## Appendix A. Calculation of Capital Stock

Following Lichtenberg (1992), capital stock is computed using the perpetual inventory method. This method requires an initial value of real capital stock. For each plant, we select the earliest available book value of capital in the CMF/ASM. To account for depreciation, we multiply this value by the 2-digit SIC adjustment factor from the Bureau of Economic Analysis (BEA). This adjustment factor is the ratio of industry net capital stock in current dollars to industry gross capital stock in historical dollars. The adjusted book value of capital is then divided by the 4-digit SIC investment deflator from the NBER-CES Manufacturing Industry Database. If the earliest available book value of capital corresponds to the year in which the plant was “born” (as identified by the birth flag in the LBD), no adjustment for depreciation is needed. In this case, the book value is simply divided by the 4-digit SIC investment deflator. The initial value of real capital stock is then written forward using the recursive perpetual inventory formula

$$K_{it} = (1 - \delta_{it}) \times K_{it-1} + I_{it},$$

where  $i$  indexes plants,  $t$  indexes years,  $K$  is the value of real capital stock,  $\delta$  is the 2-digit SIC depreciation rate from the BEA, and  $I$  is capital expenditures divided by the 4-digit SIC investment deflator. Until the 1997 Census, all necessary variables are available separately for buildings and machinery. Accordingly, we calculate the capital stock for each asset category, and add them together to obtain the final measure of capital stock. As of 1997, only aggregate capital stock variables are available.

## Appendix B. Economic Interpretation of Other Policy Control Variables

In this section we consider the economic interpretation of other policy control variables in the main specifications from Table 3. In these specifications, the sales tax rate has no measured impact on the number of establishments, but UI policy and the property tax share do have statistically significant effects. For UI, the effect is best explained by considering the mean values of the inputs and then calculating the comparative static of changing the UI rate by a certain number of basis points. The mean UI base wage is \$10,658 and the mean UI tax rate is 6.47%, so the log of these means is  $\log(10,658 \times 6.47\%) = 6.54$ .<sup>1</sup> An increase in the UI rate

---

<sup>1</sup>Note that this is larger than the average of the log UI contribution shown in Table 2, due to Jensen’s

by 100 basis points will increase the log of the UI contribution by 0.14. Since the coefficient in column (1) is  $-0.189$ , this implies a 100 basis point increase in the UI tax rate would lead to a decrease in the number of establishments by  $-0.189 \times 0.14 = -0.026$  establishments, a magnitude that is between that of the coefficients  $\beta_{P,P} = -0.016$  and  $\beta_{C,C} = -0.037$  above. The property tax share variable indicates that companies have fewer establishments in states with a greater property tax burden. A one-standard deviation (0.05) increase in the property-tax share variable is correlated with 0.019 fewer establishments.

On the labor adjustment margin, we also find an impact of UI contribution requirements. An increase in the UI rate by 100 basis points will increase the log of the UI contribution by 0.14. Since the coefficient in column (4) is  $-0.022$ , this implies a 100 basis point increase in the UI tax rate would lead to a decrease in the number of establishments by  $-0.022 \times 0.14 = -0.31\%$ . The tax incentive index also enters with a statistically significant coefficient of 0.0008. A one standard deviation change in this index by 6 points therefore has an effect on employment of 0.5% at existing establishments. Compared to column (1), the tax incentives index seems to have a greater effect on employment within existing establishments than on the setting up of new establishments.

## Appendix C. Robustness

In this section, we present analysis that examines the robustness of the results to a number of possible confounding factors.

*Matching.* Appendix Table A5 presents the results of regressions on the sample that is restricted to privately-held firms (identified as those firms without Compustat coverage) whose size lies between the 45th and 55th percentiles of the size of pass-through entities.<sup>2</sup> We do this to address the possibility that the results reflect differential trends in larger versus smaller firms around the time of tax changes, since in the full sample the C-Corps are substantially larger than the pass-through entities. Here we find effects on pass-through entities that are slightly larger on both the extensive and intensive margins. The size-matched C-corps, on the other hand, have elasticities that are about one-third smaller than in the baseline specification. This suggests that smaller C-corps respond less than the larger firms in the full-sample.

---

Inequality.

<sup>2</sup>In columns (1)-(2), all firm-year observations of companies that fulfill these criteria are included, whereas in columns (3)-(4), all firm-year observations of companies that *ever* fulfill these criteria are included.

