

Uncertainty and the Social Cost of Carbon

Richard S.J. Tol

Introduction

- Most climate policy analyses pull a target out of thin air and then spend a lot of effort in meeting that target in some clever way
- Many analysts would hide behind a policy maker, who does not know what target to select either
- The few targets around were picked by people bold enough to stick their neck out, not smart or wise enough to pick a target, and typically without an electoral mandate

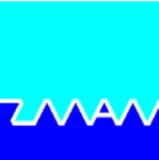

Introduction -2

- In von Neumann-Morgenstern terms, one can justify cost-effectiveness if variance of the benefits is infinite, and one should then select at least that target that renders the impact of climate change finite again
- Note that this still does not justify parroting Hartmut Grassl that 2°C is dangerous
- So, is the variance of the crucial variable, the social cost of carbon, finite?

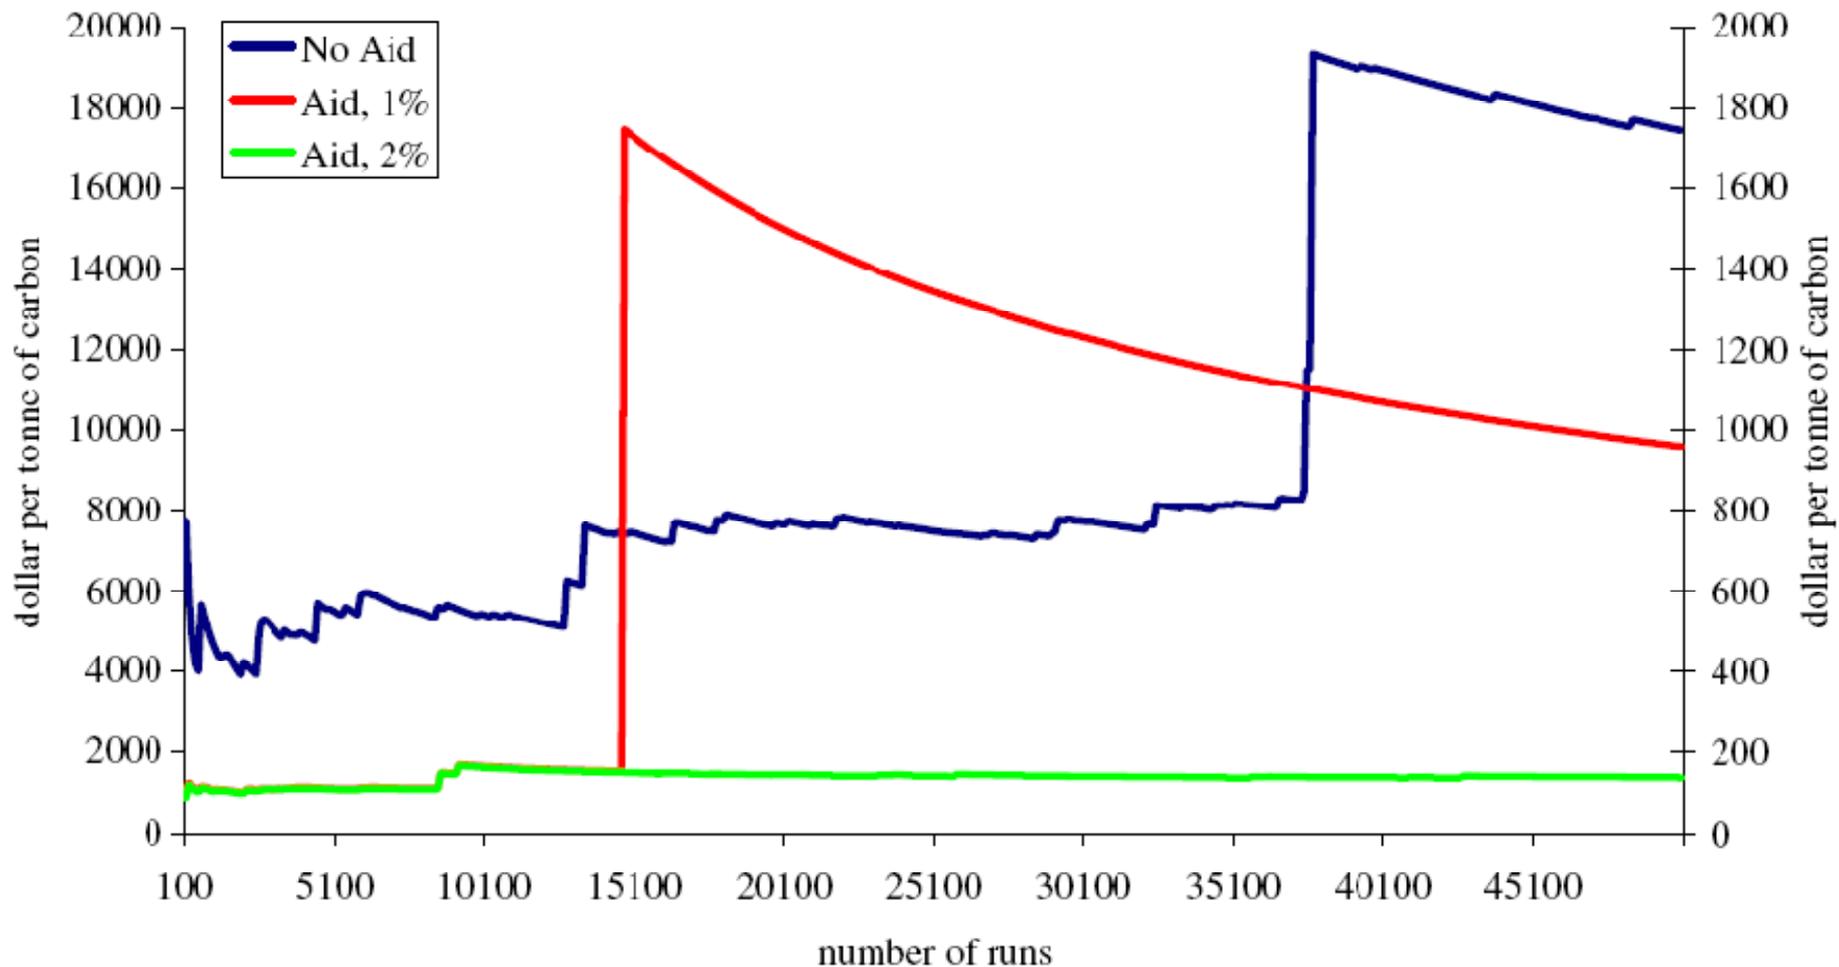

Fig. 1 The standard deviation of the marginal damage costs of carbon dioxide emissions with and without aid as a function of the number of Monte Carlo runs for a 1% pure rate of time preference; impacts are equity-weighted; annual aid is limited to 1 or 2% of OECD GDP. The “No Aid” estimates are measured against the *left-hand vertical axis*; the 1 and 2% Aid cases are calibrated by the *right-hand vertical axis*

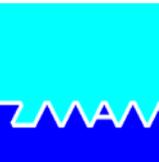

Infinite impacts?

