# At First Blush on Tenterhooks: About Selectional Restrictions Imposed by Nonheads<sup>1</sup>

JAN-PHILIPP SOEHN AND MANFRED SAILER

## 9.1 Introduction

Selection is one of the major mechanisms in formal grammar, such as HPSG (Pollard and Sag, 1994), and is used for two purposes which are usually applied in the same contexts: First, syntactic and semantic arguments are specified and their relation to the selector is indicated. This is usually expressed in terms of thematic role assignment. Second, the properties of elements that may be combined are restricted. When a verb selects its complements, it imposes both kinds of restrictions at the same time. If on the other hand the selector is a nonhead, as in the case of modifiers, the question of thematic role assignment is less clear. When it comes to complementizers which select a clause, only the second function of selection appears to be relevant. In this paper we will present evidence that all nonheads, including complements, can impose this kind of selectional restrictions on the heads they combine with.

As a starting point we will look at PPs that contain a *unique nominal*

---

<sup>1</sup>This paper originated within the Special Research Center 441 at the University of Tübingen. The full data and a more comprehensive discussion of the approach is given in Soehn (2003). We are grateful to Koenraad Kuiper, Stefan Müller, Frank Richter, Beata Trawiński and to the FGVienna reviewers for helpful comments and to Guthrun Love and Carmella Payne for help with the challenges of English.

*complement* (UNC), i.e., a noun that only occurs in combination with a particular preposition. English examples are *on tenterhooks* (*nervous, worried*), or *in a trice* (*in an instant*). Note that the underlined nouns cannot be used in any other environment. For German a large number of PPs with UNC's have been identified. We will show that the data can be adequately described if we allow nonheads to select heads. Thus we will generalize the HPSG treatment of adjuncts (which select by MOD) and of functional words such as determiners and complementizers (which select by SPEC) to all nonheads. This analysis requires only minor changes to the HPSG architecture, whereas alternative attempts either fail to account for the data or would require a far stronger mechanism. In this context we will discuss a constructional analysis (Riehemann, 2001) and a collocational analysis (Sailer and Richter, 2002). While the need for constructions for other phenomena is indisputable (Fillmore et al., 1988, Jackendoff, 1995), we will demonstrate that our new architecture can not only account for the data that Sailer and Richter have used to motivate their collocational approach, but also implies a number of restrictions on the kinds of collocational effects that may arise. These predictions are consolidated by a data base of approximately 300 highly collocationally restricted lexical items in German.

## 9.2 Data

The data we use as motivation for our analysis are *unique nominal complements* (UNC) of prepositions. They can only occur within a PP, as illustrated by the example *auf Anhieb* (*at first go*). To use Tseng (2000)'s terminology: *Anhieb* is an *internal trigger* of the preposition *auf*. In the following examples, the unique element is underlined and the preposition is printed in bold face.

- (15) Das "PC-Kummerbuch" ist **auf Anhieb** auf großes Interesse  
 the PC-sorrow-book is at first-go on great interest  
 gestoßen.  
 hit  
 'The "PC Troubleshooting Companion" triggered interest right  
 away.'

It is important to note that combining another preposition with *Anhieb* is ungrammatical, see (16) for comparison to a non-unique noun.

- (16) **auf**/\***bei** Anhieb (at first go) vs.  
 auf den/beim ersten Versuch (at first attempt)

Similar English expressions are *by rote* (*mechanical*) or *in a trice* (*as quickly as possible*). For German, we have compiled about 300 highly

collocationally restricted lexical elements from the phraseological literature (Dobrovolskij, 1988, Dobrovolskij and Piirainen, 1994, Fleischer, 1989, 1997). This list contains about 90 PPs with UNC's. These comprise:

- (17) **im Brustton** (der Überzeugung) (with utter conviction), **zum Steinerweichen** (bitterly), **von/durch Geisterhand** (by magic), **um Haaresbreite** (by a hair's breadth), **im Nachhinein** (with hindsight), **aus/nach Herzenslust** (ad libitum), **ohne Unterlass** (without intermission)

These expressions have a highly restricted environment, as only one or a few prepositions are possible.

