Engineering, University of Colorado

Stanford Energy Modeling Forum  
Snowmass, Colorado  
30 July 2013

Where are the principal unquantified uncertainties in land ice (“barystatic” or “new water”) SL contributions?

What has been done about these to date?

What is being done to reduce overall SLR uncertainty?

What should we be doing differently?

# Components of Sea Level Rise (SLR)

## 1. Steric (thermal expansion)

- a. Upper ocean (top 700 m)
- b. Deep ocean

## 2. Barystatic (new water)

- a. Antarctica
- b. Greenland
- c. Glaciers and Ice Caps (GIC)

### d. Terrestrial storage

- 1. Ground water
- 2. Surface water
  - a. Reservoir storage

Global

## 3. Relative (local)

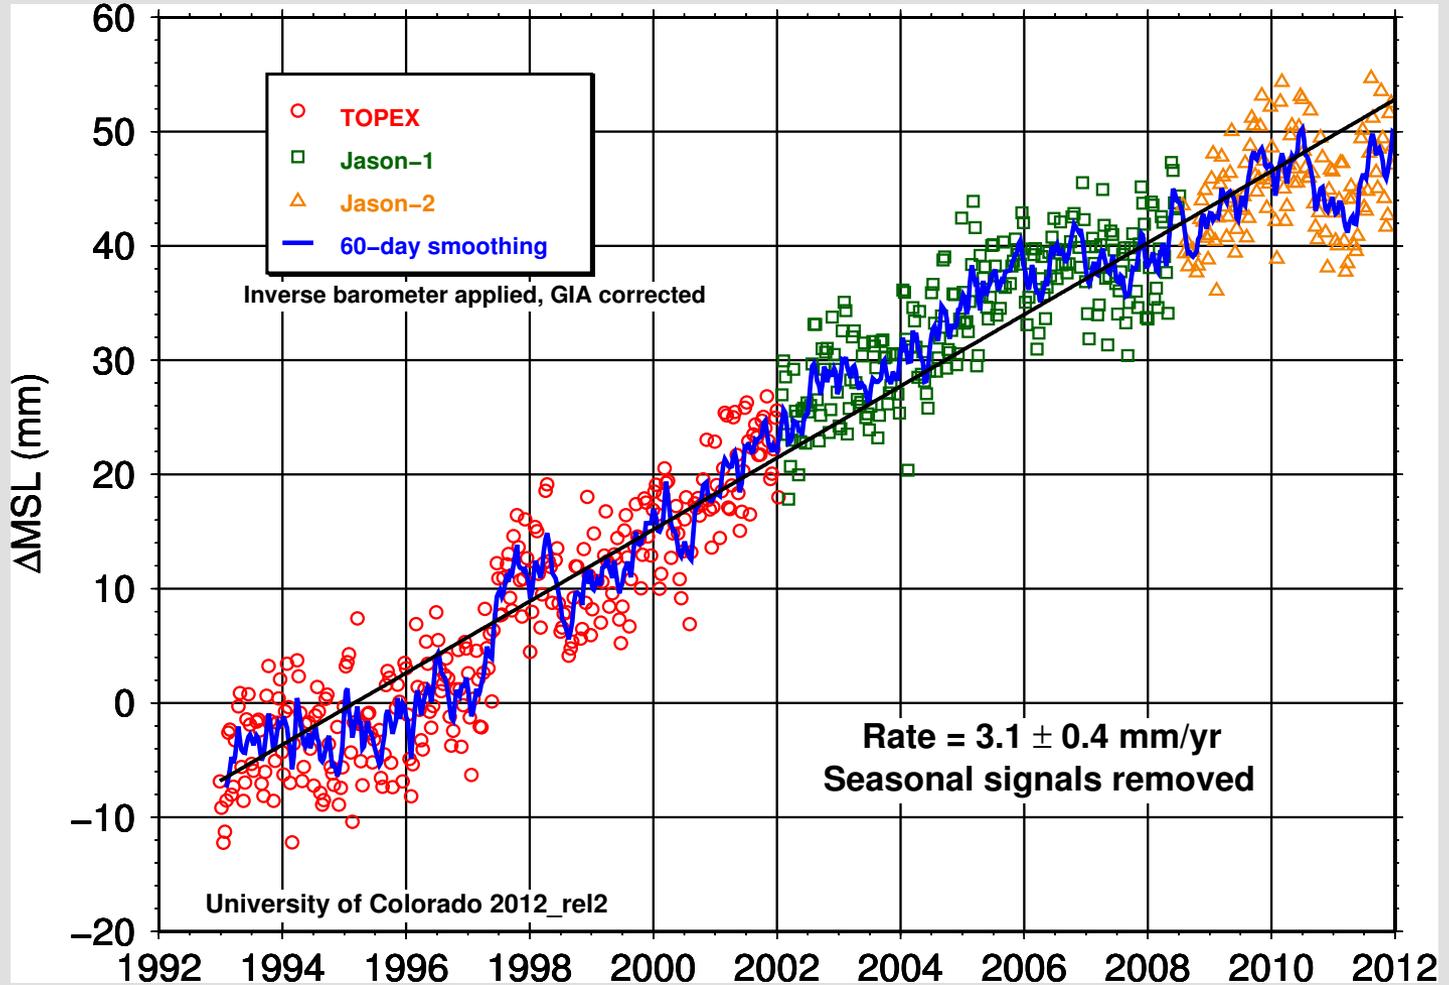

- a. Dynamics (winds/currents)
- b. Gravitational (fingerprinting)
- c. Isostatic rebound
- d. Coastal subsidence
  - 1. Infrastructure loading
  - 2. SLR loading
  - 3. Upstream sediment trapping
  - 4. Groundwater depletion

May dominate locally

*(very long-term components, e.g. tectonics, are not considered here)*

# Observed Sea Level Change (satellite altimetry)

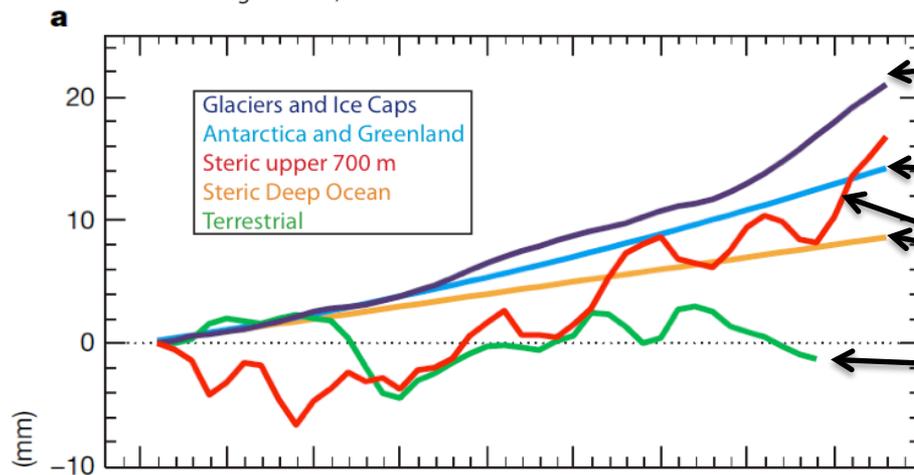

Observed Sea Level Rise – Nerem Group, University of Colorado, V 16 April 2012

# Observed components of globally-averaged Sea Level Rise

from Domingues et al, Nature 2008

[ **thermosteric** / **barystatic** ]

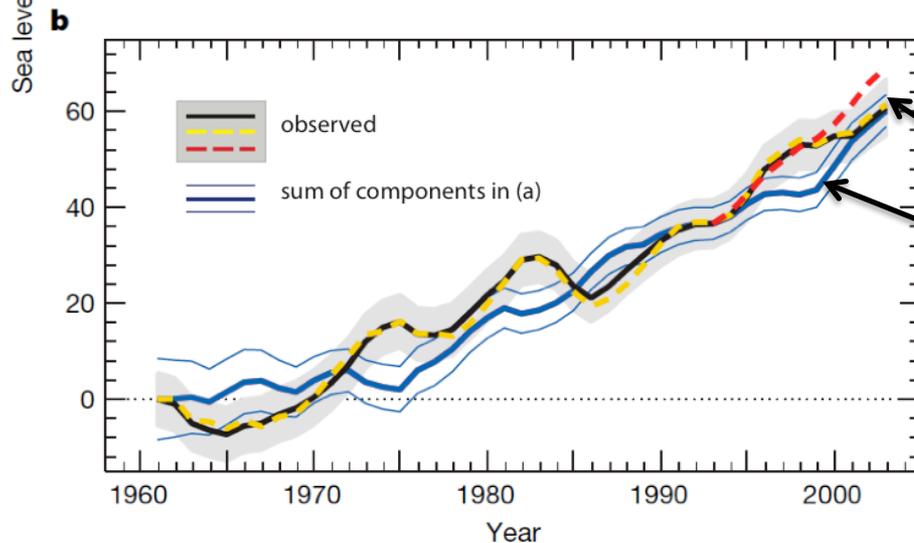

Glaciers, Ice Caps exclusive of ice sheets

Greenland, Antarctic Ice Sheets

Thermal expansion of ocean water

Changes in land storage (ground water, reservoirs)

