

# Key uncertainties in future non-Kyoto emissions

Zig Klimont ([klimont@iiasa.ac.at](mailto:klimont@iiasa.ac.at))

GAINS (<http://gains.iiasa.ac.at>)

Workshop on Climate Change Impacts and Integrated Assessment (CCI/IA)  
Snowmass, Colorado July 23–August 3, 2012

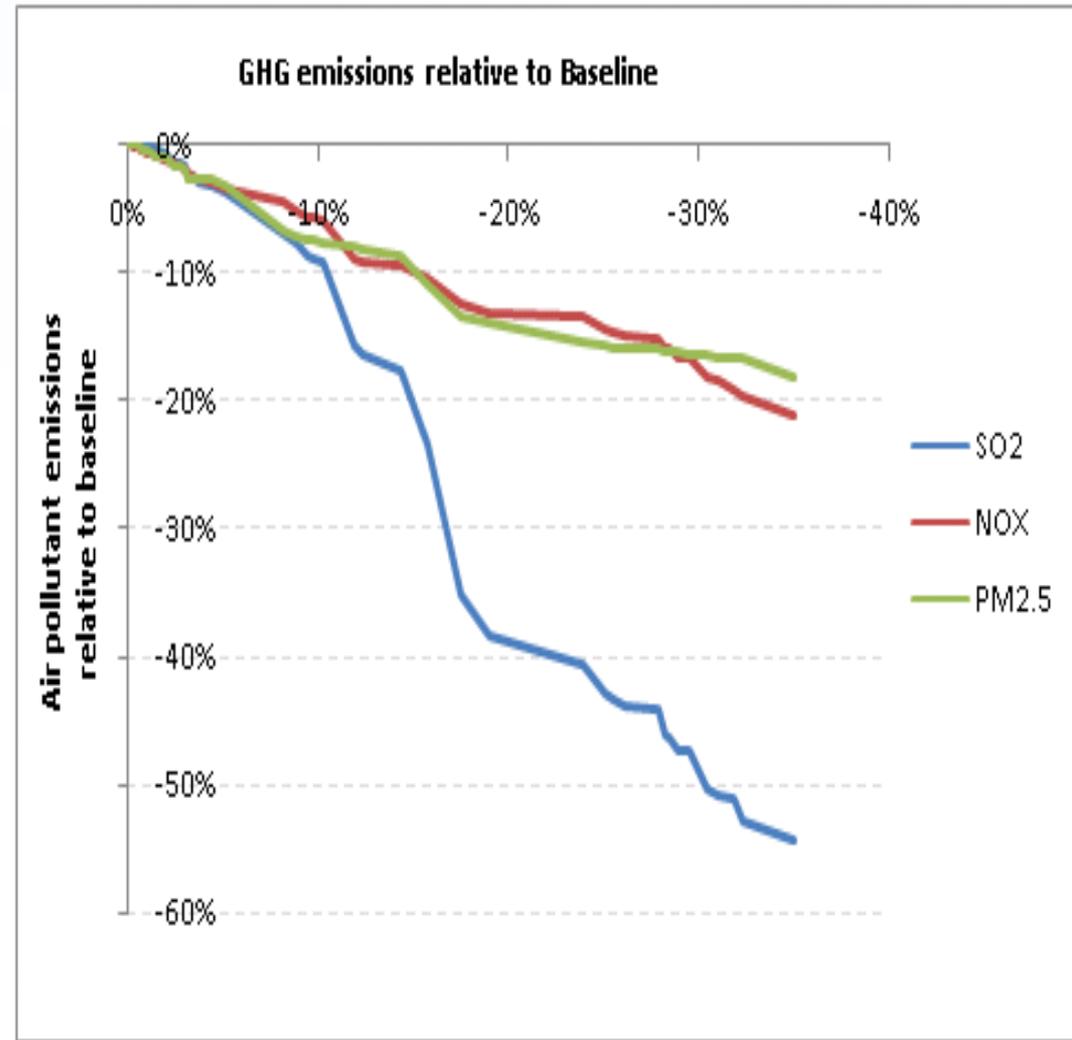

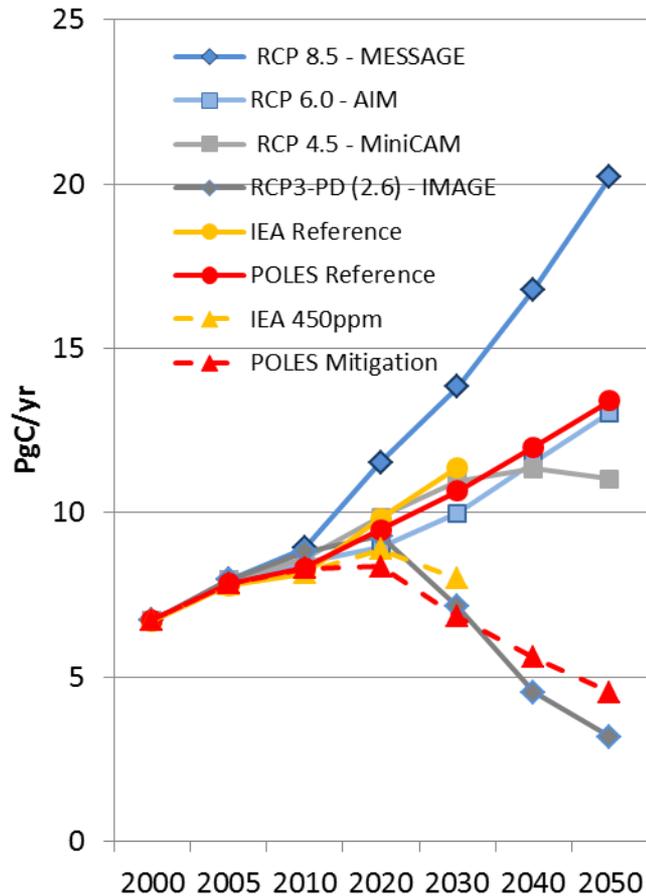

# Things that come to my mind as relevant... beyond economic growth

- Stringency and efficiency of legislation
- Real-life performance of technology and availability of new tech
- High emitting vehicles
- Brick kilns, coke ovens, flaring in oil and gas industry
- Stoves...of course
- What do we know about Africa and Latin America?
- Solvent use emissions
- Open burning of agricultural waste
  
- International shipping (Arctic)
- Human diet and improved N use efficiency
- Change in regional and sectorial importance
- Co-emitted species; consistency of emission scenarios
- There is no clear relationship between implementation of environmental technology and economic growth

# One CO<sub>2</sub> slide: RCP vs IEA/POLES scenarios implemented in GAINS

Annex I countries, 2020; GAINS calculation

# Decomposition of EU-27 SO<sub>2</sub> emissions; projection and 'reality'

*Source:*  
EU CAFE strategy and  
Amann et al., 2012

# Decomposition of EU-27 NOx emissions; projection and 'reality'

# Regional/sectoral differences

- Effective implementation of current air pollution policies will exhaust reduction potential for several technologies in some regions
- Poorly characterized (non-regulated) sources become more important (e.g., off-road, residential)
- Power sector and industry; NA, Europe reduces while most other regions continue to increase
- Brick production; mostly south Asia although locally important in several development countries
- Flaring in oil and gas industry; most of the activity concentrated in few areas but emissions in high latitudes occur in clean environment

### 1<sup>st</sup> approach to quantify high emitter emission contribution:

- **Bench mark:** 5% of high emitters in the U.S. (Bond *et al.*, 2004; CRC E-23 study; Ban-Weiss *et al.*, 2000)
- **Definition of emission factors (EF)** : median above (superemitter)/below (normal emitter) 95%;
- **Amplification factor (AF):** ratio between EF of super and normal emitters

**PROBLEM of this approach and motivation for further work:** a statistical cutoff (e.g. 5%) can be fitted to any kind of distribution and does not necessarily refer to high emitters only. There remains a need for a more technical definition for high emitters.

