   - Question
Scalar Convection-Diffusion Equation

- Combines the convection (or advection) and diffusion equations to describe physical phenomena where physical quantities are transferred inside a physical system due to two processes, namely, convection and diffusion.
- Convection is a transport mechanism of a substance or conserved property by a fluid due to the fluid’s bulk motion.
- Diffusion is the net movement of a substance from a region of high concentration to a region of low concentration.
- Also referred to by different communities as the drift-diffusion, Smoluchowski, or scalar transport equation.

\[
\frac{\partial c}{\partial t} + \nabla \cdot (\vec{a}c) = \nabla \cdot (D \nabla c) + S
\]

where \(c\) is the variable of interest (species concentration for mass transfer, temperature for heat transfer, \(\cdots\)), \(D\) is the diffusivity (or diffusion coefficient), \(\vec{a}\) is the average velocity of the quantity that is moving, and \(S\) describes sources or sinks of the quantity \(c\).
Scalar Convection-Diffusion Equation

<td>the diffusion coefficient is constant, there are no sources or sinks, and the velocity field describes an incompressible flow ($\vec{\nabla} \cdot \vec{a} = \vec{\nabla} \cdot \vec{v} = 0$)</td>
</tr>
</tbody>
</table>

$$\frac{\partial c}{\partial t} + \vec{a} \cdot \nabla c = D \nabla^2 c$$

in this form, the convection-diffusion equation combines both parabolic and hyperbolic partial differential equations

- Why is it a good representative model problem?
  - for an incompressible flow, the Navier-Stokes equations can be written as

\[
\frac{\partial (\rho \vec{v})}{\partial t} + \vec{v} \cdot \nabla (\rho \vec{v}) = \nabla^2 \left( \frac{\mu}{\rho} (\rho \vec{v}) \right) + (\vec{f} - \nabla p) \tag{1}
\]

where

\[
\nabla^2(\rho \vec{v}) = \left( \nabla^2(\rho v_x), \nabla^2(\rho v_y), \nabla^2(\rho v_z) \right)^T
\]

\[
= \left( \nabla \cdot \nabla (\rho v_x), \nabla \cdot \nabla (\rho v_y), \nabla \cdot \nabla (\rho v_z) \right)^T
\]

and $\vec{f}$ is a body force such as gravity
Why is it a good representative model problem? (continue)

- for an incompressible flow, the Navier-Stokes equations can be written as

\[
\frac{\partial (\rho \vec{v})}{\partial t} + \vec{v} \cdot \nabla (\rho \vec{v}) = \nabla^2 \left( \frac{\mu}{\rho} \rho \vec{v} \right) + (\vec{f} - \nabla p)
\]

- compare with the convection-diffusion equation when \( D \) is constant and the velocity field describes an incompressible flow (\( \nabla \cdot \vec{v} = 0 \))

\[
\frac{\partial c}{\partial t} + \vec{a} \cdot \nabla c = \nabla^2 (Dc) + S
\]

\(\Rightarrow\) the convection-diffusion equation mimics the incompressible Navier-Stokes equations
Dropping the pressure term from the incompressible Navier-Stokes equations (1) leads to

$$\frac{\partial (\rho \vec{v})}{\partial t} + \vec{v} \cdot \nabla (\rho \vec{v}) = \nabla^2 \left( \frac{\mu}{\rho} (\rho \vec{v}) \right) + \vec{f}$$

In one-dimension and assuming that $\mu$ is constant, the above equation simplifies to Burgers equation (proposed in 1939 by the Dutch scientist Johannes Martinus Burgers)

$$\frac{\partial v_x}{\partial t} + v_x \frac{\partial v_x}{\partial x} = \nu \frac{\partial^2 v_x}{\partial x^2} + g_x$$

where $\nu = \frac{\mu}{\rho}$ and $g_x = \frac{f_x}{\rho}$
The above equation can be transformed into a linear parabolic equation using the Hopf-Cole transformation (\(v_x = -2\nu\phi\frac{\partial \phi}{\partial x}\)) then solved exactly.

This allows one to compare numerically obtained solutions of this nonlinear equation with the exact one.

For all these reasons, the Burgers equation is often used to investigate the quality of a proposed CFD scheme.
For $\nu = 0$ and $g_x = 0$, the Burgers equation simplifies to

$$\frac{\partial \nu_x}{\partial t} + \nu_x \frac{\partial \nu_x}{\partial x} = 0$$

which is known as the inviscid Burgers equation.

- It is a prototype for equations whose solution can develop discontinuities (shock waves).
- It can be solved by the method of characteristics.
- It can be written in strong conservation law form as follows

$$\frac{\partial \nu_x}{\partial t} + \frac{\partial \left( \frac{\nu_x^2}{2} \right)}{\partial x} = 0$$
Consider the following inviscid Burgers problem

\[
\frac{\partial v_x}{\partial t} + \frac{\partial \left(\frac{v_x^2}{2}\right)}{\partial x} = 0
\]

\[v_x(x, 0) = \begin{cases} 
v_{xL} & \text{if } x < 0 \\
v_{xR} & \text{if } x > 0
\end{cases}
\]
Consider the following inviscid Burgers problem (continue)

- consider now scaling $x$ and $t$ by a constant $\alpha > 0$

$$\bar{x} = \alpha x, \quad \bar{t} = \alpha t, \quad \alpha > 0$$

- since

$$\frac{\partial}{\partial t} = \alpha \frac{\partial}{\partial \bar{t}}, \quad \text{and} \quad \frac{\partial}{\partial x} = \alpha \frac{\partial}{\partial \bar{x}}$$

the inviscid Burgers equation is not affected by this scaling

- furthermore, since the initial condition depends only on the sign of $x$, it is not affected by the above scaling

$$\implies$$ the inviscid Burgers problem defined above is scale invariant
Inviscid Burgers Equation