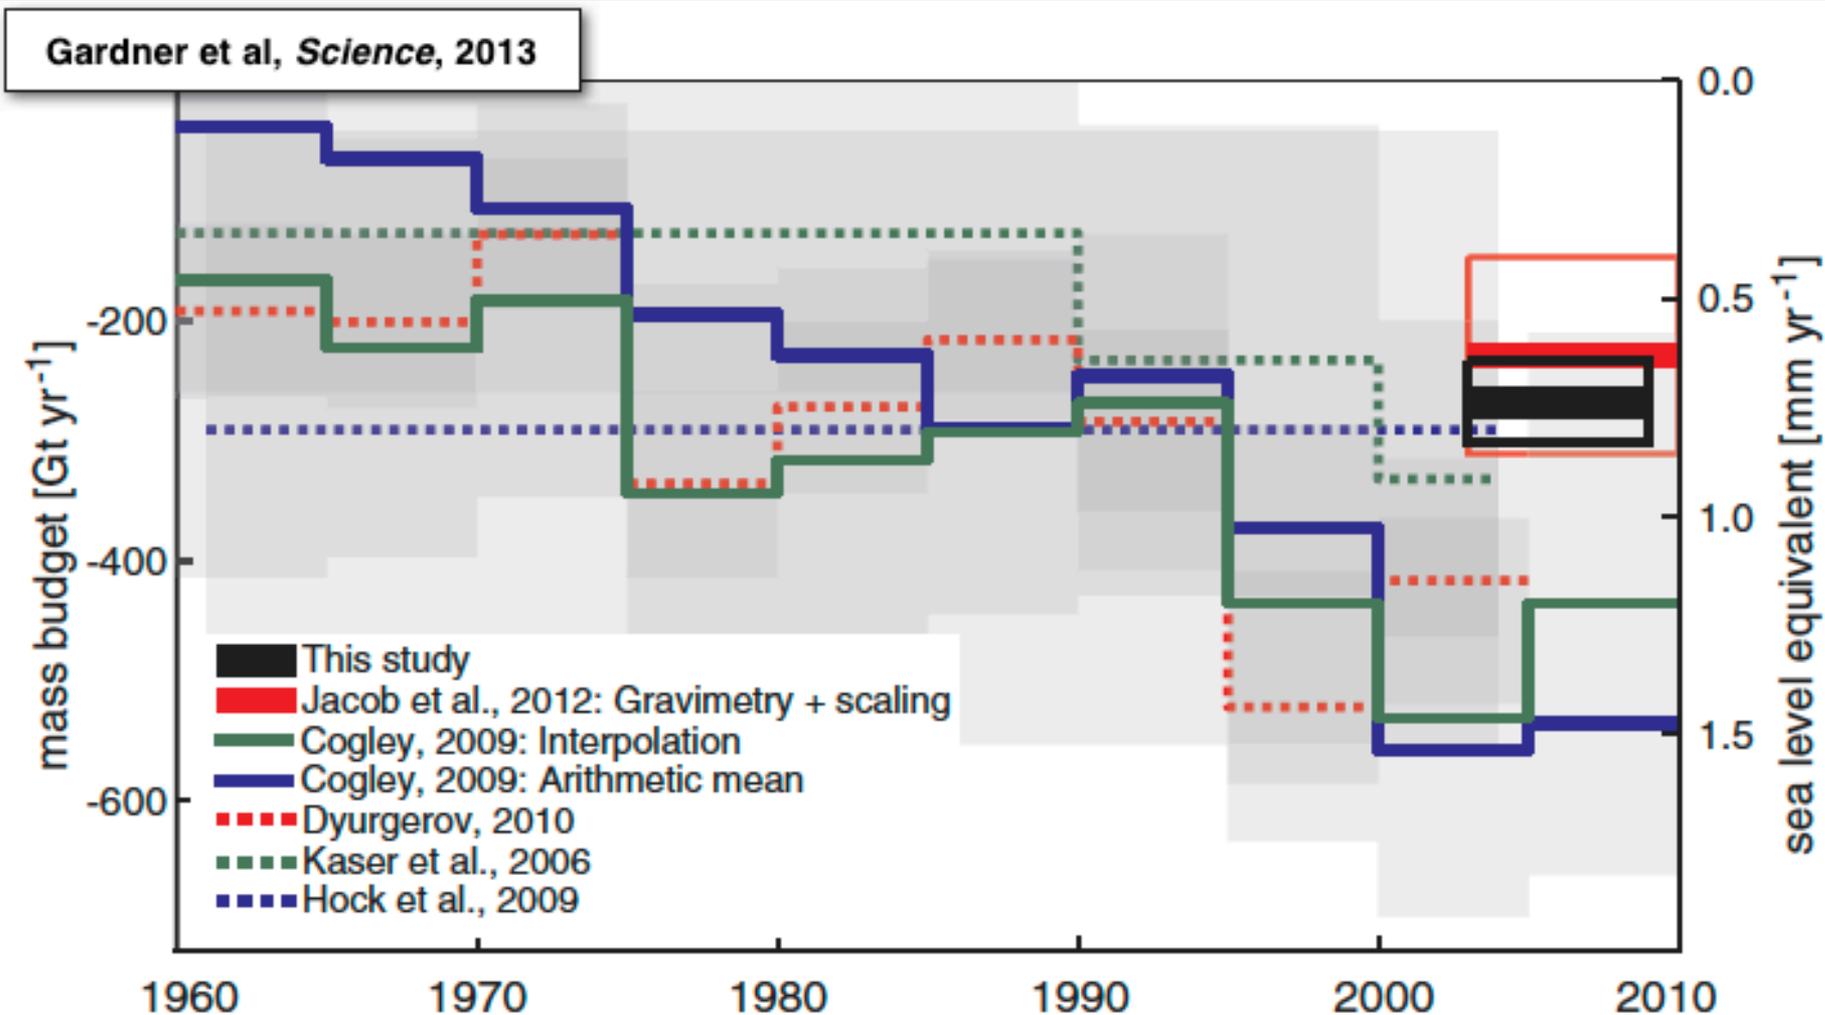

Observed SLR from gauges, altimetry

Sum of components

20<sup>th</sup> C Rate: ~ 0.20 m/C

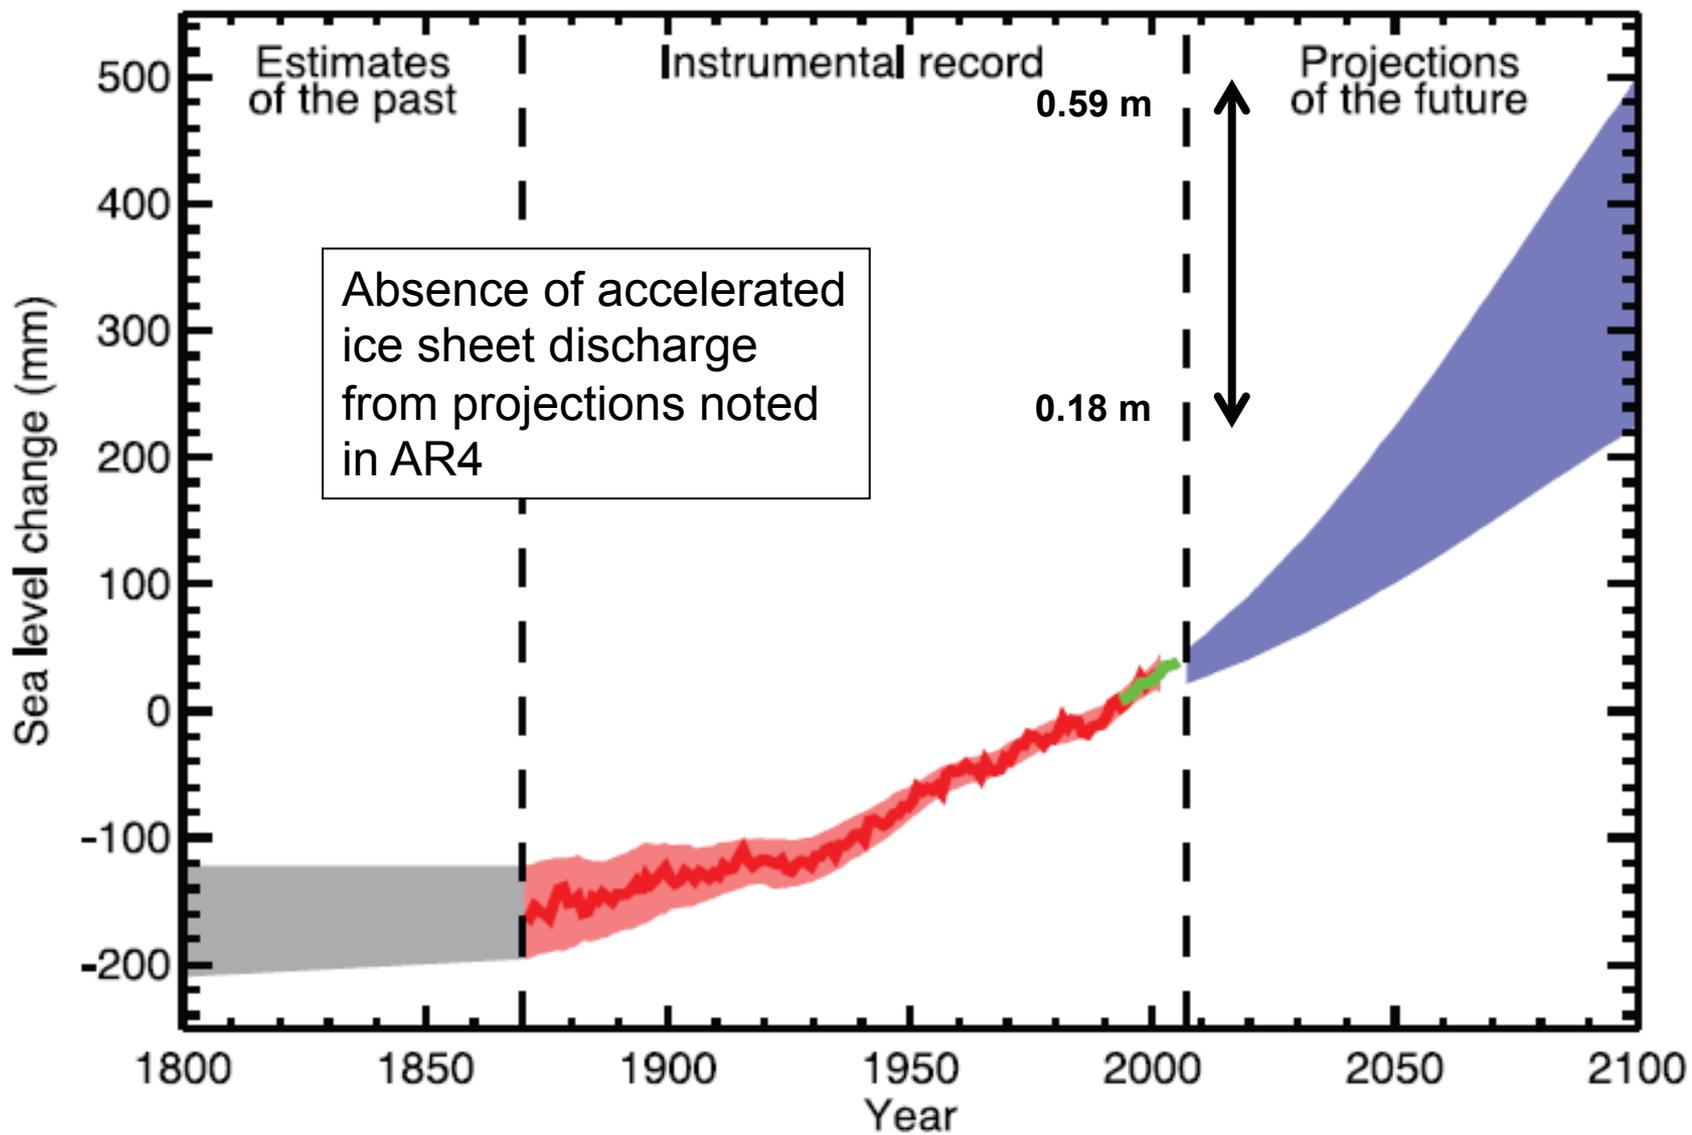

~2000-2010 Rate: ~ 0.30 m/C

# Optimal assessment of global glacier (excluding ice sheets) loss rates over 50 years

Actual loss rate is actually highly variable on  $\sim 5$  year time scale, but significant noise is also present from lack of basic measurements

# 2007 IPCC AR4 Sea Level Projection

IPCC AR4 2007 Sea Level Projection: Less than 1 m,  
***but with caveats concerning 'rapid dynamics'***

# THE

Orrin H. Pilkey *and* Rob Young

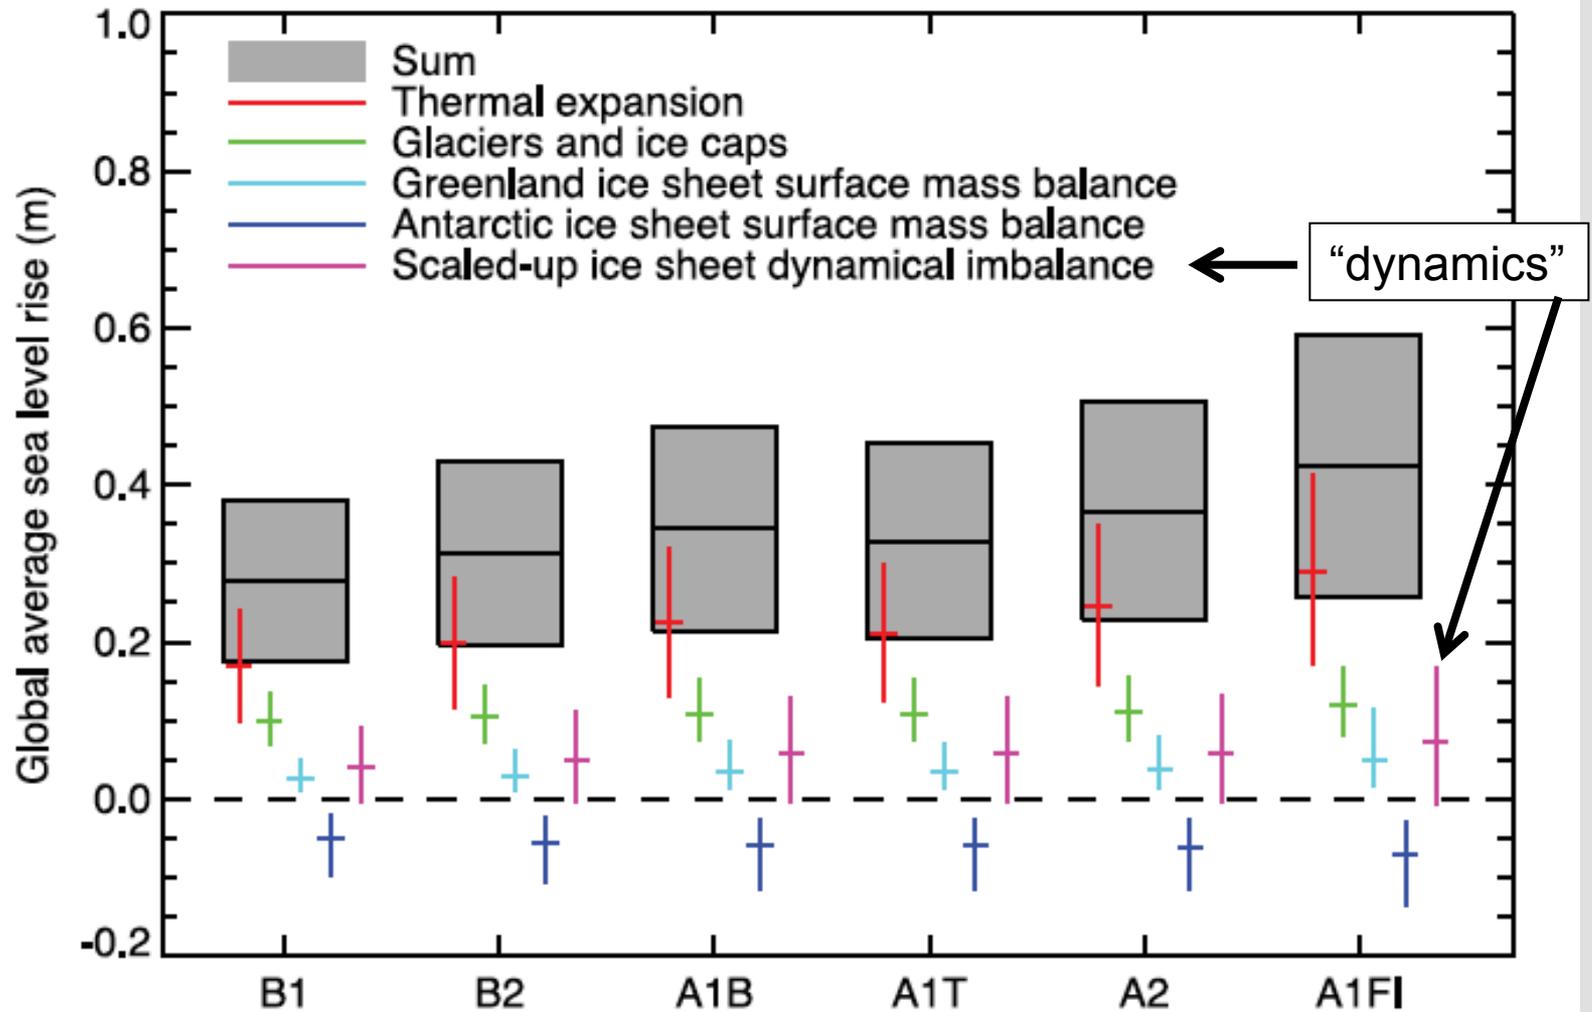

# RISING

# S

*“These confusions are a result of the IPCC’s decision for its AR4 report to provide actual predictions for only some of the causes of sea level rise (those it could predict with mathematical models). It produced predictions **based on sea level rise from thermal expansion and mountain glacier melting while refusing to assign numbers** – because committee members didn’t have a mathematical model they agreed on – **to what is likely to be the most important source of sea level rise in the twenty-first century: ice sheet melting.**”*

(pg. 50, *The Rising Sea*, Pilkey and Young, Shearwater, 2009)

# 2007 IPCC AR4 Sea Level Summary Figure 10.33

Sea Level Rise projections to 2100 as of 2007  
Including Rapid Dynamics kludge

## Rapid Dynamics (RD) Assessment AR4:

Two future RD scenarios:

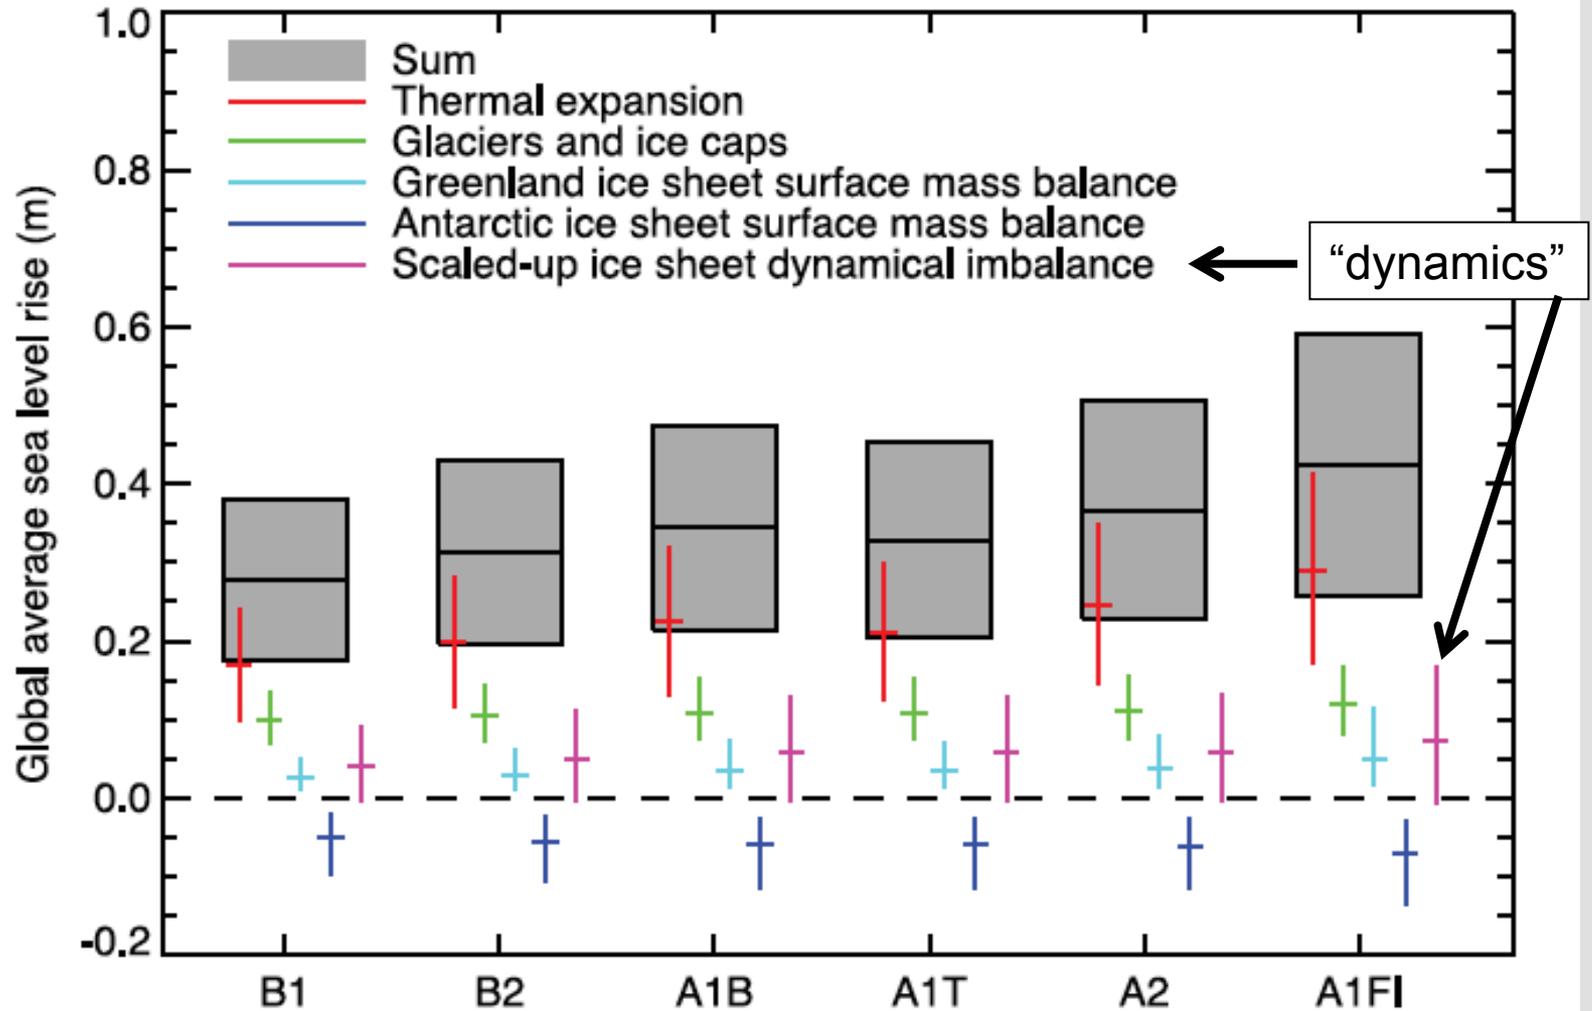

1. Presently (2007) observed RD are transient and will fade.
2. Presently (2007) observed RD will continue and scale in magnitude with modeled future global average Temperature  $T_{GM}$  according to:

$$SLR_{RD} = 0.32 \times (T_{GM}(t) / 0.63^{\circ}\text{C}) \quad \text{mm yr}^{-1}$$