# High emitters

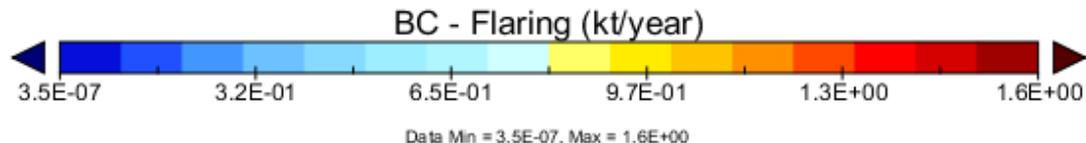

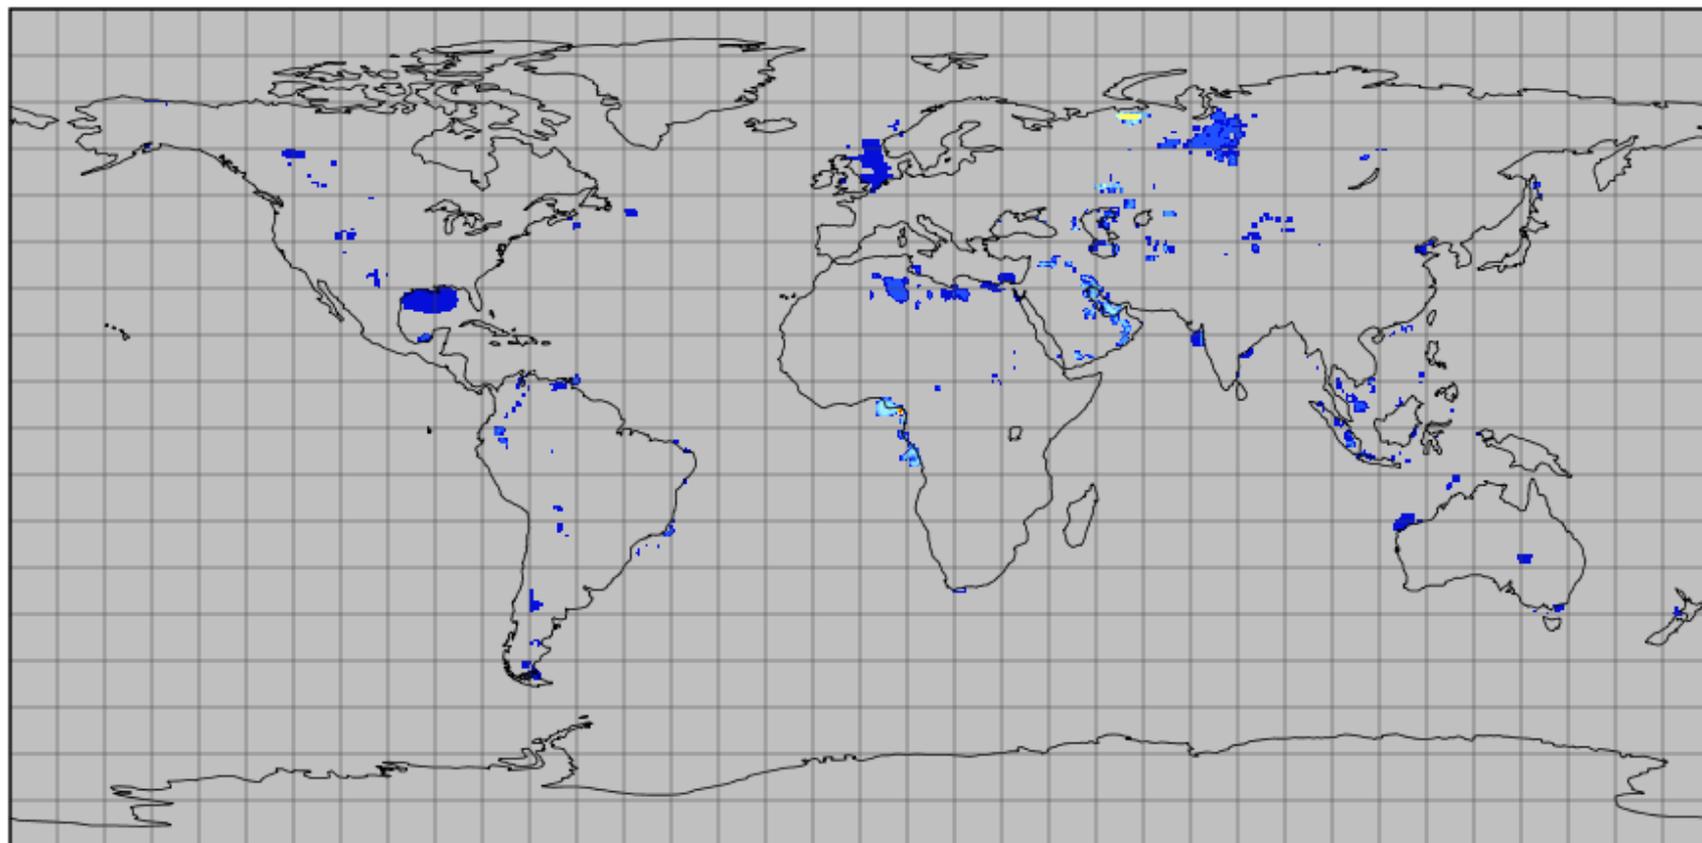

## GAINS estimate for NO<sub>x</sub> and BC

Are aerosol emissions from flares included?  
How are they changing over time?  
Consequences of increasing production in the arctic?

Location of flares: Source: *NASA, World Bank, GAINS model*

BC - Flaring

# Stoves... it is not only emission factors

- “Chimney stoves help, but not enough” (Kirk’s Guatemala study)
- “New stoves aren’t adopted” (MIT study)
- “More black carbon from some stoves” (Ram’s Surya study)
- Lab improvements not seen in the field (our [T.Bond et al.] study)

Summary courtesy of Tami Bond

- *Consistent assessment of co-emitted species missing*

Measuring emission factors...

How do we include such information (if available)?