We are now faced with the question of how these expressions can be analyzed. One possibility would be to put the entire P+UNC sequence in the lexicon as a multiword lexeme (such as *of course*). This would not be adequate for three reasons: Firstly, the whole expression is syntactically formed like a regular PP and can be interpreted compositionally (see 18). Following Fillmore et al. (1988) we want to adopt phrasal lexical entries only for phrases with idiosyncratic properties. Secondly, the complements of the preposition can be modified (see 19). However this is not a property of all UNC's and the modifiability has to be examined case by case. Thirdly, a UNC can be coordinated with another UNC or even with a free noun (see 20 and 21). From here it follows that the relevant PPs are not unstructured entities. Rather they are formed like regular PPs and even their semantics is decomposable. Consequently, regarding them as multiword lexemes would postulate too much irregularity of the language.

- (18) Sie erhalten dieses Modell **auf** Anfrage.  
 you get this model on request  
 'This model is available upon request.'
- (19) Er nahm an dem Gewinnspiel **aus** reinem Daffke teil.  
 He took at the lottery ex pure fun part  
 'He took part in the lottery just for fun.'
- (20) Das Mädchen schmetterte ein Lied **aus** [Herzenslust und  
 the girl belted out a song from heart.delight and  
Leibeskräften].  
 body.power  
 'The girl belted out a song to the top of her bent and with all her heart.'

- (21) Damit brachte er sie **in** [Teufels Küche und jede Menge  
with-it brought he her in devil's kitchen and every amount  
Schwierigkeiten].  
trouble  
'With that he got her in hot water and big trouble.'

The next step is to make sure that the UNC combines with (and only with) the correct preposition. Moreover, where a UNC cannot be modified, the possibility of modification has to be excluded. In the following section we will take a closer look at various approaches to analyzing the data.

### 9.3 Alternative Analyses

#### 9.3.1 Preposition selecting the NP

In all grammar frameworks, selection or subcategorization is a central issue, which is realized within HPSG by valence lists in the CATEGORY value of a sign. Subcategorization is rather general: a typical domain would be for example a verb subcategorizing a subject and an object, both noun phrases being capable of receiving a particular theta-role. To account for the vast variety of grammatical expressions, values of subcategorized signs are specified only to a certain extent. Underspecification is the mechanism which allows the selection of many different signs and keeps subcategorization to the required degree of generality.

If we were to use a preposition to select a UNC as its complement, we would encounter problems. First of all, even if we introduced the possibility of selecting particular lexemes, we could not prevent the UNC from occurring elsewhere, because of underspecification. Additionally, if we defined a preposition that selected a particular UNC we would have to postulate a certain amount of homophonous prepositions, where each one subcategorized for a different UNC. This postulation would be rather counterintuitive. Even worse, the appearance of a UNC in coordination, such as in (20) and (21) would be rendered ungrammatical.

Thus the present selection mechanism for HPSG is not sufficient, as selection of the argument by the preposition would not be able to correctly restrict the occurrence of a UNC to a particular preposition and it would wrongly exclude the coordination data above.

#### 9.3.2 Constructional Approach

Riehemann (2001) offers a concrete analysis of idioms within HPSG based on the ideas of Construction Grammar (Fillmore et al., 1988, Sag, 1997). She describes idioms as units of several words, i. e. constructions. One of her central ideas is to relate each word in an idiom

with its literal counterpart. For our data this approach is not adequate because the lack of a literal lexical counterpart is a defining feature of UNC's such as *Anhieb* or *Daffke*. If we were to introduce lexical entries such as these, we would not be able to prevent the words from occurring freely in other contexts. Alternatively, we can adopt a constructional analysis in which the UNC's are *idiomatic words* not related to any literal counterpart.

