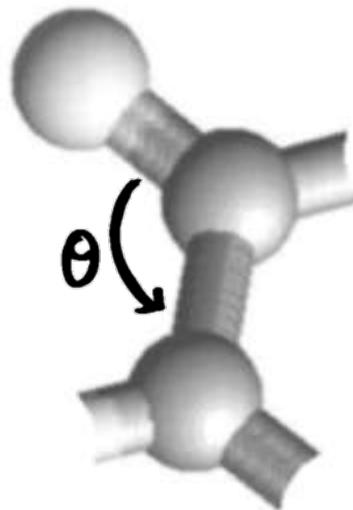

# Bond length stretching

- A covalently bonded pair of atoms is effectively connected by a “spring” with some preferred (natural) length. Stretching or compressing this spring requires energy.

# Bond angle bending

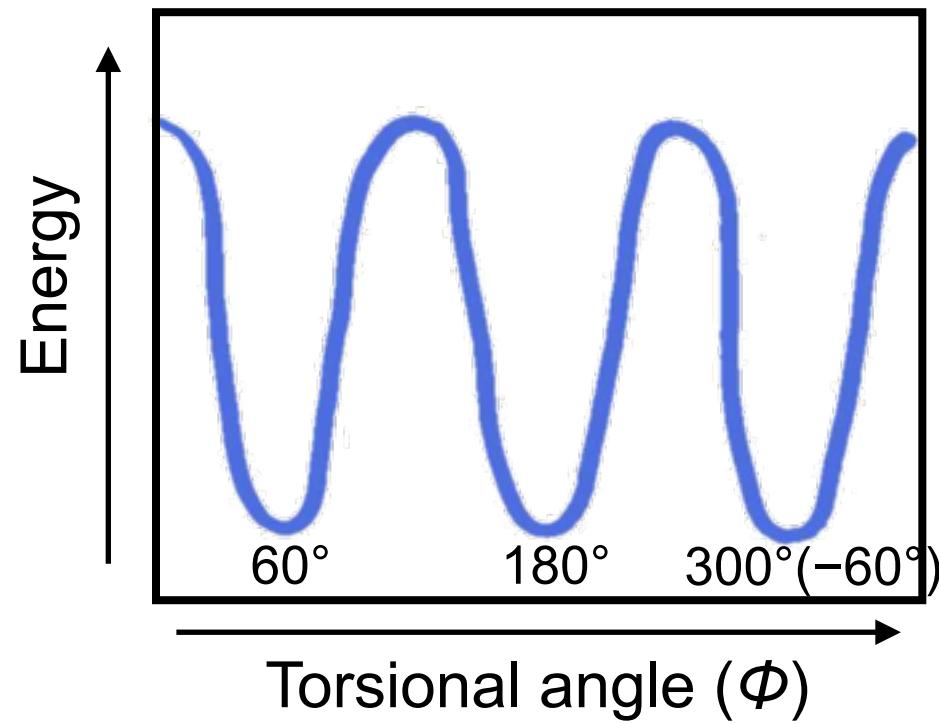

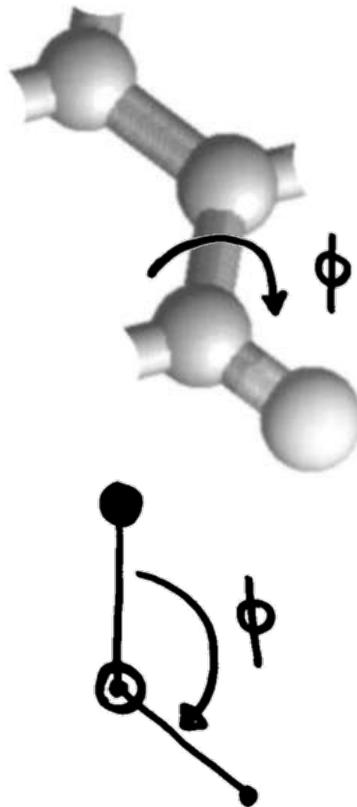

- Likewise, each bond angle has some natural value. Increasing or decreasing this angle requires energy.

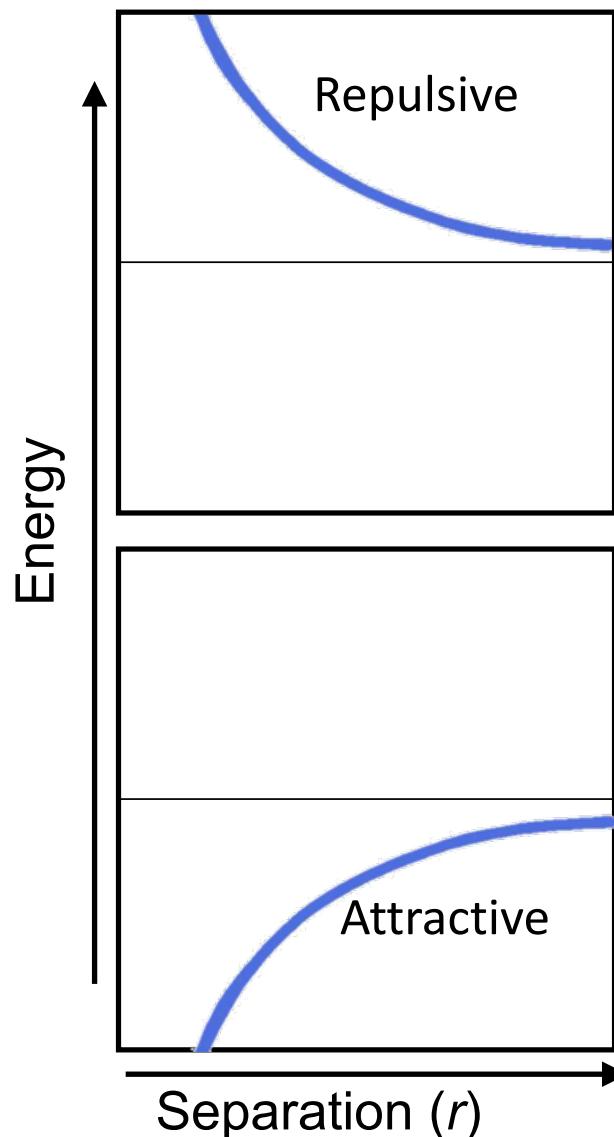

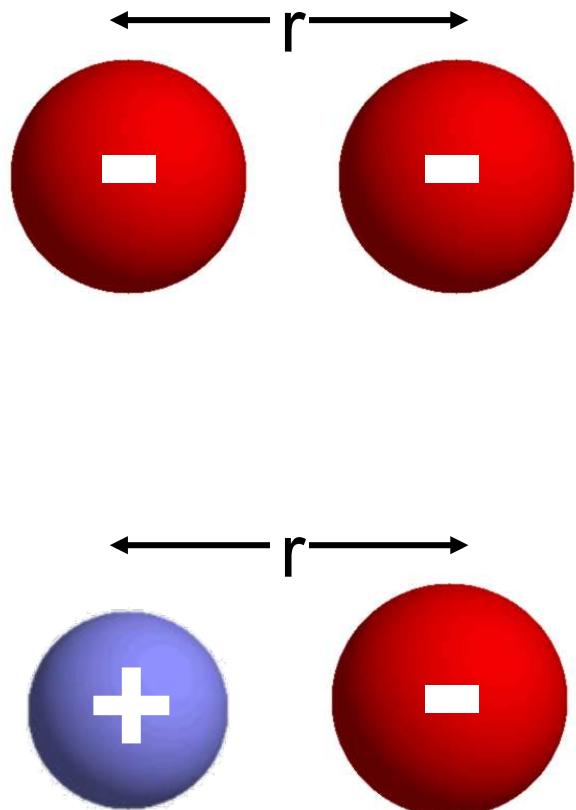

# Torsional angle twisting

- Certain values of each torsional angle are preferred over others.

defined for a set of 4 atoms covalently bonded in a row (1-2-3-4)

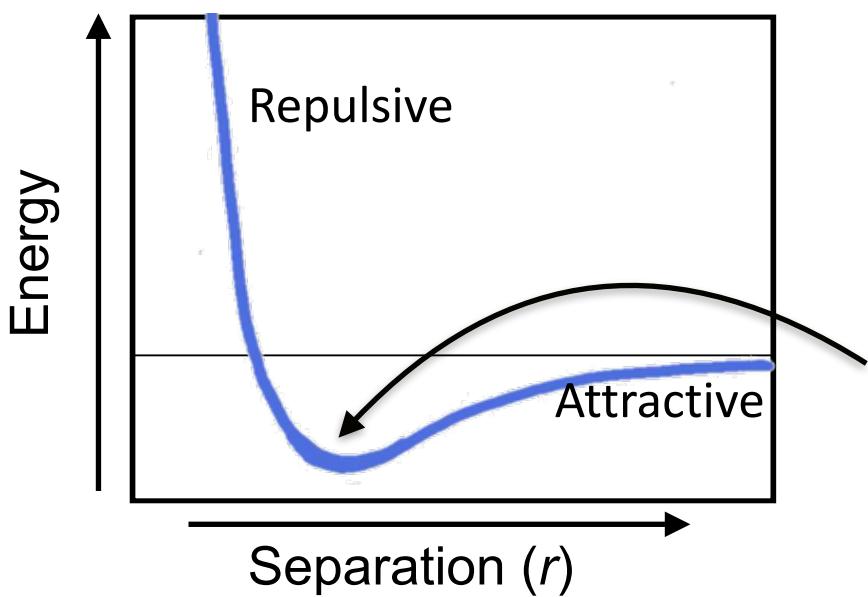

# Electrostatic interaction

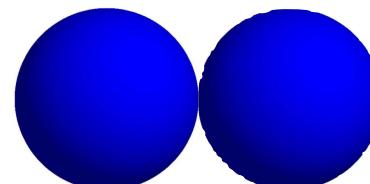

- Like charges repel.  
Opposite charges attract.
- Electrostatic forces act between all pairs of atoms, including those in different molecules.
- Each atom carries some “partial charge” (may be a fraction of an elementary charge), which depends on its element type and on which other atoms it’s connected to.