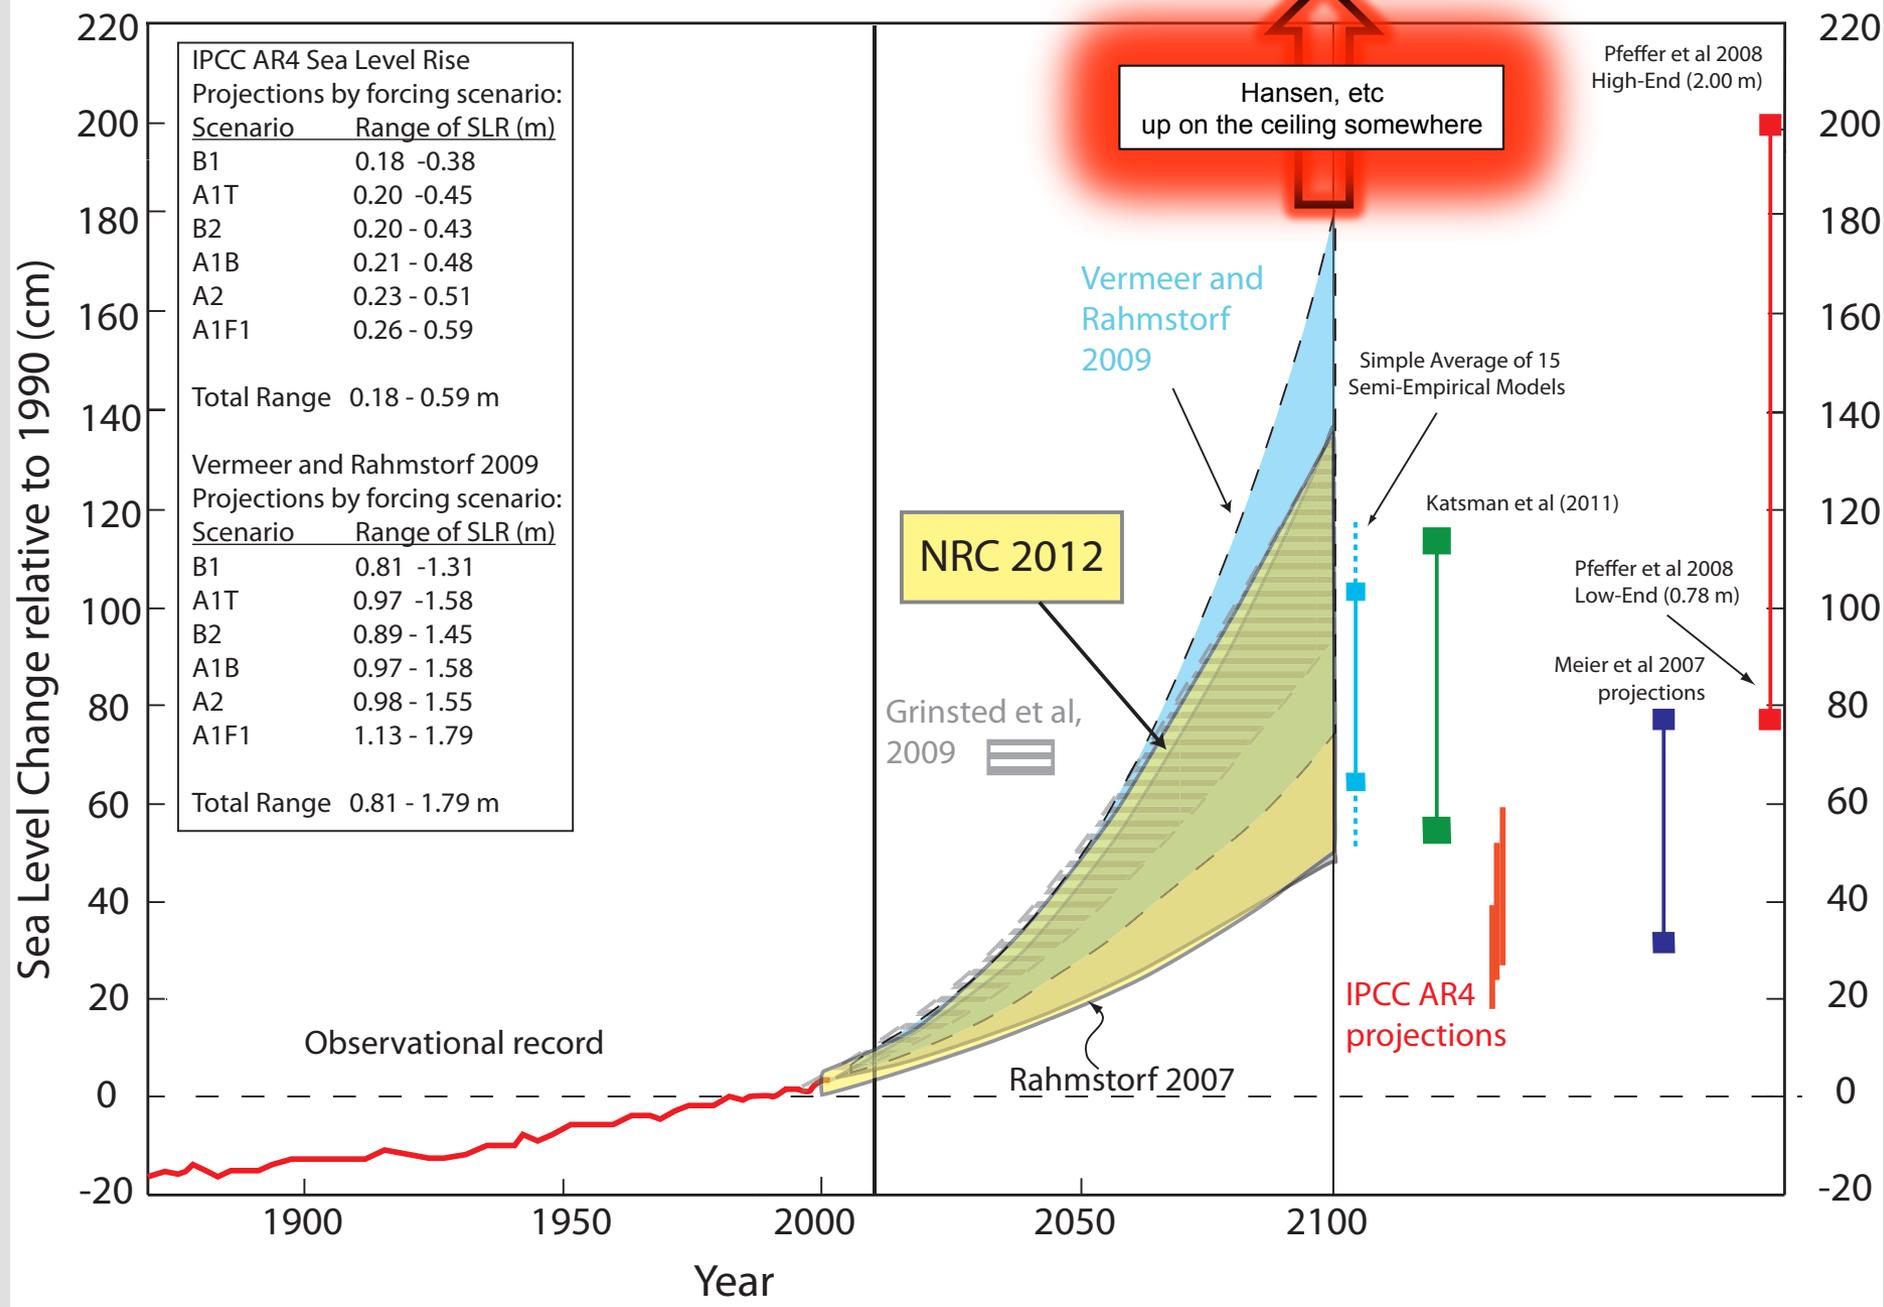

Range of RD Result:

Added SL Increment of -0.1 to +0.17 m SLR by 2100  
Increased SLR Rate of 0.0 to 3.9 mm/yr

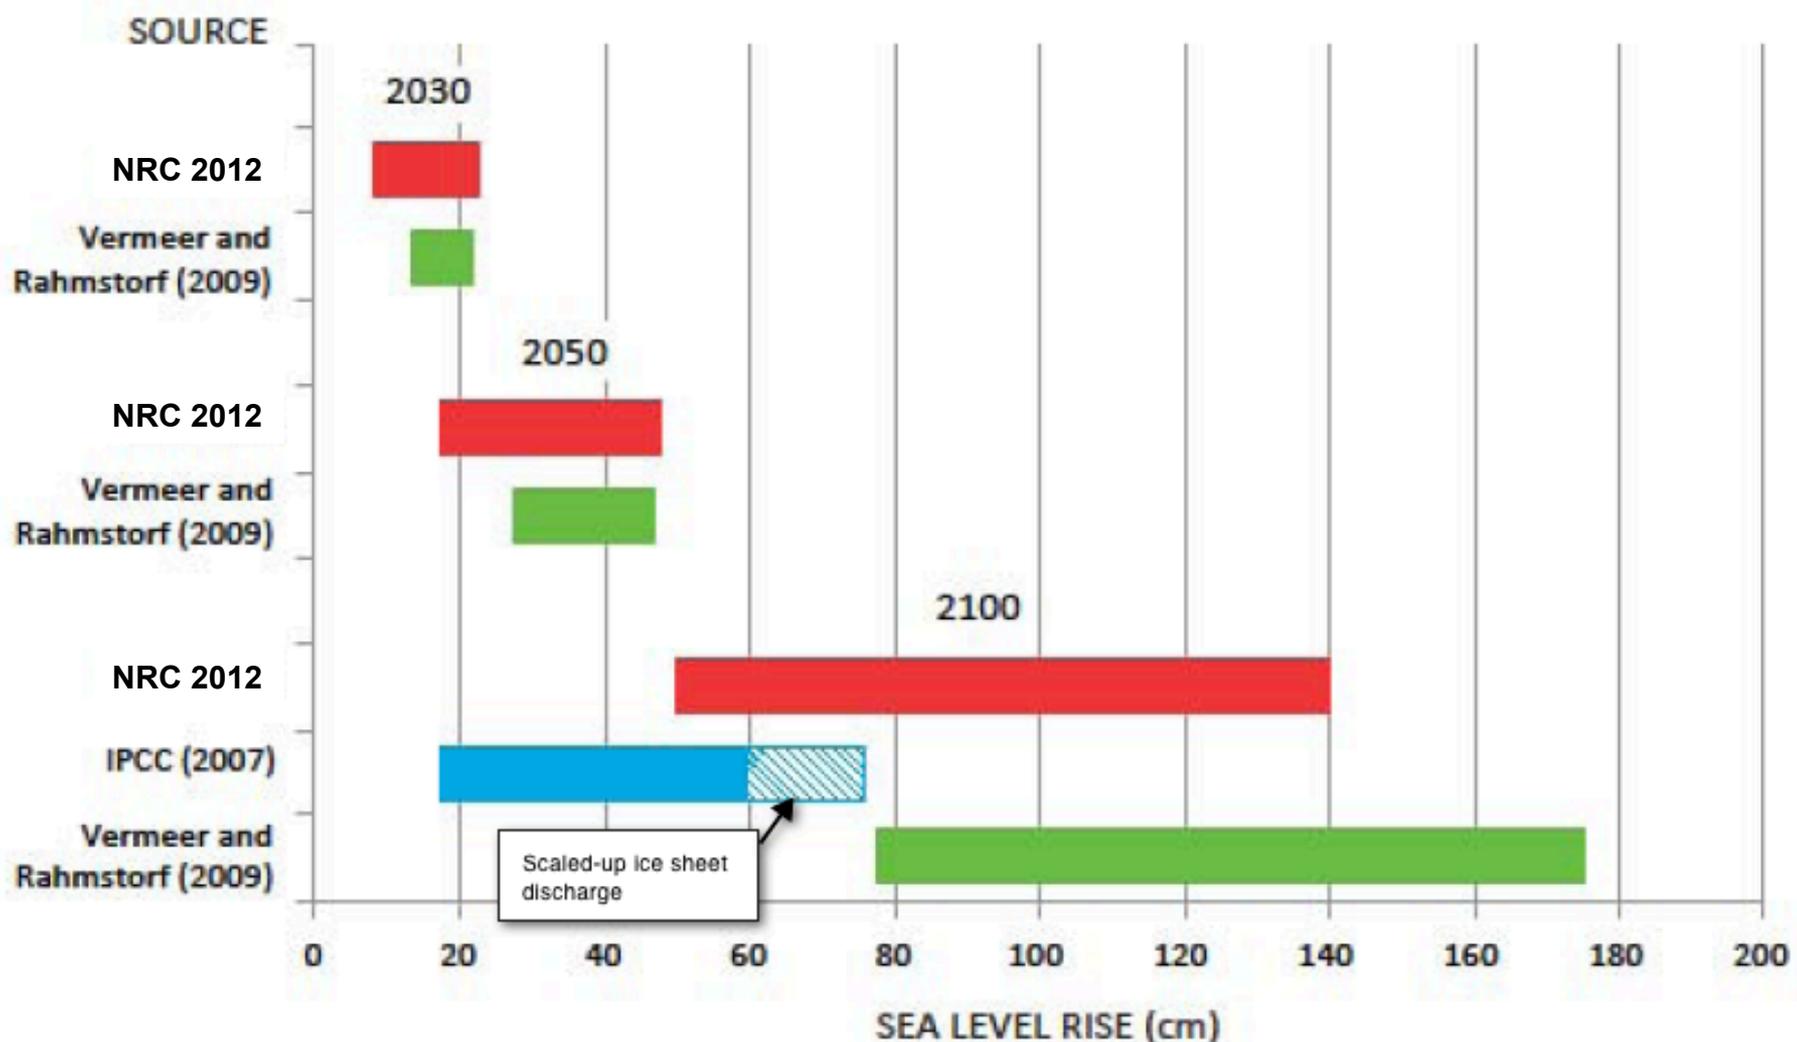

# 2007 IPCC AR4 Sea Level Summary Figure 10.33

Sea Level Rise projections to 2100 as of 2007  
Including Rapid Dynamics kludge

# National Research Council, 2012 Total Sea Level Projection

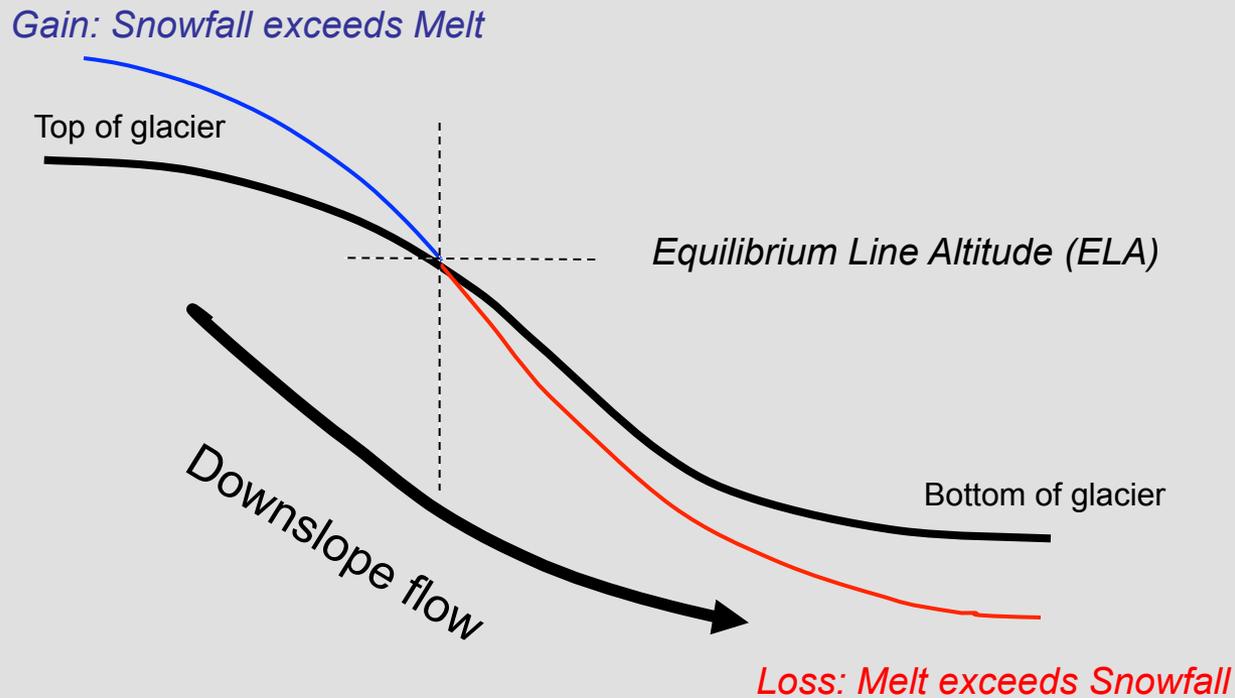

“Rapid  
Dynamics:”