- Net present value of a constant stream of impacts
- Now suppose that impacts grow with income
- Or impacts reduce economic growth
- Convergence is no longer guaranteed, and a small chance is enough

$$V^* = \sum_{t=0}^{\infty} \frac{V}{(1 + \rho + \eta g)^t}$$

$$V^* = \sum_{t=0}^{\infty} \frac{V(1 + \varepsilon g)^t}{(1 + \rho + \eta g)^t}$$

$$V^* = \sum_{t=0}^{\infty} \frac{V}{(1 + \rho + \eta(g - \delta))^t}$$

The “No Aid” estimates are measured against the *left-hand vertical axis*; the 1 and 2% Aid cases are calibrated by the *right-hand vertical axis*

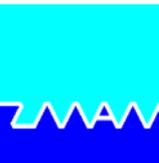

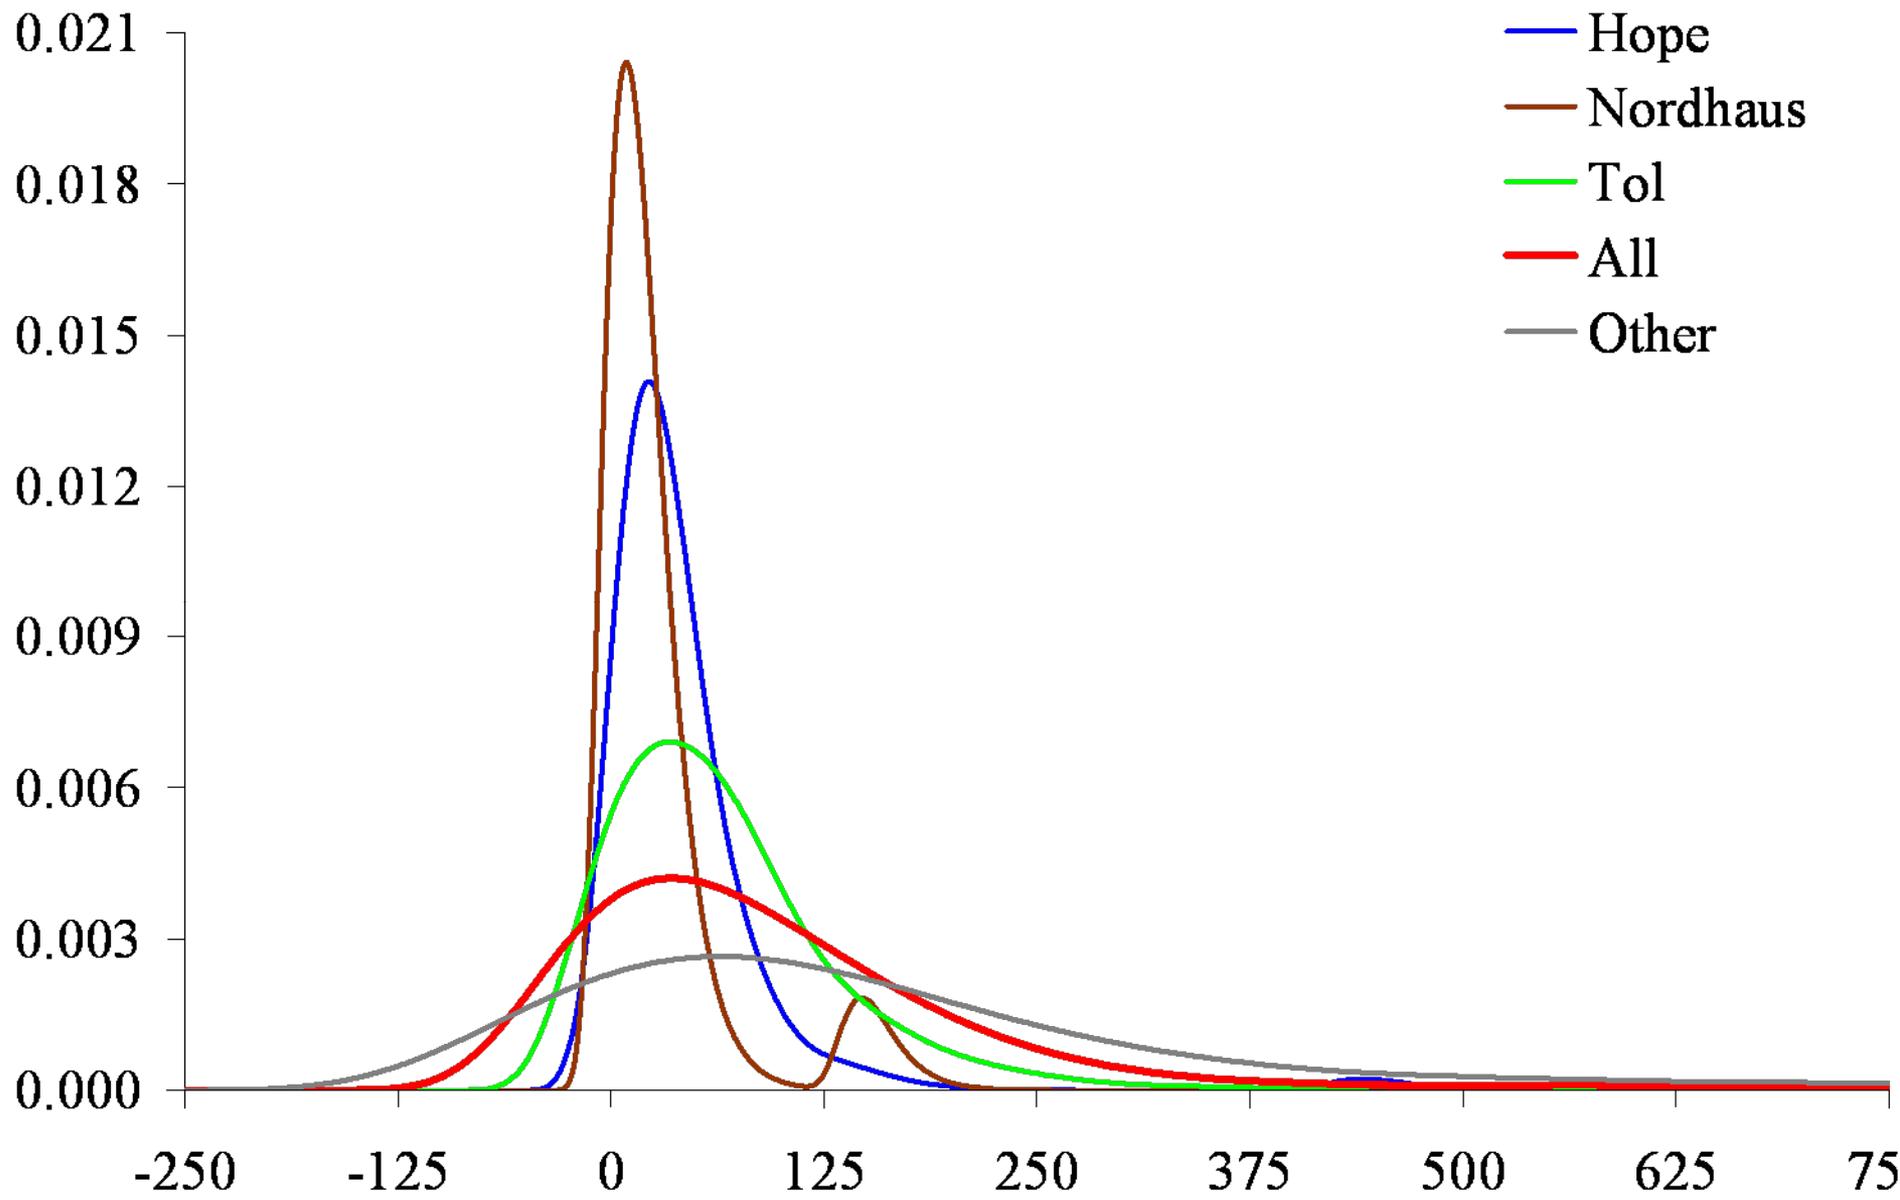

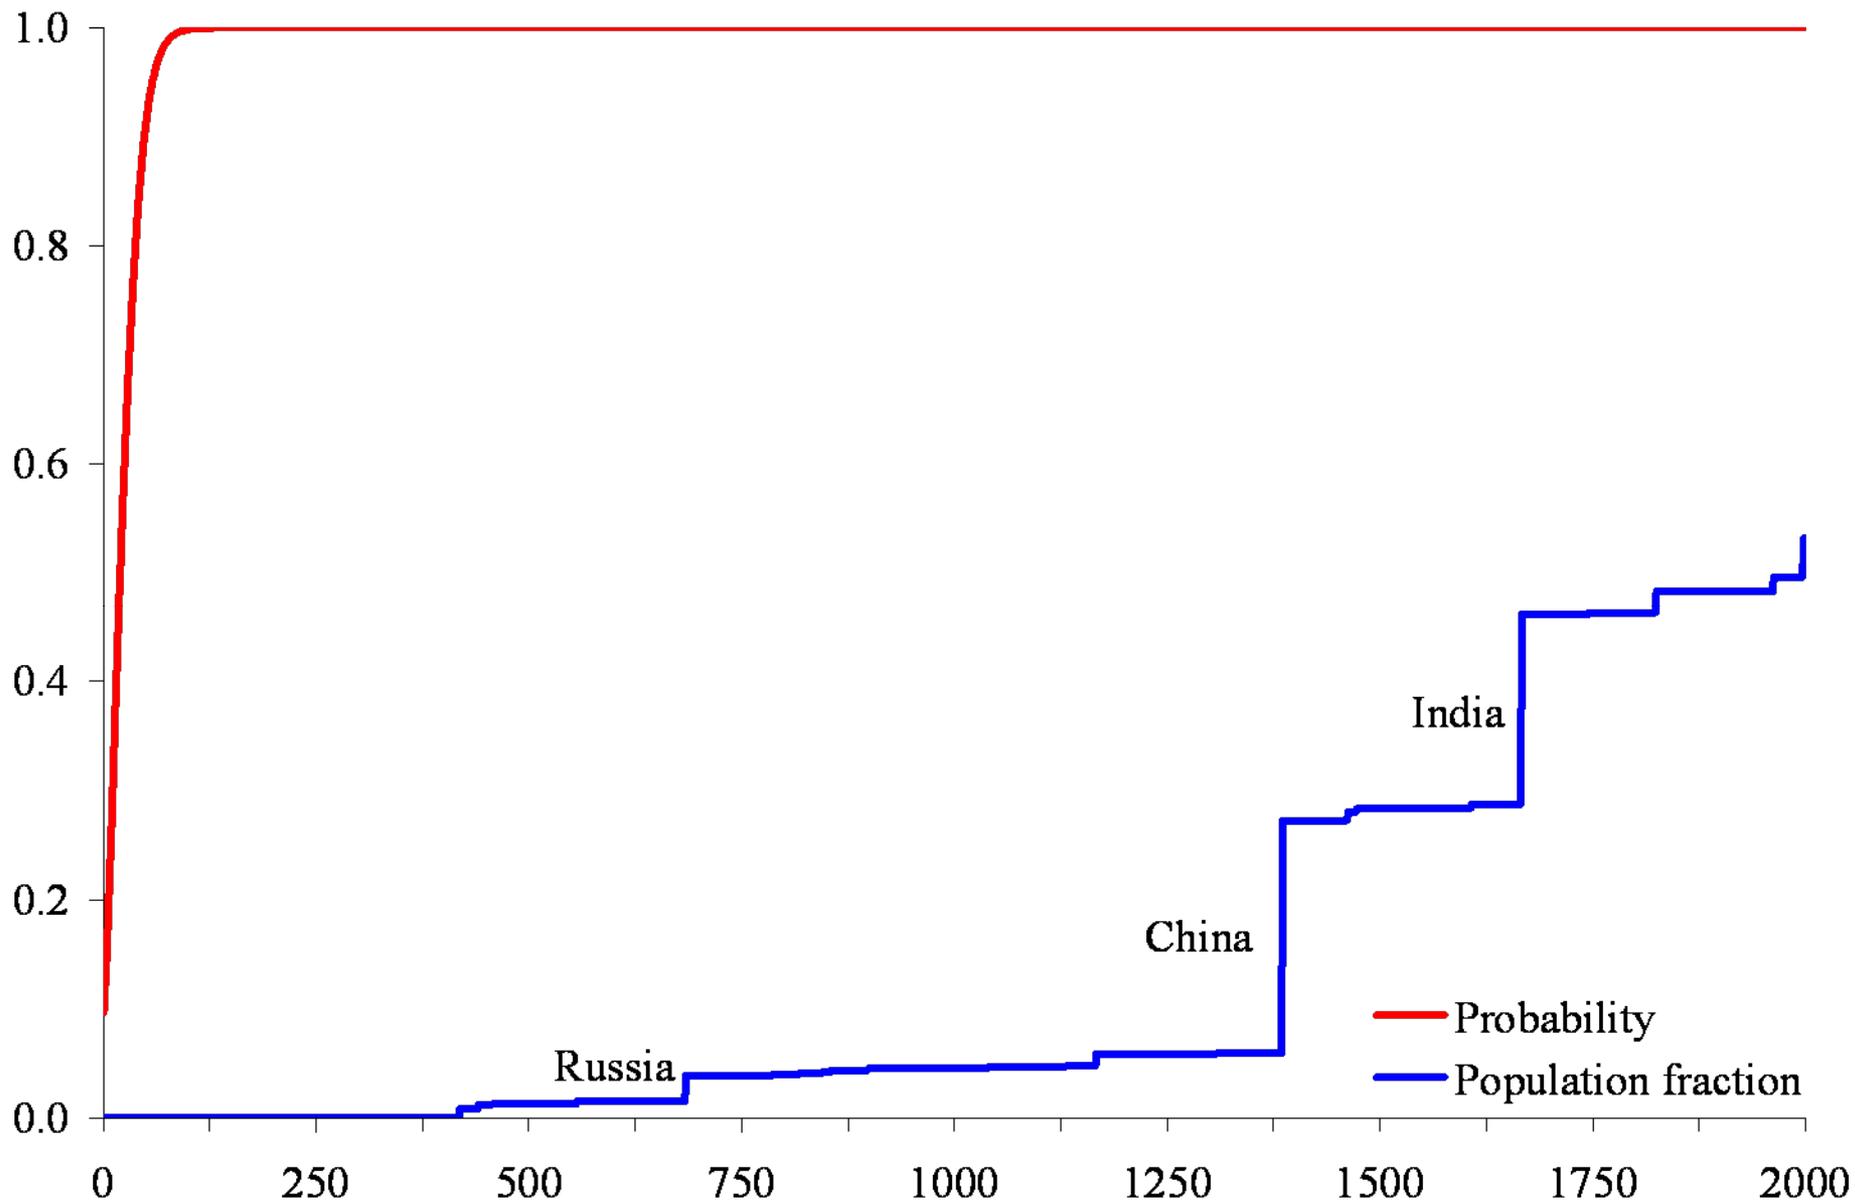

Infinite uncertainty?