Riehemann (2001) introduces a complex mechanism to restrict the distribution of idiomatic words to the correct contexts, defining new sorts and attributes which keep track globally of all parts of idiomatic expressions that occur in an utterance. The components of this mechanism are not independently motivated, and, as Riehemann (p. 207) acknowledges, the occurrence of pronominalized parts of idioms cannot be handled.

We conclude that the UNC data does not fit Riehemann's basic assumptions on idioms, and thus does not justify the application of her complicated apparatus.

### 9.3.3 Collocation

Sailer (2003) and Sailer and Richter (2002) propose a collocation module, introducing the COLL feature. The value of this feature is a list. This list is empty for non-lexical signs, and contains a single sign for each lexical sign. The authors define a grammar principle which imposes the following constraint: the overall utterance must be identical with the sign in the COLL lists of all the lexical signs for this utterance. Thus the entire utterance is available at the COLL value of every lexical sign, so that occurrence restrictions can be specified. This means that any property of the utterance can be mentioned in the lexical entry of such a sign. For example, the word *Anhieb* specifies in its COLL list a sign dominating a PP with the head *auf*, *Anhieb* being the complement of *auf*.

This module is explicitly designed for elements with limited distribution. However it is extremely powerful, because the element of the COLL list makes available the structure of the entire expression available. Therefore the mechanism does not impose any principled constraints on the kinds of occurrence restrictions that may be found. For our data, i.e. very local dependencies, the mechanism seems far too powerful and requires quite a few changes within the grammar. In the next section we will argue for a different approach, using an existing mechanism in HPSG and making only minor changes.

### 9.4 External Selection

As indicated already in the introduction, there is a mechanism of external selection provided within the HPSG framework. External selection means that nonheads select their heads. This has been assumed for adjuncts (which select by MOD) and for functional words such as determiners and complementizers (selecting by SPEC). We will now generalize this mechanism and apply it to all nonheads by specifying a feature XSEL (for *external selection*) for the sort *head*. By XSEL the features MOD and SPEC are subsumed and become dispensable. Pollard and Sag (1994, p. 55) themselves state that these two features are analogous in their use. The function of MOD and SPEC is now incorporated into XSEL, and everything that they have accomplished can be achieved by the new attribute. The value of XSEL is *synsem*. This results in the analysis illustrated in (22), the details of which will be examined below.

(22) Structure of the PP *auf Anhieb*:

The changes to be made affect only two points of our grammar. First, as already noted, we define an attribute XSEL for the sort *head* and remove MOD and SPEC from the signature. As we have introduced XSEL for the sort *head*, the value percolates via the HEAD FEATURE PRINCIPLE (HFP). Second, we redefine the SPEC-PRINCIPLE as PRINCIPLE OF EXTERNAL SELECTION, stated in (23).

(23) PRINCIPLE OF EXTERNAL SELECTION (PXS):

The SYNSEM value of a word is identical to the XSEL value of each element on its ARG-ST list.

In a head-adjunct phrase and in a head-marker phrase the SYNSEM value of the HEAD-DTR is identical to the XSEL value of the nonhead daughter.

Ideally we could have formulated the PXS in a uniform way on all headed structures with a selectional relation between the daughters. Then the PXS would enforce identity between the nonhead's XSEL and the head's SYNSEM value. However, in argument-raising constellations

a *synsem* object may occur on several COMPS lists, while still only occurring on one ARG-ST list.<sup>2</sup> Therefore we refer to the ARG-ST list for complements, instead of giving a structural account of the XSEL requirements of complements. Head-filler structures are exempt from the PXS, as there is no selectional relation between head and filler.

Using the attribute XSEL, a UNC can select a particular preposition by the LEXEME feature. The introduction of a mechanism to select particular lexemes will be deferred to section 9.5. What we get by these adaptations has already been illustrated in (22), where *Anhieb* (*first go*) selects the preposition *auf* (*at*) through the XSEL feature. Additionally, we give the lexical entry of *Anhieb* in (24). Note that there is a restriction on the content: the CONTENT of the complement of the preposition must be identical to the CONTENT of *Anhieb* itself. This excludes the occurrence of modifiers with *Anhieb*.