*Endogeneity of legal form of organization.* We next address the question of whether changes in firms’ organizational form could be driving the results. Note first that since the extensive margin specification includes firm-by-state fixed effects and the legal form of organization is constant within a firm across states, the indicator for *C-Corp* in Table 3 reflects the change in the number of establishments when a firm changes its legal form of organization. In these regressions, when companies change to C-Corp status, there is a substantial increase in the number of establishments, which is intuitive as C-Corp status will typically only make sense for larger firms and particularly those with dispersed ownership, which in some cases (e.g., publicly traded corporations) will be required to organize as C-Corps. There is no significant change in the number of employees in existing establishments when a firm switches to C-Corp status.

Each year, 1.4% of C-Corps in our sample become pass-through entities and 1.1% of pass-through entities become C-Corps. It seems unlikely that the state corporate tax code is determining the tax filing status of multi-state companies, given the relative importance of this decision for the firm’s liability under the federal tax code. However, we address the possibility that the firm’s legal form of organization could be endogenous to state tax policy empirically in several ways. Columns (1) and (4) of Appendix Table A6 include trends in the legal form of organization interacted with year fixed effects, to allow C-Corps and pass-through entities to be on different trends. This addresses the possibility that corporate tax reforms might take place at times when C-Corp activity would have declined independent of the tax reform. Columns (2) and (5) exclude all observations within a 5-year window around any change in the legal form of organization, and the results remain robust.

In Appendix Table A7 we directly consider the question of changes in legal form of organization by showing the results of a linear probability model at the firm-year level. Specifically, we estimate

$$1(CCorp_{it}) = \alpha_i + \alpha_t + \beta_C (\overline{\tau_C}) + \beta_P (\overline{\tau_P}) + \Gamma' \mathbf{X} + \varepsilon_{it},$$

where the dependent variable is an indicator variable that equals one if the firm is a C-Corp, and the tax variables are the average tax rates across states where firm  $i$  has establishments. The explanatory variables are the tax variables, computed as (employee-weighted) averages across all states where the firm has establishments. We find that the state-level tax variables have no statistically significant effect on the likelihood of changing organizational form, except that fewer state-level tax incentives may marginally increase the probability of being a C-Corp. Since

firms must choose one organizational form for the entire firm, it is reasonable to believe that federal tax policy has the strongest effect here.

*Unpredicted component of state taxation.* A further general critique that has been brought against studies that rely on variation in policy parameters is that firms may plan their investment, employment, and location decisions in part in expectation of future changes in government policy (Lucas (1976), or more recently Hennessy and Strebulaev (2015)).<sup>3</sup> More generally, if changes in tax policy are predictable by simple economic variables then it would call the overall identification strategy into question.

To address this, we estimate predicted values of corporate and personal tax rates based on one-year lags of those tax rates and other macroeconomic variables:

$$\tau_{C,t} = \alpha + \lambda_1 \tau_{C,t-1} + \lambda_2 \log(GDP)_{t-1} + \lambda_3 UnemploymentRate_{t-1} + \lambda_4 \%BudgetSurplus_{t-1} + \epsilon_{\tau(C)}$$

$$\tau_{P,t} = \alpha + \lambda_1 \tau_{P,t-1} + \lambda_2 \log(GDP)_{t-1} + \lambda_3 UnemploymentRate_{t-1} + \lambda_4 \%BudgetSurplus_{t-1} + \epsilon_{\tau(P)}$$

where  $\%BudgetSurplus$  is calculated as  $\frac{Revenues - Expenditures}{Expenditures}$  at the state level using data from the Census of Governments State & Local Finances, and the state-level unemployment rate is obtained from the Bureau of Labor Statistics. The estimates from these regressions are provided in Appendix Table A8.<sup>4</sup> We then re-estimate our primary specifications using  $\epsilon_{\tau(C)}$  instead of  $\tau_C$  and  $\epsilon_{\tau(P)}$  instead of  $\tau_P$ . The results are provided in columns (3) and (6) of Appendix Table A6. The coefficients reflect the effects of tax changes that would be unpredictable based on lags of tax rates, GDP, unemployment, and budget surpluses or deficits. Using only this unpredicted component does not change the results appreciably from the baseline.