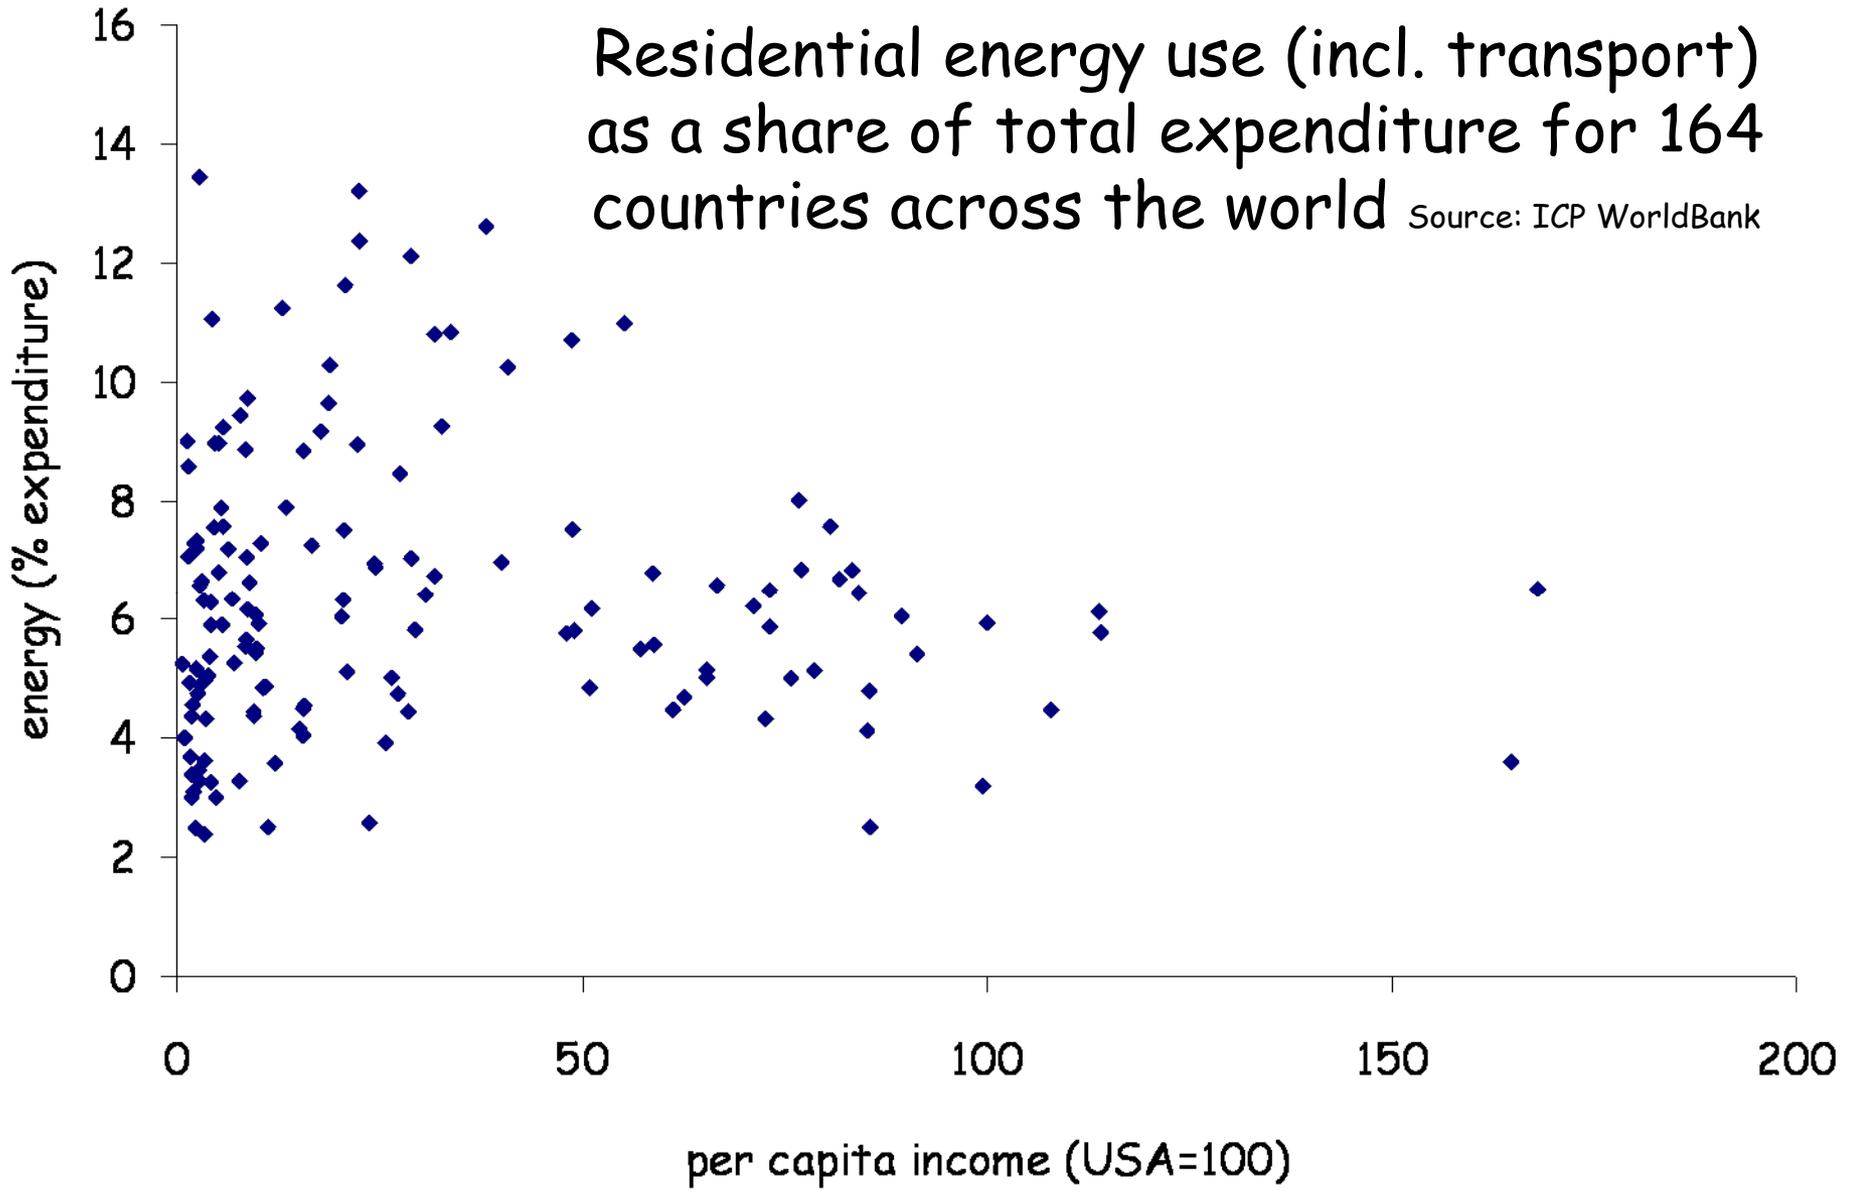

- In the latest version of FUND, uncertainty is perhaps bounded but definitely large with a fat tail
- Fat tail is confirmed by meta-analysis