(24) Outline of the lexical entry of *Anhieb*:

In (25) we have sketched the XSEL value of *Daffke* for comparison. *Daffke* simply selects the preposition *aus*. As there are no further restrictions on the complement NP of this preposition, it follows from the normal selection mechanism that modification is possible, like in *aus reinem Daffke* (*just for pure fun*).

(25) The XSEL value of *Daffke*:

<sup>2</sup>Following Meurers (2000), we assume that argument raising takes place only via the COMPS list.

In principle the content of complement NPs are available for marking semantic restrictions. This allows further specification of the character of modification in the lexical entry. Ultimately it is possible for the UNC to select its preposition.

### 9.5 Selection of Lexemes

In the previous section we have examined how PPs with unique nominal complements can be accounted for. Some of these expressions go together with one particular verb, as in *zu Potte kommen* (*get to the point*) or *in Mitleidenschaft ziehen* (*to affect*). With our PXS we can account for this data too. We simply specify a *synsem* object in the XSEL value, in this case of *Potte*, that triggers the preposition *zu*. This preposition has another XSEL value, requiring the verb *kommen* (see 26).<sup>3</sup> The verb *kommen* cannot yet be selected as we are missing an important tool: the possibility to select a particular lexeme.

(26) The XSEL value of *Potte*:

Krenn and Erbach (1994) have proposed a method of lexeme selection, introducing an attribute LEXEME below the CONTENT INDEX feature. This has three advantages: the LEXEME value is below SYNSEM and thus available for subcategorization; it percolates along the head line (i.e., a projection has the same LEXEME value as its lexical head); and a pronoun (always sharing the INDEX with its antecedent according to the HPSG Binding Theory) also gets the same LEXEME value as its antecedent.<sup>4</sup> Nevertheless, their approach has one major disadvantage: Only nouns have an INDEX value of their own, which leaves open the question of what to do with verbs (lacking an INDEX) or adjectives (sharing the INDEX with the modified noun).

The solution we propose is a new definition of the INDEX feature for all parts of speech. We separate LEXEME from the traditional INDEX

<sup>3</sup>The PXS makes correct predictions for cases of argument raising, as assumed for German verbal complexes (Meurers, 2000). In (i) the PP *zu Potte* is realized as a complement of the modal verb *sollte*. Still, it only occurs on the ARG-ST list of the verb *kommen*, whose LEXEME value is as required in the XSEL value in the lexical entry of *Potte* in (26).

(i) dass Peter zu Potte kommen sollte  
that Peter to pot come should ‘that Peter should get to the point’

<sup>4</sup>See (30) for illustration.

features PERSON, NUMBER and GENDER, pooled together below a new feature PHI (see 27). As subsorts of *lexeme*, we introduce a new atomic sort for each lexeme.

(27) The new INDEX value:

$$\left[ \text{INDEX} \left[ \begin{array}{l} \text{LEXEME } \textit{lexeme} \\ \text{PHI} \left[ \begin{array}{ll} \text{PERSON} & \textit{person} \\ \text{NUMBER} & \textit{number} \\ \text{GENDER} & \textit{gender} \end{array} \right] \end{array} \right] \right]$$

These changes have no consequences for nouns. For verbs and prepositions we leave the PHI values underspecified, nevertheless LEXEME receives a non-trivial value. In the lexical entries of adjectives we define the PHI values to be identical with those of the modified noun, but give each adjective its individual LEXEME value. We also adapt the SEMANTICS-PRINCIPLE in a way in which INDEX values are inherited along the syntactic head (whereas all other values like NUCLEUS percolate along the semantic head). This facilitates a selection of individual lexemes and extends our analysis of UNC to combinations with fixed verbs as in (26).