# van der Waals interaction

- van der Waals forces act between all pairs of atoms and do not depend on charge.
- When two atoms are too close together, they repel strongly.
- When two atoms are a bit further apart, they attract one another weakly.

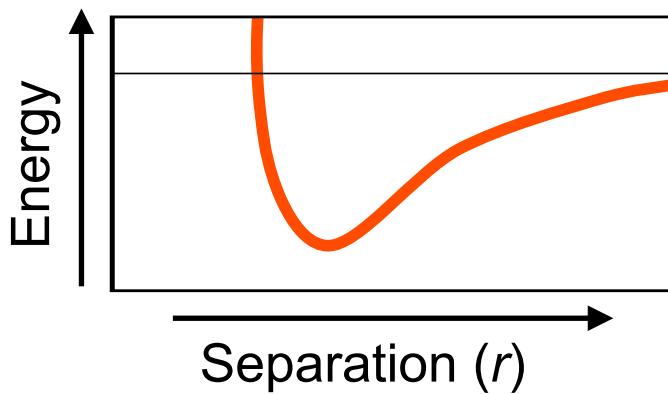

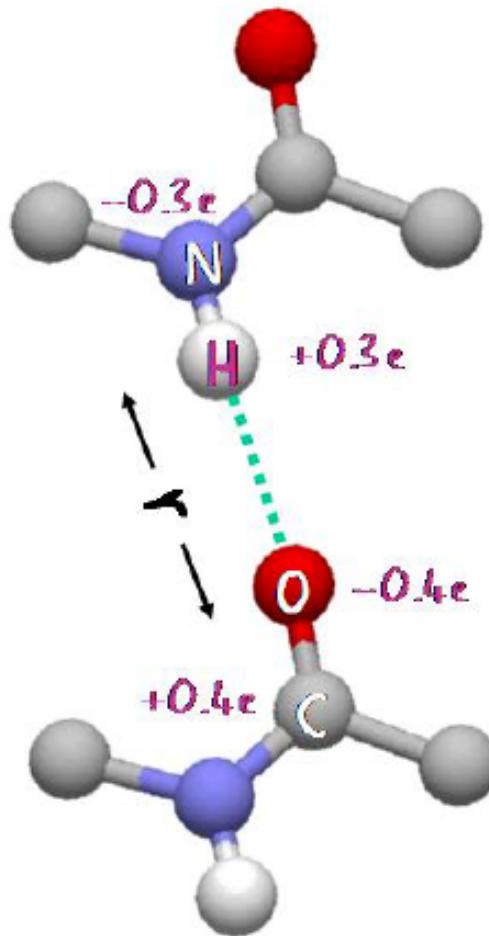

Energy is minimal when atoms are “just touching” one another

What determines the 3D structure of a protein?  
Physics underlying biomolecular structure

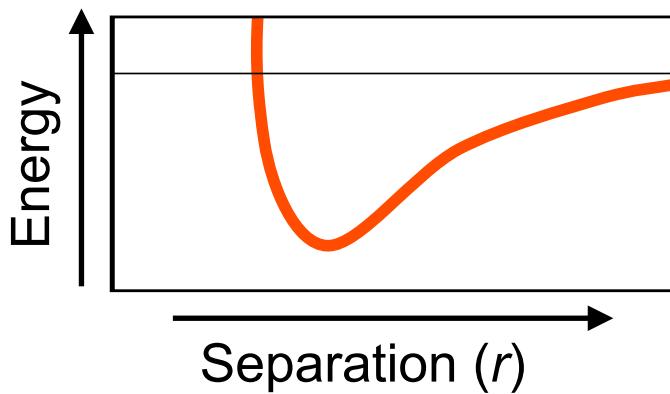

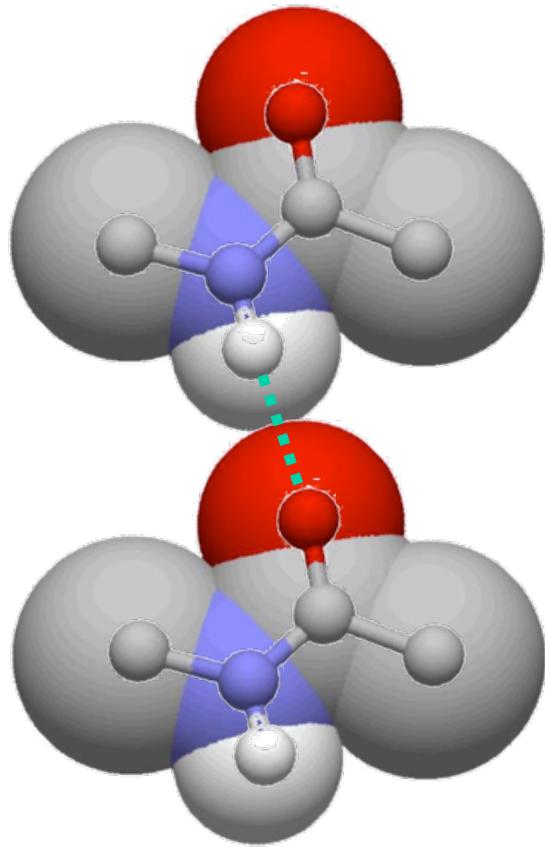

**Complex interactions**

# Hydrogen bonds

- Favorable interaction between an electronegative atom (e.g., N or O) and a hydrogen bound to another electronegative atom
- Result of multiple electrostatic and van der Waals interactions
- Very sensitive to geometry of the atoms (distance and alignment)
- Strong relative to typical van der Waals or electrostatic forces
- Critical to protein structure

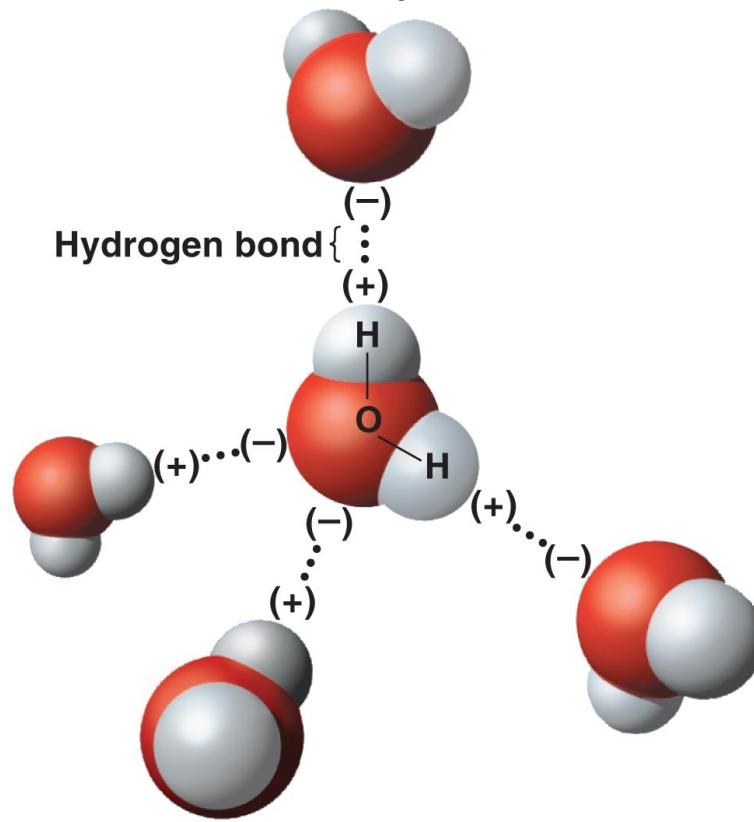

# Hydrogen bonds

- Favorable interaction between an electronegative atom (e.g., N or O) and a hydrogen bound to another electronegative atom
- Result of multiple electrostatic and van der Waals interactions
- Very sensitive to geometry of the atoms (distance and alignment)
- Strong relative to typical van der Waals or electrostatic forces
- Critical to protein structure

# Water molecules form hydrogen bonds

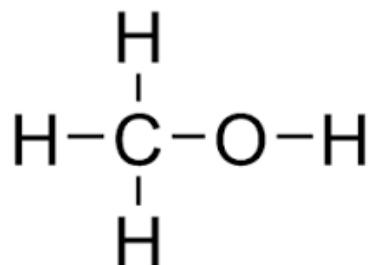

- Water molecules form extensive hydrogen bonds with one another and with protein atoms
- The structure of a protein usually depends on the fact that the protein is surrounded by water

# Hydrophilic vs. hydrophobic

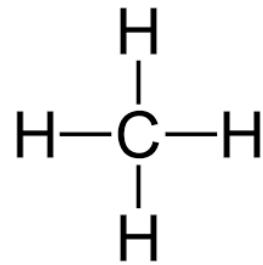

- Hydrophilic molecules are polar and thus form hydrogen bonds with water
  - Polar = contains charged atoms. Molecules containing oxygen or nitrogen are usually polar.
- Hydrophobic molecules are apolar and don't form hydrogen bonds with water