Changes in  
glacier or ice  
sheet geometry,  
speed, mass, rate  
of mass change

modulated by  
internal  
dynamical  
interactions

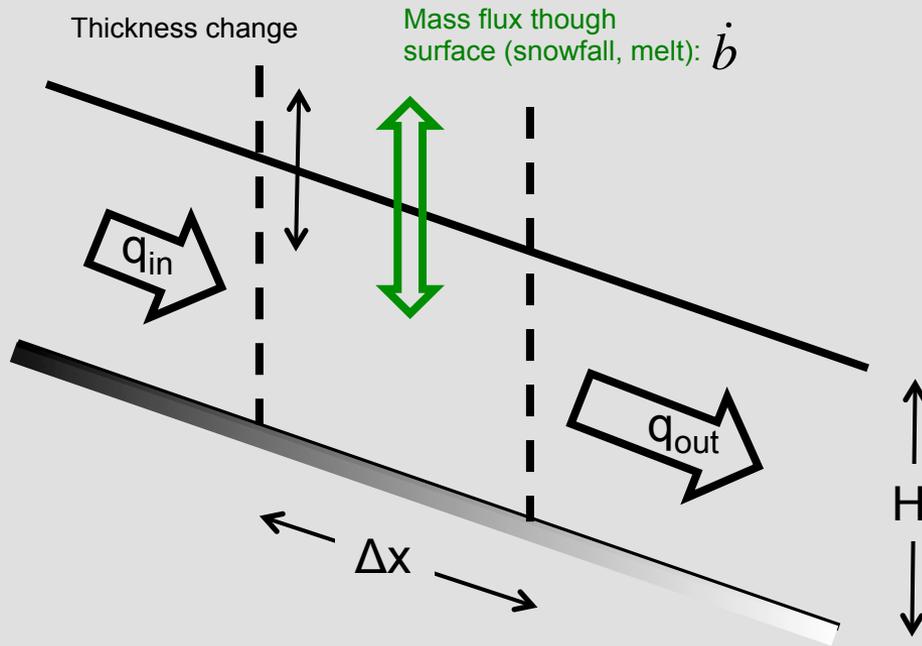

at rates faster  
than  
accompanying  
rates of  
environmental  
mass balance

# Surface Mass Balance and Glacier Equilibrium

Downslope flow *may or may not* compensate for surface mass balance

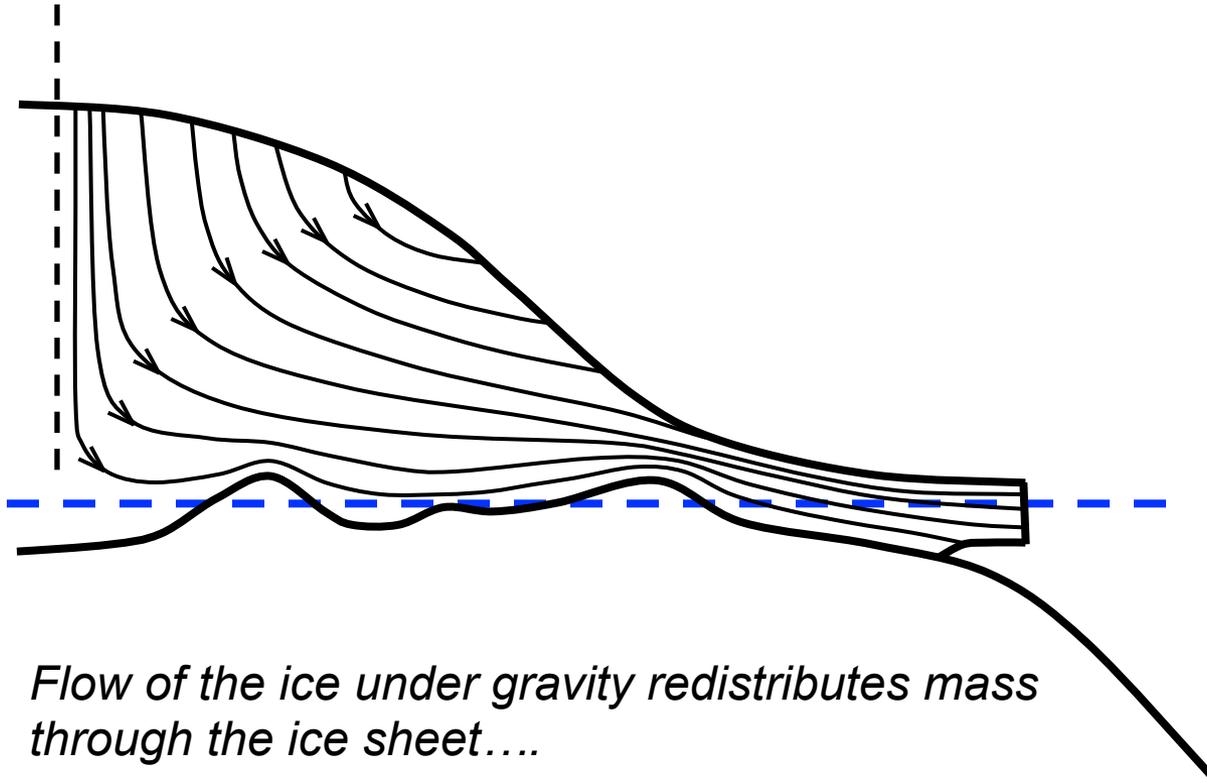

# Surface Mass Balance and Glacier Equilibrium

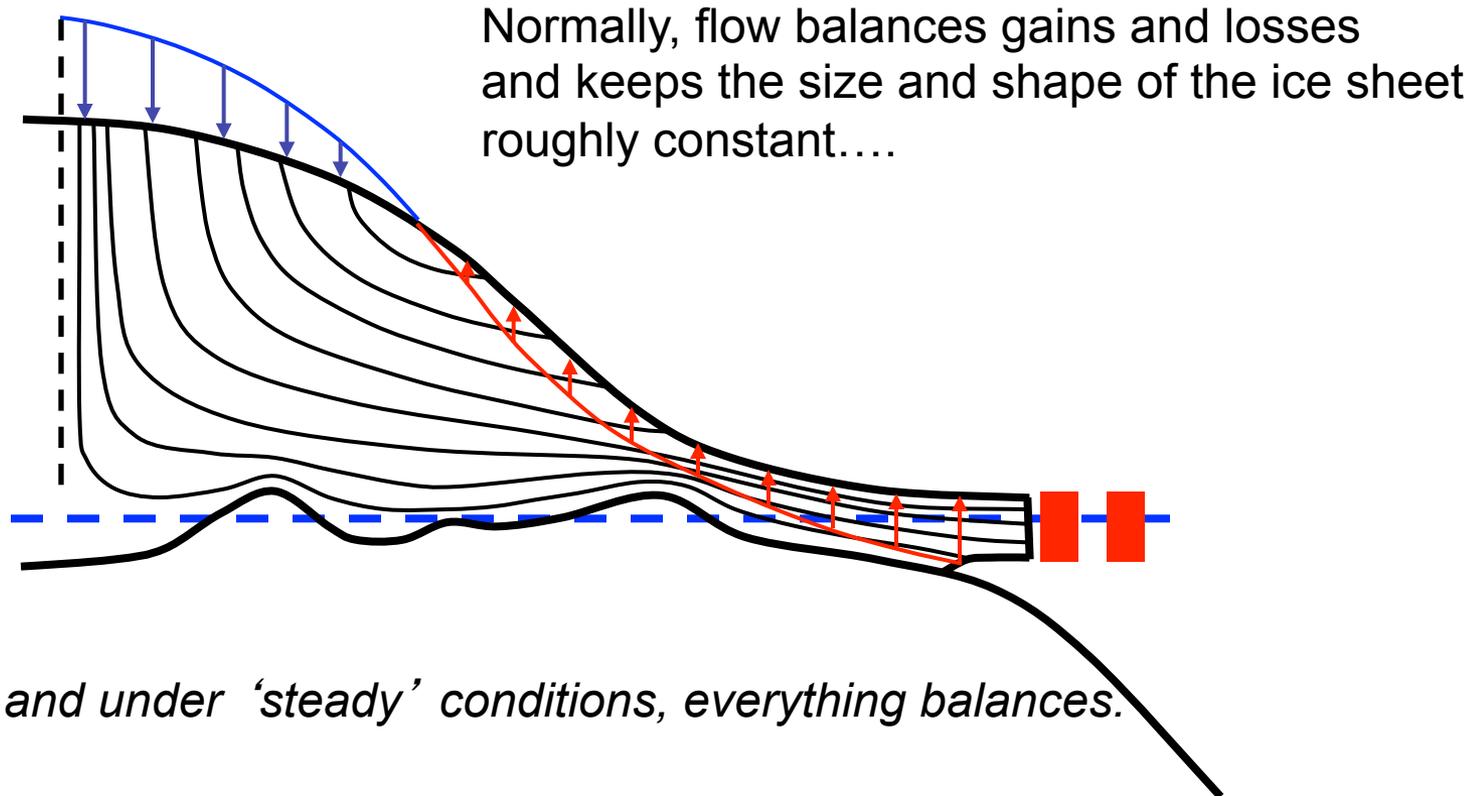

$$\frac{\partial q}{\partial x} + \frac{\partial h}{\partial t} = \dot{b}$$

The Continuity Equation

# Ice Sheet flow

# Ice Sheet in equilibrium

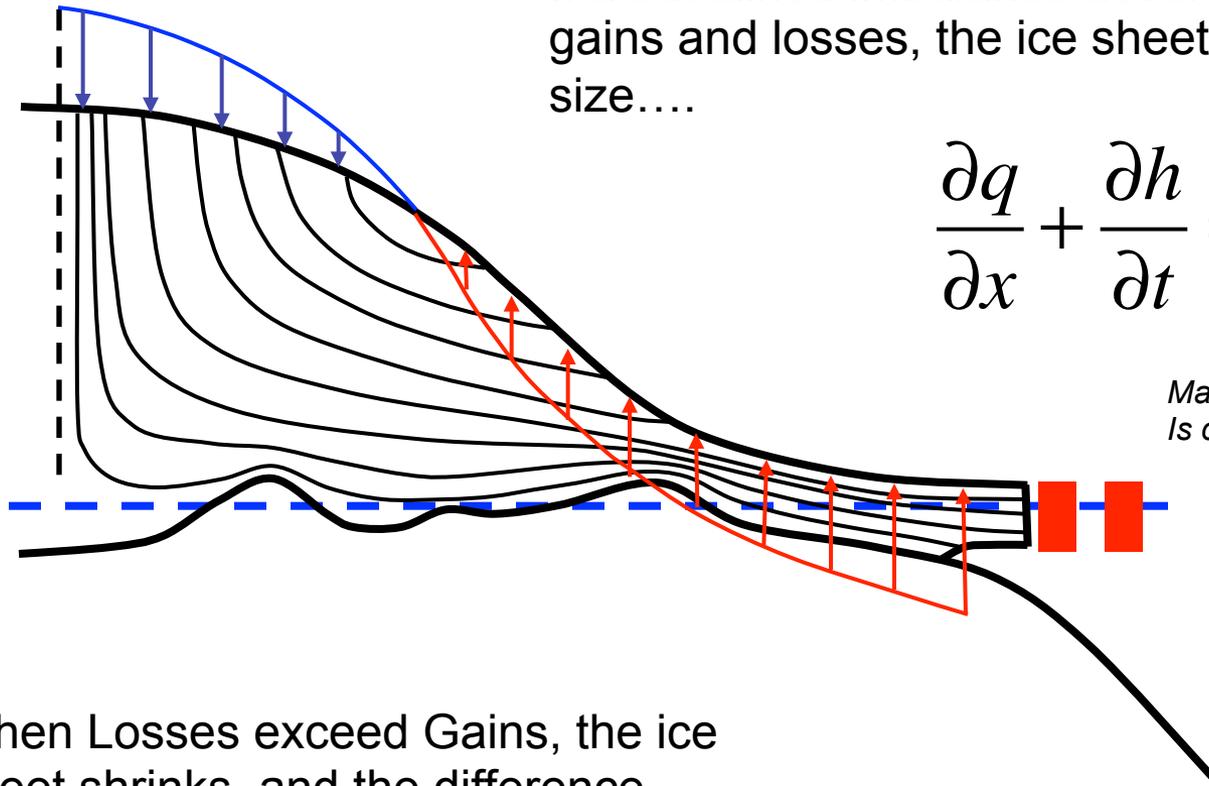

# Ice Sheet warming

If a sustained imbalance develops between gains and losses, the ice sheet will change size....