*Unobserved trends at the regional level.* Columns (1) and (4) of Appendix Table A9 include region-by-year fixed effects, to control for possible correlations between shifts in the regional composition of establishments over time and state tax policy.<sup>5</sup> So for example, if tax rates moved relatively lower over time in the Mountain region, while economic activity was on a

---

<sup>3</sup>For example, if firms expect taxes to increase at date  $t$  and then taxes do increase at that date but by less than expected, the tax increase would in effect amount to a tax cut relative to expectations, making estimated coefficients difficult to interpret.

<sup>4</sup>Appendix Table A8 indicates that corporate tax rate increases are weakly correlated with higher lagged GDP growth and a lower lagged unemployment rate, whereas personal tax rate increases are correlated with a smaller lagged budget surplus (or a larger lagged budget deficit).

<sup>5</sup>The regions are the 9 Census regions: Pacific, Mountain, West North Central, East North Central, West South Central, East South Central, South Atlantic, Middle Atlantic, and New England.

general upward trend in this region, specifications without region-by-year fixed effects would attribute all of the increase in economic activity to the tax policy and not to secular regional effects. We find that the inclusion of regional trends if anything strengthens the results.

*Unobserved trends at the industry level.* Relatedly, columns (2) and (5) of Appendix Table A9 include industry-by-year fixed effects to control for possible correlations between shifts in the industry composition of establishments over time and state tax policy. So for example, if tax rates moved relatively higher in states that had industries in decline for unrelated reasons, specifications without industry-by-year fixed effects would attribute all of the decrease in economic activity to the tax policy and not to the industry declines. The inclusion of industry trends on the extensive margin reduces the magnitude of the corporate tax coefficient from 0.037 to 0.030, and the personal tax coefficient from 0.016 to 0.008. Industries are measured at the two-digit SIC level, so in this specification all variation that is due to changes in the industry composition of economic activity at the state level is absorbed. Similar patterns are observed on the intensive margin.

*“Extensive-extensive” margin.* In column (3) of Appendix Table A9, the dependent variable is a dummy variable indicating whether the company has at least one establishment in the state—that is, this specification is a linear probability model that examines whether state taxation affects companies at the “extensive-extensive” margin. The overall pattern is again similar. Specifically, we find that a 100 basis point increase in the corporate (personal) income tax rate reduces the probability of C-Corps (pass-through businesses) having any operations in the state by 0.3% (0.2%).

*Sample selection.* Our baseline sample includes all firm-year units that have at least 100 employees and operate in multiple states. In Appendix Table A10, we extend the sample by including all firm-year units corresponding to companies that fulfill these criteria in *any* year during the sample period. As is shown, our results change little.

*Functional form.* In our baseline regression at the extensive margin, the dependent variable is the count of establishments at the firm-state-year level. One caveat of this specification is that the dependent variable is not size-adjusted, which may affect the calculation of the tax elasticities. To address this point, we consider alternative functional forms. In column (1) of Appendix Table A11, we scale the count of establishments by the total number of establishments of the firm in the preceding year  $\frac{\# \text{ Establishments}_{ist}}{\sum_s \# \text{ Establishments}_{ist-1}}$ . As is shown, the coefficient

of  $\tau_C \times CCorp$  is  $-0.0009$ . Since the average number of establishments of C corporations is 51, this implies that the number of establishments decreases by  $0.0009 \times 51 = 0.045$ , which is in the ballpark of our baseline estimate in Table 3. Similarly, for pass-through entities, the coefficient of  $\tau_P \times PassThrough$  corresponds to a decrease in the number of establishments by  $0.0008 \times 15 = 0.012$ . Again, this is in the ballpark of our baseline estimate in Table 3. In column (2), we consider another variant of our baseline specification in which we use  $\log(1 + \# Establishments_{ist})$  as dependent variable. As can be seen, the coefficients of  $\tau_C \times CCorp$  and  $\tau_P \times PassThrough$  are  $-0.4\%$  and  $-0.3\%$ , which is again in the ballpark of the elasticities that are implied by our baseline coefficients. Overall, the estimates in Appendix Table A11 indicate that our results are not sensitive to the choice of the functional form.