Hydrophilic (polar)

methanol

Hydrophobic (apolar)

methane

# Hydrophobic effect

- Hydrophobic molecules cluster in water
  - “Oil and water don’t mix”

note: full explanation of hydrophobic effect is still being actively researched

<http://science.taskermilward.org.uk/mod1/KS4Chemistry/AQA/Module2/Mod%202%20img/Oil-in-Water18.jpg>

- This is critical to protein structure

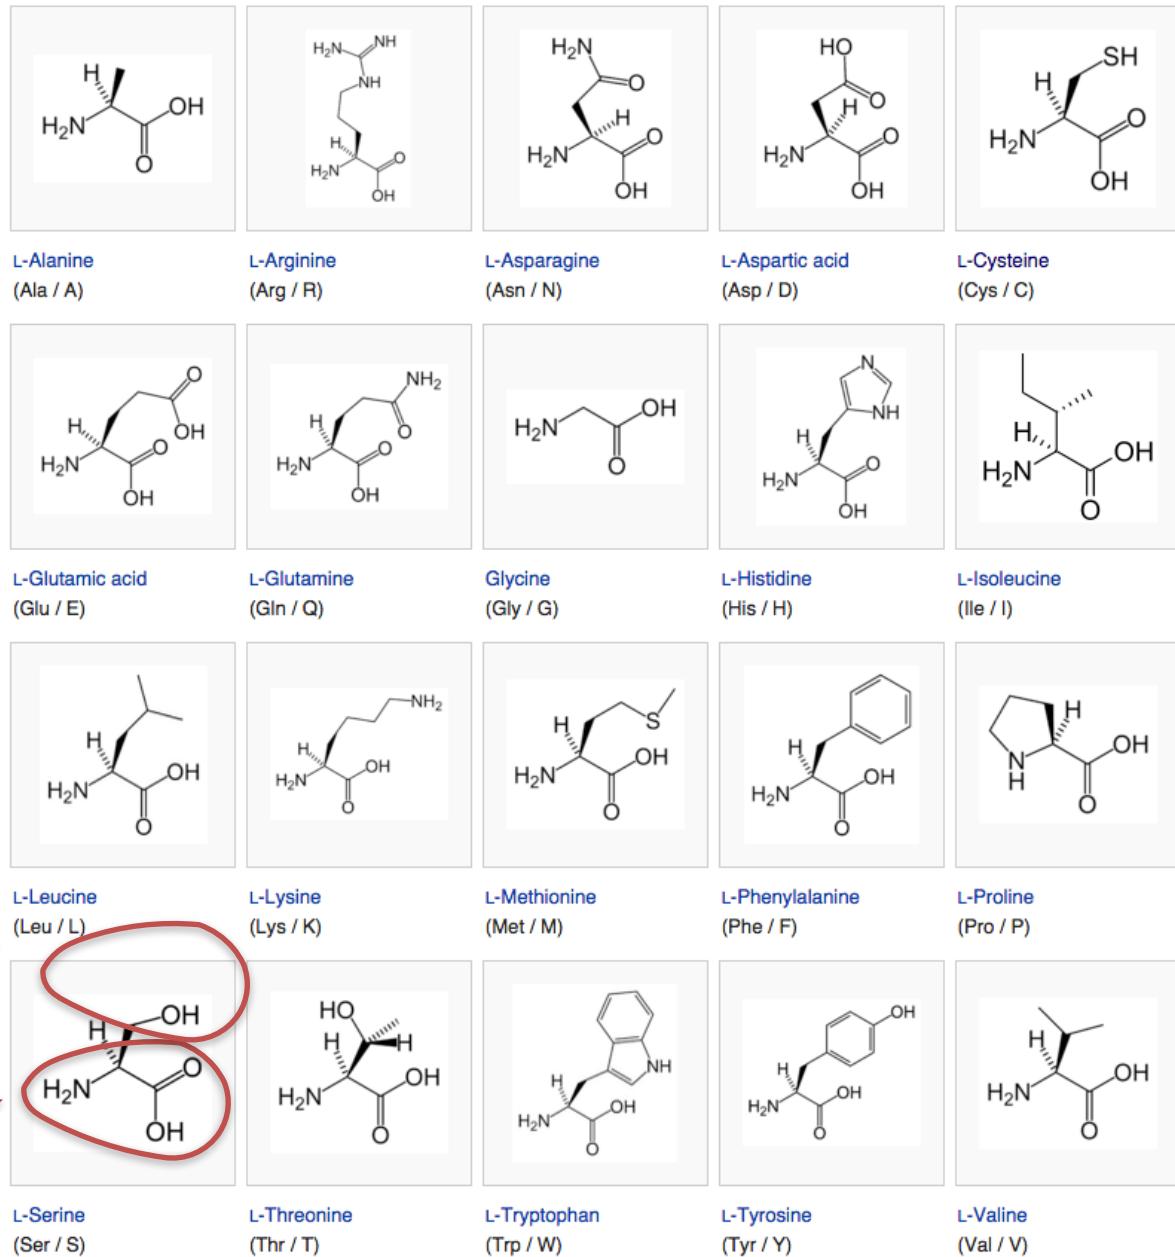

# Protein structure: a more detailed view

Protein structure: a more detailed view

## Properties of amino acids

# Proteins are built from amino acids

- 20 “standard” amino acids
- Each has three-letter and one-letters abbreviations (e.g., Threonine = Thr = T; Tryptophan = Trp = W)

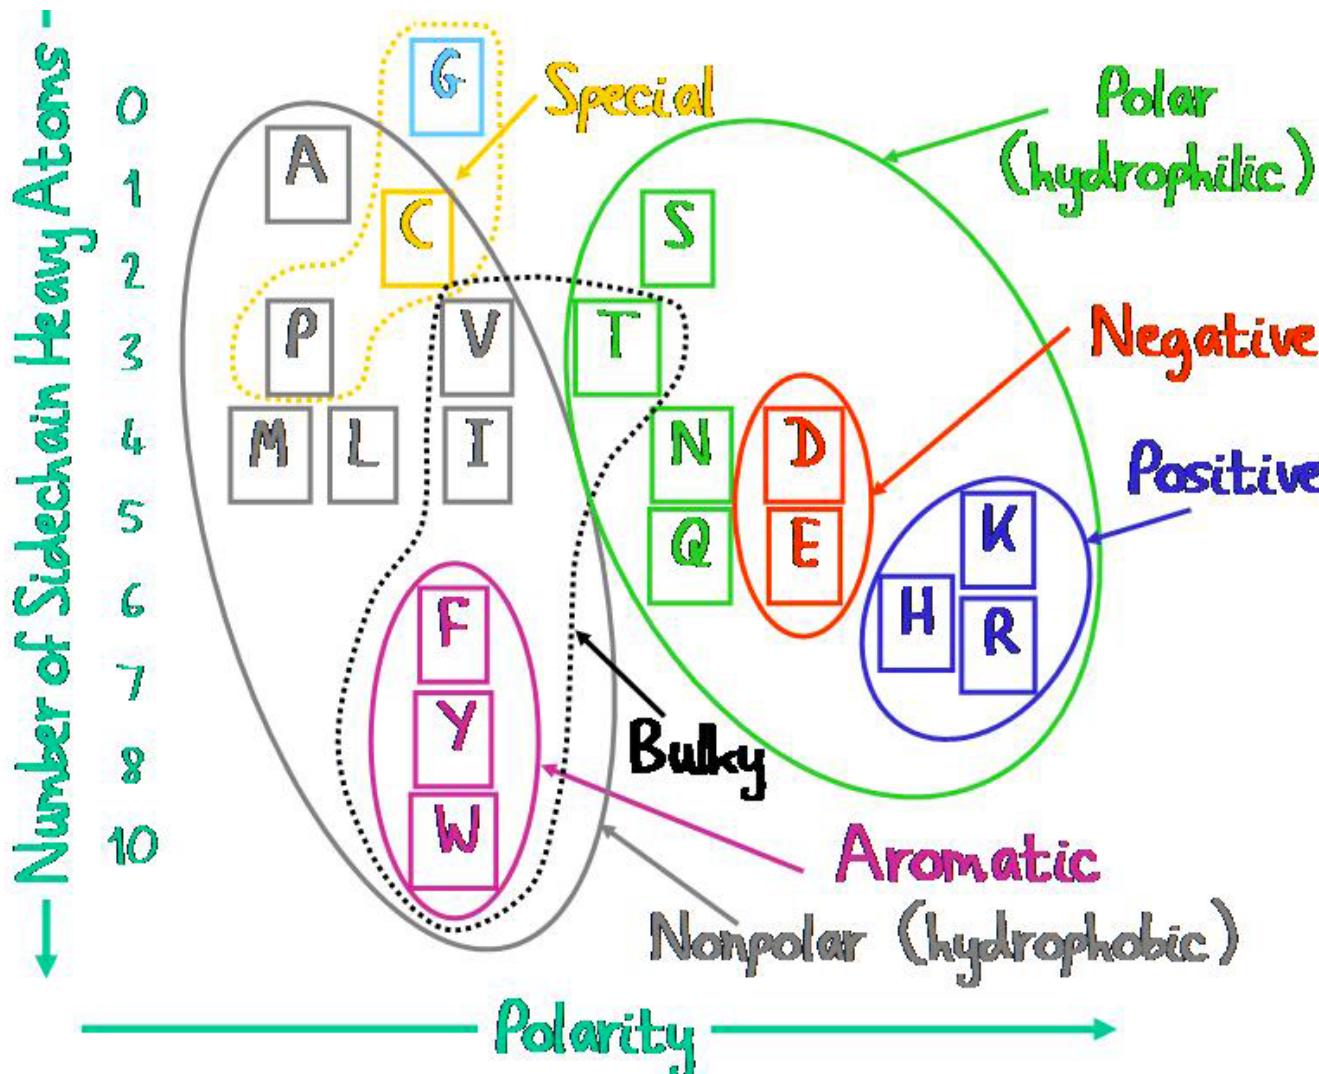

The “side chain” is different in each amino acid

All amino acids have this part in common.