- Scale invariance often implies the risk of multiple solutions
  - if $v_x(x, t)$ is the solution of problem (2), then $u(x, t) = v_x(\alpha x, \alpha t)$ is also a solution of problem (2) for any $\alpha > 0$
  - hence, desiring uniqueness of the solution of the above problem is desiring $u \equiv v_x$ — that is
    \[
    v_x(x, t) = \bar{v}_x(\frac{x}{t})
    \]
  - this implies that the solution $v_x(x, t)$ is constant on the rays (characteristics) $x = ct$, and therefore the solution is said to be self-similar
  - in a homework, it will be shown that more precisely, the solution of problem (2) is
    \[
    v_x(x, t) = \bar{v}_x(\frac{x}{t}) = \frac{x}{t}
    \]
  - this solution is called a rarefaction wave centered at the origin ($x = t = 0$)
- A rarefaction wave can be attached to a constant solution.
- It can also join two constants.
In many circumstances, the uniqueness of the solution is enforced by imposing the condition that characteristics must impinge on a discontinuity from both sides, which is known as the \textit{Lax Entropy Condition}.

- Consider a shock located along the curve \( x = \gamma(t) \) and traveling at the speed \( V = \frac{dx}{dt} = \frac{d\gamma}{dt} \).

- Let \( v_{x_-}(t) \) and \( v_{x_+}(t) \) denote the left and right limits of the solution \( v_x(x, t) \) of problem (2), respectively.

- The Lax Entropy Condition states that

\[
v_{x_+}(t) < V < v_{x_-}(t)
\]

- In particular, the Lax Entropy Condition states that the solution must \textit{jump down}.

- For problem (2), it can be shown that for \( \alpha > 0 \), the solution jumps up at the discontinuity. Thus, the only admissible solution — that is, the solution in which any shock satisfies the Lax Entropy Condition — is the continuous solution which has no shock.
Scalar conservation laws are simple scalar models of the Euler equations.

They can be written in strong conservation form as

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = 0$$

(3)

Their integral form in the space-time domain \([x_1, x_2] \times [t^1, t^2]\) is

$$\int_{x_1}^{x_2} [u(x, t^2) - u(x, t^1)] \, dx + \int_{t^1}^{t^2} [f(u(x_2, t)) - f(u(x_1, t))] \, dt = 0$$

(4)
Scalar Conservation Laws

- The solutions of the integral form (4) may contain jump discontinuities: In this case, the discontinuous solutions are called weak solutions of the differential form (3).
- Jump discontinuities in the differential form (3) must satisfy a jump condition derived from the integral form: For a jump discontinuity traveling at a speed \( V \), the jump condition is

\[
f(u_+) - f(u_-) = V(u_+ - u_-) \iff [f(u)]_+^- = V[u]_+^-
\]

(5)

and therefore is analogous to the Rankine-Hugoniot relations (recall \( \overrightarrow{\mathcal{F}}^* \) here with \( \overrightarrow{\mathcal{F}}^*(u) = (u, f(u))^T \) and \( g(x, t) = x - x_o - V(t - t^0) \))
Using chain rule, the non conservation form (or wave speed form) of a scalar conservation law is

\[ \frac{\partial u}{\partial t} + a(u) \frac{\partial u}{\partial x} = 0 \]

where

\[ a(u) = \frac{df}{du} \]

\( a(u) \) is called the wave speed.
Examples

- \( f(u) = \frac{u^2}{2} \Rightarrow \text{Burgers equation} \)
- \( f(u) = au \Rightarrow \text{linear advection} \)
- \( f(u) = \frac{u^2}{u^2 + c(1 - u)^2} \), where \( c \) is a constant \( \Rightarrow \text{Bucku-Leverett equation which is a simple model of two-phase flow in a porous medium} \)
Scalar conservation laws support features analogous to simple expansion waves.

For scalar conservation laws, an expansion wave (or a rarefaction wave) is any region in which the wave speed \( a(u) \) increases from left to right:

\[
a(u(x, t)) \leq a(u(y, t)), \quad b_1(t) \leq x \leq y \leq b_2(t)
\]

A centered expansion fan is an expansion wave where all characteristics originate at a single point in the \( x - t \) plane (hence, the solution of problem (2) is a centered expansion fan).

Centered expansion fans must originate in the initial conditions or at intersections between shocks or contacts (see definitions below).
Scalar conservation laws support features analogous to simple compression and shock waves.

For scalar conservation laws, a compression wave is any region in which the wave speed $a(u)$ decreases from left to right:

$$a(u(x, t)) \geq a(u(y, t)), \quad b_1(t) \leq x \leq y \leq b_2(t)$$

A centered compression fan is a compression wave where all characteristics converge on a single point in the $x - t$ plane.

The converging characteristics in a compression wave must eventually intersect, creating a shock wave.

A shock wave is a jump discontinuity governed by the jump condition (5): From the mean value theorem, it follows that

$$V = \frac{df}{du}(\xi) = a(\xi), \quad u_- \leq \xi \leq u_+$$
A shock wave may originate in a jump discontinuity in the initial conditions or it may form spontaneously from a smooth compression wave.

In addition to the jump condition (5), shock waves must satisfy (think of the Lax Entropy Condition)

\[ a(u_-) \geq V \geq a(u_+) \]

If wave speeds are interpreted as slopes in the \( x - t \) plane, then the above equation implies that waves (characteristics) terminate on shocks and never originate in shocks (shocks only absorb waves — they never emit waves).
Scalar conservation laws support features analogous to the contact discontinuities.