*Size quintiles.* In Appendix Table A12, we further examine the relationship between size and our extensive margin estimates. Specifically, we divide the sample into firm-size quintiles (based on the number of employees at the firm level). The upper panel reports the regression estimates, while the bottom panel reports the implied elasticities. As can be seen, higher coefficients tend to map into higher elasticities. This confirms that the quantitative estimates from equation (2) can be compared across firms of different size.<sup>6</sup>

*Deductibility of state taxes.* State income taxes are deductible from federal taxes. In Appendix Table A13, we take into account the deductibility of state taxes by using  $\tau_C - \tau_{C,federal} \times \tau_C$  instead of  $\tau_C$ , and  $\tau_P - \tau_{P,federal} \times \tau_P$  instead of  $\tau_P$ . (Since the federal tax rate enters multiplicatively, it is not fully absorbed by the year fixed effects.) As is shown, the coefficients are about 1.5 to 1.8 larger than our baseline estimates. This mirrors the fact that the unadjusted tax rates are on average 1.6 to 1.8 larger than the tax rates net of the deductibility of federal taxes.

## Appendix D. Use of Apportionment-Factor-Adjusted Tax Rates for Manufacturing

The regression analysis in Appendix Table A17 measures the firm’s response to a change in the actual tax claim on a dollar of total (national) corporate profit by one percentage point.

---

<sup>6</sup>In column (6), we further report the regression estimates and implied elasticity pertaining to multinational firms. As can be seen, in terms of their (domestic) presence, multinational firms are comparable to firms in the top quintile of the size distribution. Yet, multinational firms have a somewhat smaller elasticity with respect to the corporate income tax ( $-0.53\%$  compared to  $-0.64\%$  for firms in the fifth quintile of size). This could reflect differences in the taxation of domestic versus multinational firms (e.g., if multinational firms have more discretion allowing them to reduce their U.S. tax burden through paper transactions).

Equation (1) shows this construction in the absence of throwback or throwout rules. In this equation, the company would at first glance appear to have a break in state  $i$ , getting a lower effective tax rate than the state's corporate tax rate ( $\tau_C^i$ ) based on the fact that it was selling outside of state  $i$ .

However, if state  $i$  has a throwback rule, all “nowhere” sales (sales to states where the firm's activities are not taxed because the firm has no physical presence) must be added into the final term of the formula:

$$\tau_C^i \times \left[ \alpha_{\text{payroll}}^i \times \frac{\text{payroll in } i}{\text{total payroll}} + \alpha_{\text{property}}^i \times \frac{\text{property in } i}{\text{total property}} + \alpha_{\text{sales}}^i \times \frac{\text{sales to } i + \text{nowhere sales}}{\text{total sales}} \right].$$

If instead the state has a throwout rule, the nowhere sales must be subtracted from the denominator:

$$\tau_C^i \times \left[ \alpha_{\text{payroll}}^i \times \frac{\text{payroll in } i}{\text{total payroll}} + \alpha_{\text{property}}^i \times \frac{\text{property in } i}{\text{total property}} + \alpha_{\text{sales}}^i \times \frac{\text{sales to } i}{\text{total sales} - \text{nowhere sales}} \right].$$

We are not able to compute “nowhere sales” since we only observe the shipments generated by each establishment, not the geographical distribution of those shipments. The calculation of an apportionment- and throwback-adjusted effective tax rate therefore requires an assumption about the location of the shipments. In this specification, we assume that all the shipments of the plant go to states where the firm has no nexus. The effective tax rate we implement in this case is

$$\tau_{C(AF \text{ and } TB \text{ adj})} = \tau_C^i \times \left[ \alpha_{\text{payroll}}^i \times \frac{\text{payroll in } i}{\text{total payroll}} + \alpha_{\text{property}}^i \times \frac{\text{property in } i}{\text{total property}} + \alpha_{\text{sales}}^i \times I_{\text{throwback}} \right].$$

Recall that the initial results on the manufacturing sample from column (6) of Table 3 showed a smaller elasticity for manufacturing firms than in the full sample. However, Appendix Table A17 shows that when we use effective state tax rates that account for apportionment factors and the firm's share of capital and labor in each state (as in equation (1)), the coefficient returns to  $-0.0045$  as shown in column (1), slightly above the full-sample estimate using statutory rates. This estimate is again consistent with an elasticity of labor with respect to the state tax rate of around 0.5. Column (2) shows a somewhat lower point estimate of the elasticity of capital with respect to the apportionment-factor adjusted effective tax rate. Columns (3) and (4) additionally

implement the throwback rule as shown above, using an effective tax rate that adjusts for both apportionment factors and throwback rules, assuming that all the shipments of the plant go to states where the firm has no nexus or states where there is no corporate tax. The results here are a labor elasticity of 0.48 and a capital elasticity of 0.32.