Residential energy use (incl. transport)
as a share of total expenditure for 164
countries across the world Source: ICP WorldBank

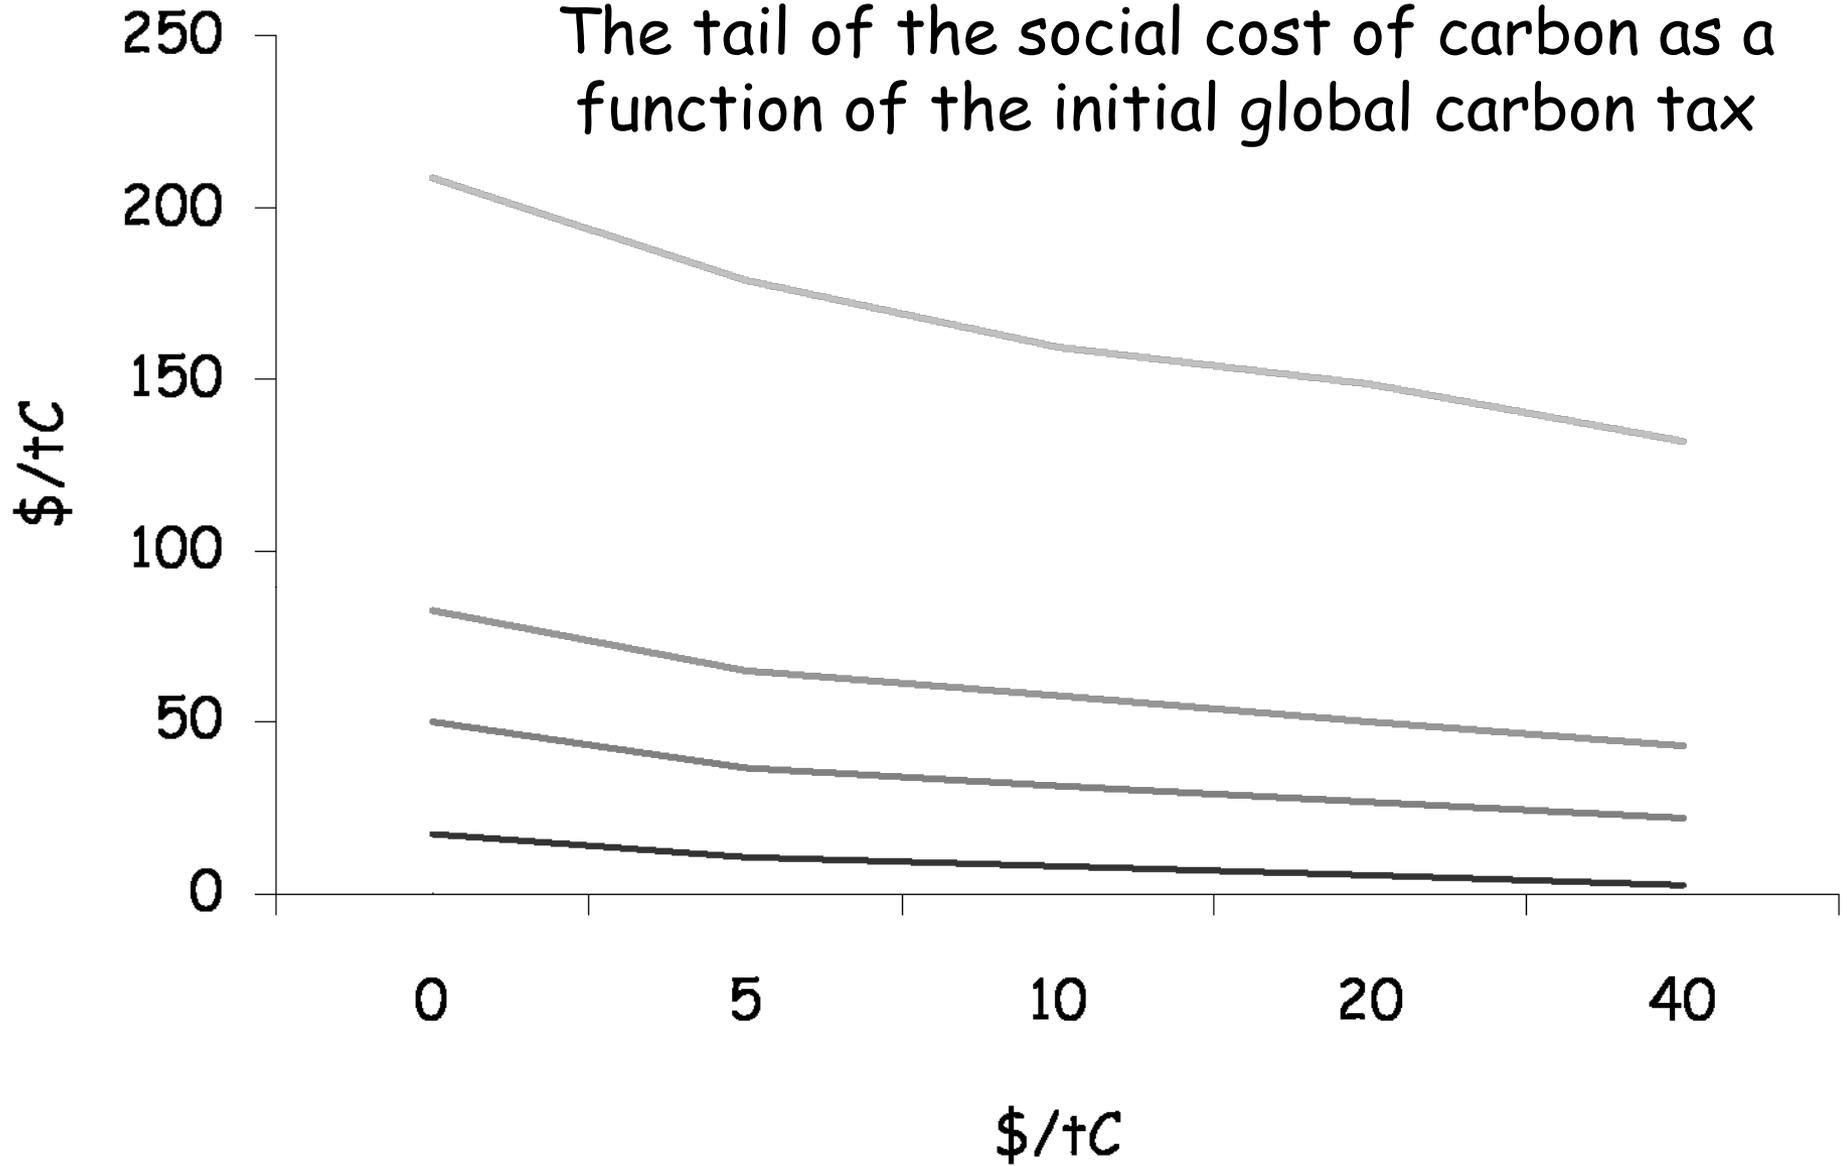

What to do?