# Amino acid properties

- Amino acid side chains have a wide range of properties. These differences bring about the 3D structures of proteins.
- Examples:
  - Large side chains take up more space than small ones
  - Negatively charged (acidic) side chains attract positively charged (basic) side chains
  - Hydrophilic side chains form hydrogen bonds to one another and to water molecules
  - Hydrophobic side chains “want” to be near one another

# Amino acid properties

There are many properties.

They cluster logically.

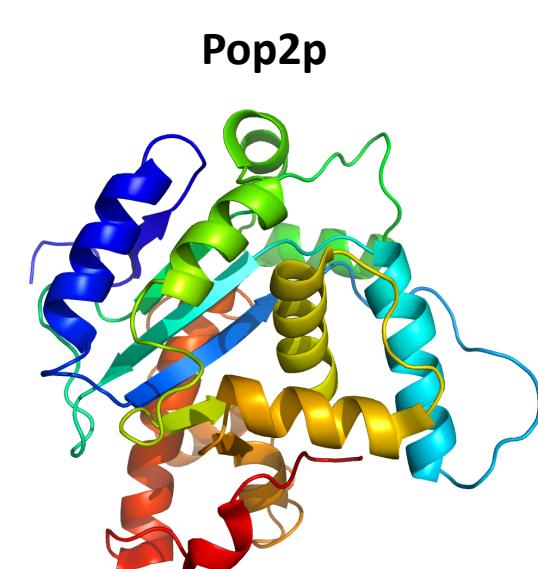

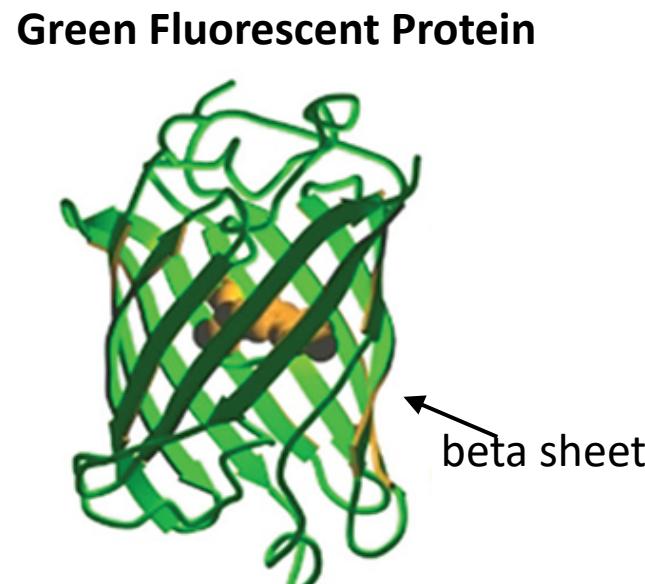

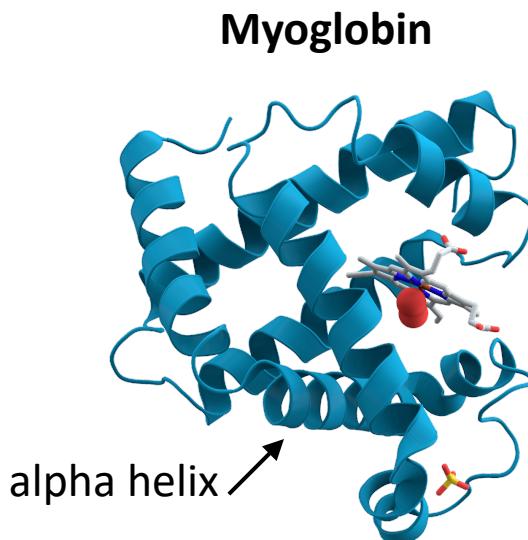

Slide from Michael Levitt

Protein structure: a more detailed view

**Secondary structure elements**

# Secondary structure elements

- Some local structural patterns are found in most proteins
  - These are called “secondary structure elements.” They are energetically favorable primarily because of hydrogen bonds between backbone atoms.
- Most common secondary structure elements:
  - alpha helix
  - beta sheet

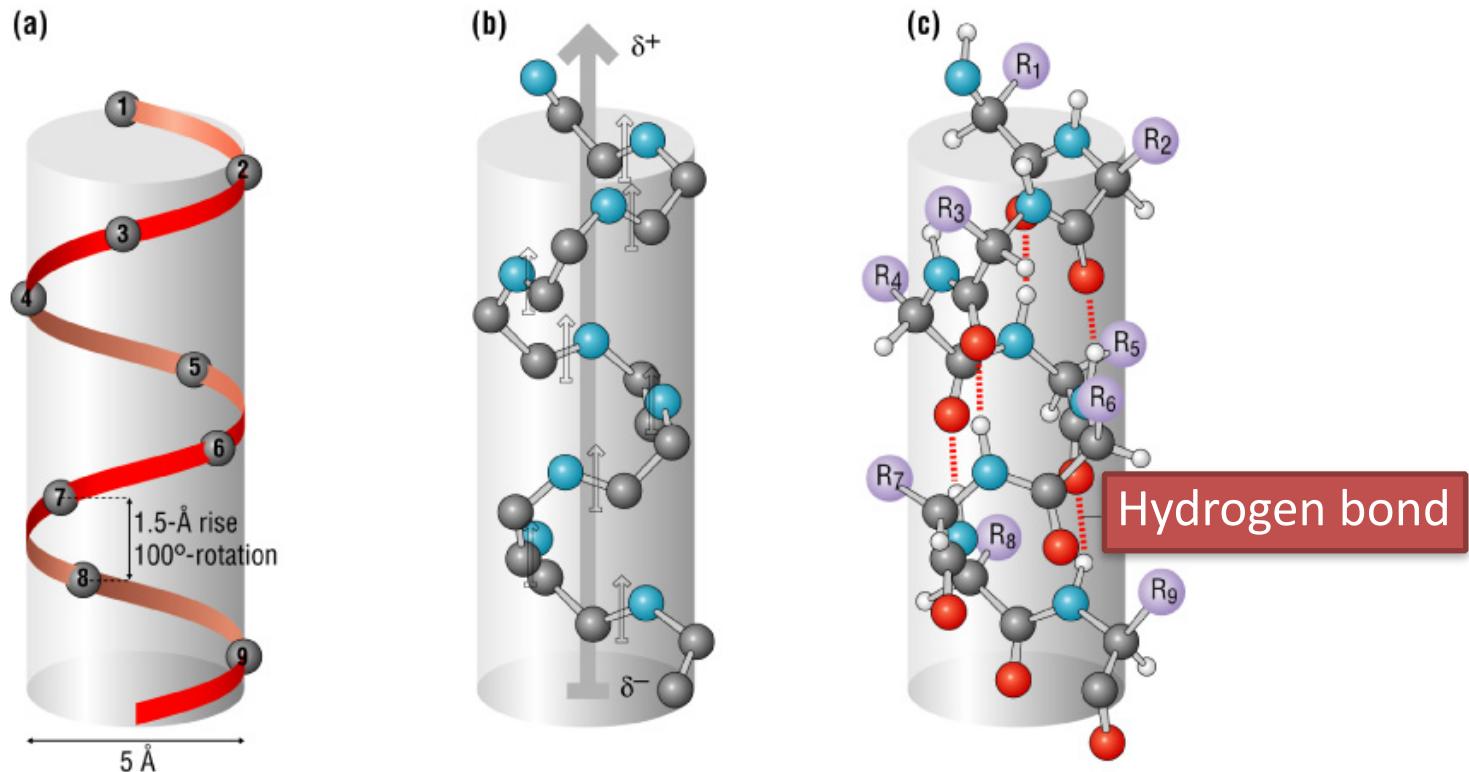

<https://upload.wikimedia.org/wikipedia/commons/>

[http://www.bioteck.com/assets/tech\\_resources/11596/figure2.jpg](http://www.bioteck.com/assets/tech_resources/11596/figure2.jpg)

