Outline

• Why do we care?
• Convolution
  – Moving averages
  – Mathematical definition
• Fourier transforms
  – Writing functions as sums of sinusoids
  – The Fast Fourier Transform (FFT)
  – Multi-dimensional Fourier transforms
• Performing convolution using Fourier transforms
Why do we care?
Why study Fourier transforms and convolution?

- In the remainder of the course, we’ll study several methods that depend on analysis of images or reconstruction of structure from images:
  - Light microscopy (particularly fluorescence microscopy)
  - Cryoelectron microscopy
  - X-ray crystallography
- The computational aspects of each of these methods involve Fourier transforms and convolution
- These concepts also underlie algorithms used for
  - Ligand docking and virtual screening
  - Molecular dynamics simulations
Convolution

A more descriptive name than convolution would be “weighted moving average”
A function, as stored in a computer
Convolution

Moving averages
Original data (measurements)
Called a “moving” average, because you average the values surrounding your data point of interest.

Areas of fast change (i.e., when time is between 4-8 minutes) can have problems!
Using a weighting function is less noisy and allows you to better estimate areas of fast change.
A convolution is basically a \textit{weighted moving average}

- We’re given an array of numerical values
  - We can think of this array as specifying values of a function at regularly spaced intervals
- To compute a moving average, we replace each value in the array with the average of several values that precede and follow it (i.e., the values within a \textit{window})
- We might choose instead to calculate a \textit{weighted moving average}, where we again replace each value in the array with the average of several surrounding values, but we weight those values differently
- We can express this as a \textit{convolution} of the original function (i.e., array) with another function (array) that specifies the weights on each value in the window
Example

\[ f = \text{function of measurement} \]

\[ g = \text{weighting function} \]

\[ f \text{ convolved with } g \text{ (written } f \ast g) \]

Same as \( g \) convolved with \( f \)

Graphs showing the functions and their convolution.
Convolution

Mathematical definition
Convolution: mathematical definition

- If $f$ and $g$ are functions defined at evenly spaced points, their convolution is given by:

\[
(f * g)[n] = \sum_{m=-\infty}^{\infty} f[m]g[n-m]
\]
Convolution

Multidimensional convolution
Images as functions of two variables

• Many of the applications we’ll consider involve images

• A grayscale image can be thought of as a function of two variables
  – The position of each pixel corresponds to some value of $x$ and $y$
  – The brightness of that pixel is proportional to $f(x,y)$
Two-dimensional convolution

• In two-dimensional convolution, we replace each value in a two-dimensional array with a weighted average of the values surrounding it in two dimensions
  – We can represent two-dimensional arrays as functions of two variables, or as matrices, or as images
Two-dimensional convolution: example

\( f \star g \) (f convolved with g)
Multidimensional convolution

• The concept generalizes to higher dimensions
• For example, in three-dimensional convolution, we replace each value in a three-dimensional array with a weighted average of the values surrounding it in three dimensions
Fourier transforms
Fourier transforms

Writing functions as sums of sinusoids
Writing functions as sums of sinusoids

- Given a function defined on an interval of length $L$, we can write it as a sum of sinusoids whose periods are $L$, $L/2$, $L/3$, $L/4$, … (plus a constant term)

Starting and ending values ($x = -50$, and $x = 50$) are same

Original function

Sum of sinusoids below

Sinusoid = wave
Writing functions as sums of sinusoids

• Given a function defined on an interval of length $L$, we can write it as a sum of sinusoids whose periods are $L, L/2, L/3, L/4, \ldots$ (plus a constant term)
You can do this for any function!

Writing functions as sums of sinusoids

- Each of these sinusoidal terms has a magnitude (scale factor) and a phase (shift).

Original function

- Original function

Sum of sinusoids below

- Magnitude: 1.9
  - Phase: -0.94

- Magnitude: 0.27
  - Phase: -1.4

- Magnitude: 0.39
  - Phase: -2.8

Writing functions as sums of sinusoids

- Original function

![Graph of original function]

- Magnitude: 3.0
  - Phase: 0 (arbitrary)

- Sum of sinusoids below

![Graph of sum of sinusoids]

- Magnitude: 1.9
  - Phase: -0.94

- Magnitude: 0.27
  - Phase: -1.4

- Magnitude: 0.39
  - Phase: -2.8

Magnitude: How high the peaks are

Phase: x position of first maximum
Expressing a function as a set of sinusoidal term coefficients

- We can thus express the original function as a series of magnitude and phase coefficients.
  - If the original function is defined at $N$ equally spaced points, we’ll need a total of $N$ coefficients.
  - If the original function is defined at an infinite set of inputs, we’ll need an infinite series of magnitude and phase coefficients—but we can approximate the function with just the first few.