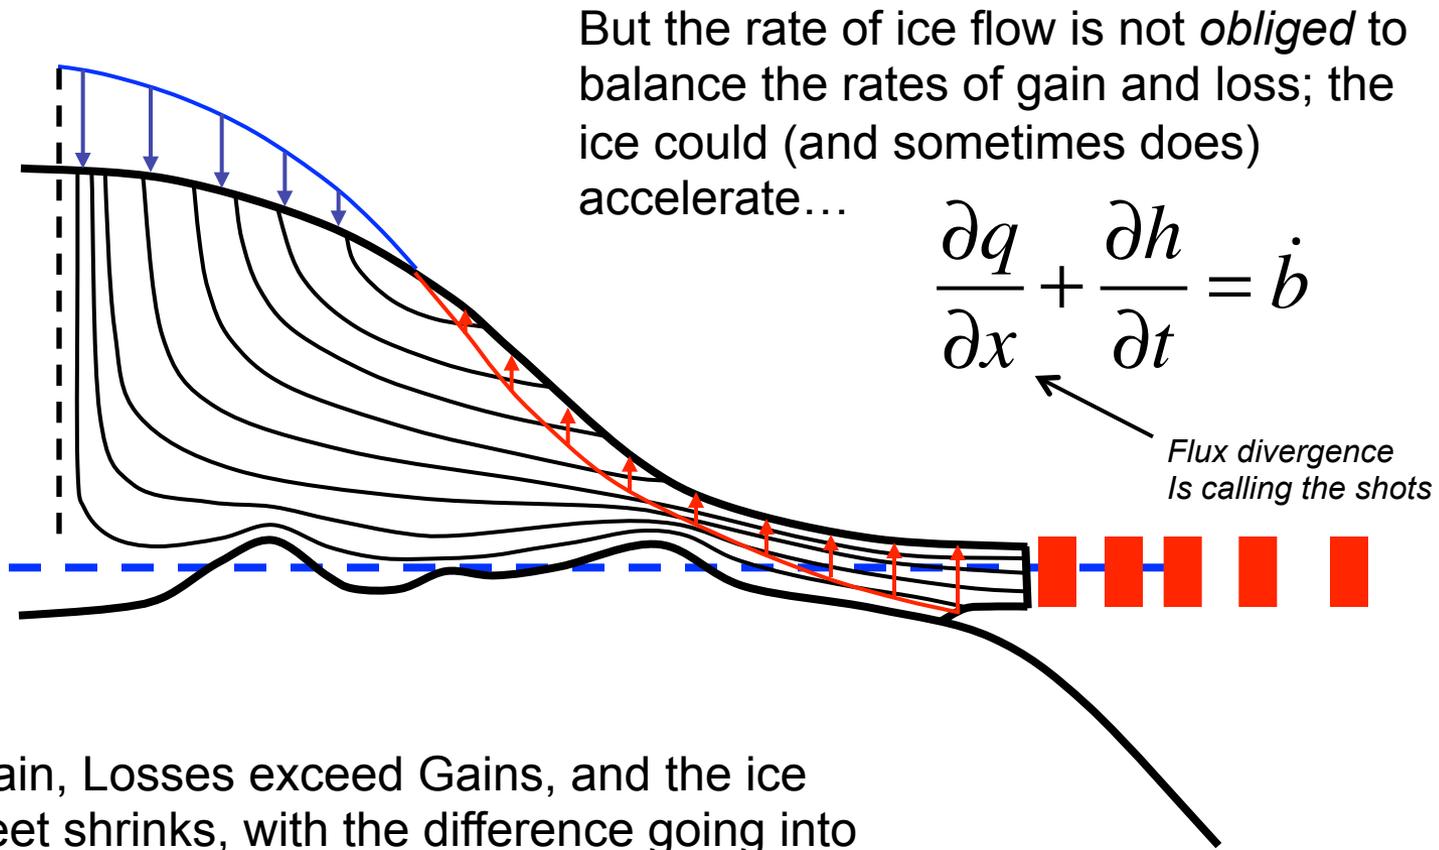

$$\frac{\partial q}{\partial x} + \frac{\partial h}{\partial t} = \dot{b}$$

↑  
*Mass balance  
Is calling the shots*

When Losses exceed Gains, the ice sheet shrinks, and the difference goes into the ocean, either via iceberg calving or melt and runoff.

# Ice Sheet accelerating: Rapid Dynamics

But the rate of ice flow is not *obliged* to balance the rates of gain and loss; the ice could (and sometimes does) accelerate...

$$\frac{\partial q}{\partial x} + \frac{\partial h}{\partial t} = \dot{b}$$

Flux divergence  
is calling the shots

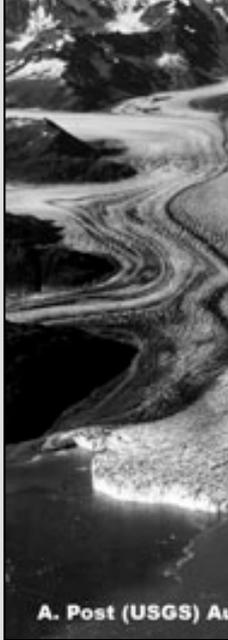

Again, Losses exceed Gains, and the ice sheet shrinks, with the difference going into the ocean.

## The Future

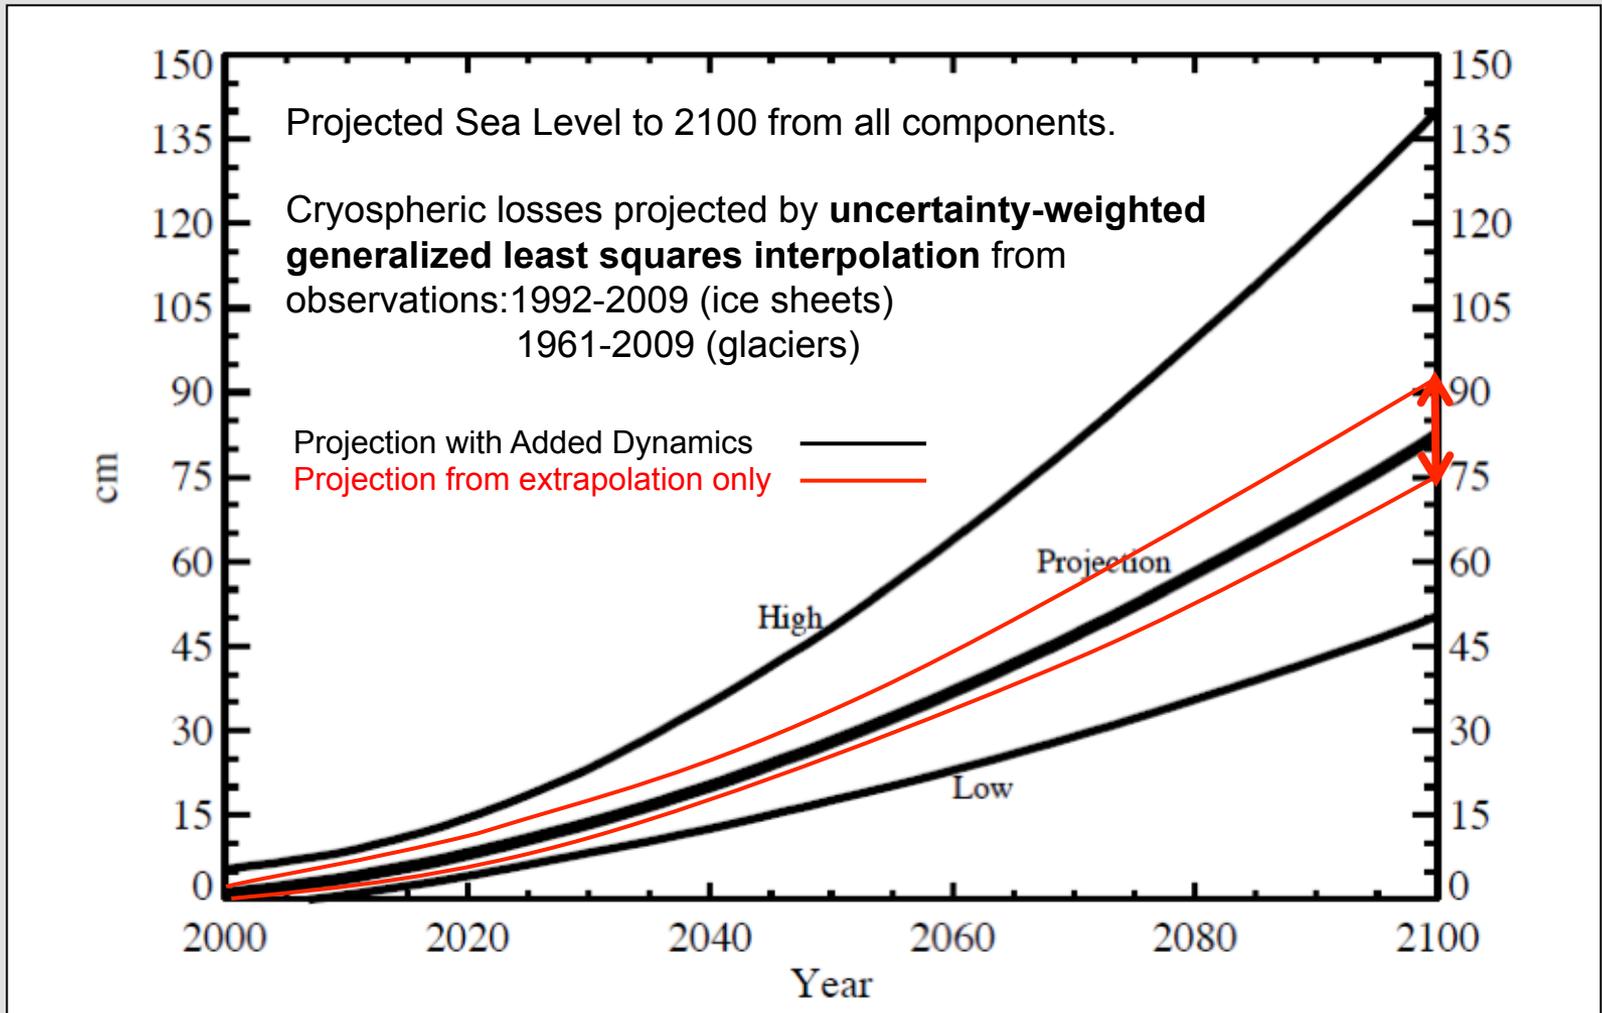

Methods of cryospheric projection in use or in development:

1. Full processed-based models (e.g. Navier-Stokes)
2. Extrapolation based models (fully empirical)
3. Semi-empirical models (empirical fit of output to modeled input)
4. Hybrid models (semi-empirical components in process models)
5. Assessment/Compilation (e.g. IPCC, NCA)

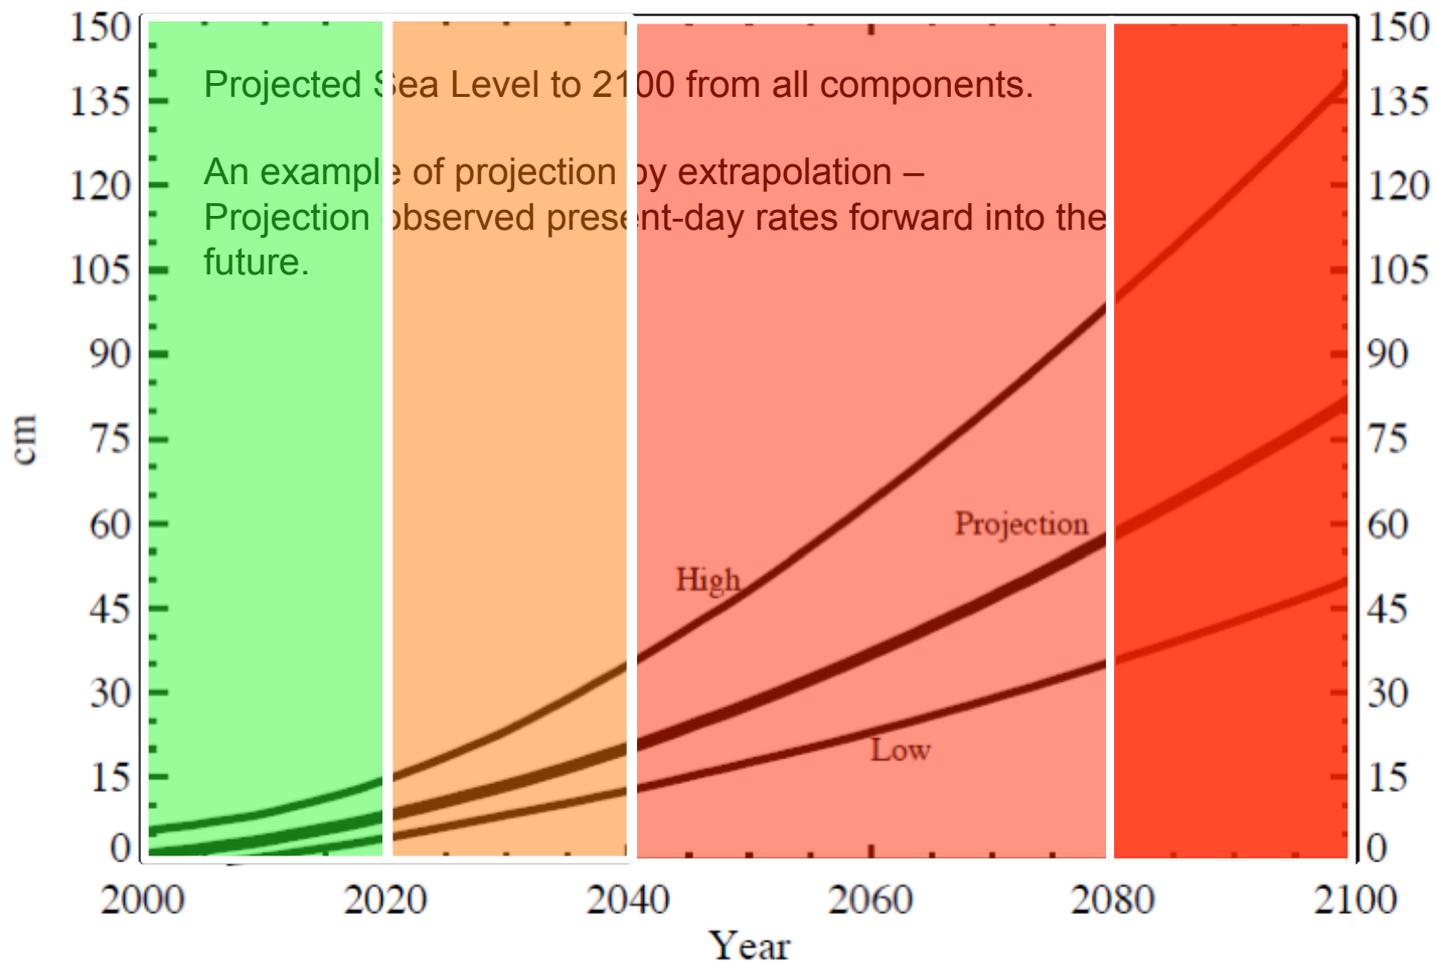

Radic and Hock, 2011

Process-based glacier contribution to projected sea level rise,  
AOGCM forced surface mass balance, no dynamic response