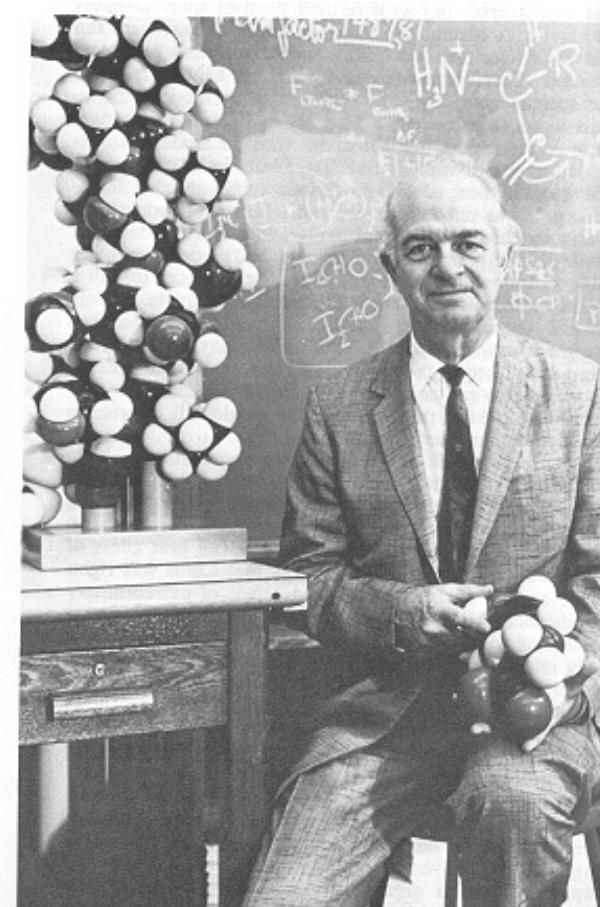

[http://upload.wikimedia.org/wikipedia/commons/e/e6/Spombe\\_Pop2p\\_protein\\_structure\\_rainbow.png](http://upload.wikimedia.org/wikipedia/commons/e/e6/Spombe_Pop2p_protein_structure_rainbow.png)

# The alpha helix

*Image from “Protein Structure and Function”  
by Gregory A Petsko and Dagmar Ringe*

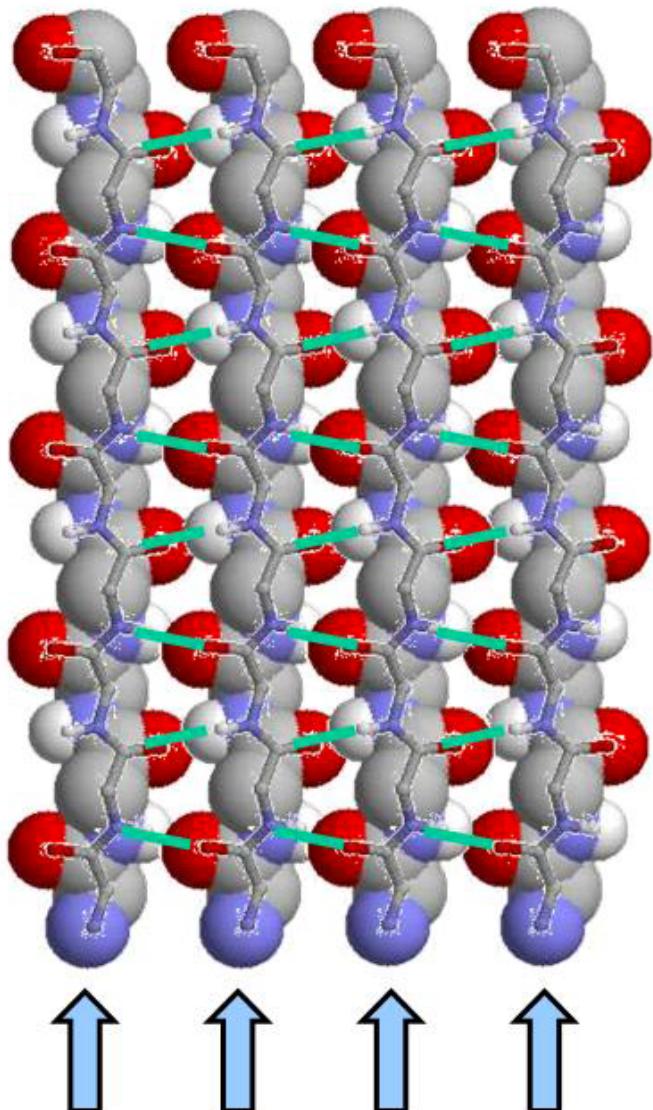

# The alpha helix

*Linus Pauling with his atomic models.*

Linus Pauling

# The beta sheet

A *beta sheet* is made up of two or more *beta strands*, connected by hydrogen bonds

From Michael Levitt

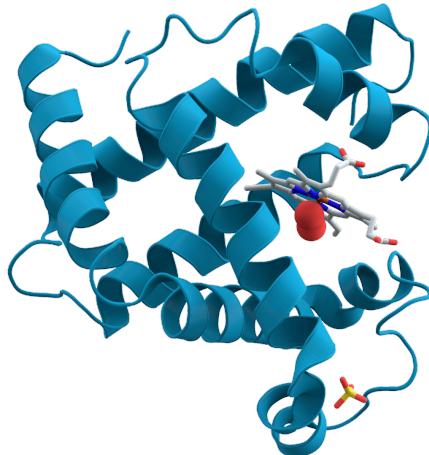

Protein structure: a more detailed view

**Tertiary structure, quaternary structure,  
and domains**

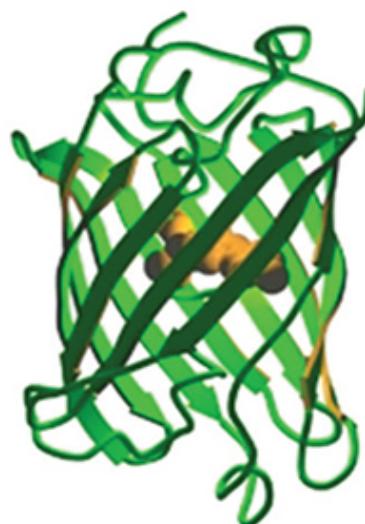

# Tertiary structure

- Tertiary structure: the overall three-dimensional structure of a polypeptide chain