For scalar conservation laws, a *contact discontinuity* is a jump discontinuity from $u_-$ to $u_+$ such that

$$ a(u_-) = a(u_+) $$

Like contacts in the Euler equations, contacts in scalar conservation laws must originate in the initial conditions or at the intersections of shocks.
In the theory of hyperbolic equations, a Riemann problem (named after Bernhard Riemann) consists of a conservation law equipped with uniform initial conditions on an infinite spatial domain, except for a single jump discontinuity.

In one-dimension (1D), for a hyperbolic problem governing the field $u$, the Riemann problem centered on $x = x_0$ and $t = t^0$ has the following initial conditions:

$$u(x, t^0) = \begin{cases} u_L & \text{if } x < x_0 \\ u_R & \text{if } x > x_0 \end{cases}$$

For example, problem (2) is a Riemann problem.

For convenience, the remainder of this chapter uses $x_0 = 0$ and $t^0 = 0$. 
In 1D, the Riemann problem has an exact analytical solution for the Euler equations, scalar conservation laws, and any linear system of equations.

Furthermore, the solution is self-similar (or self-preserving): It stretches uniformly in space as time increases but otherwise retains its shape, so that $u(x, t^1)$ and $u(x, t^2)$ are “similar” to each other for any two times $t^1$ and $t^2$. In other words, the solution depends on the single variable $\frac{x}{t}$ rather than on $x$ and $t$ separately.

The Riemann problem is very useful for the understanding of the Euler equations because shocks and rarefaction waves may appear as characteristics in the solution.

Riemann problems appear in a natural way in finite volume methods for the solution of equations of conservation laws due to the discreteness of the grid: They give rise to the Riemann solvers which are very popular in CFD.
Consider a 1D tube containing two regions of stagnant fluid at different pressures.

Suppose that the two regions are initially separated by a rigid diaphragm.

Suppose that this diaphragm is instantly removed (for example, by a small explosion):

- pressure imbalance $\Rightarrow$ 1D unsteady flow containing a steadily moving shock, a steadily moving simple centered expansion fan, and a steadily moving contact discontinuity separating the shock and expansion.
- the shock, expansion, and contact separate regions of uniform flow.
Riemann Problems

1D Riemann Problems for the Euler Equations
Riemann Problems

1D Riemann Problems for the Euler Equations

Shock Tube

- The flow in a shock tube has always zero initial velocity.
- Removing this restriction, the shock tube problem becomes the Riemann problem and thus is a special case of the Riemann problem.
- Major result:
  - like the shock tube problem, the Riemann problem may give rise to a steadily moving shock, a steadily moving simple centered expansion fan, and a steadily moving contact separating the shock and expansion, and the shock, expansion, and contact separate regions of uniform flow.
  - unlike the shock tube however, one or two of these waves may be absent.
Riemann Problems

1D Riemann Problems for the Euler Equations

**Governing Equations**

\[
\frac{\partial W}{\partial t} + \frac{\partial F_x}{\partial x} = 0
\]

\[
W = (\rho, \rho v_x, E)^T, \quad F_x = (\rho v_x, \rho v_x^2 + p, (E + p) v_x)^T
\]

\[
W(x, 0) = \begin{cases} 
W_L = (\rho_L, \rho_L v_{xL}^2, E_L)^T & \text{if } x < 0 \\
W_R = (\rho_R, \rho_R v_{xR}^2, E_R)^T & \text{if } x > 0 
\end{cases}
\]

(6)

with \( p = (\gamma - 1) \left( E - \rho \frac{v_x^2}{2} \right) \), and the speed of sound \( c \) given by

\[
c^2 = \frac{\gamma p}{\rho}
\]
First, consider the shock

- **in a frame moving with the shock**, the Riemann-Hugoniot conditions can be written as

\[
\begin{align*}
\rho_2 (v_{x2} - V) &= \rho_1 (v_{x1} - V) \\
\rho_2 (v_{x2} - V)^2 + p_2 &= \rho_1 (v_{x1} - V)^2 + p_1 \\
(E_2 + p_2) (v_{x2} - V) &= (E_1 + p_1) (v_{x1} - V)
\end{align*}
\]

where \( V \) is the speed of the shock
First, consider the shock (continue)

from the Rankine-Hugoniot conditions applied in a frame moving with the shock it follows that

\[
\frac{c_2^2}{c_1^2} = \left( \frac{p_2}{p_1} \right) \frac{\frac{\gamma+1}{\gamma-1} + \frac{p_2}{p_1}}{1 + \frac{\gamma+1}{\gamma-1} \left( \frac{p_2}{p_1} \right)} \tag{10}
\]

\[
v_{x_2} = v_{x_1} + c_1 \frac{\frac{p_2}{p_1} - 1}{\gamma} \sqrt{\frac{\gamma+1}{2\gamma} \left( \frac{p_2}{p_1} - 1 \right) + 1} \tag{11}
\]

\[
V = v_{x_1} + c_1 \sqrt{\frac{\gamma + 1}{2\gamma} \left( \frac{p_2}{p_1} - 1 \right) + 1} \tag{12}
\]
1D Riemann Problems

1D Riemann Problems for the Euler Equations

Exact Solution

Next, consider the contact discontinuity
- by definition

\[ \begin{align*}
    v_{x2} &= v_{x3} \\
    p_2 &= p_3
\end{align*} \tag{13, 14} \]