## 9.6 Some Empirical Predictions

In the preceding sections we presented a selectional analysis of UNCs. A combination of three factors made this possible: (i) the generalized use of selection by nonheads (by XSEL), (ii) the fact that the CONTENT value of a sign is part of its SYNSEM value (see 24), and (iii) the possibility of lexeme selection (by LEXEME). In this section we will continue to explore the potential of this approach. We will show specifically that the interaction of these three factors accounts for the phenomena that Sailer and Richter provide as evidence for their unconstrained collocational mechanism: cranberry words (Richter and Sailer, 2003) and polarity items (Sailer and Richter, 2002). Furthermore, a set of non-trivial constraints on potential collocational restrictions follow from our approach which have been empirically confirmed by the above-mentioned corpus of approximately 300 distributionally restricted lexical elements.<sup>5</sup>

### 9.6.1 Restrictions on Lexeme Selection

Richter and Sailer (2003) discuss so called *cranberry words* (CW), i.e., lexical elements that can only occur together with a particular other

<sup>5</sup>See Webelhuth and Ackermann (1994) and Everaert and Kuiper (1996) for other applications of this method.

lexeme. This clearly subsumes the UNCs considered so far. They distinguish three possible cases, depending on the selectional relation between the CW and its collocate: either the CW selects its collocate (28a), or the collocate selects the CW (b), or there is no direct selectional relation (c).

- (28) a. jemandem **Angst**/ einen **Schrecken**/ \*Entsetzen einjagen  
 someone fear/ a fright/ horror in.chase  
 ‘to frighten sb.’
- b. Tacheles **reden**/ \*sprechen  
 goal talk/ speak ‘talk straight’
- c. **schimpfen**/ \*meckern wie ein Rohrspatz  
 grumble/ grumble like a reed.sparrow  
 ‘inveigh vehemently’

Richter and Sailer (2003) claim that the (a)-case is problematic because HPSG does not provide the means for selecting individual lexemes. With the new treatment of lexeme selection illustrated in (27), this argument loses ground. The case in (28b) is resolved by the XSEL mechanism because we have allowed all nonheads to impose selectional restrictions on the heads with which they combine. Together with the possibility of lexeme selection, the data conform to our proposal as well.

Finally in (28c), there is no direct selection between the CW *Rohrspatz* and its collocate, the lexeme *schimpfen* (*grumble*). Nonetheless, the NP headed by the CW is selected by *wie* (*like*), whose projection acts as an adjunct to the verb *schimpfen*. Therefore the preposition *wie* occurs on the XSEL value of the CW and the verb *schimpfen* on the XSEL value of the preposition. Thus we are in the same situation as with *zu Potte kommen* in (26).

Our approach can accurately handle the data discussed above. Moreover, we predict that there are certain restrictions on lexeme selection. In particular a head cannot select a certain adjunct lexeme. This follows from the fact that we have generalized the potential of nonheads to select heads by XSEL, but we have not enlarged the selectional potential of heads. Our collection of 300 German expressions with CWs does not contain a single counter-example to this restriction, and there are abundant examples of lexeme selection of and by complements, and of adjuncts that select particular heads.

We also incorporate a locality restriction. A selector has access to the LEXEME value of a directly selected element, and, as shown for *zu Potte kommen*, to the LEXEME value of signs that are externally selected by these. We predict that there are no CWs which ask for a

specific **complement** of a verb (instead of a specific verb). The hypothetical constellation is sketched in (29), where the bold face NP is a complement to the verb V, and the collocate of the CW. In this case the information about the lexeme of the complement NP is not available at the VP level, i.e. part of the SYNSEM value of the VP. The prediction is fully confirmed in our corpus.

(29) [<sub>VP</sub> V **NP**] [<sub>PP</sub> P CW]

On the other hand, the apparent non-locality of lexeme selection is not a problem. The data show that lexeme information must be present at the phrasal projection, (30a), and must be shared between a pronoun and its antecedent, (30b,c).