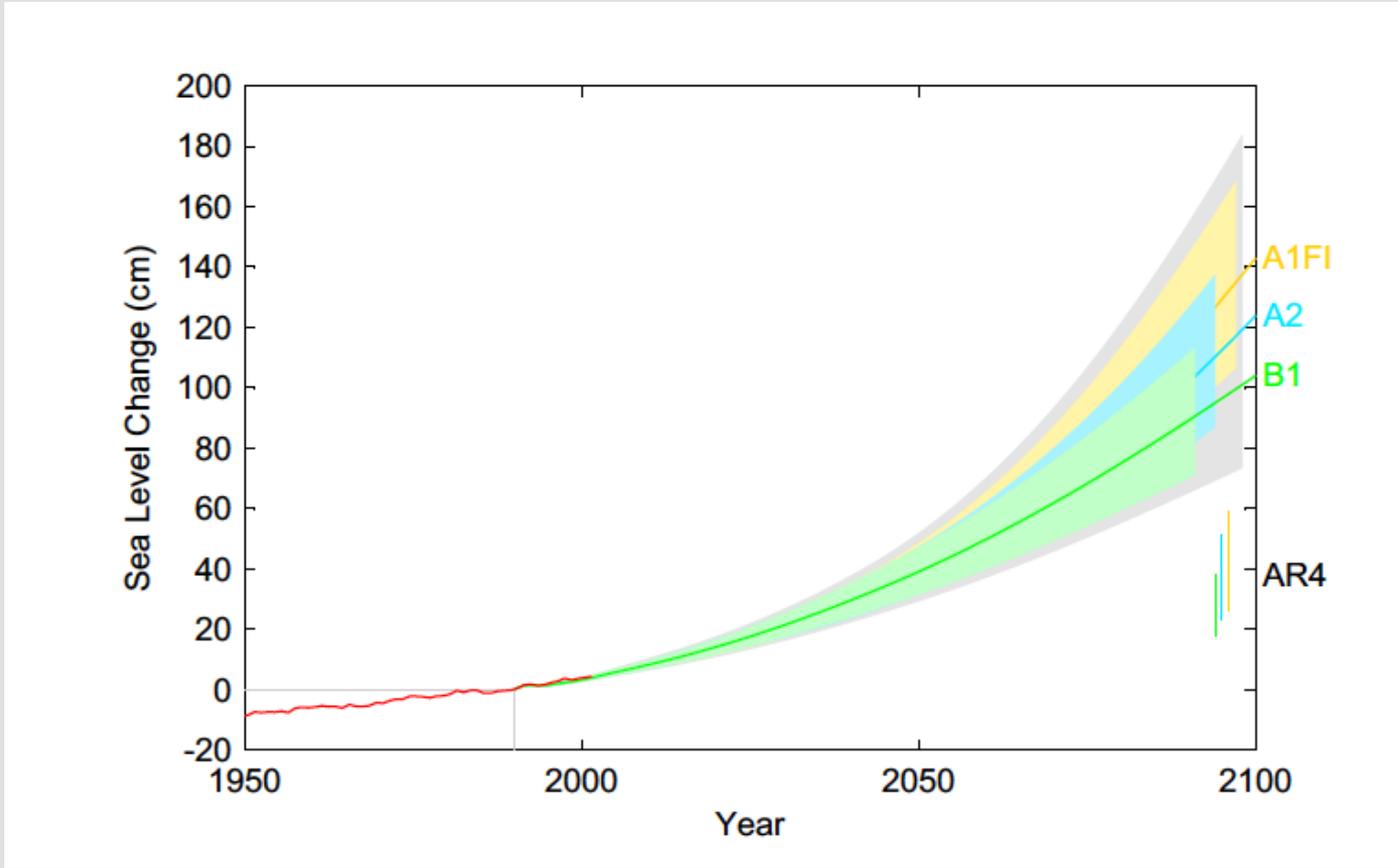

National Research Council, 2012

Extrapolation assumes statistical stationarity: whatever is driving accelerated mass loss today *continues* into the future

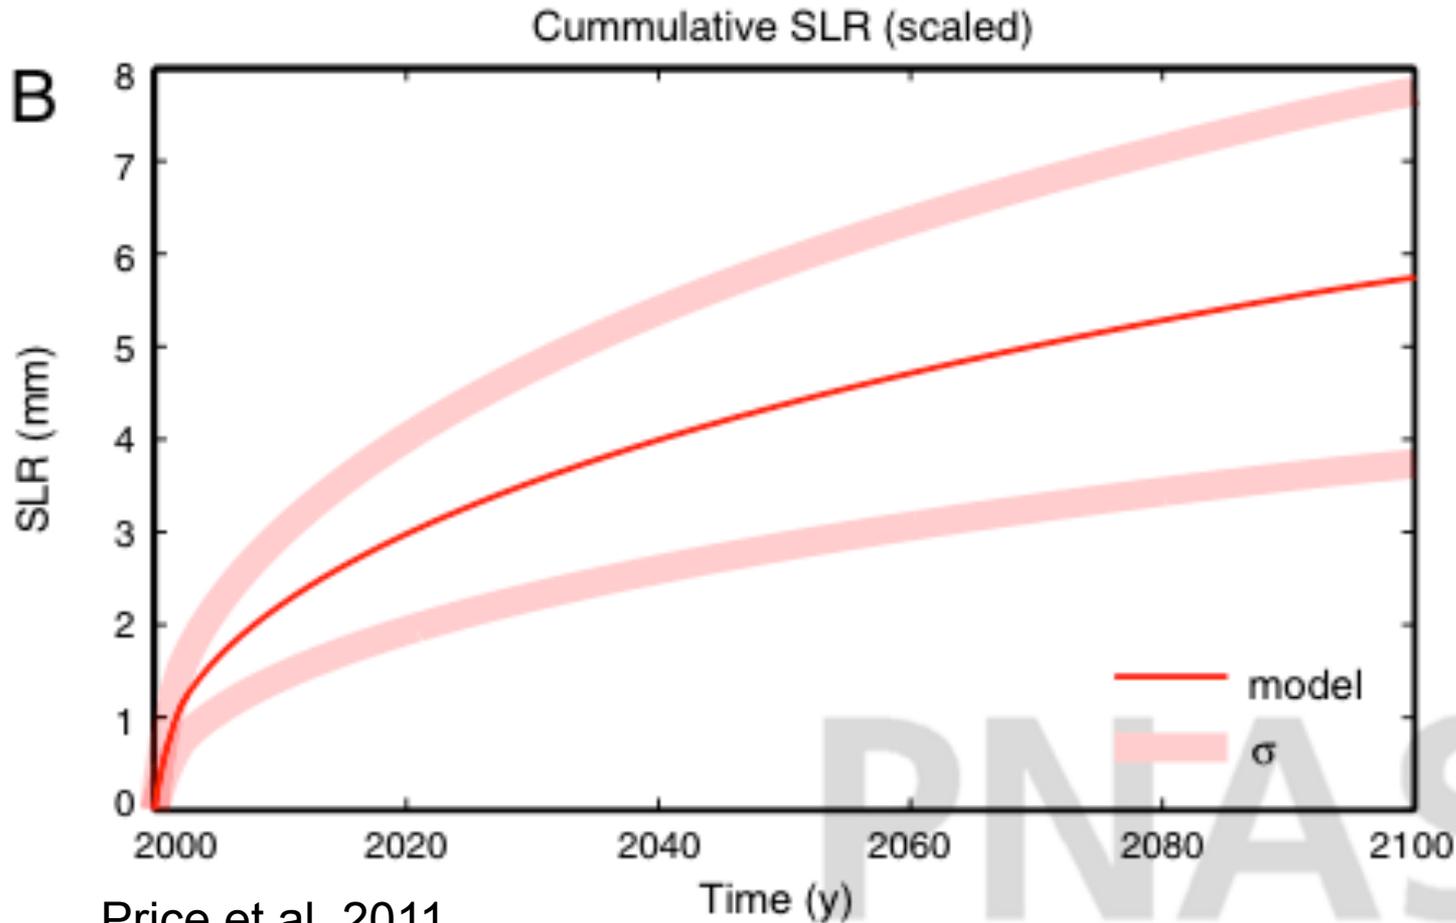

*National Research Council, 2012*

Assign declining overall confidence in projection with time: Projected  $\pm$  uncertainty represents “known unknowns” only.

### Vermeer and Rahmsdorf, 2009

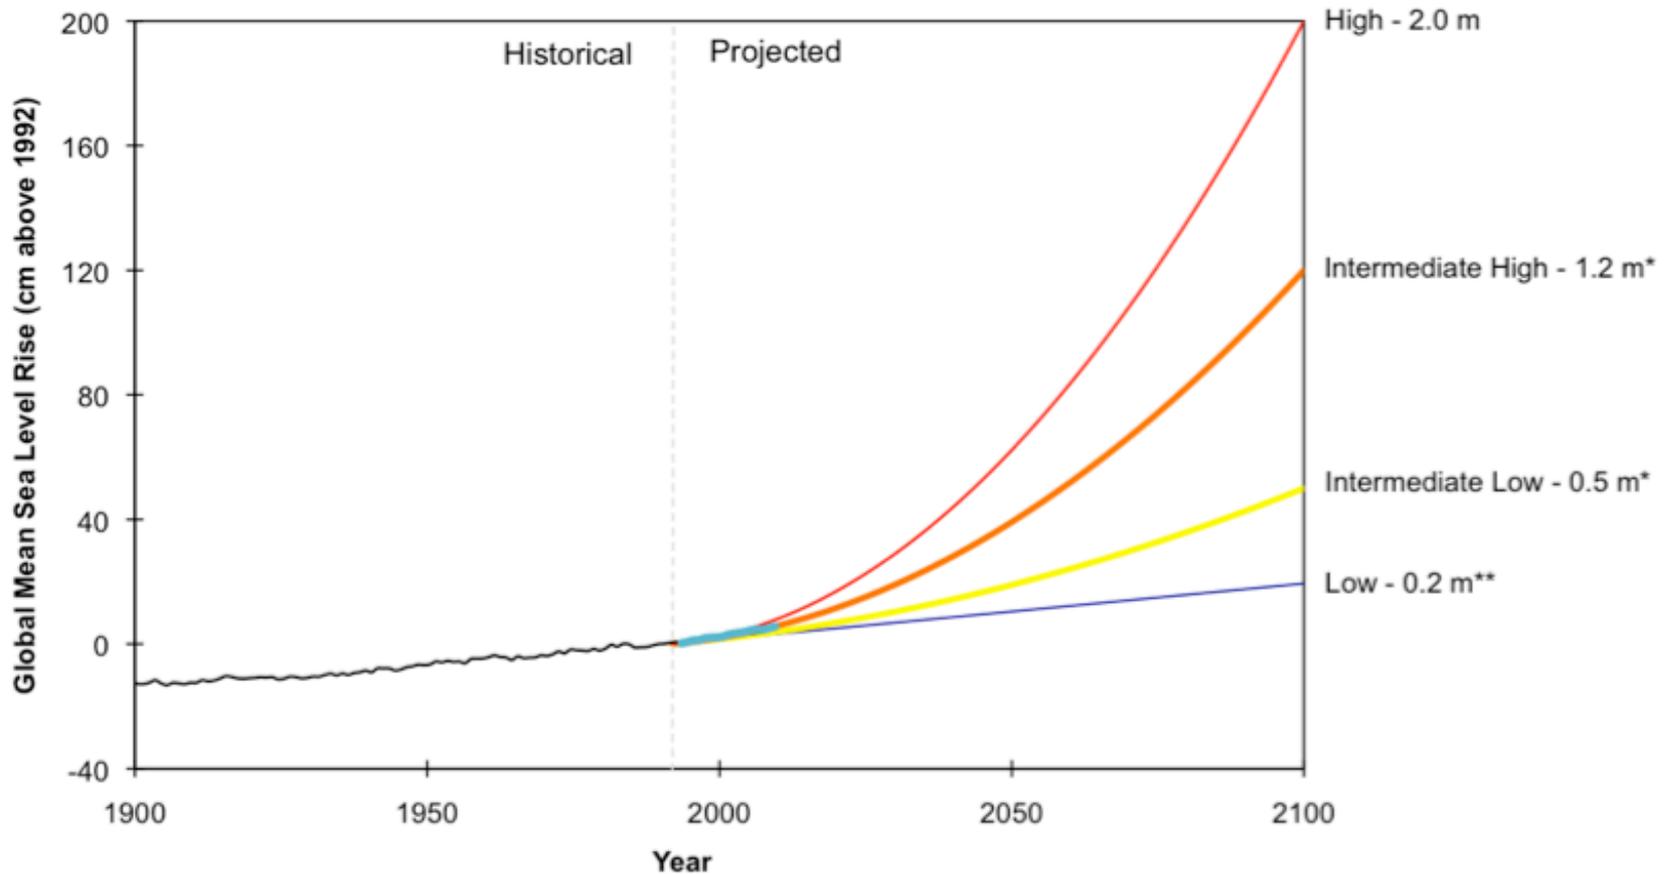

Projected total sea level rise, undifferentiated sources, observation record of sea level rise scaled to observational record of temperature and projected into future using modeled temperature

Price et al, 2011

Hybrid semi-empirical model

Projected sea level rise, Greenland ice sheet only, dynamics modeled, but timing simulated empirically

National Climate Assessment/Copilation, USGCRP, 2012

End points only assessed from literature; simple curves drawn from present

Stranded iceberg, Columbia Glacier, Alaska

W.T. Pfeffer

The current state of the art on sea level projection  
from the policy maker's perspective:

## **SLR at 2100 Could Be About Anything (i.e. the uncertainties are too large)**

### **Why?**

1. Wide range of potential forcings (RCPs).
2. Fundamental process knowledge lacking in certain areas: **rapid dynamics** via ice/rock interface interaction, iceberg calving. Also snow and englacial hydrology effects on surface mass balance.
3. Observations missing (but attainable in principal). e.g. detailed subglacial topography.

but also...

## **The time scales are poorly defined, and in conflict with planner's needs.**

1. Most SLR projections done by geoscientists (including IPCC) tend to be focused on 2100 and *beyond*.
2. Research strategies are pure-science driven, and result (coincidentally) is focus on processes with long lead times (hence focus on 2100 and beyond)
3. Processes critical in short-term (decades to 2100) but possibly insignificant in long-term (after 2100) very poorly represented.
4. Geoscientists response to AR4 “Rapid Dynamics” problem was to work harder on the *same problems they'd pursued for the past 30 years*.

## Why Rapid Dynamics for Ice Sheets only?

- Ocean-terminating glaciers account for 38% of global *glacier* area (ca. 280,000 km<sup>2</sup>)
- Alaska, currently discharges 17 GT/yr via calving, accounting for 36% of Alaska's mass loss, from only 13% of Alaska's glacier-covered area.
- Alaska contains only 4% of the world's ocean-ending area outside of the icesheets. No estimates exist of the global calving fraction.

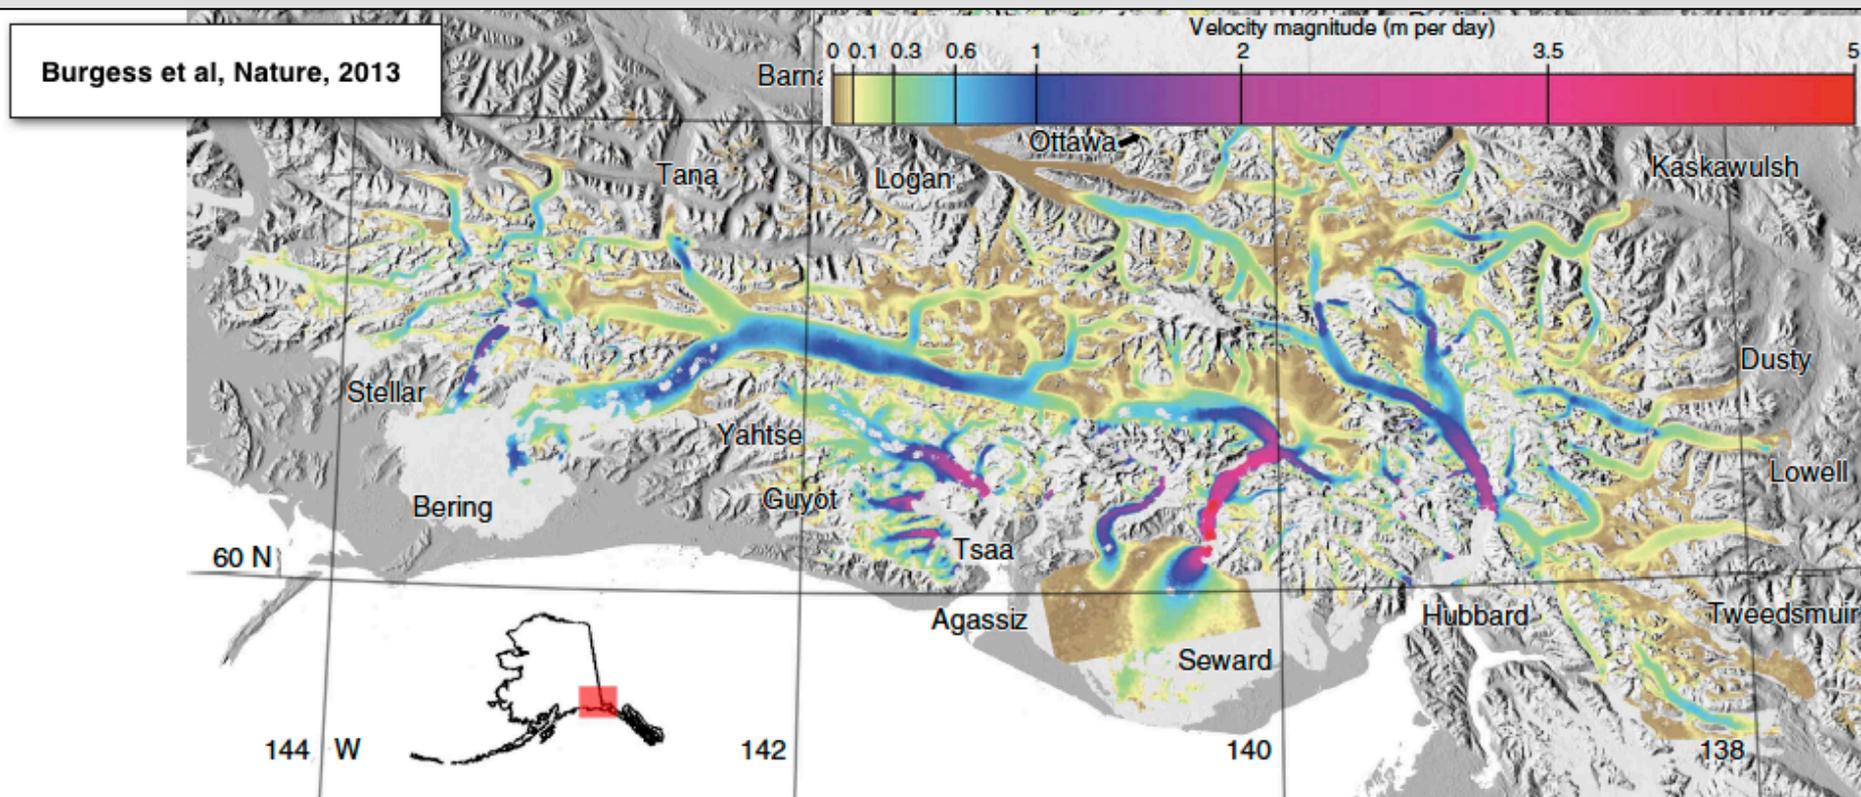

Figure 1 | Surface velocity map of the Wrangell and St Elias Ranges. Light grey glacier outlines<sup>47</sup> indicate missing data.