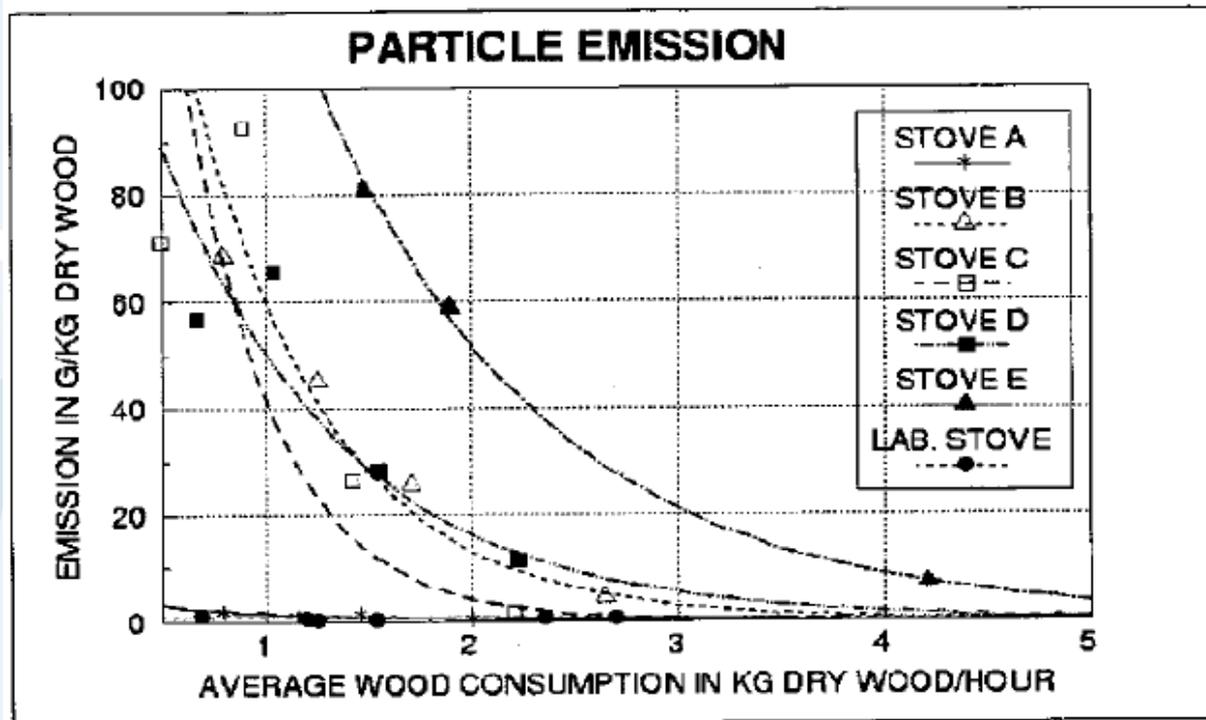

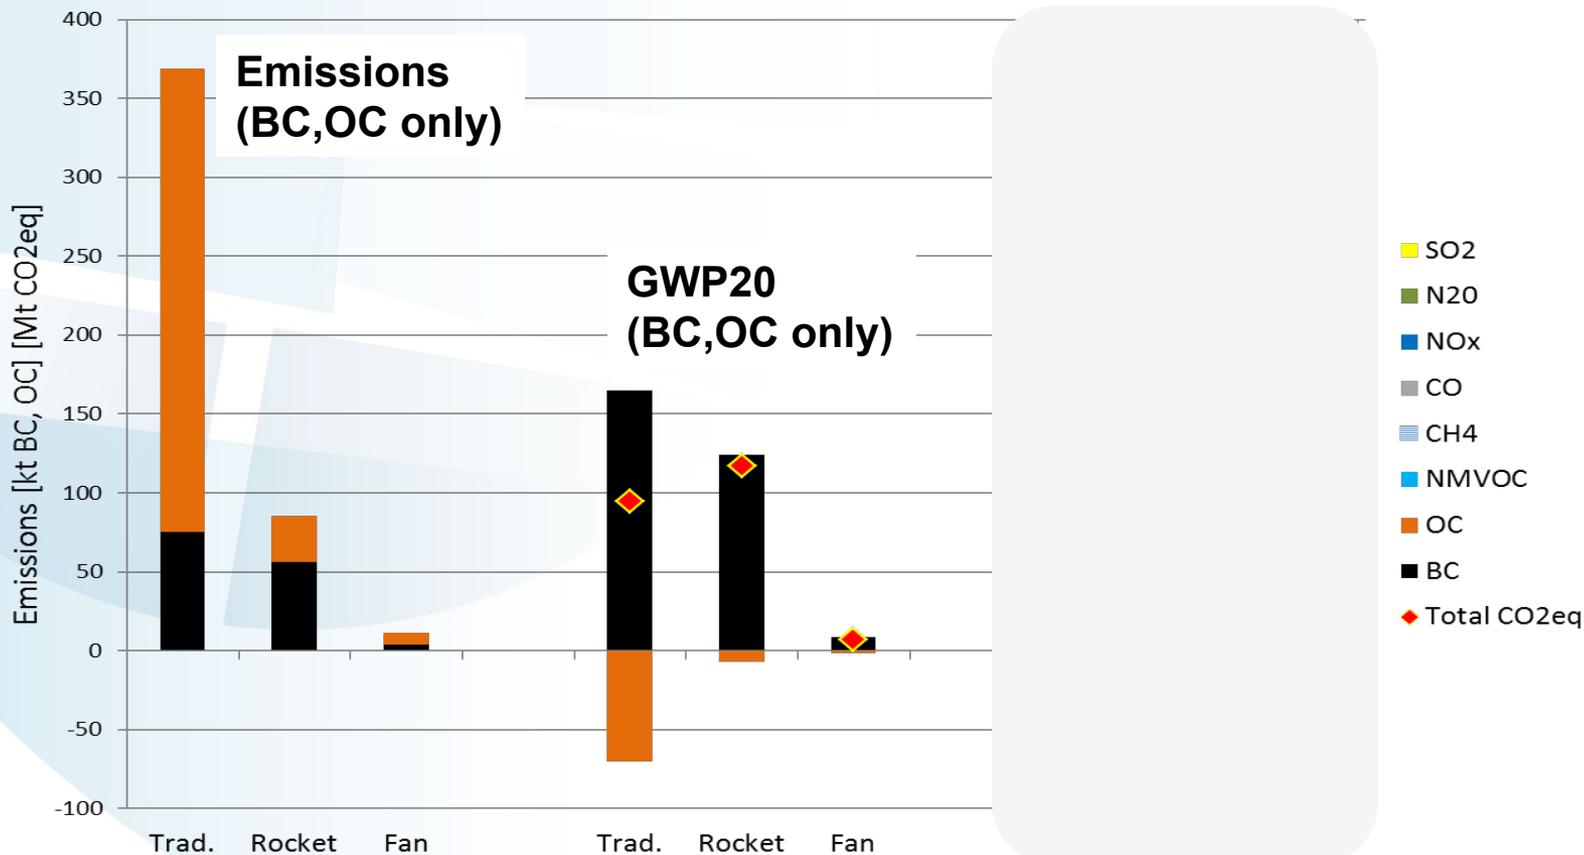

Figure 12. PM emission of 6 wood fired stoves. Dependency of wood consumption rate. A: catalytic stove, B-D: old stoves, E: open fireplace (Haakonsen and Kvingedal, 2001).