- (30) a. Das hat mir [einen riesigen **Schrecken**] eingejagt  
 this has me [a huge fright] in.chased  
 ‘This gave me a big fright.’
- b. Der **Schrecken**<sub>i</sub>, **den**<sub>i</sub> mir das eingejagt hat, war riesig.  
 the fright which me this in.chased has was huge  
 ‘The fright which he gave me was huge.’
- c. Das war ein riesiger **Schrecken**<sub>i</sub> für mich. Und ausgerechnet du  
 this was a huge fright for me and just you  
 hast **ihn**<sub>i</sub> mir eingejagt.  
 have it me in.chased  
 ‘This was a huge shock for me and you were the one who caused it.’

These non-local effects, which can cross root sentences (see 30c), result from the inclusion of the lexeme information as part of the INDEX value. In contrast, Richter and Sailer (2003) would be required to assume that collocations are possible across root sentences in general.

We have shown two restrictions on potential lexeme-specific co-occurrence requirements. They are a direct consequence of the XSEL mechanism and appear to be empirically robust. In the analysis of Richter and Sailer (2003) it is not possible to express these constraints, let alone have them be the independent outcome of the way their collocational mechanism is built.

### 9.6.2 CONTENT Restrictions

The collocational requirements of the German verb *fackeln* (*dither*) are discussed in Sailer and Richter (2002). The authors base their study on a corpus investigation, according to which the verb occurs together with *nicht lange* (*not for long*) in 86% of the cases (i.e. 241 out of 280). See (31):

- (31) Der neue Geschäftsführer fackelte nicht lange.  
 the new manager dithered not long  
 ‘The new manager didn’t dither for very long.’

They demonstrate that the adverb *lange* must be considered a modifier, i.e., as not selected by the verb *fackeln*. This seems, therefore, to be a counter-example to the restrictions on XSEL because heads cannot impose lexeme restrictions on their modifiers. However Sailer and Richter (2002) give a more refined characterization of the occurrence restrictions of *fackeln*: In 95% of the corpus data and in all of the introspectively grammatical data, a negation and a durational modifier that have scope over the verb *fackeln* are present, but not necessarily *nicht* and *lange*, see (32). This variation is expected in the XSEL approach: again, there is no lexeme restriction imposed by the head verb on its modifier.

- (32) Keiner hat einen Moment gefackelt, bevor er ins Wasser  
 nobody has a moment dithered before he into the water  
 gesprungen ist.  
 jumped has  
 ‘Nobody dithered for a single moment before jumping into the water.’

Before we turn to the analysis of *fackeln*, we should address a remaining issue in connection with the XSEL value. The PXS in (23) and the HFP determine the XSEL values of all signs that are part of a phrase that will eventually occur as a nonhead daughter in a sentence. Nothing is said, however, about the XSEL value of signs which occur along the head projection line of a root sign. To avoid spurious ambiguity, we can simply assume that the SYNSEM value of the root sign is the XSEL value in these cases. The notion of a “root sign” is needed independently in grammar (Richter, 1997).<sup>6</sup> In accordance with Riehemann (2001, p. 189f.) we assume a subsort of *sign* for this purpose, which we will call *root-sign*. The XSEL value of root signs is then determined by the constraint in (33).

$$(33) \textit{root-sign} \rightarrow \left[ \text{SYNSEM} \left[ \boxed{1} \left[ \text{LOC CAT HEAD} \left[ \text{XSEL} \left[ \boxed{1} \right] \right] \right] \right] \right]$$

As an effect of the constraint in (33) the CONTENT value of an utterance is in principle accessible to the XSEL specification of every word in the utterance. This can be done by recursively accessing the XSEL value of the *synsem* object in the XSEL value. We can use this property

<sup>6</sup>Root properties include the presence of illocutionary force and the absence of unfilled gaps.

to account for the *fackeln* data of Sailer and Richter, in which the distributional restrictions of the verb *fackeln* (*dither*) are characterized in terms of the particular CONTENT values of the utterances in which it may occur.