Finally, consider the simple centered expansion fan
- recall that a simple wave is a wave where all states lie on the same integral curve of one of the characteristic families
- recall that for the 1D Euler equations, an expansion wave is a wave where the speeds \( v_x \pm c \) increase monotonically from left to right
- recall that a simple wave in the entropy characteristic family is a wave in which \( v_x = cst \) and \( p = cst \) \( \Rightarrow \) entropy waves cannot create expansions
- it follows that the simple centered expansion fan here is a simple centered acoustic fan associated with the characteristic curve

\[ dx = (v_x - c) dt \]
Finally, consider the simple centered expansion fan (continue)

along the integral curve of a simple centered expansion fan associated with the characteristic curve \( dx = (v_x - c)dt \), the two Riemann invariants \( \xi_0 \) and \( \xi_+ \) are constant

\[
\xi_0 = s = \text{cst} \Rightarrow p = \text{cst} \rho^\gamma \quad \text{and} \quad c = \sqrt{\text{cst} \gamma \rho^{-2}} \Rightarrow \int \frac{dp}{\rho c} = \frac{2c}{\gamma - 1}
\]

\[
\xi_+ = v_x + \int \frac{dp}{\rho c} \Rightarrow \quad \xi_+ = v_x + \frac{2c}{\gamma - 1} \quad \text{for} \quad dx = (v_x + c)dt
\]

(and \( \xi_- = v_x - \frac{2c}{\gamma - 1} \) for \( dx = (v_x - c)dt \))

hence, along the integral curve of a simple centered expansion fan associated with the characteristic curve \( dx = (v_x - c)dt \) and on this characteristic curve

\[
s = \text{cst}, \quad v_x + \frac{2c}{\gamma - 1} = \text{cst}, \quad \text{and} \quad v_x - \frac{2c}{\gamma - 1} = \text{cst}
\]

therefore in this flow region, all flow properties are constant and \( dx = (v_x - c)dt \) becomes the straight line \( x = (v_x - c)t + \text{cst} \)
Finally, consider the simple centered expansion fan (continue)

now, along the integral curve of a simple centered expansion fan
associated with the characteristic curve $x = (v_x - c)t + cst$

$$v_x + \frac{2c}{\gamma - 1} = v_{x_4} + \frac{2c_4}{\gamma - 1}$$

hence along this integral curve and on the characteristic curve
$x = (v_x - c)t \Leftrightarrow c = v_x - \frac{x}{t}$ the following holds

$$v_x + \frac{2}{\gamma - 1} \left( v_x - \frac{x}{t} \right) = v_{x_4} + \frac{2c_4}{\gamma - 1}$$

$$\begin{align*}
    v_x(x, t) &= \frac{2}{\gamma + 1} \left( \frac{x}{t} + \frac{\gamma - 1}{2} v_{x_4} + c_4 \right) \\
    c(x, t) &= \frac{2}{\gamma + 1} \left( \frac{x}{t} + \frac{\gamma - 1}{2} v_{x_4} + c_4 \right) - \frac{x}{t} \\
    p &= p_4 \left( \frac{c}{c_4} \right)^{\frac{2\gamma}{\gamma - 1}}
\end{align*}$$

(15)
Riemann Problems

1D Riemann Problems for the Euler Equations

Combine now the shock, contact, and expansion results to determine \( \frac{p_2}{p_1} \) across the shock in terms of the known ratio \( \frac{p_4}{p_1} = \frac{p_L}{p_R} \)

- simple wave condition \( v_x + \frac{2c}{\gamma - 1} = \text{cst} \) implies

\[
v_{x_3} + \frac{2c_3}{\gamma - 1} = v_{x_4} + \frac{2c_4}{\gamma - 1}
\]

(16)

- from the third of equations (15) and (16) it follows that

\[
v_{x_3} = v_{x_4} + \frac{2c_4}{\gamma - 1} \left[ 1 - \left( \frac{p_3}{p_4} \right)^{\frac{\gamma-1}{2\gamma}} \right]
\]

(17)

- from (13), (14) and (16) it follows that

\[
v_{x_2} = v_{x_4} + \frac{2c_4}{\gamma - 1} \left[ 1 - \left( \frac{p_2}{p_4} \right)^{\frac{\gamma-1}{2\gamma}} \right] = v_{x_4} + \frac{2c_4}{\gamma - 1} \left[ 1 - \left( \frac{p_1}{p_4} \frac{p_2}{p_1} \right)^{\frac{\gamma-1}{2\gamma}} \right]
\]

(18)
Riemann Problems

1D Riemann Problems for the Euler Equations

- Solving equation (18) for \( \frac{p_4}{p_1} \) gives

\[
\frac{p_4}{p_1} = \frac{p_2}{p_1} \left[ 1 + \frac{\gamma - 1}{2c_4} (v_{x_4} - v_{x_1}) \right]^{-\frac{2\gamma}{\gamma - 1}} \tag{19}
\]

- Finally, combining (11) and (19) delivers the nonlinear equation in \( \frac{p_2}{p_1} \)

\[
\frac{p_4}{p_1} = \frac{p_2}{p_1} \left\{ 1 + \frac{\gamma - 1}{2c_4} \left[ v_{x_4} - v_{x_1} - \frac{c_1}{\gamma} \frac{p_2}{p_1} - 1 \right] \right\}^{-\frac{2\gamma}{\gamma - 1}} \tag{20}
\]

which can be solved by a preferred numerical method to obtain \( \frac{p_2}{p_1} \) and therefore \( p_2 \).
Once $p_2$ is found, equation (11) gives $v_{x_2}$, equation (10) gives $c_2$, and equation (12) gives the speed of the shock $V$, which completely determines the state 2.

Then, equations (13) and (14) give $v_{x_3}$ and $p_3$ and equation (16) gives $c_3$, which completely determines state 3.