## **Alternative strategies could include:**

Set goals based on obtaining certain projected values (e.g. global mean SLR),

with quantified uncertainty (target tolerance),

for specific dates in the future (e.g. 2030, 2050, 2100),

to be delivered early enough to be of use (ideally before it happens).

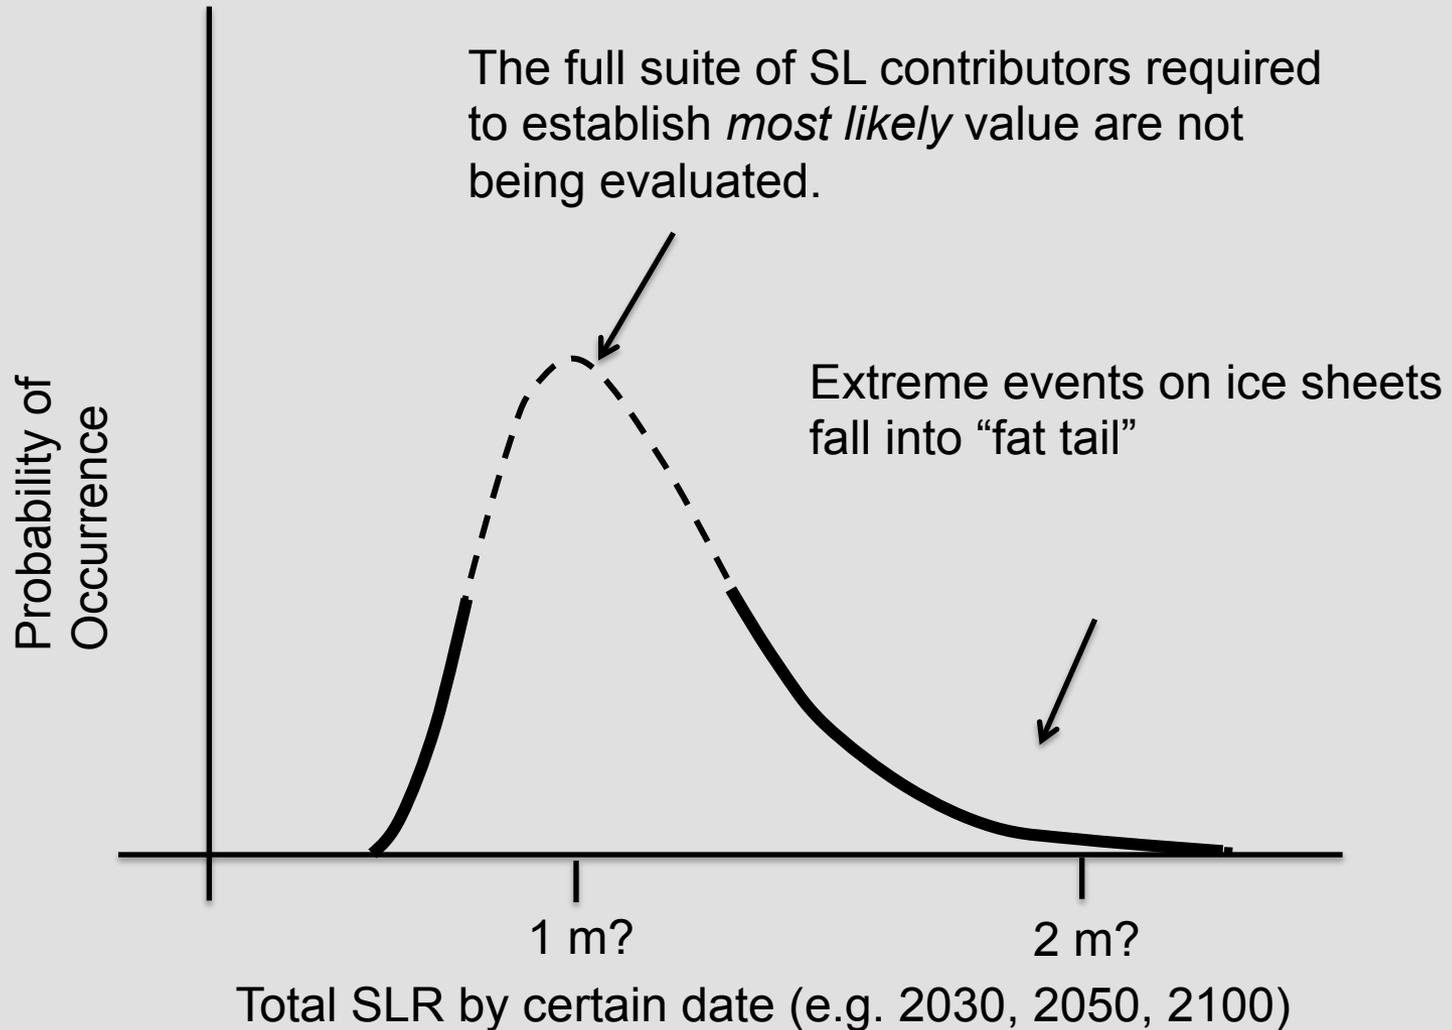

## **Need to decide:**

What time periods do we project for?

What is an acceptable level of uncertainty?

How much advance notice do we need?

SLR projections will ideally be delivered as a PDF.

This weakness is *more* pronounced at *nearer* forecast target dates

The short-term is important, but don't forget about the long term...

*from MOMA Rising Currents (September 2010)*

Time scales matter:

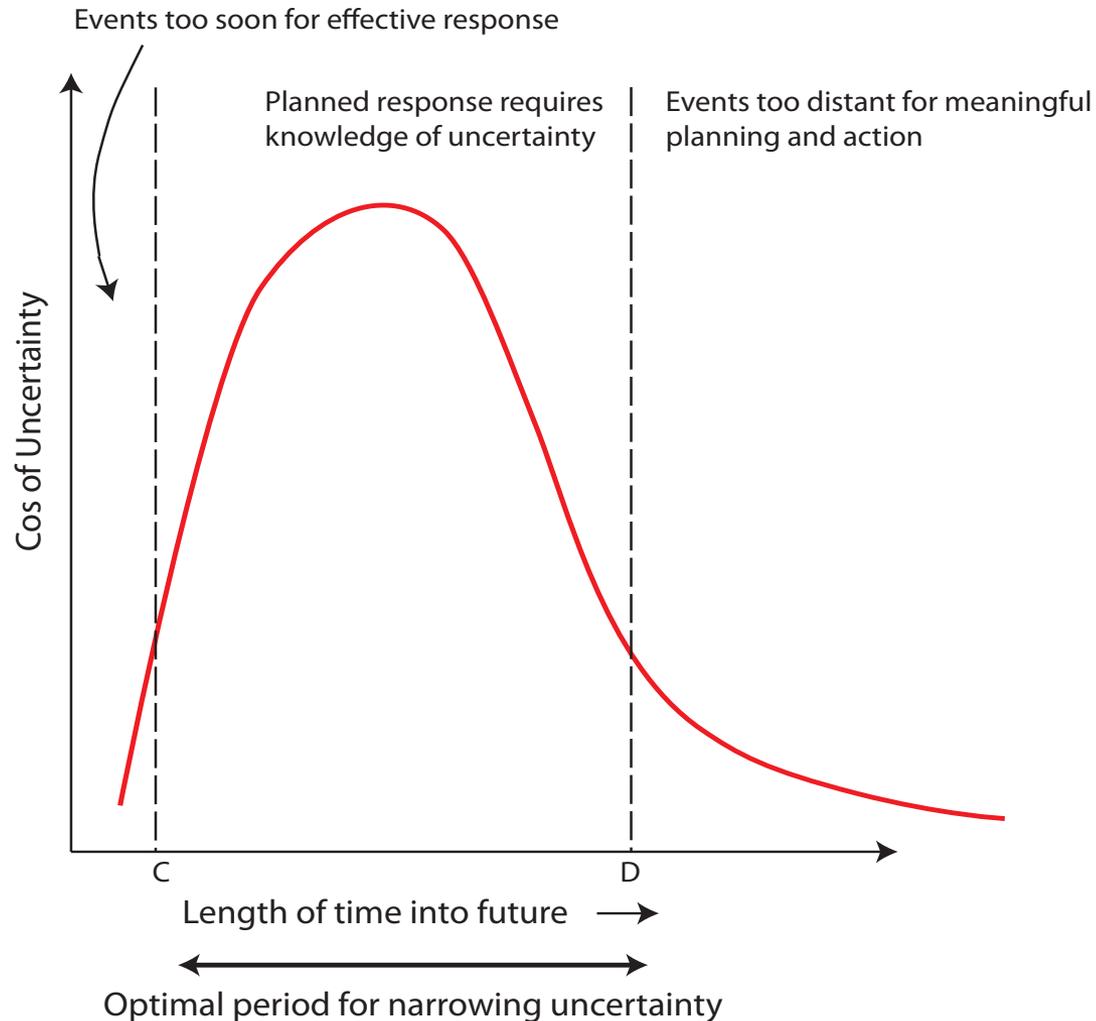

Long scales (100 yrs +) important for major long-term infrastructure replacement

Short scales (10 – 50 yrs) important for far more numerous infrastructure maintenance and replacement over normal lifetime-of-infrastructure (50 – 75 years).

Average or interval of life expectancy	Estonia	Sweden	Austria	France	Germany	Spain	The Netherlands
Buildings	8-50	10-35	25	50	10-50	50	
Civil engineering works			20	70	75-75	75	
Superstructure	8-50	40	25	30-50	20-25	18-40	33 <sup>38</sup>
New construction in progress	N/a	N/a	N/a	N/a	N/a	N/a	N/a
Transmission lines	8-50	10-35	15	20			33
Signalling equipment					20-20		11
Telecommunications equipment		5-20	4	15	5-20		
Safety installations			4	15			25
Vehicles / rolling stock	3-15		5	5	15-30	10-30	
Plant and machinery	3-15	3-25	9				
Office, computer and other equipment, tools	3-5	3-25	4	3-7	2-20	5-40	

from Infrastructure Expenditures and Costs (Eur. Comm., 2005)

# Predictions and Cost of uncertainty (value of reducing uncertainty) varies over time

What are time scales C and D?

C: Possibly ~ 1 year (reducing uncertainty in sea level forecast on much shorter time scales isn't useful).

D: Possibly 50-100 years (reducing uncertainty in sea level forecast 500 years from now isn't politically/economically usable).

*Long-term determinations not useful in the absence of medium-short term determinations*

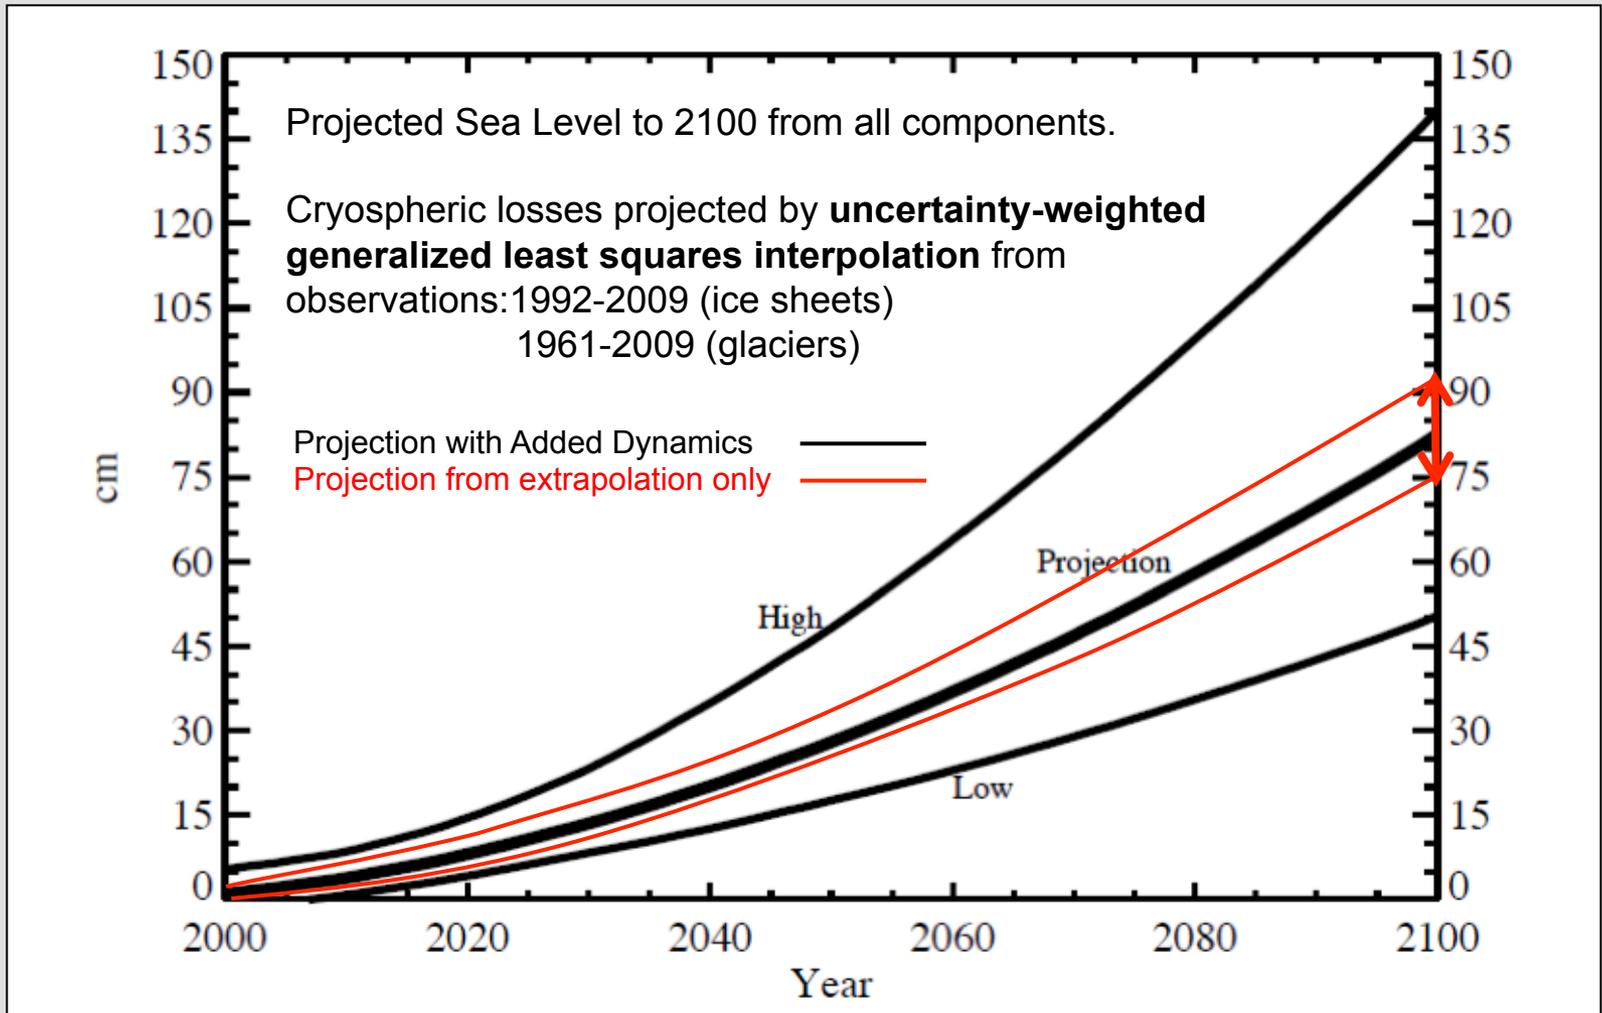

**What are the optimal windows for making projections? Is it better to have a more uncertain 50-year projection for 2050 now, or wait until 2025 and get a better 25-year projection?**

## A few Advantages to Rapid Dynamic Response

The biggest events have comparatively long time scales: West Antarctic Ice Sheet collapse (2-3 m/century SLE) requires removal of major ice shelves first; requires 100-200 years (Maybe? – requires investigation). We get advance warning.