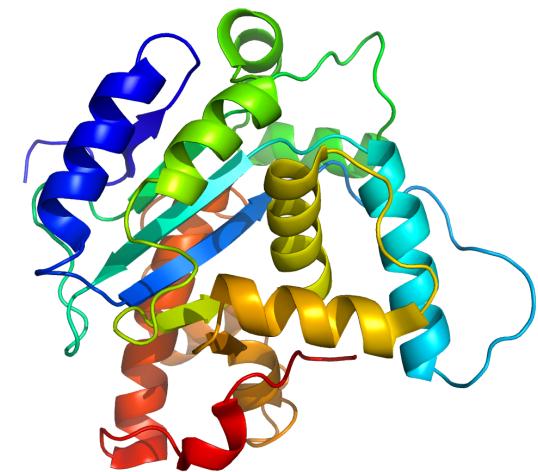

Myoglobin

Green Fluorescent Protein

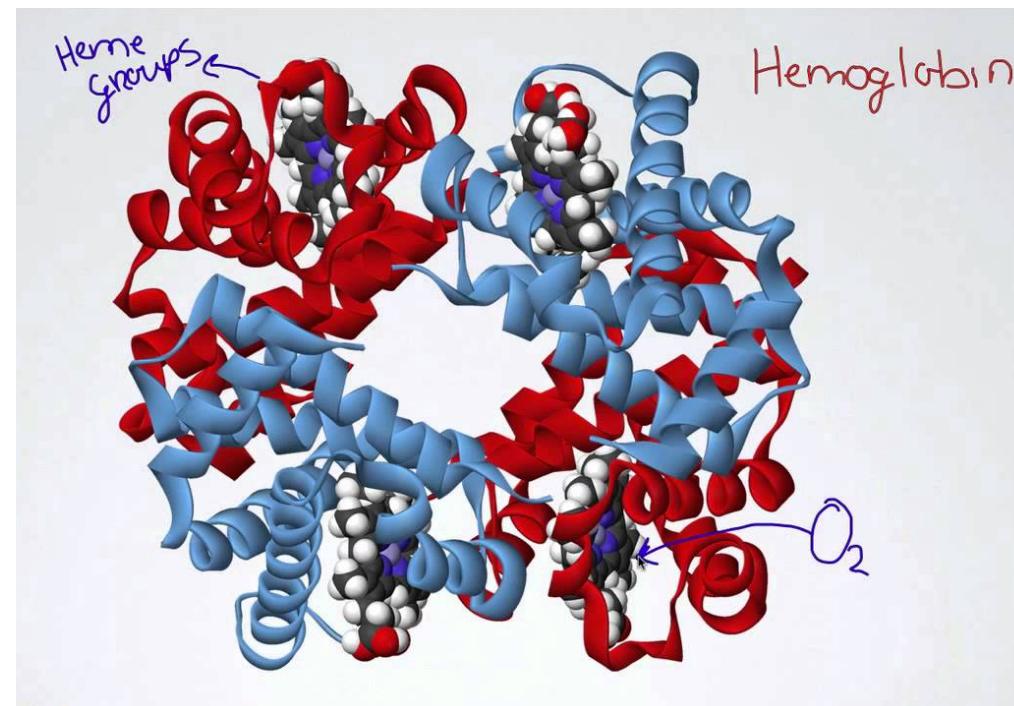

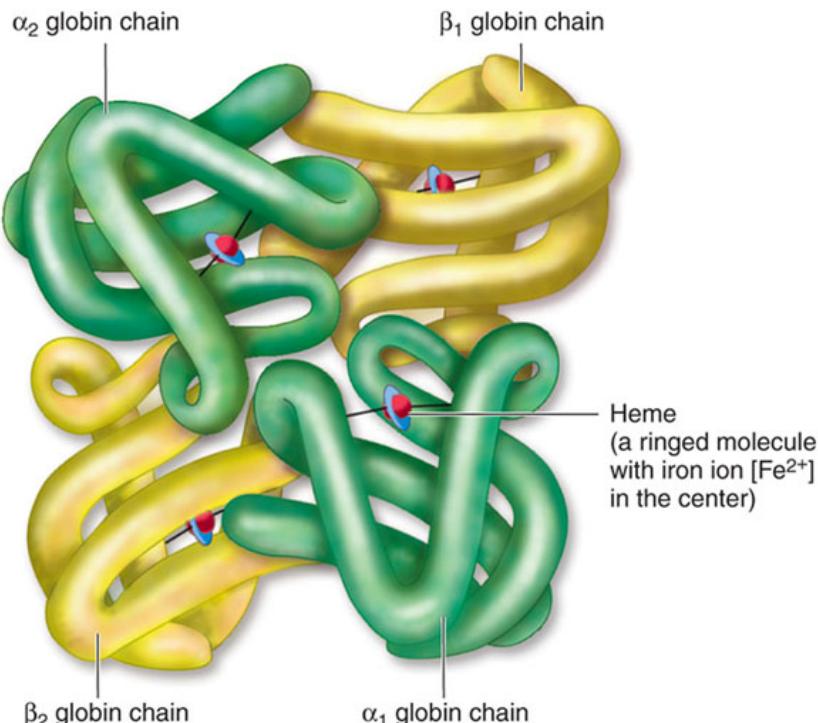

Pop2p

# Quaternary structure

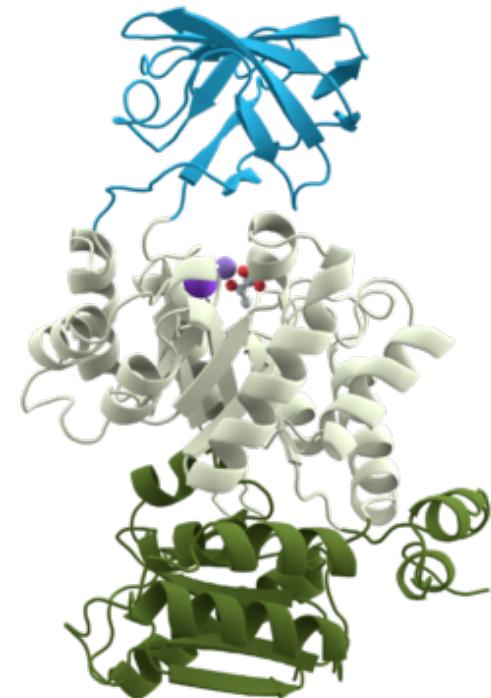

- Quaternary structure: the arrangement of multiple polypeptide chains in a larger protein

## Molecular Structure of Hemoglobin

# Domains

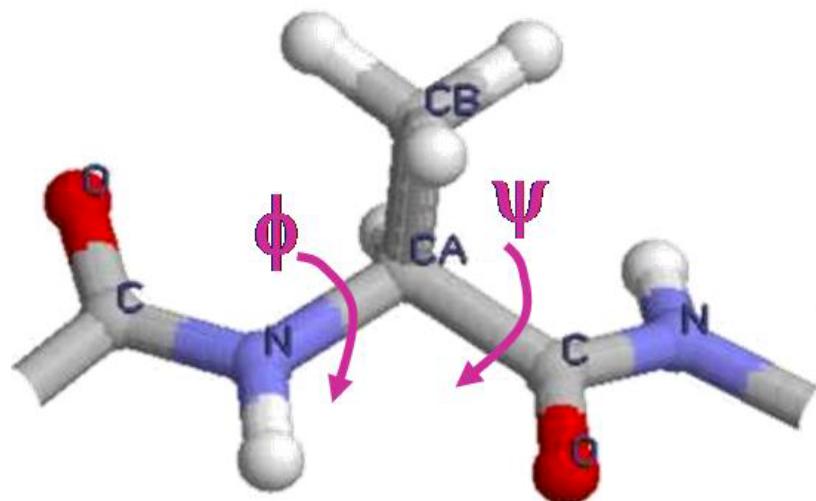

- Large proteins often consist of multiple compact 3D structures called *domains*
  - Many contacts within a domain.  
Few contacts between domains.
  - “Domain  $\approx$  blob”
- One polypeptide chain can form multiple domains, and a single domain may include portions of several polypeptide chains

Protein structure: a more detailed view

**Describing protein backbone structure**

# BACKBONE DEGREES OF FREEDOM

- The torsion angle rotating about the N-CA bond is called  $\phi$

- The torsion angle rotating about the CA-C bond is called  $\psi$

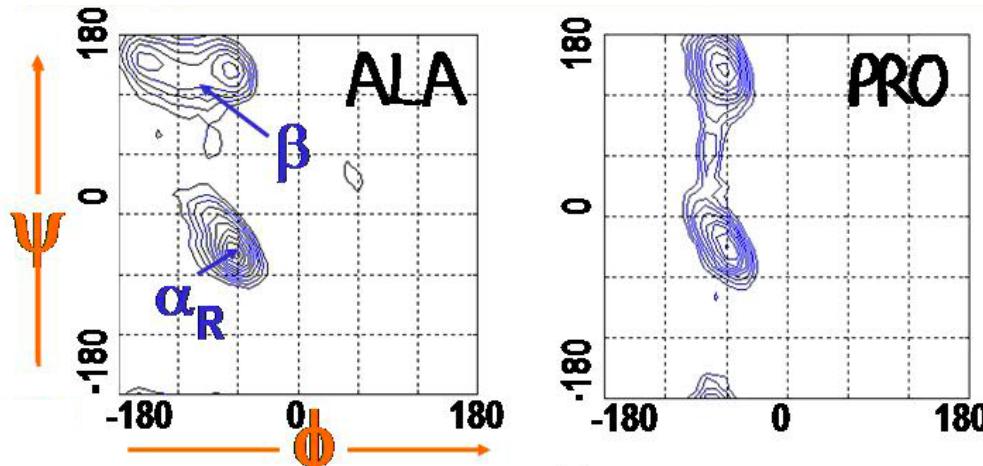

- Together they are the  $(\phi, \psi)$  angles

From Michael Levitt

- We only need two backbone torsion angles per amino acid residue because the third backbone bond (N-C, the “peptide bond”) is rigid
  - Specifying side chain structure requires additional torsion angles
- This is a useful way to specify protein structure—used, for example, in recent large language models for proteins

# Ramachandran diagrams

- A plot showing a distribution in the  $(\Phi, \Psi)$  plane is called a Ramachandran diagram
  - Such a diagram can be a scatterplot, or a two-dimensional histogram visualized as a contour map or heat map
  - For example, one might make a Ramachandran diagram for many residues of the same amino acid type
- Some amino acid types have distinctive Ramachandran diagrams

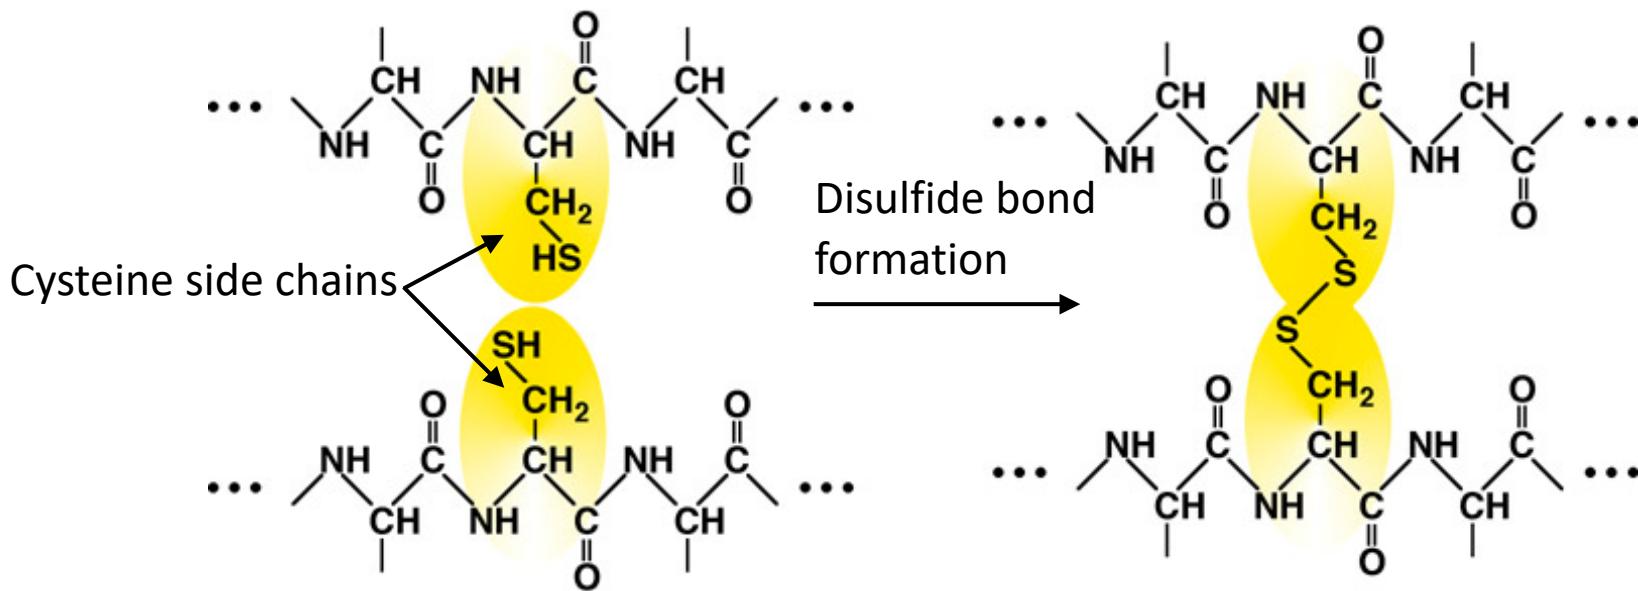

Ala is typical  
Pro is unusual

Image from  
Michael Levitt

- Alpha helices and beta sheets have characteristic Ramachandran diagrams

# One more note: Disulfide bonds

- One particular amino acid type, cysteine, can form a covalent bond with another cysteine (called a disulfide bond or bridge)
- Disulfide bonds often connect amino acid residues that are distant in the peptide chain
- In a typical cellular environment, disulfide bonds can be formed and broken quite easily