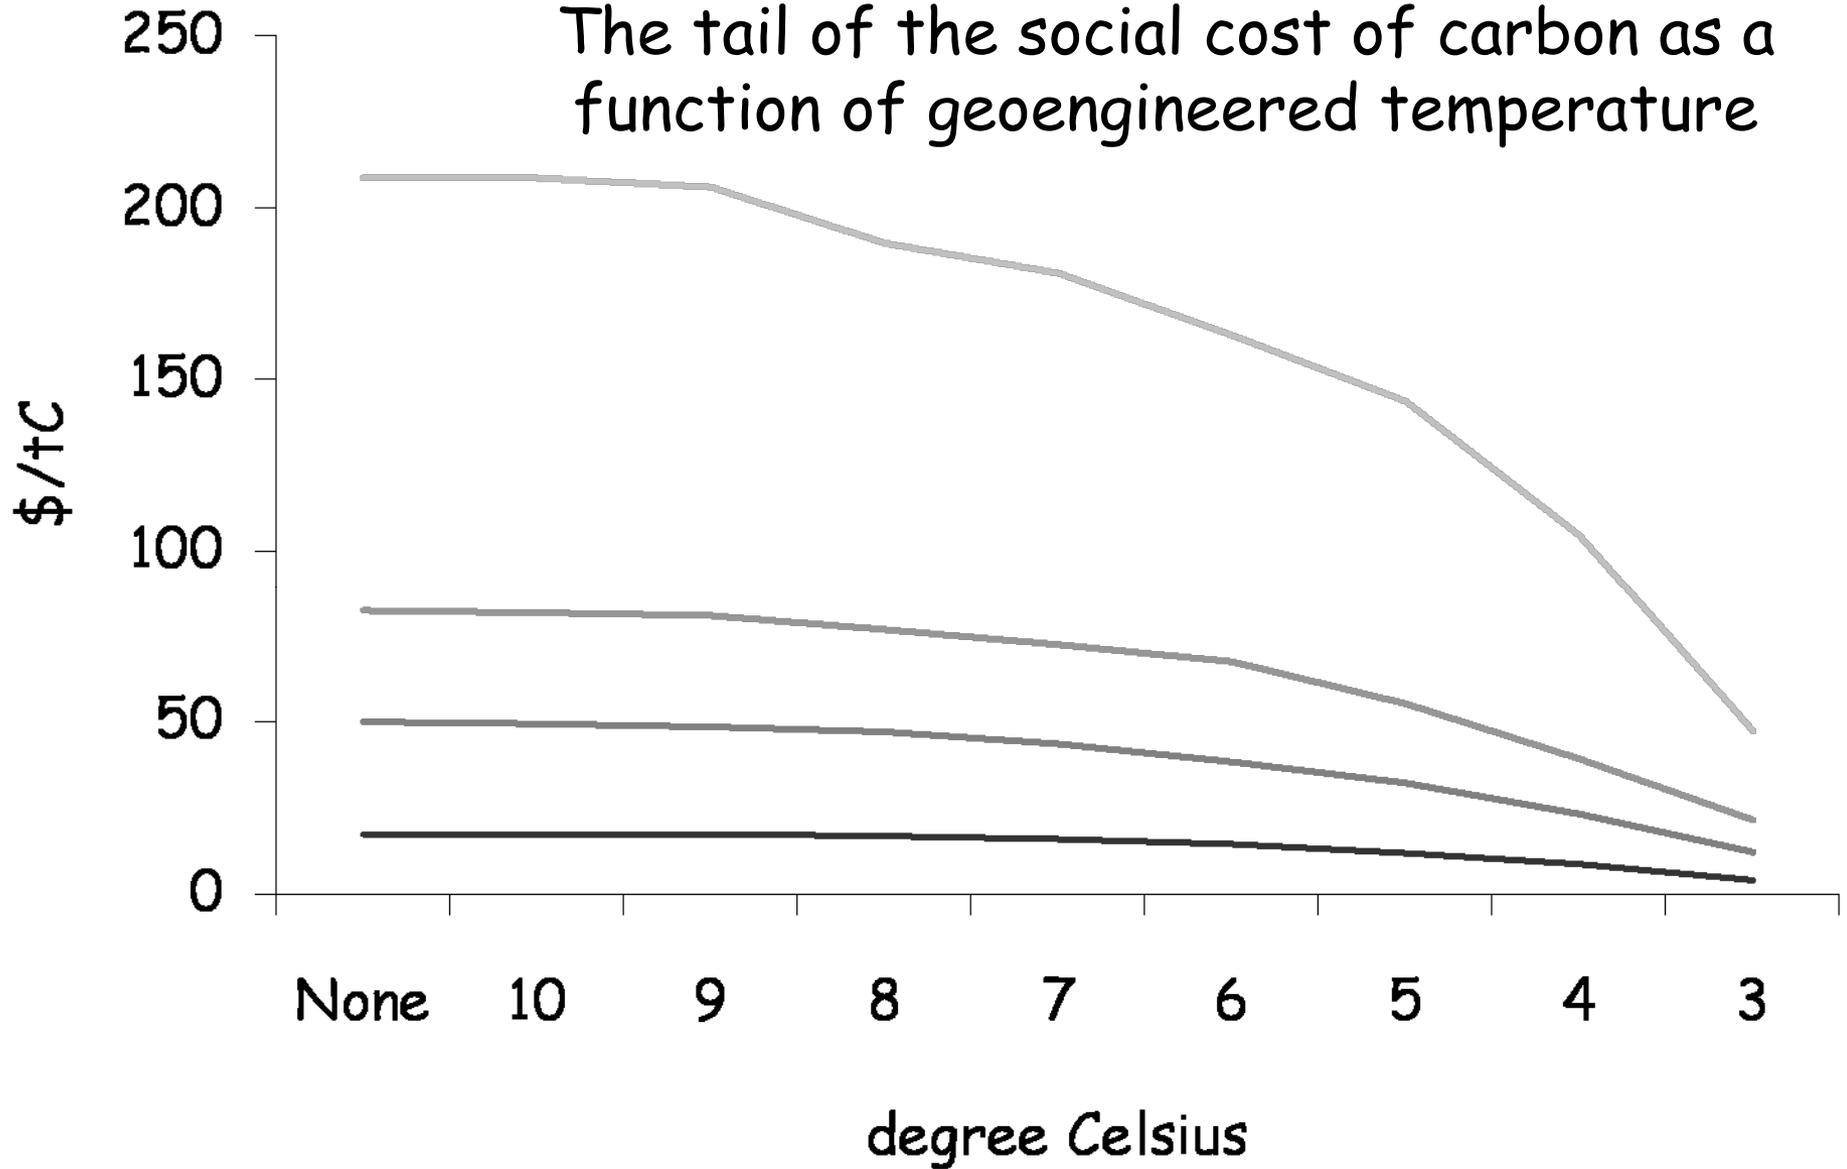

- Uncertainty is large with a fat tail and may not be bounded
- Policy should thus focus on reducing the uncertainty