# It matters which stoves are going to 'make it'\*

Importance of considering all pollutants

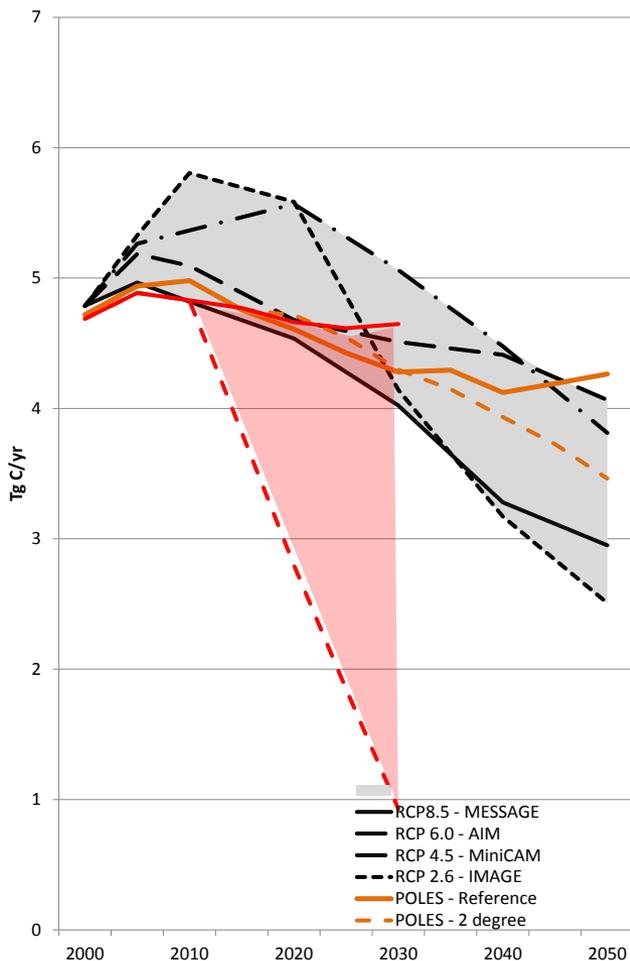

Example: Fuelwood cooking stoves (fuel efficiency improvement considered)

\* The GWP20 is used for demonstration purpose. While the choice of GWP (100 or 20 years) would not change the conclusion about the selected measures the shown here CO<sub>2eq</sub> emissions were not used in the analysis, i.e., the emissions of various pollutants for specific measures were put directly into the climate model.

## Global BC emissions from anthropogenic sources

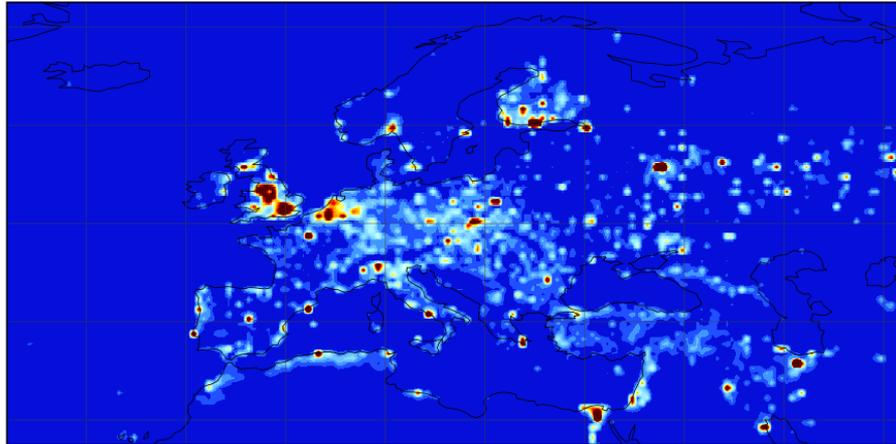

*Can I add a chart with the rocket stove vs fan stove for BC and OC?  
Maybe I should use the RCP slide chart with red POLES? To demonstrate that?*

- RCP scenarios suggest declining anthropogenic BC emissions in the longer run
- No correlation between climate mitigation and BC emissions – BC control not a co-benefit of climate mitigation
- The 16 UNEP measures would cut BC emissions by up to 80%

# Spatial downscaling artifacts: Change in industrial NOx in Europe from 2005 to 2030

NOx - Industry (combustion and processing) ( $10^{-1}$  kt NOx/year)

# Concluding remarks

- Impact of current air pollution and climate policies on future emissions
  - Effective implementation of current policies will exhaust reduction potential for several technologies in some regions
  - Significantly different regional structure of emissions in the future will determine further mitigation strategies; there might not be ‘one for all’ recipe
  - Evaluation of projections with increased use of biofuels necessary; considering sustainability
  - Estimated mid-term air pollutants reductions in RCP seem optimistic while ‘CLE’ approaches are on the conservative side but might be not ‘conservative enough’
  - Choice of control policy and measures will determine the mix of pollutants – additional impact of air pollution technologies

# Concluding remarks

- Emissions of various pollutants will not be reduced proportionally with increasing wealth; e.g. stationary NO<sub>x</sub> controls lagging behind FGD
- Understanding future technology transitions is essential, including conscious incorporation in projections, e.g., co-emitted species emissions and reductions
- Tools that build on consistent assumption with respect to pollutant-technology interactions and covering all relevant species should be used more
- Megacities might play an important role in accelerating mitigation of GHG and air pollutants