Finally, the first, second, and third of equations (15) deliver $v_x$, $c$, and $p$ inside the expansion, respectively.

In some cases (depending on the values of $W_L$ and $W_R$), the Riemann problem may yield only one or two waves, instead of three: To a large extent, the solution procedure described above handles such cases automatically.
The exact solution of the Riemann problem (6) is (relatively) expensive because finding $p_2$ requires solving the nonlinear equation (20).

To this effect, approximate Riemann problems are often constructed as surrogate Riemann problems for the Euler equations.

Here, the family of approximate Riemann problems based on a linearization of problem (6) is considered in the general case of $m$ dimensions.
Riemann Problems

Riemann Problems for the Linearized Euler Equations

Consider the linear Riemann problem

\[
\frac{\partial W}{\partial t} + A \frac{\partial W}{\partial x} = 0
\]

\[
W(x,0) = \begin{cases} 
W_L & \text{if } x < 0 \\
W_R & \text{if } x > 0 
\end{cases}
\]  

(21)

where \( A \) is a constant \( m \times m \) matrix whose construction is discussed in the next section.

Assume that \( A \) is diagonalizable

\[
A = Q^{-1} \Lambda Q, \quad \Lambda = \text{diag}(\lambda_1, \cdots, \lambda_m)
\]

where \( Q \) and \( \Lambda \) are constant matrices, and that \( r_i \) and \( l_i \), \( i = 1, \ldots, m \) are its right and left eigenvectors, respectively

\[
Ar_i = \lambda_i r_i, \quad A^T l_i = \lambda_i l_i \quad (\text{or } l_i^T A = \lambda_i l_i^T)
\]
Riemann Problems

Riemann Problems for the Linearized Euler Equations

In the linear case, the change to characteristic variables \( d\xi = QdW \) simplifies to

\[ \xi = QW \]

and leads to the following characteristic form of problem (21)

\[ \frac{\partial \xi}{\partial t} + \Lambda \frac{\partial \xi}{\partial x} = 0 \]

\[ \xi(x, 0) = \begin{cases} 
\xi_L = QW_L & \text{if } x < 0 \\
\xi_R = QW_R & \text{if } x > 0 
\end{cases} \]

The individual form of the above problem is

\[ \frac{\partial \xi_i}{\partial t} + \lambda_i \frac{\partial \xi_i}{\partial x} = 0, \quad i = 1, \ldots, m \]

\[ \xi_i(x, 0) = \begin{cases} 
\xi_{Li} = I_i^T W_L & \text{if } x < 0 \\
\xi_{Ri} = I_i^T W_R & \text{if } x > 0 
\end{cases} \]
Riemann Problems

Riemann Problems for the Linearized Euler Equations
Since $\lambda_i$ is constant, the solution of problem (22) is trivial: For $m = 3$, it can be written as $(\lambda_1 > \lambda_2 > \lambda_3)$

$$
\xi(x, t) = \xi\left(\frac{x}{t}\right) = \begin{cases} 
(\xi_{L1}, \xi_{L2}, \xi_{L3})^T & \text{if } \frac{x}{t} < \lambda_3 \\
(\xi_{L1}, \xi_{L2}, \xi_{R3})^T & \text{if } \lambda_3 < \frac{x}{t} < \lambda_2 \\
(\xi_{L1}, \xi_{R2}, \xi_{R3})^T & \text{if } \lambda_2 < \frac{x}{t} < \lambda_1 \\
(\xi_{R1}, \xi_{R2}, \xi_{R3})^T & \text{if } \frac{x}{t} > \lambda_1
\end{cases}
$$

(23)

If $\Delta W = W_R - W_L$, then $\Delta \xi = Q \Delta W$, and $\Delta \xi_i = I_i^T \Delta W$ is often referred to as the strength or amplitude of the $i$-th wave.

Let

$$
\Delta \xi^1 = (\Delta \xi_1, 0, 0)^T, \quad \Delta \xi^2 = (0, \Delta \xi_2, 0)^T, \quad \Delta \xi^3 = (0, 0, \Delta \xi_3)^T
$$

Note that the superscripts used above are NOT powers: They are used only to distinguish each of the above vector quantities from the scalar jump $\Delta \xi_i$ in the $i$-th characteristic.
Riemann Problems

Riemann Problems for the Linearized Euler Equations

Noting that $\Delta \xi_1 + \Delta \xi_2 + \Delta \xi_3 = \Delta \xi = \xi_R - \xi_L$, the solution (23) can be rewritten as

$$
\xi(x, t) = \xi\left(\frac{x}{t}\right) = \begin{cases} 
\xi_L = \xi_R - \Delta \xi_3 - \Delta \xi_2 - \Delta \xi_1 & \text{if } \frac{x}{t} < \lambda_3 < \lambda_2 < \lambda_1 \\
\xi_L + \Delta \xi_3 = \xi_R - \Delta \xi_2 - \Delta \xi_1 & \text{if } \lambda_3 < \frac{x}{t} < \lambda_2 < \lambda_1 \\
\xi_L + \Delta \xi_3 + \Delta \xi_2 = \xi_R - \Delta \xi_1 & \text{if } \lambda_3 < \lambda_2 < \frac{x}{t} < \lambda_1 \\
\xi_L + \Delta \xi_3 + \Delta \xi_2 + \Delta \xi_1 = \xi_R & \text{if } \lambda_3 < \lambda_2 < \lambda_1 < \frac{x}{t}
\end{cases}
$$

(24)