Using complex numbers to represent magnitude plus phase

- We can express the magnitude and phase of each sinusoidal component using a complex number.

Complex number = a single number with a real term and an imaginary term.

Magnitude = length of the blue arrow.
Phase = angle of the blue arrow.

![Diagram of a complex number in the complex plane with the real part a, imaginary part b, magnitude, and phase indicated.]}
Using complex numbers to represent magnitude plus phase

• We can express the magnitude and phase of each sinusoidal component using a complex number

• Thus we can express our original function as a series of complex numbers representing the sinusoidal components
  – This turns out to be more convenient (mathematically and computationally) than storing magnitudes and phases
The Fourier transform

• The Fourier transform maps a function to a set of complex numbers representing sinusoidal coefficients
  – We also say it maps the function from “real space” to “Fourier space” (or “frequency space”)
  – Note that in a computer, we can represent a function as an array of numbers giving the values of that function at equally spaced points.

• The inverse Fourier transform maps in the other direction
  – It turns out that the Fourier transform and inverse Fourier transform are almost identical. A program that computes one can easily be used to compute the other.
Why do we want to express our function using *sinusoids*?

- Sinusoids crop up all over the place in nature
  - For example, sound is usually described in terms of different frequencies
- Sinusoids have the unique property that if you sum two sinusoids of the same frequency (of any phase or magnitude), you always get another sinusoid of the same frequency
  - This leads to some very convenient computational properties that we’ll come to later
Fourier transforms

The Fast Fourier Transform (FFT)
The Fast Fourier Transform (FFT)

Fourier transforms become computationally intense with large number of data points

- The number of arithmetic operations required to compute the Fourier transform of $N$ numbers (i.e., of a function defined at $N$ points) in a straightforward manner is proportional to $N^2$
- Surprisingly, it is possible to reduce this $N^2$ to $N\log N$ using a clever algorithm
  - This algorithm is the Fast Fourier Transform (FFT)
  - It is arguably the most important algorithm of the past century
  - (For this class, you’re not required to know just how this algorithm works, although it’s really interesting!)
Fourier transforms

Multidimensional Fourier Transforms
Images as functions of two variables

- Many of the applications we’ll consider involve images
- A grayscale image can be thought of as a function of two variables
  - The position of each pixel corresponds to some value of $x$ and $y$
  - The brightness of that pixel is proportional to $f(x,y)$
Two-dimensional Fourier transform

- We can express functions of two variables as sums of sinusoids.
- Each sinusoid has a frequency in the $x$-direction and a frequency in the $y$-direction.
- We need to specify a magnitude and a phase for each sinusoid.
- Thus the 2D Fourier transform maps the original function to a complex-valued function of two frequencies.

On the left, the sinusoid is plotted as a surface, while on the right, the sinusoidal function is shown as an image.

$$f(x, y) = \sin(2\pi \cdot 0.02x + 2\pi \cdot 0.01y)$$
Three-dimensional Fourier transform

- The 3D Fourier transform maps functions of three variables (i.e., a function defined on a volume) to a complex-valued function of three frequencies.
- 2D and 3D Fourier transforms can also be computed efficiently using the FFT algorithm.
Performing convolution using Fourier transforms
Relationship between convolution and Fourier transforms

• It turns out that convolving two functions is equivalent to *multiplying* them in the frequency domain
  – One multiplies the complex numbers representing coefficients at each frequency

• In other words, we can perform a convolution by taking the Fourier transform of both functions, multiplying the results, and then performing an inverse Fourier transform
Why does this relationship matter?

• First, it allows us to perform convolution faster
  – If two functions are each defined at \( N \) points, the number of operations required to convolve them in the straightforward manner is proportional to \( N^2 \)
  – If we use Fourier transforms and take advantage of the FFT algorithm, the number of operations is proportional to \( N \log N \)

• Second, it allows us to characterize convolution operations in terms of changes to different frequencies
  – For example, convolution with a Gaussian will preserve low-frequency components while reducing high-frequency components