Ignoring details of the semantic representation, Sailer and Richter give a description of a CONTENT value which contains a negation and a durational modifier, both having scope over the semantic contribution of the verb *fackeln*. Let  $\delta$  be this description. The occurrence restrictions on *fackeln* can then be captured in the following lexical entry.

(34) Outline of the lexical entry of *fackeln*:

$$\left[ \begin{array}{l} \text{PHON } \langle \textit{fackeln} \rangle \\ \text{SYNS LOC } \left[ \begin{array}{l} \text{CAT} \left[ \begin{array}{l} \text{HEAD } \left[ \begin{array}{l} \textit{verb} \\ \text{XSEL } [(\text{LOC CAT HEAD XSEL})^* \text{ LOC CONT } \delta] \end{array} \right] \\ \text{ARG-ST } \langle \text{NP} \rangle \end{array} \right] \end{array} \right] \end{array} \right] \end{array} \right]$$

where  $\delta$  describes a *content* object iff it contains a negation, a durative operator and the lexical content of *fackeln*, where the negation and the durative operator both have scope over the latter.

In (34) we use a Kleene-star operator with paths in the AVM. The notation is to be interpreted as describing the existence of a path of the given form. Even though this is not standard in HPSG, a formalization of HPSG such as RSRL (*Relational Speciate Re-entrant Language*, see Richter, 2000) will provide a way to formalize the idea expressed in this rather intuitive notation.

It can be seen that the XSEL requirements of *fackeln* are met in sentence (31). The XSEL value of the sentence in this case is identical to its own SYNSEM value. Since *fackeln* is the syntactic head of the sentence, this very same *synsem* object occurs in its XSEL value. Thus the XSEL LOC CONT value of *fackeln* is identical to the CONT of the root sentence. This content was described by  $\delta$  in (31). The absence of a negation or a durational modifier would lead to a violation of the lexical specification of the XSEL value of *fackeln*.

If we consider the occurrence of *fackeln* in embedded sentences, the non-trivial effects of the Kleene-star operator in (34) can be observed.

(35) Niemand behauptet, dass Peter lange fackelt.  
 nobody claims that Peter long dithers  
 ‘Nobody claims that Peter dithers for long.’

In (35) it is only the CONT value of the root clause that contains the negation, the durational modifier and the verb *fackeln*. This CONT value appears as the XSEL LOC CONT value of the highest verb, *be-*

*hauptet* (claims). *Fackeln* is the lexical head of the complement clause to the verb *behauptet*. Thus the XSEL value of *fackeln* is identical to the SYNSEM value of *behauptet*. Consequently, the XSEL LOC CAT HEAD XSEL LOC CONT value of *fackeln* is identical to the CONT value of the root clause. As this path is part of the specification in the lexical entry of *fackeln*, the occurrence restriction of the verb is captured correctly.

This example shows that the non-local effect of the occurrence restriction on *fackeln* is fully accounted for in our approach, while we correctly exclude the possibility of constraints specific to the particular lexemes that occur, to the phonology of the required context elements or to details of the syntactic structure. On the other hand, the CONTENT of the utterance is available for imposing constraints.

## 9.7 Conclusion

In this paper we have offered a more concise generalization of the selectional mechanism of HPSG. We have shown that this allows us to handle the phenomenon of PPs with unique nominal complements. The same mechanism extends naturally to other phenomena of distributional restrictions. Our proposal relies above all on the overall architectural design of HPSG. This design restricts selection to *synsem* objects, where lexeme information and the content are part of *synsem*. The discussion in section 9.6 revealed that the interaction of these components leads to interesting and empirically valid predictions concerning what kinds of collocational restrictions are possible. Nonetheless, the question of whether it is adequate to include lexeme information and the entire content within *synsem* deserves further discussion.<sup>7</sup>