Noting that $Q^{-1} \Delta \xi_i = \Delta \xi_i r_i$, $i = 1, 2, 3$, the solution (24) can be rewritten in terms of the original variables $W = Q^{-1} \xi$ as follows

$$
W\left(\frac{x}{t}\right) = \begin{cases} 
W_L = W_R - \Delta \xi_3 r_3 - \Delta \xi_2 r_2 - \Delta \xi_1 r_1 & \text{if } \frac{x}{t} < \lambda_3 < \lambda_2 < \lambda_1 \\
W_L + \Delta \xi_3 r_3 = W_R - \Delta \xi_2 r_2 - \Delta \xi_1 r_1 & \text{if } \lambda_3 < \frac{x}{t} < \lambda_2 < \lambda_1 \\
W_L + \Delta \xi_3 r_3 + \Delta \xi_2 r_2 = W_R - \Delta \xi_1 r_1 & \text{if } \lambda_3 < \lambda_2 < \frac{x}{t} < \lambda_1 \\
W_L + \Delta \xi_3 r_3 + \Delta \xi_2 r_2 + \Delta \xi_1 r_1 = W_R & \text{if } \lambda_3 < \lambda_2 < \lambda_1 < \frac{x}{t}
\end{cases}
$$

(25)
Riemann Problems for the Linearized Euler Equations

Many CFD methods do not use the solution of a Riemann problem directly, whether expressed in terms of $\xi$ or $W$, but use instead only the flux at $x = 0$.

Here, the flux function at $x = 0$ is $AW(0)$.

From (25), it follows that

$$AW(0) = \begin{cases} 
AW_L = AW_R - \Delta \xi_3 \lambda_3 r_3 - \Delta \xi_2 \lambda_2 r_2 - \Delta \xi_1 \lambda_1 r_1 & \text{if } 0 < \lambda_3 < \lambda_2 < \lambda_1 \\
AW_L + \Delta \xi_3 \lambda_3 r_3 = AW_R - \Delta \xi_2 \lambda_2 r_2 - \Delta \xi_1 \lambda_1 r_1 & \text{if } \lambda_3 < 0 < \lambda_2 < \lambda_1 \\
AW_L + \Delta \xi_3 \lambda_3 r_3 + \Delta \xi_2 \lambda_2 r_2 = AW_R - \Delta \xi_1 \lambda_1 r_1 & \text{if } \lambda_3 < \lambda_2 < 0 < \lambda_1 \\
AW_L + \Delta \xi_3 \lambda_3 r_3 + \Delta \xi_2 \lambda_2 r_2 + \Delta \xi_1 \lambda_1 r_1 = AW_R & \text{if } \lambda_3 < \lambda_2 < \lambda_1 < 0 
\end{cases}$$

Let $\lambda_i^- = \min(0, \lambda_i)$ and $\lambda_i^+ = \max(0, \lambda_i) \Rightarrow \lambda_i^+ - \lambda_i^- = |\lambda_i|$

Then, the flux function at $x = 0$ can be rewritten as

$$AW(0) = AW_L + \sum_{i=1}^{3} \lambda_i^- \Delta \xi_i r_i = AW_R - \sum_{i=1}^{3} \lambda_i^+ \Delta \xi_i r_i$$

$$= \frac{1}{2} A(W_R + W_L) - \frac{1}{2} \sum_{i=1}^{3} |\lambda_i| \Delta \xi_i r_i \quad (26)$$
Riemann Problems

Riemann Problems for the Linearized Euler Equations

Note that

\[ \lambda_i^+ - \lambda_i^- = |\lambda_i| \implies \Lambda^+ - \Lambda^- = |\Lambda| \]

\[ \lambda_i^+ + \lambda_i^- = \lambda_i \implies \Lambda^+ + \Lambda^- = \Lambda \]

(Definitions)

\[ A^+ = Q^{-1}\Lambda^+ Q, \quad A^- = Q^{-1}\Lambda^- Q, \quad |A| = Q^{-1}|\Lambda|Q \]

\[ A^+ + A^- = A, \quad A^+ - A^- = |A| \]

It follows that

\[ \sum_{i=1}^{3} |\lambda_i| \Delta \xi_i r_i = Q^{-1}\sum_{i=1}^{3} |\lambda_i| \Delta \xi^i = Q^{-1}|\Lambda| \left( \sum_{i=1}^{3} \Delta \xi^i \right) = |A|(W_R - W_L) \]

Hence, the solution (26) can be written as

\[ AW(0) = AW_L + A^-(W_R - W_L) = AW_R - A^+(W_R - W_L) \]

\[ = \frac{1}{2}A(W_R + W_L) - \frac{1}{2}|A|(W_R - W_L) \]  \hspace{1cm} (27)
Consider first any nonlinear scalar function \( f(w) \), where \( w \) is also a scalar variable, and let

\[
a(w) = \frac{df(w)}{dw}
\]

Two linear approximations of this function are the *tangent* line and *secant* line approximations.
Tangent line approximations

about $w_R$: $f(w) \approx f(w_R) + a(w_R)(w - w_R)$

about $w_L$: $f(w) \approx f(w_L) + a(w_L)(w - w_L)$

These two approximations are more accurate near $w_R$ and $w_L$, respectively.
Secant line approximation

\[ f(w) = f(w_R) + a_{RL}(w - w_R) \iff f(w) = f(w_L) + a_{RL}(w - w_L) \]

where

\[ a_{RL} = \frac{f(w_R) - f(w_L)}{w_R - w_L} \]

It is more accurate on average over the entire region between \( w_L \) and \( w_R \).
The mean value theorem connects tangent line and secant line approximations as follows

\[ a_{RL} = a(\eta) \quad \text{for} \ \eta \ \text{between} \ w_L \ \text{and} \ w_R \]

which essentially states that secant line slopes are average tangent line slopes
Roe’s Approximate Riemann Solver for the Euler Equations