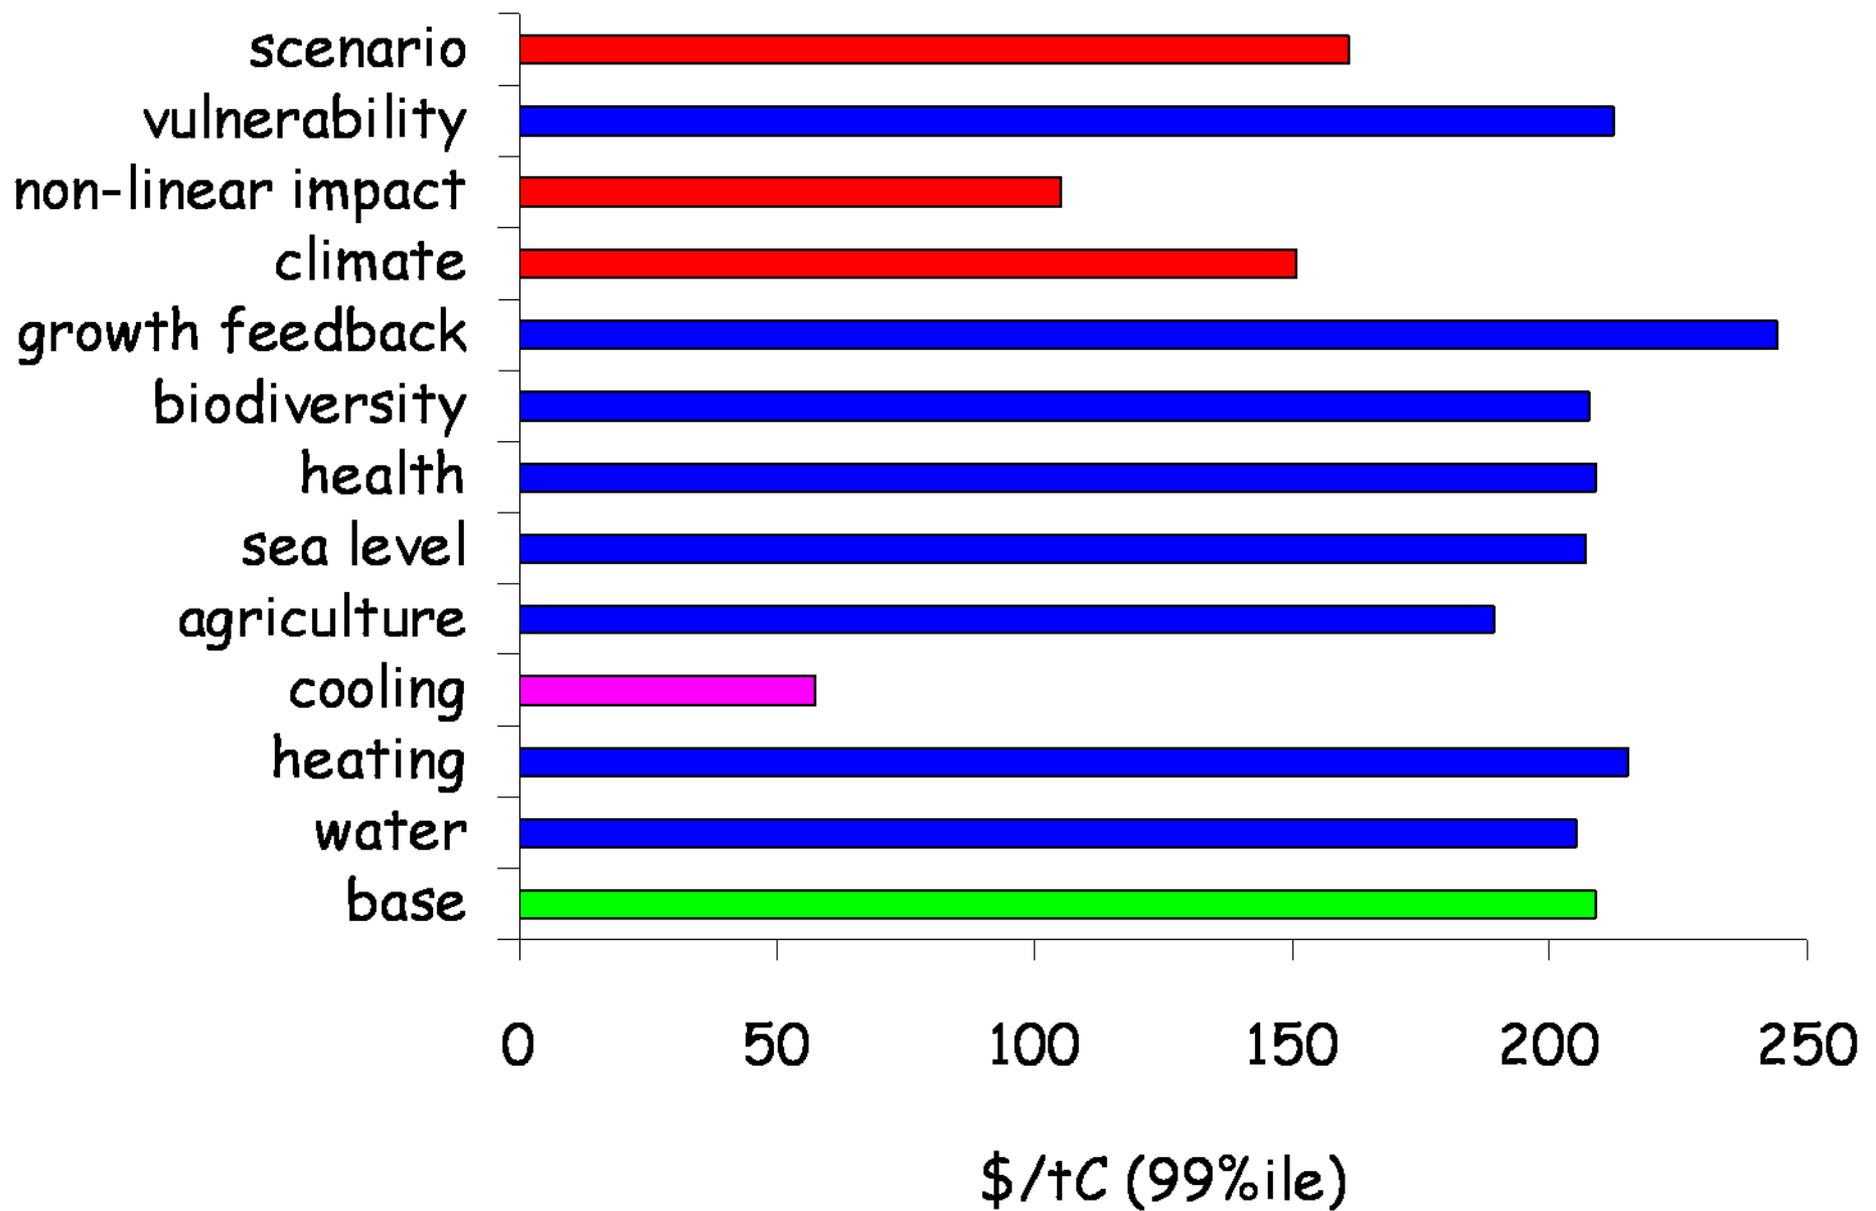

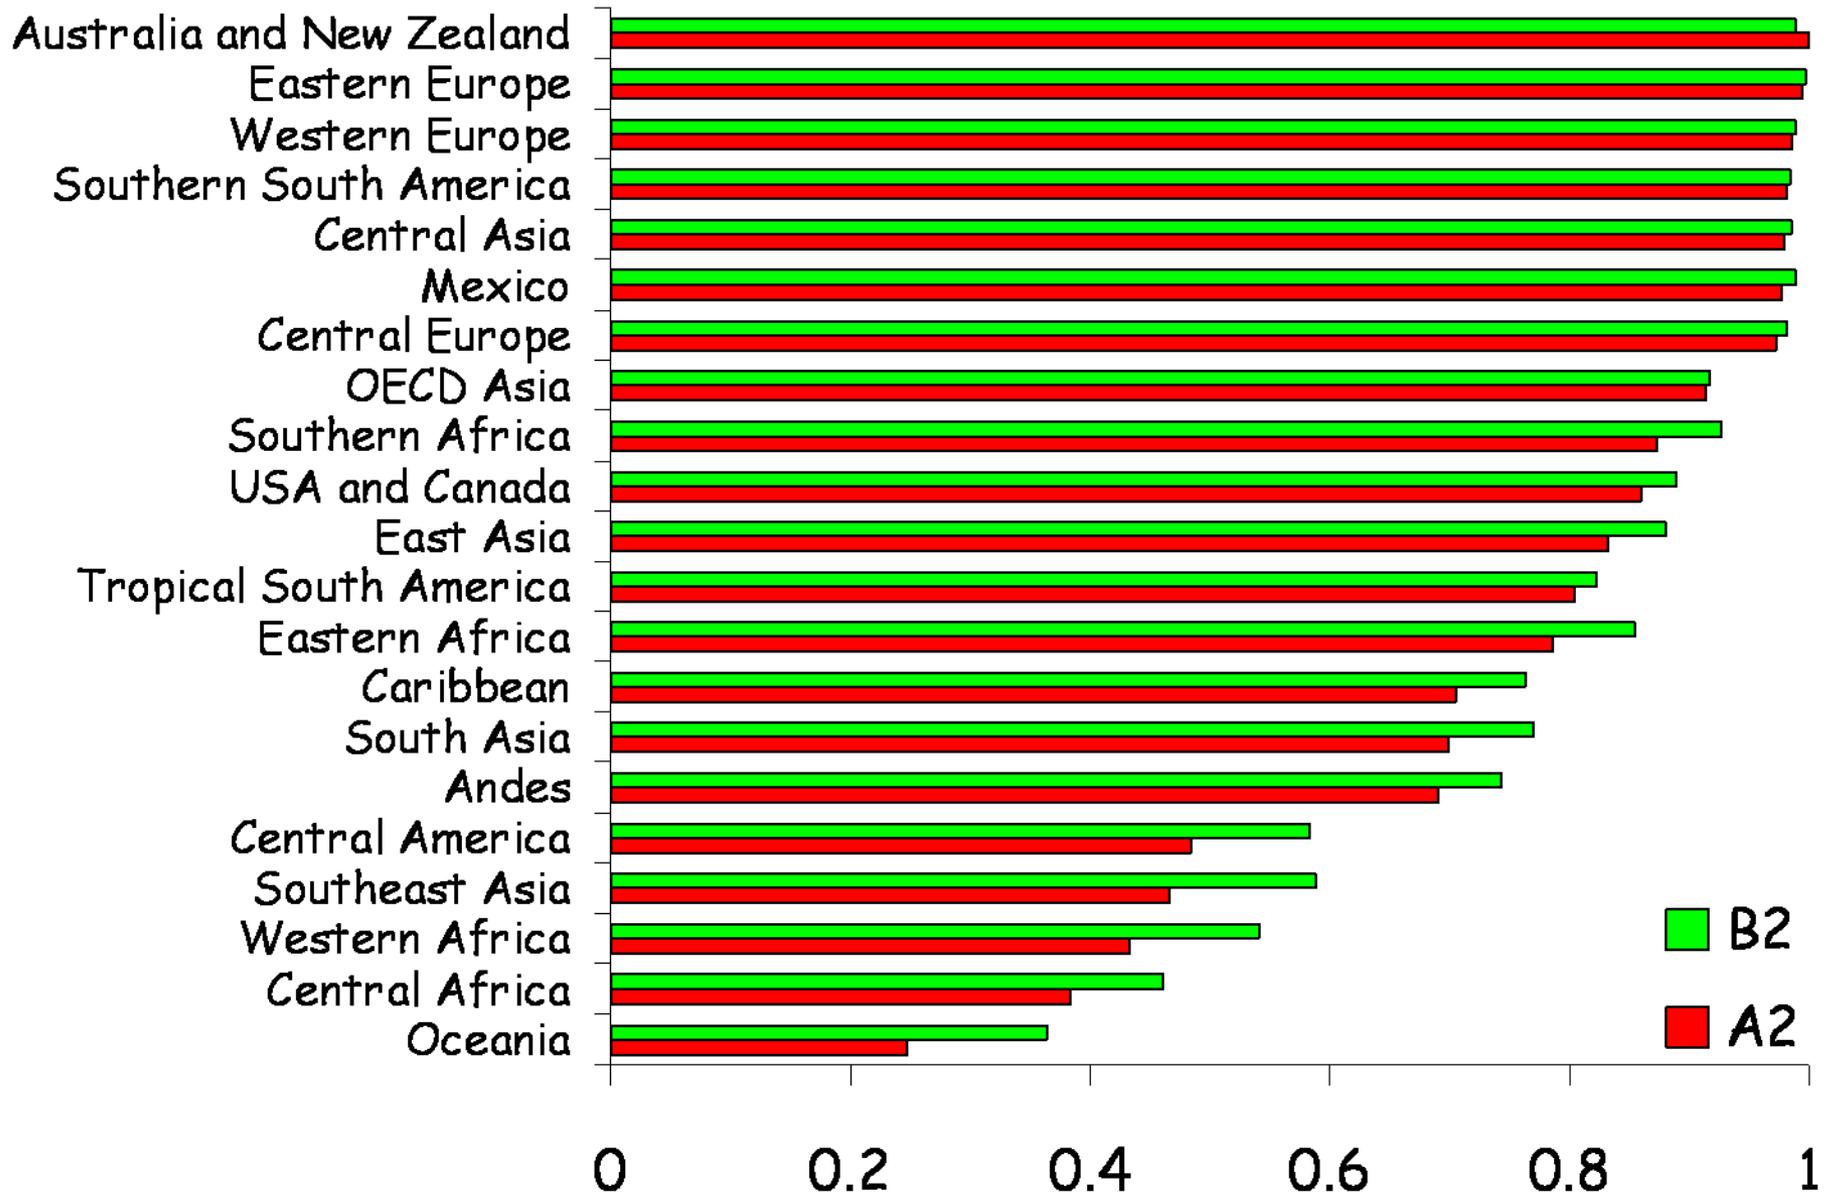

The tail of the social cost of carbon as a function of the initial global carbon tax

The tail of the social cost of carbon as a function of geoengineered temperature

Conclusions

- Uncertainty about the impact of climate change is very large indeed
- While research may help and emission reduction does help, a large share of the uncertainty is irreducible in the medium term
- This suggests that emission reduction should be driven as hard as palatable, while adaptive capacity should be improved as much as possible too