Greenland Ice Sheet contains ca. 6 m SLE but no capacity for catastrophic West Antarctic style collapse. Could reach high loss rates, but not by an exceptionally non-linear path.

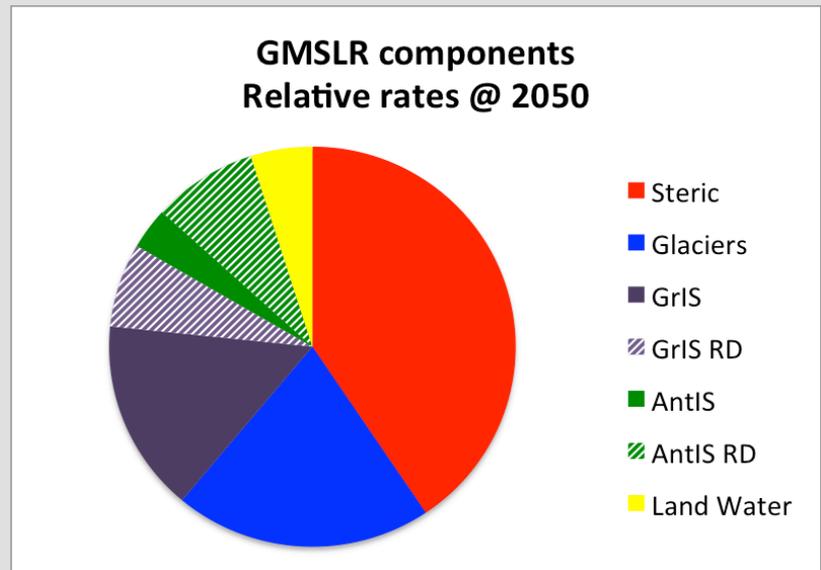

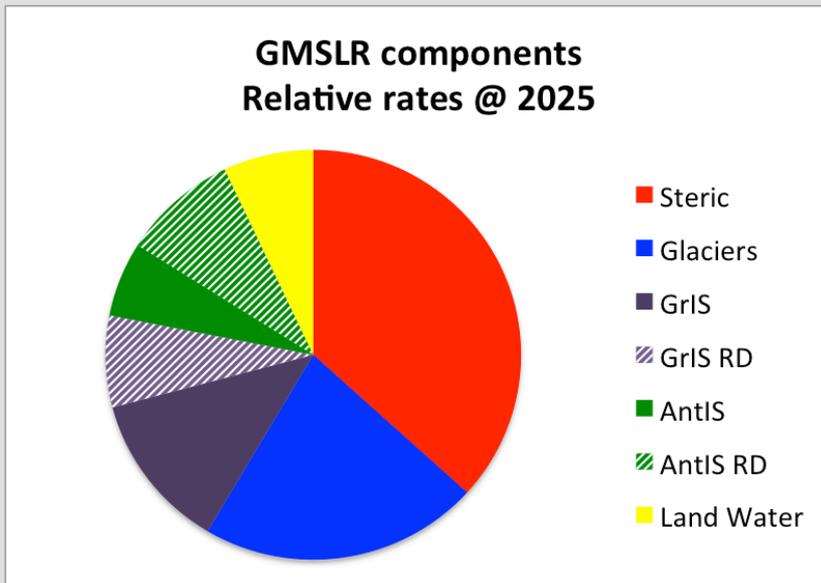

National Research Council, 2012

**Projected in red:** Best estimate of what *will* happen  
 Projected in black: What could happen if RD occurs, but no probability occurrence attached to this.

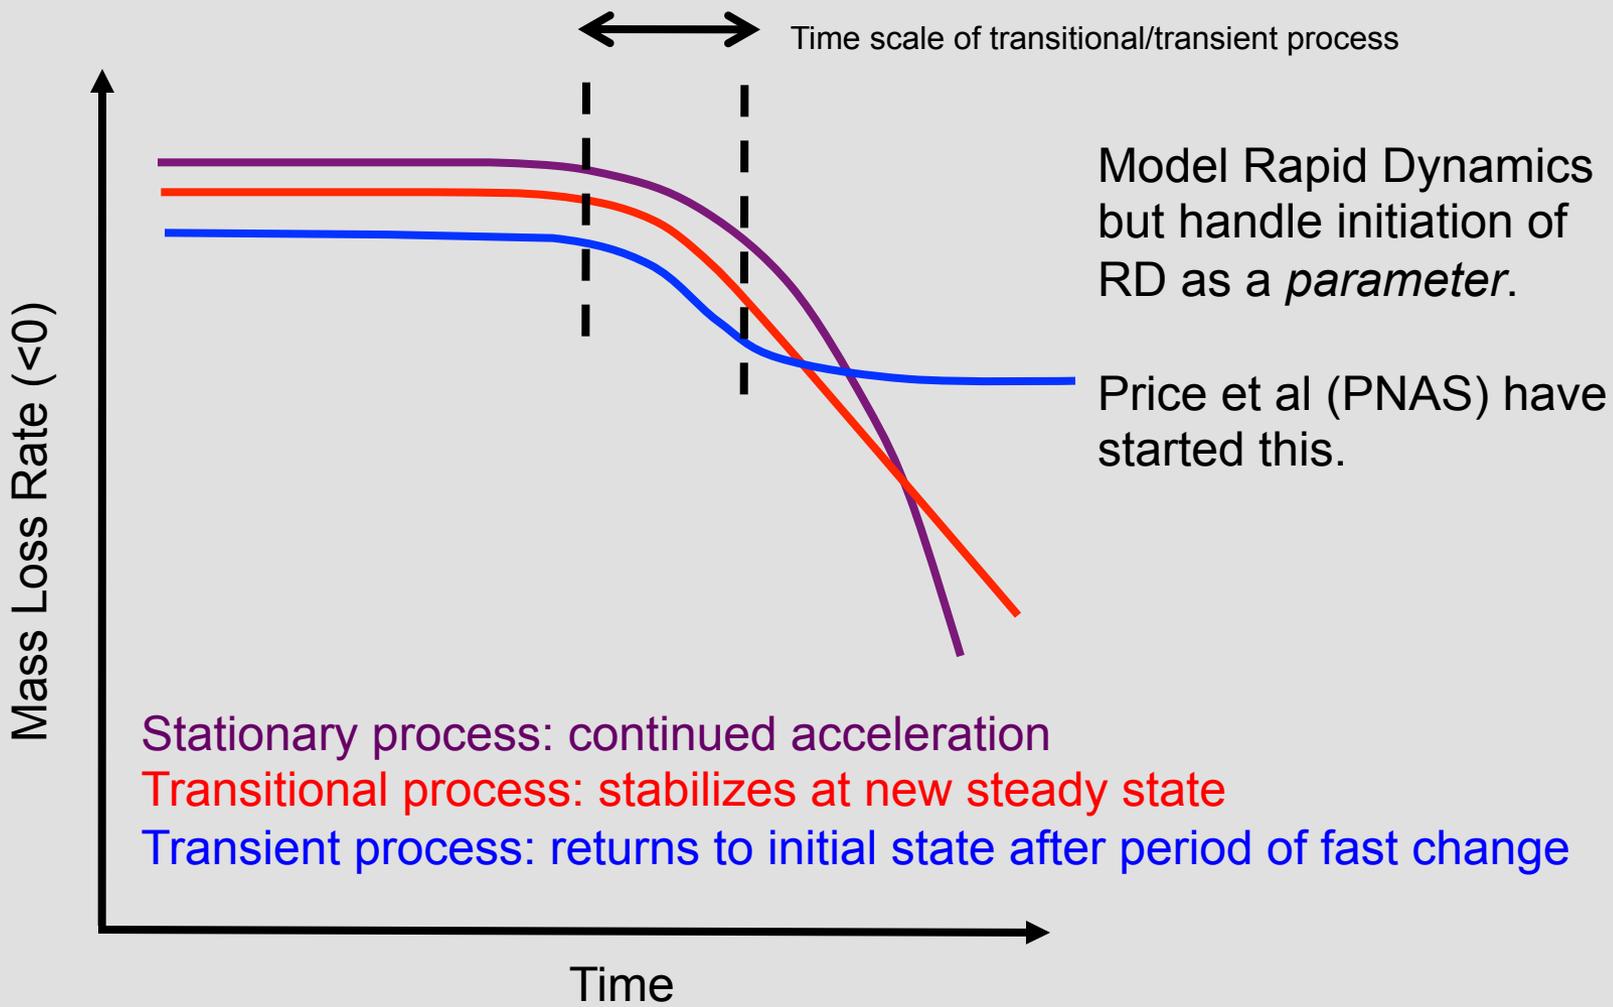

## Modeling improvements/alternatives:

1. Model all sources, not just the biggest ones.

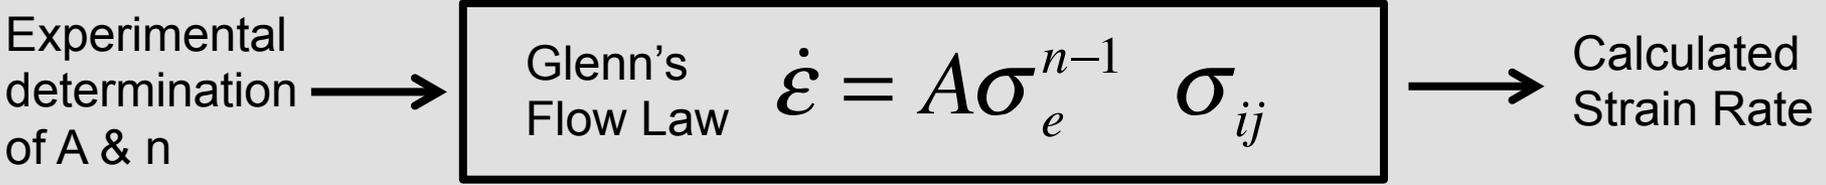

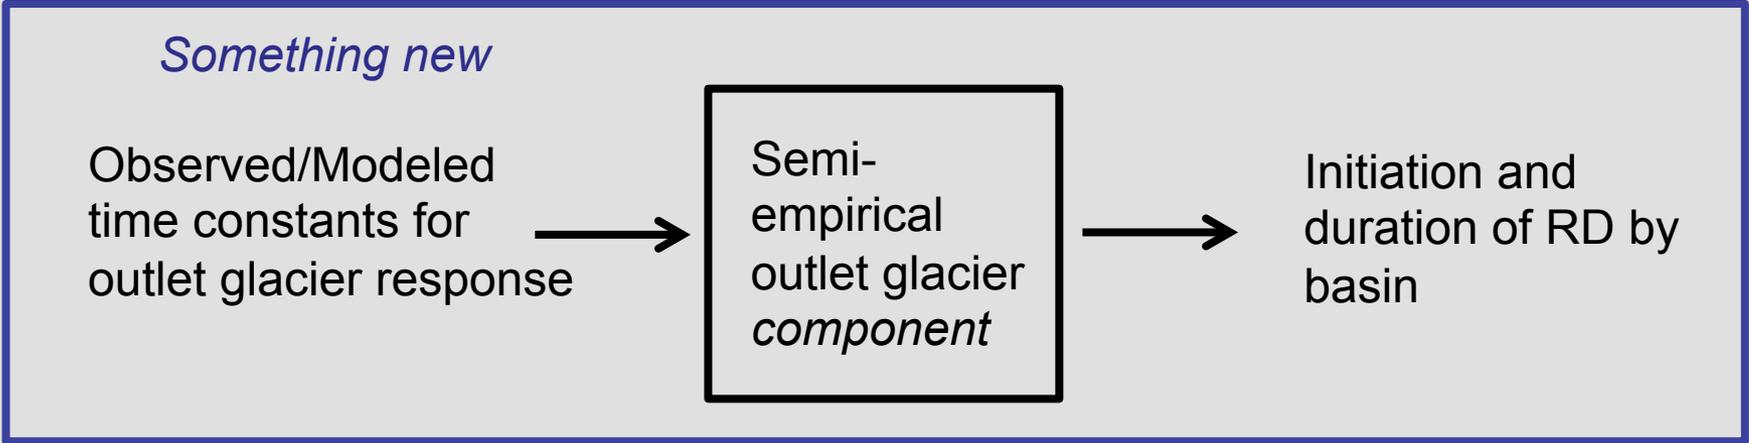

Uncertainty for glacier and ice sheet projections are approximately equal

Pursue parallel modeling tracks. Embrace non-deterministic modeling and hybrid models

Pursue parallel modeling tracks. Embrace non-deterministic modeling and hybrid models

Extend Semi-empirical strategy to hybrid models:

Sea Level forecasting can be substantially improved simply by thinking carefully about **goals** and communicating them.

| A COMMENT

## GLACIOLOGY NEEDS TO COME OUT OF THE IVORY TOWER

W. Tad Pfeffer

**W**hat happens when a field of scientific inquiry that starts out as a subject motivated purely by curiosity and driven by the simple desire to understand how the world works, is turned rather suddenly into a field with applications of the most urgent nature? This has happened in the study of glaciers and sea-level rise. Thus, we glaciologists need to change how we view, practice and report our science. What we say and do matters.

Fifty years ago, the study of the dynamics of glaciers and ice sheets was sufficiently arcane for the term "glaciology" to merit an entry in "Mrs. Byrne's Dictionary of Unusual, Obscure, and Preposterous Words." Today, with the growing prominence of climate change and the role of glaciers in sea-level rise, what was once a research topic pursued by a relatively small, scattered community of geoscientists working at a comparatively leisurely pace is now a

were estimated using some simple approximations, and the need for improvements in basic knowledge of glacier dynamics, glacier-ocean interactions, and computer models to simulate them stood out as paramount goals for future investigation.

The assessment authors were

very clear about the limitations of the sea-level projections, as well as what they