In these regressions we do not find statistically significant coefficients on the pass-through entity response to the personal tax rate. However, this may to some extent reflect the relatively small number of manufacturing firms operating in multiple states as pass-through entities with more than 100 employees. As shown in Table 1, there are only 11,100 firms in the U.S. that fit this description, compared to 93,300 manufacturing C-Corps.

### Appendix Table A1. Persistence in $\tau_c$ and $\tau_p$

This table examines the persistence of the changes in  $\tau_c$  and  $\tau_p$ . Each column reports the coefficient  $\gamma^k$  from the following linear projection:

$$\tau_{s,t+k} - \tau_{s,t+k-1} = \alpha^k + \gamma^k (\tau_{s,t} - \tau_{s,t-1}) + \beta^k \mathbf{X}_{s,t} + \varepsilon_{s,t+k} \quad \text{for } k = 1, 2, \dots, 5$$

where the left-hand side variable,  $\tau_{s,t+k} - \tau_{s,t+k-1}$ , is the change in the change in the corporate or personal income tax rate in state  $s$  from  $t+k-1$  to  $t+k$ ,  $\tau_{s,t} - \tau_{s,t-1}$  is the corresponding change in the same-state tax rate  $k$  periods earlier, and  $\mathbf{X}$  is the control of vector variables. The last row reports the sum  $\gamma^1 + \dots + \gamma^5$ , which represents the fraction of in-sample state-level tax rate changes that are reversed, on average, within five years.  $\tau$  is the corporate income tax in columns (1)-(2) and the personal income tax in columns (3)-(4). The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

### Appendix Table A3. Conditional Logit

This table presents variants of the regression in column (1) of Table 3, except that the dependent variable is a dummy variable indicating the state with the largest increase (and decrease, respectively) in the number of establishments for a given firm in a given year. The regressions are estimated using a conditional logit. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

### Appendix Table A4. Firm-Level Regressions

This table presents firm-level analogues of the regressions in Tables 3 and 4.  $\bar{\tau}_C$  refers to the average corporate income tax rate in all states in which the company has operations. The average is computed using the share of the company's employees in each state as weights.  $\bar{\tau}_P$  is computed analogously. The sample period is from 1977 to 2011. Standard errors are clustered at the firm level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	LBD (all sectors)		ASM/CMF (manufacturing)

### Appendix Table A5. Matching

This table presents variants of the regressions in columns (1) and (4) of Table 3, restricting the sample to i) firms whose size (i.e., the number of employees) lies between the 45<sup>th</sup> and 55<sup>th</sup> percentiles of the size of pass-through entities, and ii) private firms. Private firms are those without coverage in Standard & Poor's Compustat. Compustat is matched to the LBD using the SSEL-Compustat Bridge maintained by the U.S. Census Bureau. In columns (1)-(2), all firm-year observations of companies that fulfill these criteria are included (contemporaneous matching); in columns (3) and (4), all firm-year of companies that *ever* fulfill these criteria are included (non-contemporaneous matching). The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	Contemporaneous matching		Non-contemporaneous matching	
	# Establishments	Log(employees)	# Establishments	Log(employees)
	(1)	(2)	(3)	(4)
$\tau_c \times \text{C-Corp}$	-0.020*** (0.006)	-0.0028*** (0.0010)	-0.022*** (0.005)	-0.0028*** (0.0009)

Observations	2,459,900	871,500	2,663,100	964,500

### Appendix Table A6. Robustness

This table presents variants of the regressions in columns (1) and (4) of Table 3. In columns (1) and (4), the regressions include LFO-by-year fixed effects, where LFO is the Legal Form of Organization—C-Corp or Pass-through. In columns (2) and (5), we exclude firm-year observations within a five-year window around a change in LFO. In columns (3) and (6), we replace  $\tau_c$  and  $\tau_p$  by their respective residuals from the predictive regressions provided in Appendix Table A8. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	# Establishments			Log(employees)		
	LFO trends	Excluding 5-year window around LFO change	Unpredicted component of $\tau_c$ and $\tau_p$	LFO trends	Excluding 5-year window around LFO change	Unpredicted component of $\tau_c$ and $\tau_p$
	(1)	(2)	(3)	(4)	(5)	(6)