Secant Approximations

- Consider next any nonlinear vector function $f(W)$, where $W$ is also a vector.
- The tangent plane approximation about $W_L$ is defined as
  
  $$f(W) \approx f(W_L) + A(W_L)(W - W_L)$$
  
  where $A = \frac{df}{dW}$ is the Jacobian matrix.
- A secant plane is any plane containing the line connecting $W_L$ and $W_R$: There are an infinite number of such planes.
- Secant plane approximations are defined as follows
  
  $$f(W) \approx f(W_L) + A_{RL}(W - W_L)$$
  
  where $A_{RL}$ is any matrix such that
  
  $$f(W_R) - f(W_L) = A_{RL}(W_R - W_L)$$

  (28)

- Note that if each of $W$ and $f(W)$ is a vector with $m$ components, $A_{RL}$ is a matrix with $m^2$ elements: Hence, equation (28) consists of $m$ equations with $m^2$ unknowns.
Roe’s Approximate Riemann Solver for the Euler Equations

Secant Approximations
Roe’s Approximate Riemann Solver for the Euler Equations

Secant Approximations

**Example 1**

\[
\begin{pmatrix}
\frac{f_1(W_R) - f_1(W_L)}{W_{R1} - W_{L1}} & 0 & 0 \\
0 & \frac{f_2(W_R) - f_2(W_L)}{W_{R2} - W_{L2}} & 0 \\
0 & 0 & \frac{f_3(W_R) - f_3(W_L)}{W_{R3} - W_{L3}}
\end{pmatrix}
\]

**Example 2**

\[
\frac{1}{3} \begin{pmatrix}
\frac{f_1(W_R) - f_1(W_L)}{W_{R1} - W_{L1}} & \frac{f_1(W_R) - f_1(W_L)}{W_{R2} - W_{L2}} & \frac{f_1(W_R) - f_1(W_L)}{W_{R3} - W_{L3}} \\
\frac{f_2(W_R) - f_2(W_L)}{W_{R1} - W_{L1}} & \frac{f_2(W_R) - f_2(W_L)}{W_{R2} - W_{L2}} & \frac{f_2(W_R) - f_2(W_L)}{W_{R3} - W_{L3}} \\
\frac{f_3(W_R) - f_3(W_L)}{W_{R1} - W_{L1}} & \frac{f_3(W_R) - f_3(W_L)}{W_{R2} - W_{L2}} & \frac{f_3(W_R) - f_3(W_L)}{W_{R3} - W_{L3}}
\end{pmatrix}
\]
By analogy with the scalar case, suppose one requires that in the vector case, secant planes be average tangent planes: In this case

\[ A_{RL} = A(W_{RL}) \]

where \( W_{RL} \) is an average between \( W_R \) and \( W_L \), and there are only \( m \) unknowns — the components of \( W_{RL} \) — that can be determined by solving equation (28).
Consider now the one-dimensional Euler equations: For these equations, the conservative state vector \( W \), flux vector \( F_x \), and Jacobian matrix \( A = \frac{\partial F_x}{\partial W} \) can be written as

\[
W = \left( \rho, \rho v_x, \frac{1}{\gamma} H + \frac{1}{2\gamma} (\gamma - 1) \rho v_x^2 \right)^T
\]

\[
F_x = \left( \rho v_x, \rho v_x^2 + p, (E + p)v_x \right)^T = \left( \rho v_x, \frac{\gamma - 1}{\gamma} H + \frac{\gamma + 1}{2\gamma} \rho v_x^2, Hv_x \right)^T
\]

\[
A = \begin{pmatrix}
    0 & 1 & 0 \\
    \frac{\gamma - 3}{2} v_x^2 & (\gamma - 1) v_x^2 & 0 \\
    -v_x \frac{H}{\rho} + \frac{1}{2} (\gamma - 1) v_x^3 & \frac{H}{\rho} - (\gamma - 1) v_x^2 & \gamma - 1
\end{pmatrix}
\]

where \( H = E + p \) is the total enthalpy per unit volume (and \( h = \frac{H}{\rho} \) is the specific enthalpy)
Roe’s Approximate Riemann Solver for the Euler Equations

Roe Averages

Choose $A_{RL} = A(W_{RL})$: In this case, equation (29) leads to the Roe-average Jacobian matrix

\[
A_{RL} = \begin{pmatrix}
0 & 1 & 0 \\
\frac{\gamma-3}{2} v^2_{xRL} & (3 - \gamma) v_{xRL} & \gamma - 1 \\
-v_{xRL} h_{RL} + \frac{1}{2} (\gamma - 1) v^3_{xRL} & h_{RL} - (\gamma - 1) v^2_{xRL} & \gamma v_{xRL}
\end{pmatrix}
\]

(30)

Solving equation (28) using the above Roe-average Jacobian matrix leads after several algebraic manipulations to

\[
v_{xRL} = \frac{\sqrt{\rho R} v_{xR} + \sqrt{\rho L} v_{xL}}{\sqrt{\rho R} + \sqrt{\rho L}}
\]

\[
h_{RL} = \frac{H_R}{\sqrt{\rho R}} + \frac{H_L}{\sqrt{\rho L}} = \sqrt{\rho R} h_R + \sqrt{\rho L} h_L
\]

\[
\rho_{RL} = \sqrt{\rho R \rho L}
\]

\[
\implies c_{RL} = \sqrt{(\gamma - 1) \left( h_{RL} - \frac{1}{2} v^2_{xRL} \right)}
\]
Roe’s approximate Riemann solver
Roe’s approximate Riemann solver for the Euler equations ($f = \mathcal{F}_x$) is based on two ideas:

1. the linear (secant) approximation of the flux vector

$$\mathcal{F}_x(W) \approx \mathcal{F}_x(W_L) + A_{RL}(W - W_L) = \mathcal{F}_x(W_R) + A_{RL}(W - W_R)$$  \hspace{1cm} (31)

where $A_{RL}$ is the Roe-average Jacobian given in (30), and

2. the exact solution of the Riemann problem (21) with $A = A_{RL}$ (see also (25) for $A = A_{RL}$)

Indeed, substituting (31) into the Euler equations (6) gives

$$\frac{\partial W}{\partial t} + \frac{\partial}{\partial x} \{\mathcal{F}_x(W_L) + A_{RL}(W - W_L)\} = \frac{\partial W}{\partial t} + A_{RL} \frac{\partial W}{\partial x} = 0$$

From (31) and (27), it follows that Roe’s approximate Riemann solver computes the fluxes at $x = 0$ as

$$\mathcal{F}_x(W(0)) \approx \mathcal{F}_x(W_L) + A_{RL}(W(0) - W_L) = \mathcal{F}_x(W_R) + A_{RL}(W(0) - W_R)$$

$$\approx \frac{1}{2} (\mathcal{F}_x(W_R) + \mathcal{F}_x(W_L)) + A_{RL}(W(0)) - \frac{1}{2} A_{RL}(W_R + W_L)$$

$$= \frac{1}{2} (\mathcal{F}_x(W_R) + \mathcal{F}_x(W_L)) + \frac{1}{2} A_{RL}(W_R + W_L) - \frac{1}{2} |A_{RL}|(W_R - W_L)$$

$$- \frac{1}{2} A_{RL}(W_R + W_L)$$

$$= \frac{1}{2} (\mathcal{F}_x(W_R) + \mathcal{F}_x(W_L)) - \frac{1}{2} |A_{RL}|(W_R - W_L)$$
Roe’s Approximate Riemann Solver for the Euler Equations

Algorithm and Performance

- Like the true (exact) Riemann solver, Roe’s approximate Riemann solver yields three equally-spaced waves (see previous Figure).
- Unlike in the true Riemann solver however, all three waves in Roe’s approximate Riemann solver have zero spread (hence, Roe’s approximate Riemann solver cannot capture the finite spread of the expansion fan).
- Roe’s approximate Riemann solver for the Euler equations is roughly 2.5 times faster than the exact Riemann solver.
Roe’s Approximate Riemann Solver for the Euler Equations

Algorithm and Performance

- Suppose that the exact Riemann problem yields a single shock or a single contact with speed $V$.
- The shock or contact must satisfy the Rankie-Hugoniot conditions:
  \[ F_x(W_R) - F_x(W_L) = V(W_R - W_L) \]
- For Roe’s approximate Riemann solver, $A_{RL}$ must satisfy the secant plane condition:
  \[ F_x(W_R) - F_x(W_L) = A_{RL}(W_R - W_L) \]
- It follows that
  \[ A_{RL}(W_R - W_L) = V(W_R - W_L) \]
  which implies that $V$ is an eigenvalue of $A_{RL}$ and $W_R - W_L$ is a right eigenvector of $A_{RL}$.
Roe’s Approximate Riemann Solver for the Euler Equations

Algorithm and Performance

- Let $V = \lambda_j$ and $W_R - W_L = r_j$: then, the strength of the $i$-the wave is given by

$$\Delta \xi_i = I_i^T r_j = \delta_{ij} (QQ^{-1} = I) = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases}$$

- In other words, two of the three waves have zero strength and the single non trivial wave makes the full transition between $W_L$ and $W_R$ at the speed $V$ (recall (25))

- It follows that for a single shock or a single contact, Roe’s approximate Riemann solver — as a matter of fact, any secant plane approximation — yields the exact solution!

- Except in the above case however, Roe’s approximate Riemann solver deviates substantially from the true Riemann solver: more specifically, unlike the true nonlinear flux function, Roe’s linear flux function allows for expansion shocks — that is, jump discontinuities which satisfy the Rankine-Hugoniot relations — which expand rather than compress the flow and therefore violate the second law of thermodynamics
Recall that Roe’s solver computes the flux at zero as

\[ \mathcal{F}_x(W(0)) \approx \mathcal{F}_x(W_L) + A_{RL}(W(0) - W_L) = \mathcal{F}_x(W_R) + A_{RL}(W(0) - W_R) \]

\[ \approx \frac{1}{2} (\mathcal{F}_x(W_R) + \mathcal{F}_x(W_L)) + A_{RL}(W(0)) - \frac{1}{2} A_{RL}(W_R + W_L) \]

\[ = \frac{1}{2} (\mathcal{F}_x(W_R) + \mathcal{F}_x(W_L)) + \frac{1}{2} A_{RL}(W_R + W_L) - \frac{1}{2} |A_{RL}|(W_R - W_L) \]

\[ \quad - \frac{1}{2} A_{RL}(W_R + W_L) \]

\[ = \frac{1}{2} (\mathcal{F}_x(W_R) + \mathcal{F}_x(W_L)) - \frac{1}{2} |A_{RL}|(W_R - W_L) \]

Why computing \( \frac{1}{2} (\mathcal{F}_x(W_R) + \mathcal{F}_x(W_L)) - \frac{1}{2} |A_{RL}|(W_R - W_L) \) instead of simply computing \( \mathcal{F}_x(W(0)) \) after \( W(0) \) has been computed by Roe’s approximate linear solver?