# Structures of other biomolecules

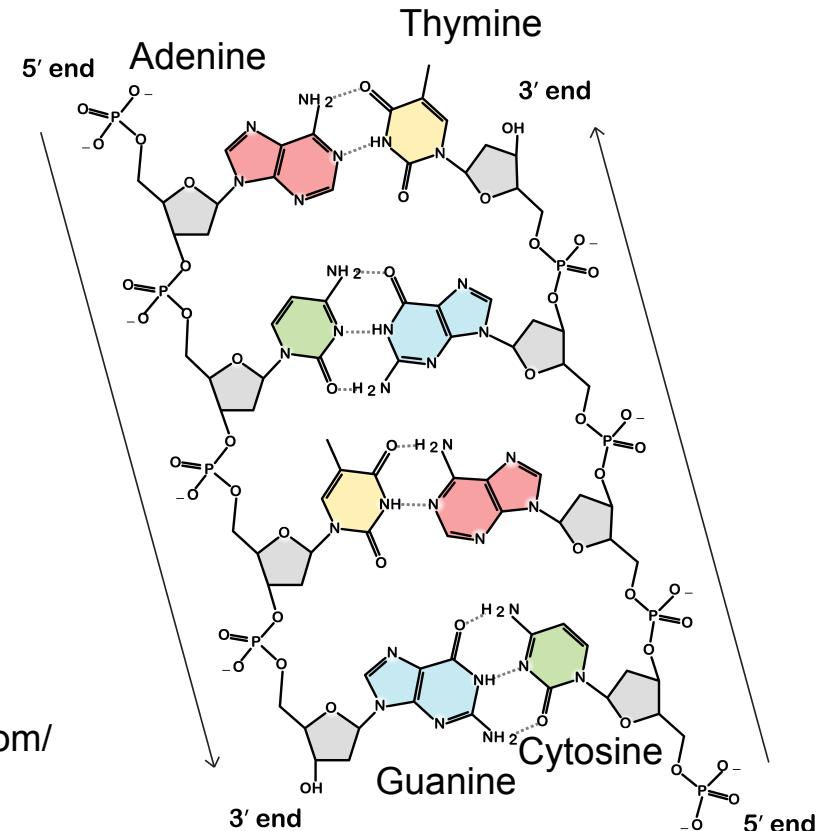

# What determines the structure of other biomolecules?

- The physical interactions that determine protein structure also determine the structures of other biomolecules including H-bonding and hydrophobic effect
  - More generally, the great majority of the material covered in this course for proteins applies to other biomolecules as well

polymer - molecule made up of a string of similar units

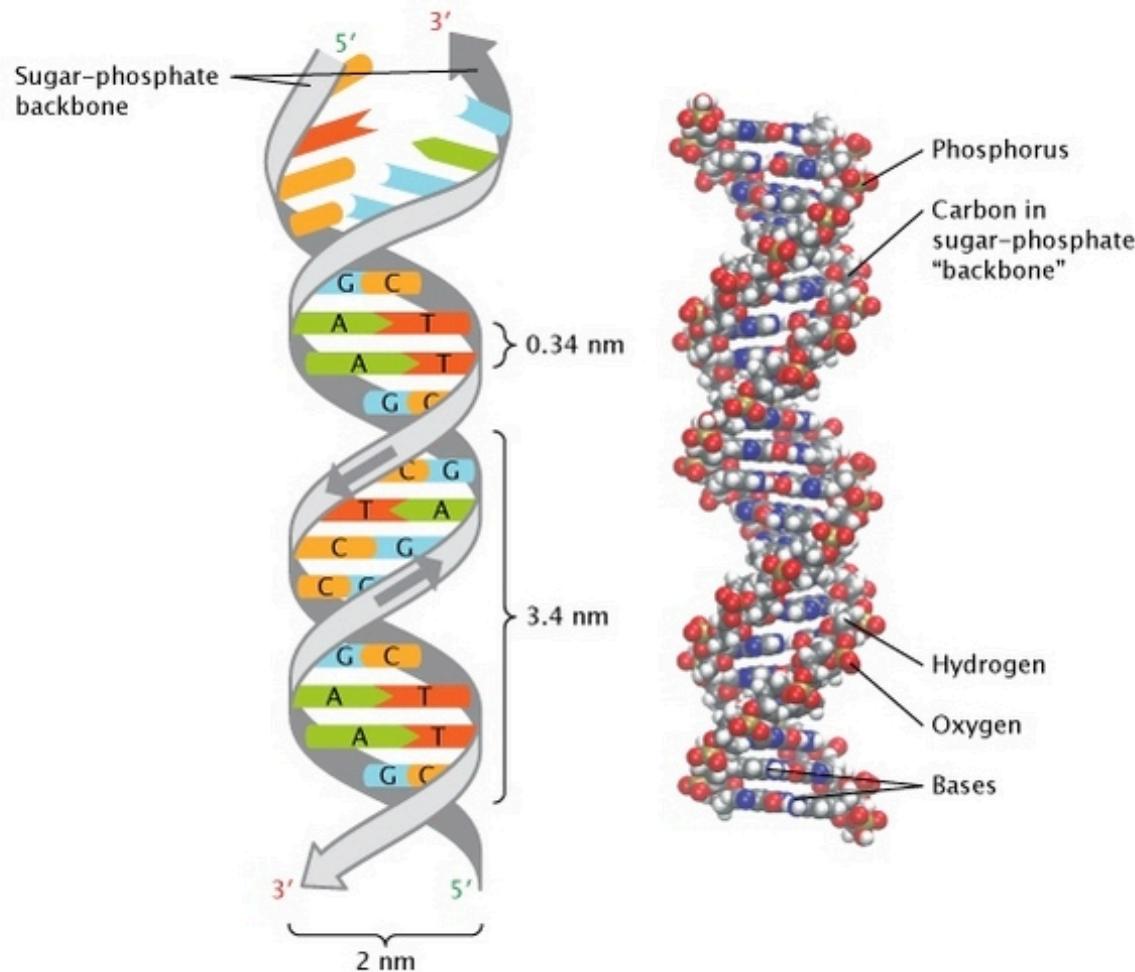

# DNA

- DNA (deoxyribonucleic acid) stores the genetic code
- DNA, like protein, is a string of units with a uniform backbone
  - The units are nucleotides, instead of amino acid residues
  - Different nucleotides contain different nucleobases (“bases”) instead of side chains
- Only four common DNA bases
  - Adenine pairs with Thymine
  - Guanine pairs with Cytosine

# DNA

- DNA forms one dominant 3D structure: a double helix
  - DNA usually acts more as information storage than as “machinery”
  - Long stretches of double helix can form coarser-scale structures

Cambridge, 1953. Shortly before discovering the structure of DNA, Watson and Crick, depressed by their lack of progress, visit the local pub.

Source unknown

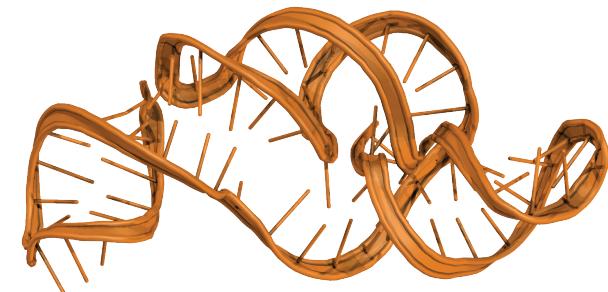

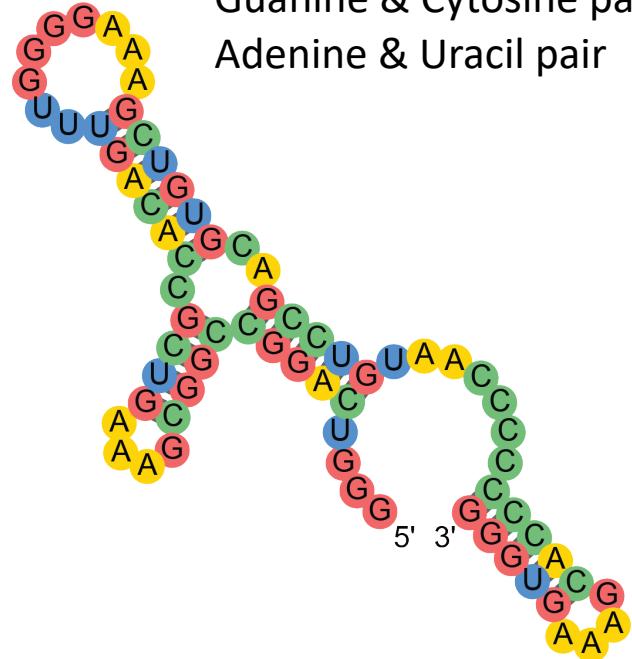

"IT'S NOT SUPPOSED TO BE A  
TRIPLE HELIX, IS IT?"