### Appendix Table A7. Changes in Legal Form of Organization

The dependent variable is a dummy indicating whether the company is a C-corporation.  $\bar{\tau}_C$  refers to the average corporate income tax rate in all states in which the company has operations. The average is computed using the share of the company's employees in each state as weights. The other tax items are computed analogously. The sample period is from 1977 to 2011. Standard errors are clustered at the firm level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	C-Corp
$\bar{\tau}_c$	-0.0009 (0.0010)
$\bar{\tau}_p$	0.0006 (0.0011)
Sales tax rate	0.0011 (0.0020)
Log(UI contribution)	-0.0099 (0.0085)

Tax incentives index	-0.0009* (0.0005)
Log(GDP)	0.0025 (0.0040)
Year FE	Yes
Firm FE	Yes
R-squared	0.79
Observations	647,000

### Appendix Table A8. Predictive Regressions for $\tau_c$ and $\tau_p$

This table reports the regressions underlying the calculation of the “unpredicted component” of  $\tau_c$  and  $\tau_p$  used in columns (3) and (6) of Appendix Table A6. *GDP* is the state’s gross domestic product (from the BEA). *Unemployment rate* is the state unemployment rate (from the BLS). *Budget surplus* is the state’s budget balance, computed as (revenues – expenditures) / expenditures, using data from the U.S. Census Bureau’s State & Local Finances database. All other variables are defined in Table 2. The sample period is from 1978 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	$\tau_{c,t}$	$\tau_{p,t}$
$\tau_{c,t-1}$	0.9930*** (0.0058)	
$\tau_{p,t-1}$		0.9636*** (0.0087)
$\text{Log}(\text{GDP})_{t-1}$	-0.0141* (0.0076)	0.0172 (0.0194)
$\text{Unemployment rate}_{t-1}$	0.0087* (0.0047)	-0.0004 (0.0115)
$\text{Budget surplus}_{t-1}$	-0.0785 (0.0906)	-0.2837*** (0.0939)
R-squared	0.98	0.96
Observations	1,734	1,734

### Appendix Table A9. Additional Robustness

This table presents variants of the regressions in columns (1) and (4) of Table 3. In columns (1) and (4), the regression includes region by year fixed effects. Regions are partitioned according to the nine Census regions. In columns (2) and (5), the regression includes industry-by-year fixed effects. Industries are partitioned according to 2-digit SIC codes. In column (3), the dependent variable is an indicator variable equal to one if the company has at least one establishment in the state. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	# Establishments		I(# Establ. > 0)	Log(employees)

### Appendix Table A10. Sample Selection

This table presents variants of the regressions in columns (1) and (4) of Table 3, except that the sample includes all firms that ever have at least 100 employees or ever have operations in more than one state during the sample period (1977 to 2011). Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	# Establishments	Log(employees)
	(1)	(2)
$\tau_c \times \text{C-Corp}$	-0.033*** (0.003)	-0.0040*** (0.0005)

R-squared	0.71	0.90
Observations	58,622,800	30,708,300

### Appendix Table A11. Functional Form

This table presents variants of the regression in column (1) of Table 3 using alternative dependent variables. In column (1), the dependent variable is the ratio of the number of establishments (of a given firm in a given state and year) divided by the total number of establishments of the firm in the previous year. In column (2), the dependent variable is the logarithm of one plus the number of establishments (of a given firm in a given state and year). The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	# Establishments relative to firm size	Log (1 + # Establishments)
	(1)	(2)
$\tau_c \times \text{C-Corp}$	-0.0009*** (0.0001)	-0.0043*** (0.0004)
$\tau_c \times \text{Pass-through}$	-0.0000 (0.0001)	-0.0001 (0.0003)
$\tau_p \times \text{C-Corp}$	-0.0001 (0.0001)	-0.0001 (0.0002)
$\tau_p \times \text{Pass-through}$	-0.0008*** (0.0001)	-0.0025*** (0.0005)
Controls	Yes	Yes
Year FE	Yes	Yes
Firm-state FE	Yes	Yes
R-squared	0.36	0.83
Observations	28,224,700	32,997,200