# RNA

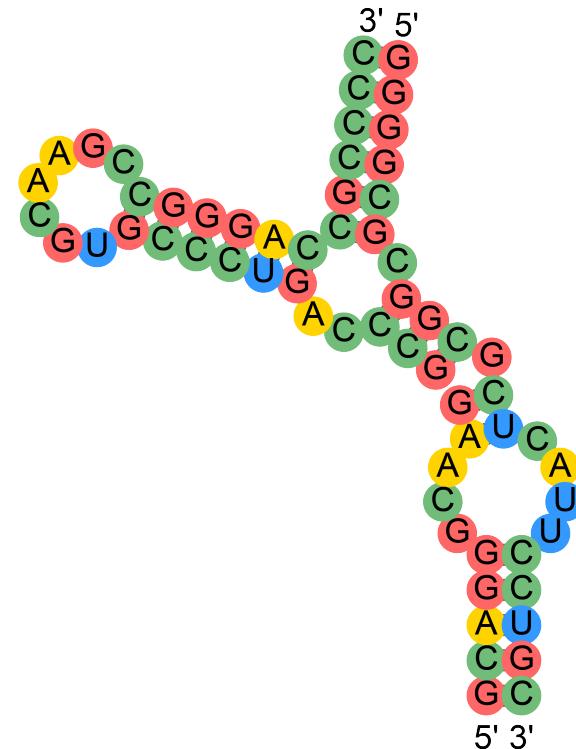

- RNA (ribonucleic acid) is a string of nucleotides, like DNA
- RNA, however, frequently occurs as a single string (strand) rather than paired strands
- RNA bases often pair with other bases in the same RNA strand
  - Much work on RNA structure focuses on the “secondary structure”: which bases pair with one another
  - Note that “secondary structure” has different meanings for RNA and protein
- Some RNAs store the genetic code of proteins, but most serve other functions
- RNAs usually form “machines” with well-defined, varied 3D structure

Typically:  
Guanine & Cytosine pair  
Adenine & Uracil pair

# RNA

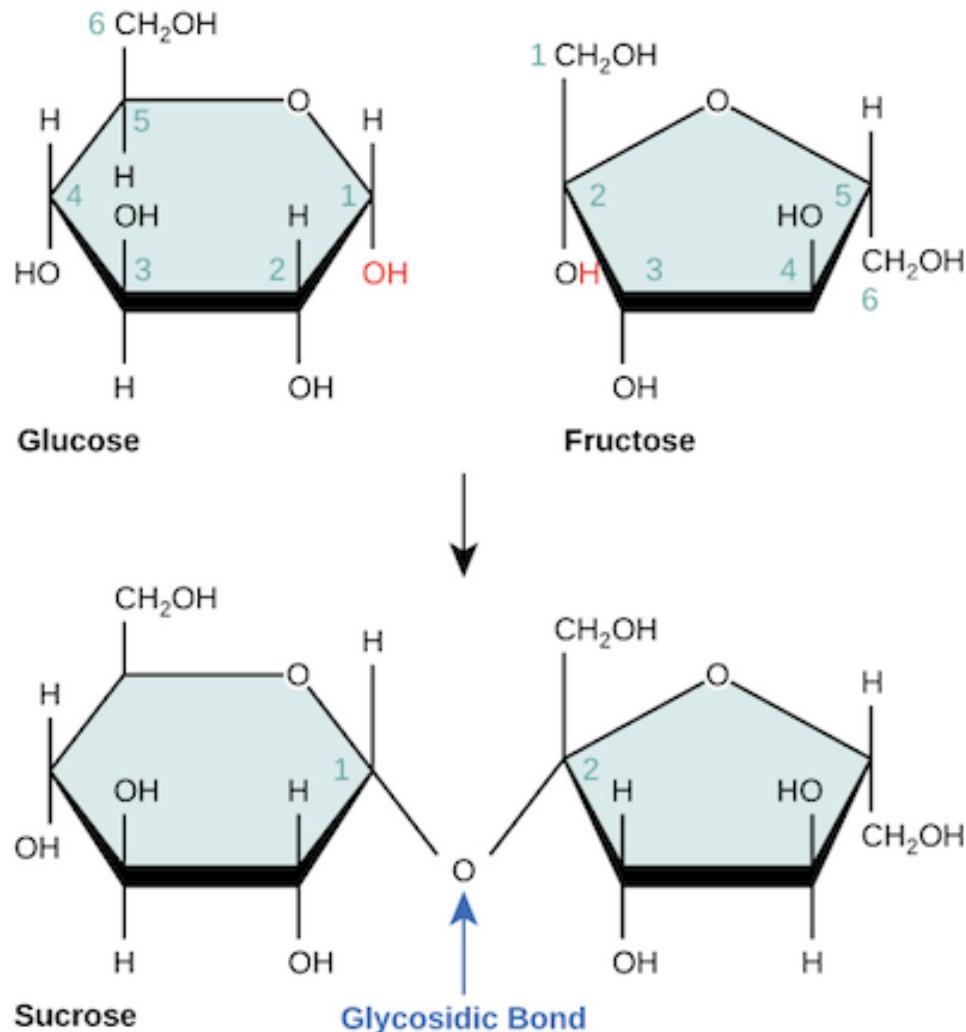

- Frequently, a single RNA is made up of multiple strands
  - Bases pair across strands
  - Secondary structure often includes multiple strands

From Andrew Watkins, Raphael Townshend

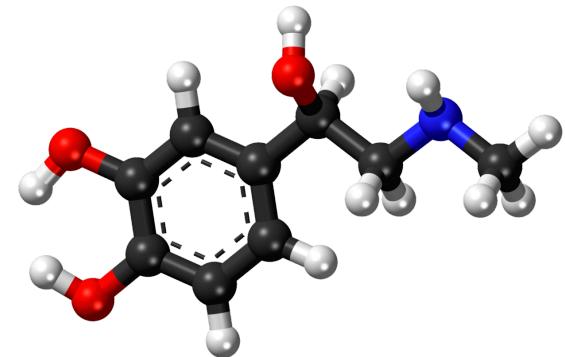

# Glycans (e.g. carbohydrates)

- The base units are called “mono-saccharides”
- When they are linked through glycosidic bond, they are called glycans
- Examples: starch, cellulose, chitin
- In cells, glycans are often attached to proteins (“glycosylation”)

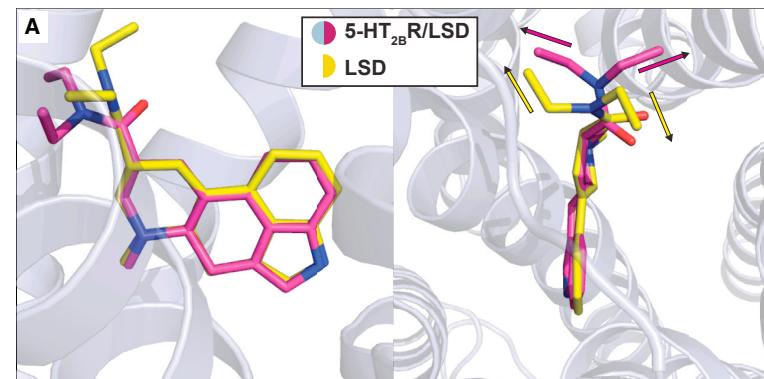

# Small molecules

- Most drugs and many hormones, neurotransmitters, and other natural signaling molecules are “small molecules” (~100 atoms or fewer)
- Cambridge Structural Database is a repository of small molecule 3D structures, generally from x-ray crystallography
- However, these molecules are usually highly flexible and thus likely to take on a different 3D structure when bound to a protein

Adrenaline (epinephrine)

[https://upload.wikimedia.org/wikipedia/commons/thumb/7/76/Epinephrine\\_ball-and-stick\\_model.png](https://upload.wikimedia.org/wikipedia/commons/thumb/7/76/Epinephrine_ball-and-stick_model.png)

LSD on its own (yellow) and receptor-bound (magenta)

Wacker et al., *Cell* (2017)

# A couple clarifications

- Nearly all PDB files don't specify bonds. When you load a PDB file into PyMOL, how can it display the covalent bonds?
  - It infers them automatically from the spatial coordinates of the atoms This is because when solving a structure, bonds are not actually visible and hydrogen atoms are too small to see
- What does “solving” a structure mean?
  - Determining it experimentally (which requires “solving” a computational problem to get atomic coordinates)

# Optional reading

- On the course website, we'll include links to papers or other materials recommended for those who wish to learn more about each lecture topic.
- This material is for students interested in learning more. It's strictly optional.

# A caveat

Wikipedia Celebrates 750 Years Of American Independence

## Wikipedia Celebrates 750 Years Of American Independence

NEWS

July 26, 2006

VOL 46 ISSUE 26

Science & Technology · Old Internet · Patriotism · Internet · History

NEW YORK—Wikipedia, the online, reader-edited encyclopedia, honored the 750th anniversary of American independence on July 25 with a special featured section on its main page Tuesday.

*Three girls march toward the White House on Elm St. in Washington, DC, as part of the Independence Day Parade.*

"It would have been a major oversight to ignore this portentous anniversary," said Wikipedia founder Jimmy Wales, whose site now boasts over 4,300,000 articles in multiple languages, over one-quarter of which are in English, including 11,000 concerning popular toys of the 1980s alone. "At 750 years, the U.S. is by far the world's oldest surviving democracy, and is certainly deserving of our recognition," Wales said. "According to our database, that's 212 years older than the Eiffel Tower, 347 years older than the earliest-known woolly-mammoth

fossil, and a full 493 years older than the microwave oven."

- This course covers a rapidly developing field. Published papers use different terminology and sometimes make contradictory claims. This includes papers I suggest as optional reading.