### Appendix Table A12. Size Quintiles

This table presents variants of the regressions in column (1) of Table 3, except that in columns (1)-(5) the sample is split in quintiles of firm size (the number of employees at the firm level). In column (6), the sample includes only multinational firms with coverage in Standard & Poor's Compustat (that is, firms that have non-domestic segments in the Compustat Segment file). The bottom rows of the table report the average number of establishments in a given state for the corresponding C-corp and Pass-through firms, along with the implied elasticity with respect to rate  $\tau_c$  and  $\tau_p$ , respectively. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	# Establ.	# Establ.	# Establ.	# Establ.	# Establ.	# Establ.
	1st size quintile	2nd size quintile	3rd size quintile	4th size quintile	5th size quintile	Multinational firms

### Appendix Table A13. Deductibility of State Taxes

This table presents variants of the regressions in columns (1) and (4) of Table 3, except that the tax rates take into account the deductibility of state taxes from federal taxes. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	# Establishments	Log(employees)
	(1)	(2)
$(\tau_c - \tau_{c, \text{federal}} \times \tau_c) \times \text{C-Corp}$	-0.056*** (0.005)	-0.0066*** (0.0008)

### Appendix Table A14. Extensive Margin: Permanent versus Transitory Treatments

This table presents variants of the regressions in Table 5, decomposing the large tax changes (“treatments”) into permanent and transitory treatments. A tax change is coded as transitory if it is reversed within three years. Otherwise, it is coded as permanent. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	# Establishments

### Appendix Table A15. Intensive Margin: Permanent versus Transitory Treatments

This table presents variants of the regressions in Table 7, decomposing the large tax changes (“treatments”) into permanent and transitory treatments. A tax change is coded as transitory if it is reversed within three years. Otherwise, it is coded as permanent. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	Log(employees)

### Appendix Table A17. Apportionment Factors and Throwback Rules—Manufacturing

This table presents variants of the regressions in columns (4), (6) and (7) of Table 3. The sample is restricted to establishments in the ASM/CMF.  $\tau_c$  (*AF-adjusted*) is the apportionment factor-adjusted corporate income tax rate.  $\tau_c$  (*AF- & TB-adjusted*) is the apportionment factor and throwback rule-adjusted corporate income tax rate.  $\tau_p$  (*AF-adjusted*) and  $\tau_p$  (*AF & TB-adjusted*) are defined analogously. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	Apportionment factors		Apportionment factors and throwback rules	
	Log(employees)	Log(capital)	Log(employees)	Log(capital)

Observations	854,700	854,700	854,700	854,700

### Appendix Table A18. Pass-Through Ownership

This table presents variants of the regressions in columns (1) and (4) of Table 3, interacting  $\tau_p \times \text{Pass-through}$  with two dummy variables indicating whether the pass-through entity owner resides in a state whose tax rate is above or below the median across all states in which the company has operations. We infer the owner's state of residence as the state with the highest percentage of S corporations and partnership tax filings (among all states in which the company has operations) using data from the IRS Data Book. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	# Establishments	Log(employees)
	(1)	(2)
$\tau_c \times \text{C-Corp}$	-0.037*** (0.003)	-0.0041*** (0.0005)
$\tau_c \times \text{Pass-through}$	-0.002 (0.003)	-0.0004 (0.0010)
$\tau_p \times \text{C-Corp}$	-0.003 (0.002)	-0.0007 (0.0004)
$\tau_p \times \text{Pass-through} \times (\text{Owner in high-tax state})$	-0.011*** (0.003)	-0.0020* (0.0011)
$\tau_p \times \text{Pass-through} \times (\text{Owner in low-tax state})$	-0.020*** (0.003)	-0.0027*** (0.0010)
Year FE	Yes	Yes
Firm-state FE	Yes	No
Establishment FE	No	Yes
R-squared	0.73	0.88
Observations	32,997,200	27,600,100

### Appendix Table A19. Weighted Least Squares

This table presents variants of the regressions in columns (1) and (4) of Table 3, but using weighted least squares (WLS) estimation. The weights are given by the number of employees at the establishment and firm-state level, respectively. Weights are winsorized at the 5% level. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	# Establishments	Log(employees)
	(1)	(2)
$\tau_c \times \text{C-Corp}$	-0.021*** (0.003)	-0.0024*** (0.0003)
$\tau_c \times \text{Pass-through}$	0.005 (0.004)	-0.0001 (0.0009)
$\tau_p \times \text{C-Corp}$	-0.004 (0.005)	0.0005 (0.0005)
$\tau_p \times \text{Pass-through}$	-0.010*** (0.003)	-0.0014** (0.0007)
Controls	Yes	Yes
Year FE	Yes	Yes
Firm-state FE	Yes	No
Establishment FE	No	Yes
R-squared	0.78	0.89
Observations	32,997,200	27,600,100

### Appendix Table A20. Davis-Haltiwanger Growth Rates

In this table, we regress the two-period Davis-Haltiwanger growth rate in employment at the firm-state level on the two-period differences in the right-hand side variables used in the baseline specification in column (1) of Table 3. The regression is estimated by WLS using as weights the number of employees at the firm-state level. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	Davis-Haltiwanger growth rate
$\Delta \tau_c \times \text{C-Corp}$	-0.0048*** (0.0015)
$\Delta \tau_c \times \text{Pass-through}$	0.0003 (0.0012)
$\Delta \tau_p \times \text{C-Corp}$	-0.0005 (0.0010)
$\Delta \tau_p \times \text{Pass-through}$	-0.0022** (0.0010)
Controls	Yes
Year FE	Yes
Firm-state FE	Yes
R-squared	0.20
Observations	3,641,600

**Table A21. General Equilibrium—Extensions**

This table presents variants of the regressions in Table 14 at the state-LFO-year level. In column (1), all LBD establishments are included. In column (2), all establishments of single-state firms are included. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	Log(employees)	
	(1)	(2)
	All establishments	Establishments of single-state firms
$\tau_c \times \text{C-Corp}$	-0.0032** (0.0016)	-0.0012 (0.0012)
$\tau_c \times \text{Pass-through}$	0.0004 (0.0014)	0.0004 (0.0012)
$\tau_p \times \text{C-Corp}$	-0.0002 (0.0009)	-0.0001 (0.0007)
$\tau_p \times \text{Pass-through}$	-0.0013* (0.0007)	-0.0007 (0.0006)
Controls	Yes	Yes
Year FE	Yes	Yes
LFO-state FE	Yes	Yes
R-squared	0.90	0.88
Observations	3,600	3,600

**Table A22. ERTA81 and TRA86 Treatments with Marginal Effective Tax Rates**

This table presents variants of the regressions in Tables 6 and 8, except that the treatment indicators are set to one for firms whose marginal effective tax rate (ETR) changes by more than 100 basis points in response to the large tax changes. The sample period is from 1977 to 2011. Standard errors are clustered at the state level. \*, \*\*, and \*\*\* denotes significance at the 10%, 5%, and 1% level, respectively.

	Large increases in ETR <sub>c</sub>		Large cuts in ETR <sub>p</sub>		Large increases in ETR <sub>p</sub>	
	# Establishments	Log(employees)	# Establishments	Log(employees)	# Establishments	Log(employees)
	(1)	(2)	(3)	(4)	(5)	(6)
Treatment (ERTA81)	-0.012* (0.007)	-0.0044** (0.0020)				
Treatment (TRA86)			0.017** (0.009)	0.0010 (0.0014)	-0.006 (0.020)	-0.0016 (0.0023)
Treatment (other exogenous)	-0.016*** (0.006)	-0.0040*** (0.0008)	0.020** (0.010)	0.0012 (0.0010)	-0.004 (0.007)	-0.0029*** (0.0011)
Treatment (endogenous)	-0.014** (0.007)	-0.0033*** (0.0009)	0.018 (0.013)	0.0012 (0.0010)	-0.005 (0.018)	-0.0024* (0.0014)
Treatment (unclassified)	-0.014*** (0.005)	-0.0035** (0.0015)	0.015** (0.007)	0.0014 (0.0018)	-0.005 (0.009)	-0.0025** (0.0013)
Controls	Yes	Yes	Yes	Yes	Yes	Yes
Year FE	Yes	Yes	Yes	Yes	Yes	Yes
